The colouring matter of the skin, or rete mucosum, as it is commonly, though improperly, called, is usually thin, and of a light colour in those parts of the bodies of quadrupeds which are covered by hair: on particular parts, however, and in certain animals, it is various in its colour. It is generally black upon the uncovered parts of the skin, as the flanks of quadrupeds, the hands of monkeys, &c. It has but rarely very vivid colours, as in the other classes of animals. The monkey kind show examples in which the cheeks have a painted white or blue colour, and the nose or if the colorities are red, violet, or carmine.

The pigment of the skin of the cetacea vastly exceeds in thickness that of all other animals. It is about the tenth of an inch thick in the porpoise, and in the larger species of the whale tribe it is proportionately thicker. It appears like a solid substance, which divides very readily after maceration into layers, and also in the vertical direction into fibres, like the pike of velvet. This laminated and fibrous structure is only the particular arrangement of the subfluentes of the pigment, and not a texture composed of different parts, for the whole is soluble, or rather miscible, in water after maceration. The rete mucosum of the cetacea is black upon the superior surface of the body, but is a silvery white on the belly.

The pigment of the skin is found within the cavities of the mouth and nose in many quadrupeds, in which places it has a dark colour.

The cutis, or true skin, varies of course very much in thickness in different animals of this class; as a general observation, we may state that the skin is thick in proportion to its nakedness, and its exposure to external friction or pressure. It is therefore most strong in many-hoofed quadrupeds, to whom these circumstances belong, as well as great bulk of the animals themselves. The skin is always thickest upon the back of the body and outside of the limbs. The thicknefs of the skin may be increased to a very extraordinary degree by artificial pressure, as is seen in the boar pigs that are used for making brawn. In these animals, the skin upon the shoulders is sometimes above an inch thick.

The skin is peculiarly tough in those animals that burrow in the ground. In the mole, although it is thin, it is so tough, that it is difficult to cut it with a pair of scissors.

The skin of cetacea mammalia is peculiar in its structure. The surface next the rete mucosum is smooth, and when examined under water, floats like a villous texture. We could not readily detect any distinct villi upon the skin of the porpoise, or grampus, they are so fine and so close to each other; but Hunter has described them as being very plain in cetaceans. It is scarcely possible to calculate the thickness of the skin of cetacea, as it is gradually lost in the cellular texture which contains the oil, but it appears to be peculiarly thin, according to the size of the animals, unless we consider the cellular substance that is filled with the oil as making a part of the skin, which appears really to be the case. Every part of the skin of the cetacean tribe is penetrated by the oil.

The skin of cetacea appears to be less sensible of external impressions than that of any other species of mammalia. The smoothness, and stretched state of the cuticle; the thickness of the rete mucosum; the absence of those small eminences of the cutis called papillae, which are peculiarly endowed with blood-veils and nerves, and the interposition of fo great a quantity of oil in the interstices of the skin and cellular substance, all contribute to obscure the impressions of foreign bodies.

Certain parts in the other mammalia, from their situation, figure, and intimate structure of the skin covering them, are rared very receive peculiar impressions and are properly speaking the organs of touch. The most delicate instruments of this kind are, the bands of the quadrumanous mammalia; the lips and jaws of many quadrupeds; the prehensile tails of monkeys, oppossums, anteaters, pangolins, &c.

The
Mammalia.

The under surfaces of the hands and feet of monkeys are organized like those of the human subject, but have not the nervous papilla so eminent as they are in the human hand. The feet of digitiated quadrupeds also are capable in a degree of the sensation of touch, particularly the under surface of the front toes in the racoon.

The lips of many quadrupeds form a very delicate sense of touch. They are largely supplied with nerves and blood-vessels, and the papilla of the skin are very eminent. The superior lip of the rhinoceros forms a process which is moveable in various directions, and is used by the animal as a prehensile member.

The snouts of the hog, mole, deermouse, and tapir, are extremely well constructed for feeling with; being very movable by the muscles already described, highly elastic in themselves, and their extremity having, like a lip, a papillated surface, which is richly endowed with nerves and vessels. But the proboscis of the elephant, as being capable of embracing bodies entirely, in addition to the great sensibility of its extremity, constitutes, perhaps, the most perfect organ of touch with which we are acquainted.

The inferior surface (which is the one applied to bodies) of the prehensile tails of mammalia, is directed to hair, and the skin is papillated as upon the end of snouts, &c. Cuvier states that he found the papilla very distinctly upon the under surface of the tail in the Cayenne opallium.

In some cafes, foreign imprefions are conveyed by the medium of infensible parts. This may be observed with respect to whiskers, nails, hoofs, and horns, which are intimately connected with parts so extremely sensible, that the slightest impression upon them in an uncovered state would be highly painful. The vascular and infensible substances, which we find clothed by these hoary integuments, are better calculated for producing the sensation of solid or resisting bodies, than any of the other organs of touch; but are incapable of furnishing any idea of the figure of foreign substances. The infensible integuments and appendages of different animals are described under their proper heads in this dictionary; and there is also a plate allotted to the illustration of their structure and mode of growth.

In the ornithorhyncus paradoxus the external branches of the fifth pair of nerves are very large, and are distributed upon the integuments of the bill of this curious animal, precisely in the same manner as in the broad bills of the sewerine birds, and thus produce a very nice organ of touch. See Anatomy of Birds, in this dictionary.

The peculiar muscles, which move the skin and the organs of touch in mammalia, are already described, along with the other muscles of the body.

The integuments of the wing of the bat are so thin, that they are transparent, and permit one to see the distribution of the nerves, which form between the membranes of the wing a beautiful plexus. A contemplation of this structure should have taught Spallanzani and Jurin that bats, when flying, must be adverted of the existence of any resisting bodies, on approaching them, by the difference in the impulfe of the air upon the concave surface of the wing; and have rendered the cruel experiments of these physiologists upon bats, in order to discover their sixth sense, unnecessary. From the first time we dissected this animal, we were convinced that it directed itself altogether by means of the sensibility of the wing. The mode of flying observable in bats appears to be perfectly consistent with this notion. They usually proceed as if they had no perception of objects, until they arrive within a near distance of them, when they either suddenly turn aside, or directly round, as if to avoid being dashed against them. Blind men are known to direct themselves by means of the feeling of resistance in the air, on approaching walls or houses, &c.; and even a person, whose sense of feeling has never been practiced to discriminate so nicely, can discern the walls in a dark room, on approaching them very nearly, without touching them with any part of the body.

Organ of Taste.—The sense of taste is generally supposed to reside altogether in the tongue; but some substances excite particular taste, in passing over the inside of the lips and the fauces. The irregular denticulated folds which the lips form in the cloven-footed quadrupeds, the dog, &c. seem particularly well calculated for receiving the impressions of rapid bodies.

Blumenbach mentions a man who was born without a tongue, yet could discern the taste of rapid substances, when passing over his palate.

The muscular structure and mechanism of the tongue have already been described, under the heads of the organs of modification and the organs of motion; it, therefore, only remains to consider some peculiarities in the form of this member, and the organization of its integuments, which alone poffefs the sense of tasting.

The tongue in the monkey kind has not quite the same figure as in man; it is longer and thinner; even in the ourang-outang it is three times as long as it is broad. In the digiti-grade quadrupeds it is long, thin, and flexible; it is fo also in the cloven and solid-hoofed tribes. The hog has a short tongue, with the edge divided into a number of processse like fringe. The tongue of the seal is thick and short, and has on each side of the point a ragged notch, or deficiency, having the appearance of a piece being bitten off. The singular long-shaped tongue of the ant-eaters has been already mentioned, and the mechanism on which it depends described. The tongue of the cetacea is short, flat, and smooth, and bears considerable resemblance to that organ in fishes.

The three kinds of papilla observed in the integuments of the human tongue, viz. the conical, fungiform, and incised, exist in mammalia. Their varieties in different genera relate principally to the form and covering of the conical, and the number of the other sorts of papilla.

In the prehensile-tailed monkeys the conic papilla are but small; they have but three incised papilla, which are arranged like the three points of a triangle. The mandril (simia maxima), and the simia cynocephalus, have also three incised papilla in the same position. The simia cynomolagus has four incised papilla arranged in the form of a portion of a circle. The Chinese monkey has seven, making an elongated triangle, with two before it in a line. Several other monkeys have been observed to have fewer incised papilla than the human subject.

The tongue of the common bat has the conical papilla very fine and long, somewhat like hairs, particularly on the back part. The inside of the mouth also has some of these papilla upon it. In the terror bat the conical papilla are horny, and at the extremity of the tongue are divided into several points.

The whole of the cat genus (felis) have the conical papilla, that are on the middle of the tongue, clothed with horny integuments. These are little hooks or claws, sharp pointed, and when on the tongue, are inflected backwards; so that when any of the larger animals of this genus employ the tongue in licking the human hand, they tear off the skin. When the papilla of the tongue are covered by a horny substance, they seem to be insensible to the impressions of rapid bodies; we therefore find, in the cat kind, soft round papilla interpolated between the horny ones, upon the middle of
of the tongue. These two kinds of papillae are placed alternately in a quincuncial order, so that there is an equal number of both upon the tongue. There are soft, conical, fungiform papillae upon the edges of the tongue. Upon the back part of the organ the horny papillae disappear; and there are many small incised papillae arranged in two lines, that approach posteriorly. In the common cat, Cuvier states that there are on the fides of the back part of the tongue some fungiform papillæ, which are pendent from long pediciles. The tongue of the civet resembles that of the cat genus.

In the other digitigrade and planigrade quadrupeds the tongue is soft and flexible. The only variations are with respect to the number and position of the incised papillæ, which are scarcely worth detailing.

The tongue of the opillsus has the anterior and middle part covered with horny scales inflected backwards, which terminate in wedge-shaped or rounded edges: the point of the tongue is fringed: there are but three incised papillæ. The tongue is, however, soft in the phalangers.

The perupæus has the upper surface of the tongue like that of the other falihigrada; but upon its fides, and at the end, there are some large fègles terminating in two or three points of a wedge-shape. There are but two large incised papillæ. The other animals of this order have also fewer incised papillæ than man.

The conical papillæ are six minute, as to be scarcely discernible in the armadillos and Cope ant-eater (aryberyces). These animals have the tongue long, narrow, and very smooth: they have also only two or three incised papillæ.

In the American ant-eaters the tongue is without papillæ, and is therefore not an organ of taste. Indeed in all the identata or infected quadrupeds, this member teems to be merely a mechanical instrument for taking and swallowing their prey.

The flatbs have the conic and fungiform papillæ but little developed, and only two papillæ in cups.

The many-hoofed quadrupeds have all the papillæ of the tongue small.

The cloven-footed order of mammalia have the conic papillæ upon about the anterior half of the tongue, terminating in flexible horny filaments. They are bent backwards, and extend into a point. In the smaller species of the larger species, the small changes of the tongue are, as to be seen with difficulty: but in the larger species, particularly the camel, these filaments are long, and give the touch of the tongue something of the feeling of velvet. The back part of the tongue, in the biforms, is covered by thick tuberculated papillæ, which are sometimes conical-shaped, and at others semi-filamental, and which become smaller towards the tongue. The incised papillæ are numerous, and situates on the fides of the back of the tongue. They are not easily diftinguished from the fungiform, except in the camel, in which they are very large, and concave on their surface.

The conical papillæ are very small and compact in the bovæs, and the fungiform papillæ are confined to the fides of the tongue. There are but three of the incised papillæ, and the surface of which is irregularly tuberculated.

There do not appear to be any conical papillæ on the tongue of cetacea. Cuvier states that they cannot be observed, even with a glass, on the tongue of the delphin and porpoise. There are on it some filaments like pimples, and at the base of the tongue there are four fifures: the edges of the extremity of the tongue form small threads. Hunter compares the tongue of the large whales to a feather bed.

In Plate XIII. of the Anatomy of Mammalia, fig. 1 is a view of the tongue of the cat: a, the part covered with the fuculated papillæ; b, the pendent fungiform papillæ; c, the two rows of incised papillæ. Fig. 2 is one of the horny hooks removed from the tongue of the leopard, and magnified to about four times the natural size. Fig. 3 shows the tongue of the porpoises: a, the point of the tongue terminating in frayed processes; b, b, b, the pimple-like eminences upon the upper surface of the tongue.

Organs of Smelling.—The apparatus for receiving the impressions of odorous effluvia is much more complicated in mammalia generally than in man, which is consistent with the great excellence of the fænæ of smelling in many of the former.

The parts of the ethmoid bone, which enter into the composition of the orbits and the parrætes of the cranium, have been described in their proper places. The foramina of the cribiform plate, through which the branches of the olfactory nerves pass, appear to be numerous in proportion to the necessities of the fænæ of smelling. They are less numerous in the monkey than the human subject.

In quadrupeds these foramina are of different sizes, and collected into groups. In some species of different tribes, as the foop, hog, ant-eater, &c. there is a row of larger holes on each side of the cribula galls of the ethmoid bone. The faligraades have the fewest foramina in the cribiform lamella, and the digitigrade the greatest number of them.

The cells of the ethmoid bone, as they are generally found in mammalia, are well described by Cuvier. He says, it is necessary to imagine a great number of hollow pedicles, all connected to the cribiform bone. They extend forwards and outwards, and in proportion as they advance, those which are nearest unite. Vehicles arise from them, which increase in size in proportion as they become less numerous: they are all hollow, and there are an infinite number of conduits or ways between them, all of which communicate with each other. The ethmoidal cells are most numerous in the carnivorous quadrupeds, which have the finest fænæ of smell.

In the faligraade order there are very few of these cells. Some genera of this tribe, as for instance the bares, and the quadrumanous mammalia, have irregular cells like those of the human subject.

The ethmoidal cells are distinct from the superior turbinate bone in many mammalia. They are sometimes separated from the rest of the nasal cavity by a particular septum. This is especially to be observed in the bares, where it is produced by a plate of the palatine bones inferiorly, and anteriorly by a process of the maxillary bones. It extends to the septum nasi, and leaves only a narrow passage above it. In the carnivorous tribe and the bovæs the projection of the maxillary bones is less considerable; but it is sufficient to separate the ethmoidal cells, which are contained in a depression behind it. In the faligraade and cloven-hoofed quadrupeds this depression is little marked.

The superior turbinate bone is formed by one of the ethmoidal cells in the boved quadrupeds. This cell is larger and much longer than the rest, and extends as far as the inferior turbinate bone, which it covers.

The inferior turbinate bones are much more complicated in mammalia than in man.

Cuvier says, in the mounks of the old continent, they are formed as in the human subject, but in the American mounks these bones are made nearly as in the many-hoofed and cloven-footed quadrupeds.

In these two orders the superior turbinate bones commence each as a single lamina, which soon forms two.

These
Mammalia.

These are coiled upon themselves in a spiral manner, and make either two or two and a half turns, according to the species, so as to produce a fort of horn or concha, closed posteriorly in a point. This horn contains two canals; the one above, the other below the principal lamina. The superior canal leads to the maxillary sinus in the cloven-hoofed quadrupeds, and in the dog it is continued posteriorly in a long groove, which ends in a canal that goes into the malar sinus. The inferior canal of the concha conducts into the back of the nafal cavity, as in the human subject.

The turbinate bones are comprised horizontally in the hippopotamus, owing to the shape of the animal's head.

The lamina of the turbinate bones are generally in the hoofed quadrupeds porous or filled with foramina, which are of various sizes in different species; in some instances the holes are so large and numerous, that the bones form merely an osseous net-work. The pig, however, has no foramina in these bones.

In the internal part of the turbinate bone there are several partitions, which are also perforated with vacanies.

In the solid-hoofed tribe, according to Cuvier, the horizontal lamina of the inferior turbinate bones does not divide into two, but at first folds downwards, then bends upwards, and is attached behind to the maxillary bone. It ascends posteriorly, to cover the opening into the inferior maxillary sinus, and even to pass into it. Lastly, it produces, towards its middle, two or three oblique laminae, which are attached to the anterior edge of this hole.

The inferior turbinate bones of the edentata and three-toed flat, very nearly resemble those described in the cloven-hoofed quadrupeds. In the two-toed anteater, however, Cuvier says, they are like two prismatic boxes closed on all parts, and divided internally by some vertical laminae. The latter has similar bones, but without any division anteriorly.

In the porcupine and marmot these bones confine of a double lamina, attached longitudinally; the two parts of which separate from each other, and ascend by a spiral convolution, giving the appearance of the periwinkle shell (turbo). The rat has the turbinate bones similar to those of the cloven-hoofed quadrupeds. The other faltigrada almost all have these bones complicated, as in the carnivorous tribes.

In these last the lamina, by which the inferior turbinate bone is affixed, divides into two branches, each of which is again divided. The last lamina form a number of canals covered by the pituitary membrane. The air passes through these canals on its way from the nostrils to the lungs, and back again. The seal and otter have the inferior turbinate bone more subdivided than any other animals of this class.

Professor Harwood has calculated that the internal surface is equal to 120 square inches in each nafal cavity of the seal. The laminae are molt numerous in the beaver amongst the faltigrada. When there are few laminae in the carnivorous and faltigrada orders, the latter lamina are spirally twirled in the same manner as where there are but two in other animals. The lion has the lamina divided into two, each of which has a double roll. It is perforated by many foramina. The civet and the viverra genetta have only the lamina convoluted and without foramina.

The intention of the divisions and convolutions of the inferior turbinate bones, is evidently to extend the surface of the pituitary membrane which is spread upon them, and as we find this surface, almost without exception, great in proportion to the acuteness of the sense of smell, we cannot but suppose the olfactory nerve is distributed to it, although its branches have not yet been clearly traced beyond the superior turbinate bone.

The olfactory nerve has been already described until its entrance into the nafal cavity. Upon arriving there, its distribution appears to be exactly the same both in man and mammalia. Cuvier mentions two branches, which are longer and plainer than the rest, upon the septum, but these appear to us to be branches of the fifth pair of nerves, distributed to the pituitary membrane for common sensation.

The sinuses of the different bones in the neighbourhood of the nafal cavity, more particularly the frontal sinuses, have been considered by Blumenbach and others as being subfervient to the organs of smelling. We must confess, however, that the use of these parts does not appear to us to be quite determined. The membrane which lines the sinuses is not organized for receiving the impregnation of odorous effluvia, and the retention of the latter in the cavities of the sinuses does not seem likely to produce much effect upon the pituitary membrane. We may observe, that when animals with to smell any substance particularly, they make short inspirations, which is called snuffing. The chief use of the sinuses, as connected with the organs of smelling, appears to be to supply a clear watery fluid for keeping those parts moist which are really the seat of this sense, for we find, when the secretion of the sinuses becomes infiltrated or suppressed by catarrhal inflammation, the sense of smelling is very much impaired.

The frontal sinesis vary very much in size and figure, even in the genera of the same tribe. They are small in the, monkey kind generally, and are even absent in some species. Those with prehensile tails, on the contrary, have them large.

The bats want these sinuses.

In the sificigrada they are large, and particularly so in the dog kind, in which they not only occupy the anterior part of the os frontis, but the post-orbital proceoses, and each side of the posteroir parietes of the orbit.

These sinuses are very extensive also in most of the plagi-grada. The badger, and the greater number of the ocelot kind, want them altogether, but have the post-orbita proceoses bellow, and communicating freely with the nafal cavity.

Most of the faltigrada quadrupeds want the frontal sinuses; yet in the porcupine they are so large as to pass into the substance of the nafal bones.

In the edentata these sinuses do not exist, in the anteater and pangolin, but the armadillo has them of some size.

In the flat they are very extensive, reaching nearly to the occiput.

The cloven-footed quadrupeds have the frontal sinuses in general very large, and in the ox, goat, and sheep, they extend into the interior of the osseous proceoses, whichfullains the horn. Cuvier thinks the flag has no frontal sinuses. Harwood says the deer want these sinuses, but have membraneous cells between the nose and internal angle of the eye.

The elephant has the sinuses corresponding to the frontal of prodigious extent. They give the remarkable prominence of the forehead which this animal possesses, and render several of the bones of the head hollow. They are divided into a great number of smaller cells, to that the texture of the cranium in the elephant has, when laid open, the appearance of a honey-comb, or rather of a sponge that has large cells.

In the dog these sinuses are larger than in any other animal, except the elephant. They extend in both these quadrupeds as far as the occiput. In the common dog and babiroussa they are divided by some laminae of bone, but do not form that intricate cellular structure found in the elephant. The hippopotamus and rhinoceros have no frontal sinuses.

These sinuses are of tolerable extent in the keme, but are confined
confined to the frontal bone, and in place of opening, as usual, into the superior part of the naso-cavity, communicate on each side, by a large opening, with the posterior maxillary sinus.

The *Malia* wants the frontal sinuses.

It will be seen, from the above account, that the magnitude of the frontal sinuses keeps pace in general, though not constantly, with the degree of excellence in which the animal possesses the sense of smelling, from whence the opinion arose, which we have already noticed, of these sinuses being particularly connected with the organ of smelling.

The *Maxillaries* sinuses are very small in many orders of mammals, as *Deinocerus*, *Planigrada*, the greater number of the *Sukhara*, and *Cettara*, and usually in all the quadrupeds in which the maxillary bone does not form a floor to the nostrils. They are left in the *monkey* and *lemon* than in man in proportion. Generally in the digitated quadrupeds, when there is a cavity in the maxillary bone, it is in common with that of the nose.

Hogs want the maxillary sinuses, but they have sinuses in the malar bone. The *hippopotamuses* has likewise a small sinus in the same situation. The maxillary sinuses of the *Elephant* are cellular, like the others of this animal. The cells communicate, and one of them opens into the nasal cavity.

The *elephant* has a pair of sinuses on each side, which extend into the maxillary sinus, but do not correspond with the latter in regard to size.

In the *bore* there are two maxillary sinuses, an anterior and posterior. The latter is the larger, and forms a projection into the nasal cavity.

The *phineal* sinuses, although, from the position of the head of quadrupeds, they must perform the same offices as the frontal sinuses, do not correspond with these in regard to size.

In the *quadra* they are less than in man in proportion.

The *canis* want small sphenoidal sinuses, and some of them, as the *otter*, *pole-cat*, and *seal*, want them.

They appear to be absent also in most of the other genera of mammals. They are found in the *dog* and *hippopotamuses*, but of a small size. The *elephant* has them of a very great magnitude. They extend into the pterygoid processes of the sphenoid bone. Their interior is not cellular, as the other sinuses of the *elephant* are.

The sphenoidal sinuses exist in the *bore*; they open into the posterior maxillary sinuses.

The entrance into the organ of smelling, is in general composed of the same cartilages in man and many mammals, only differing in form and size in the latter.

In those with *fronts*, the cartilages make in general a perfect tube. Cuvier thus describes the *front* of the *bear*. The cartilaginous septum is reflected inferiorly as well as superiorly; the superior ala bends downwards; they meet on the sides, where they are united by cellular substanances, and complete the external parietes of each nostril. The edge of each ala continues afterwards to bend inward, and forms a kind of concha, which makes an addition to the inferior turbinate bone, and which is covered, like it, by a prolongation of the pituitary membrane.

In the *bore*, a great part of the external nares is membranous. The edge of the nostrils contains a semi-lunar cartilage, which corresponds to the inferior cartilage of the human subject. It has two branches, one is long and narrow, and is nearly parallel to the septum; the other is short, almost square, and situated in the external ala of the nose. The rest of the ala is formed by the integuments, which are at first inflected to produce a fissure, which is known by the name of the *halfe nostril*. The passage into the real nares is a long slit.

The proboscis of the *elephant* and *tapir* is the most remarkable prolongation of the external parts of the organs of smelling. The two external nares are extended into two membranous tubes, which in the *elephant* are of great length. These tubes are included by the complicated muscular structure already described and the integuments.

The mucus which moves the different parts of the external nares are described along with those of the rest of the body.

We have before observed, that the *cetacea* do not possess any olfactory nerves, or apparently any organ calculated for receiving impressions from odorous substanances. Yet Mr. Hunter ascribed the sense of smelling to the *formosa*, and Cuvier seems to think, that it may exist, in a degree, in certain cavity and cells which communicate with the Eustachian tube. These are situated on the lateral parts of the base of the skull, and are partly formed by projections of the bone, and partly by projections of ligament. They are very irregularly, and are lined with a thin mucous membrane. These cells communicate with the frontal sinuses, by a canal which ascends before the orbit. There is a tolerably large opening from the principal cavity into the Eustachian tube. This last terminates in the nares. The cellular cavity, therefore, has no direct communication with the nares. There are several branches of the fifth pair of nostrils divided through these membranous cells, but there is no reason for supposing that these have any facility for conveying substanances, even if they were fairly applied to them.

The two canals corresponding to the nares, are used in *cetacea* for the transmission of the air to and from the lungs, as these animals do not require the mouth; for the larynx, instead of opening at the back of the mouth, ascends in the form of a pyramid, and is received into a fleshy tube, which is common to the two nares. *Whales*, therefore, can keep the mouth in the water, and swallow their food, without interrupting their respiration, and it is to enable them to do so frequently, that the external opening of the nares is upon the top of the head. The fleshy tube which receives the superior part of the larynx from divides into two canals, which pass on each side of the vomer, and are analogous to the posterior passages, into the nasal cavity of other mammals. They are, however, lined by a thin, dry integument, very unlike the pituitary membrane. They abound in two canals that are formed in the bones of the cranium, separated by a thin septum. Where the two canals terminate, they are provided with a fleshy valve in the shape of two semicircles. This valve is attached to the internal edge of their orifice, and closes it by means of a strong muscle, that is attached to the intermaxillary bones. On the outside of this valvular opening, there are placed two large, oval, membranous bags. These are lined by a black mucous integument, which appears to be the continuation of the skin; it is very deeply wrinkled in a relaxed state.

A strong layer of fleshy fibres arises in a radiated manner from the circumference of the cranium, and unites upon these two bags. The skin of the head covers them, and there appears externally only a small slit of a semi-lunar figure, which is a common opening to the two bags.

It is the flructure just described which enables the *cetacea* to expel any water which may get into the pharynx or nasal passages. This is done with so much force, that the jet is seen in the larger species at a considerable distance at sea. Some *whales* are reported to spout the water from their blow
Mammalia.

blow holes as high as 40 feet. When these animals with

to expel the water from these spiracles, they close the pha-

gryn and larynx by their proper muscles; the larynx retreats

from

in the bag, in which most of the circumstances in the structure

of the organ of smelling are brought into view; a, the

frontal sinuses, which are very large in this animal; b, the

sphenoidal sinuses of a small size; c, the ethmoidal cells;

d, the superior turbinate bone; e, the inferior turbinate

bone; f, the passage to the malar sinus; g, the septum

dividing the ethmoidal cells from the superior turbinate

bone.

Organs of Hearing.—The concha and cartilaginous meatus

auditorius, which constitute the external projecting ear, are

generally much larger in mammals than in man. Some,

however, that burrow in the ground, are deprived of concha,

as the mole and some forest-voles, the zemni and some mole-rats.

It is also wanting in the pangolin, the onathorbyphus, some

seals, and the morse. In the cetacea, there are no external

parts to the ear. The cartilaginous meatus commences by

a very small orifice in the skin, and leads to the membrana

tympani.

The concha is large in those mammals that have occasion

to collect distant sounds in the air, as the bat, several eveln-

fotded quadrupeds, the opossum, the hare, the rabbit, &c. In

the fugal quadrupeds, the concavity of the concha is

usually turned backwards; and in those that hunt for their

food, it is generally directed forwards. In the bat kind,

the hollow of the ear is turned forwards, probably for feel-

ing the approach of other bodies in the same manner, as the

wings of these animals do. The ears of the vespertilius

fromus are immovably fixed in the forward direction, as

they are united to each other by their internal edges. The

superior part of the external ear being pendulous, Cuvier

remarks, is an effect of domestication. The ear of the

elephant is also pendulous, but not in the same way as in
domestic animals; it being only the posterior and inferior

part of the elephant's ear which hangs down.

In proportion as the ear is found larger than in man, it

usually becomes also more elongated in its figure: it is also

thinner. It is nearly membranous in the opossum.

The eminences of the external ear are various in mammalia.
The most peculiar are seen in the bat kind. That remarkable
projection which appears like one concha, contained within another in the great eared bat, is the

eminence called the tragus prodigiously enlarged. This part is

also unusually formed in the other species of bat. It is

forked in the onathorbyphus subulatus, notched in the vespertilio

leporinus, and v. crepusculus.

The antitragus is extended forwards in the vespertilio mole-

fisus, to the angle of the mouth. It forms an orifice to the

ear in some forest-voles, particularly in the aquatic forest-vole,

which has the opening into the ear perfectly covered by this

means.

Quadrupeds often have the cartilaginous meatus auditorius

composed of two pieces; one is joined with the concha;

the other is a tube which is connected to the bony meatus

by ligament: both pieces have a longitudinal fissure. The

design of this structure is to permit the contraction and

elongation of the cartilaginous tube of the ear.

In the long-eared quadrupeds also, there is a third carti-
lage, to which nothing similar exits in the ear of the human

subject. It is situated above the cartilaginous meatus; it is

flat, and forms no part of the concavity, but merely serves

for the attachment of certain muscles. It varies in shape;

it is triangular in the horse; lunated in the sheep; pointed

posteriorly, and bilobed posteriorly in the rabbit and rhom-

boidal in the dog. Cuvier, from whom we borrow this

account, calls this cartilage the tympanum.

The external meatus auditorius is long and curiously

twisted in the onathorbyphus.

The meatus which move the external ear in most quadru-

peds are very numerous and complicated; they have received

a distinct description along with the other muscles of the

body.

The ossous portion of the meatus auditory is subject to a

good deal of variety with respect to its length and direction.

The latter seems to be influenced by the course in which the

sounds approach the animal that it is the most concerned to

hear. The ossous meatus is usually formed in the mole;

it is flattened superiorly and extended on the side. The

membrana tympani, which is very large, constitutes its

superior part; by this means the meatus is enabled to collect

the sounds and make them perceivable to the ear.

The racal tribe have no ossous meatus auditorius, but

the auditory passage is long and serpentine; it is made of
cartilages and membranes that allow its being lengthened and

shortened.

The membrana tympani is extensive in general for the acuten

ness of the sense of hearing. It is also situated more or less

obliquely in that which is near. In the mole it is nearly

flat, and forms the bottom of the cavity of the tympanum.

It is nearly as oblique, according to Cuvier, in the otter,

catfish, and badger. In the pangolin, also, it is very oblique.

Its position is nearly vertical in many other carnivorous quad-

rumps. It is nearly vertical, and turned towards the side, in

the hare, coyp, marmot, and most of the eveln-footed order.

The form of the membrana tympani depends upon the

frame of bone in which it is placed. It is generally in mamm-

alia an oval, with the great axis defending obliquely forward,

and the anterior arch less convex than the posterior.

In some of the fatigued, the membrana tympani approaches

the figure of a shell in mammals; and in the mole it is perfectly

round. It has the figure of a trefoil leaf in the cetacea.

The ossous frame of the membrana tympani is only perfect

according to Cuvier, in the guinea-pig, the paca, the foal,

and the ass. There is in other inflections of the greater or less

deficiency in the upper part of it. This is often about one

quarter of its circumference. In the elephant the half of

the upper part of the ossous frame is wanting.

In the cetacea there is no proper process of bone for a

frame.

The membrana tympani has something of the infundibular

figure in all mammalia, except in the mole, where it exhibits

no concavity on the outer surface.

The structure of this membrane appears to be the same in

all the classes of mammiferous animals. In the larger quadru-

peds there is no difficulty in exposing its three layers, and in

the elephant the medicinal layer of the middle layer is laid to

be clearly demonstrable.

The cavity of the tympanum in most mammals is dilated at

the lower part, utially into a semi-oval or semi-spherical

cell. Those of each side produce two eminences that are

visible upon the lower part of the skull. They
Mammalia.

They are seen even in the prehensile-tailed monkeys, but are most remarkable in the carnivorous mammals; they are very large in the cat kind, and the seal. These protuberances are more or less angular in the sloth, the civet, the elephant-footed, and several of the many-footed quadrupeds. They are flat in the mole, and so broad as to touch each other. In the bear there are no projections visible. In the hog they are elongated, and end in bulbous heads.

The maxillary process can hardly be said to exit in mammalia. Its place seems to be supplied by the dilatation we have just described. In the elephant-footed and guinea-pig, there is a style-shaped process from the occipital bone, which has been considered as analogous to the malloid processes from some anatomists.

The interior of the cavity of the tympanum is, in many genera, more or less subdivided into different parts. A number of the carnivorous tribes have a transverse ossified ridge from the frame of the membrana tympani, to which it appears to serve as a support. In addition to this, there is, in the cat and civet genera, an ossous process, that extends from the posterior inferior edge of the frame of the membrana tympani, to the promontory, and which, being prolonged obliquely, divides the cavity of the tympanum into two unequal parts, that only communicate with each other by a hole. The anterior of these two cavities contains the bones of the ear and the foramen ovale. The posterior cavity is much larger, and holds the foramen rotundum. It seems to correspond with the large cells of birds.

Cuvier states that prehensile-tailed monkeys and ant-eaters have an additional cell, situated before the cavity of the tympanum, and that the tholo has a cell at the root of the zygomatic process.

The interior of the tympanum is intercepted in the elephant by a number of bony processes, which cross in every direction, and produce a multitude of cells. A similar structure exists in the guinea-pig, marmot, civet, and porcupine, according to Cuvier. The two tympani of the elephant communicate by the cellular structure of the skull.

The tympanum has ossous septa in the pig and horned ibulca, which divide its cavity into cells like those of a ripe fruit.

In the hippopotamus the proper cavity of the tympanum opens by a hole into a cellular cavity. The seal and morse have the tympanum very wide, but without septa.

The ossous part of the Eustachian tube in the cat and civet, is rather a narrow fissure than a canal; in the otter, badger, and weasel, &c. it is a hole; in the civet it is a half formed canal at first, which is completed in passing through the petrous part of the temporal bone. In the elephant it is a long wide canal.

There is a large membranous sac in the back of the mouth of the horse, in which the Eustachian trumpet ends.

In the cetacea, the cavity of the tympanum, as well as the petrous portion of the temporal bone, is distinct from the rest of the skull, to which these parts are only bound by ligament and periosteum. The tympanum resembles in figure the ca shell called bula. The part which corresponds to that containing the spiral cavity in the bulla is, however, fold in the tympanum. This part is more than two inches thick in the cachalot (physteser). This tympanum adheres to the petrous bone by its posterior extremity, and by a process of the anterior part of its thin edge. Cuvier states that in the dolphin, the anterior process of the tympanum alfo ascends to the petrous bone, but in the cachalot it does not reach that part. The tympanum of the cetacea is rough upon the surface. It is very ponderous, from possefling a great quantity of earthy matter, and is lined with a strong membrane, which Hunter thought had a cuticle. There is a thick plexus of vessels in the cavity of the tympanum, one part of which is attached, and the other floats at liberty, like the plexus choroides in the ventricles of the brain. The Eustachian tube in cetacea is widest at its commencement from the tympanum, the anterior extremity of which is entirely open. The tube ascends along the pterygoid processes, penetrates the maxillary bone, and terminates by a valvular opening in the nasal passage. Both the tube and the cavity of the tympanum communicate with several ligamentous cells, which Hunter considered analogous to the malloid processes in some referents.

The two foramina which connect the cavity of the tympanum are so various in their form, that the usual name of foramen rotundum, and foramen ovale, would be improper. Cuvier, therefore, has called the first the fenestra cochlearis, and the second the fenestra vestibularis.

In the bat, the foramen of the cochlea is larger than the other.

In the mole, they have both an oval figure. There is a hollow ossous bar which gives passage to some blood-vessels extended across the fenestra vestibularis in this animal; it pales between the branches of the flap. A similar bar is found in other mammals.

In the cat and civet, the foramen of the cochlea is almost twice as large as the vestibular fenestra.

In the opusum, the foramen called oval in the human subject is round, and the one called round is small and irregular. The latter is triangular in the beaver and marmot, and in the hare it is a small fihure. The vestibular foramen in this last animal is round and large.

The cochlear fenestra is about double the size of the other in the cat and pig, and three times larger in the hippopotamus. But in the elephant it is very small and irregularly shaped. It is larger than the vestibular foramen in the horse.

The two foramina are farther asunder in the cetacea than in quadrupeds. The one of the cochlea is the larger. It has an opening for blood-vessels. The lining of the tympanum projects into the cochlear fenestra.

The fame number of officula auditus are found in mammalia as in man, with hardly any exceptions. The ornithorhynchus paradoxus has only two officula; the first corresponds to the meatus of other mammalia; the second resembles very much the single officulum of birds. Perhaps a mechanism similar, or approaching to this, would be found in some of the other echimata. There have been discovered in some of the eleven-footed quadrupeds one or two small bones in addition to the usual number. These do not appear to be a natural structure. We shall not enter into a minute description of the varieties in the form of the bones of the ear, as many of them do not appear to influence the functions of the organ. We shall only notice the more remarkable peculiarities observed in the officula auditus, and refer the reader to Cuvier's "Comparative Anatomy," vol. ii. and Mr. Carle's paper upon the flapes in the Philosophical Transactions for 1805, &c. for a more particular description of these parts.

The processus gracilis of the malleus is formed into a thin lamina at its extremity in some mammals, and in the dog and cat. In the two latter, the short process of the malleus is very prominent. And there is another process at the inner part of the neck of the officulum, which supplies the place of the small spine of the human subject.

In the mole, the processus gracilis is so broad as to make the malleus appear nearly square.

In the fuligudina, the handle of the malleus is very thin.
It is likewise so in the sloth, ana-tater, and pangolin, and in all these the short posterior processes is almost effaced.

In the rat, the handle of the malleus is also compressed, and there is hardly any processus gracilis.

In the cetacea, the handle of the malleus is different, but its place is in some degree supplied by a tendinous elongation of membrana tympani, which has more of the funnel shape than in the other mammalia, especially on the inner side. This prolongation is pointed only on the inner tympani and is inserted into the bafe of the neck of the malleus. The neck is truncated obliquely, and there is a processus gracilis which is conical and arched in its form.

There is less variation in the forms of the incus of mammalia, than in the preceding ossicula. The mole has the most remarkably shaped incus. Its inferior or flapedian process is very short and small; while the other is very large, oblong, and hollowed posteriorly like a spoon. Cuvier imagines this may be for holding a muffle.

The flapedian process is very long, and the other hardly apparent in the rat and hare.

The existence of the articular as a distinct ossiculum has been doubted by some anatomists. Blumenbach considers it only as an epiphysis of the incus. He says it is often wanting even in negroes and North American Indians, whose organs of hearing are very perfect; that it is confoliated with the incus in the adult, and that when it is found as a distinct bone it is not a natural structure. It has appeared to us to be too easily separated, and too regular in its figure, for a mere epiphysis of the incus. It is wanting altogether in the cetacea. The bottle-nosed whale, according to Hunter, has a small bone in the tendon of the flapi-deus muffle.

There are several varieties in the figure of the flapes, which are pointed out by Mr. Carile, as above-mentioned.

The form of this ossiculum is most peculiar in the mole, and in the aquatic mammalia. The former has the branches of the flapes very much arched and far asunder. The bafe of the ossiculum is an elongated oval flape. In the cetacea the parts corresponding to the branches are fo thick and close to each other, that the flapes appears as a folid bone, with a very minute foramen in the middle. The bafe is small in proportion to the reft of the ossiculum. In theoes species we have examined, the foramen was only large enough to admit the point of a pin. Cuvier describes the flapes of the lamantin as resembaling a twifled cylinder; on one fide there is an oblique groove, and the foramen has the appearance of the puncture of a pin. The figure of the bafe applied to the fenile vault is very convex. Some approachs to this figure of the flapes has been obferved in the fcel, from whence it has been fuppofed, that a folid flate of this ossiculum was favourable to hearing founds communicated through water.

The mufcles of the bones in the tympanum have not received as much investiagation as they merit, either in man or animals. The fame number appear to exift in mammalia as in man, with the exceffion of the cetacea, which feem to want all the mufcles inferted into the malleus. They have, however, the flapidus muffle. Cuvier fays, it is inferted very far up, and not in the middle of the branch of the ossiculum, as in man.

The labyrinth consists of the fame parts in mammalia as in man. The semi-circular canals were at one time not fuppofed to exift in the cetacea. They are fo extremely fmall that they even efeaped the notice, for a long time, of fo accurate an anatomi as Camper. In the porpoife we have found them juft large enough to admit a brifle to pass in them. The extreme hardness and brittleness of the petrous bone in cetacea, are additional reasons for these canals remaining undiscovered, and fland in the way of invefti-gating all the parts of the organ of hearing in fhefe animals. This bone, and indeed the tympanum also, in cetacea, are as dense and weighty as common bone, and when dried are very eafily broken in all directions. The petrous bone is not united, even by future, with any of the other bones of the cranium, but is retained by ligament and periodioleum in a vacancy formed principally in the occipital bone.

The mole, whole organ of hearing, in many refepts, is formed upon an oppofite plan to that of the cetacea, this distingufhit by the extent of the femi-circular canals, and the fcel are plainly seen on the infide of the cranium, from not being imbied in a bone harder than the reft of the cranium, as ufual in other cafes.

Some mammalia are remarkable for the great fize of their cochlea, in proportion to their parts of the ear. The cats have it of the greatest relative fize. Cuvier fates, that the fox-floe bat has the diameter of the cochlea ten times greater than that of one of the femi-circular canals. The cochlea is visible in this genus on the lower part of the cranium, generally where its form is diftinctly exhibited without any difsection of the temporal bone. It bears a perfect likeness to the small-fhell. The femi-circular canals are visible on the internal part of the cranium. There is no petrous portion, properly fo called, either in the bat or the mole, except what constitutes the labyrinth itself. In the hare-baffed bat, according to Cuvier, the cochlea projects on the infide of the cranium.

In most of the carnivorous tribes of mammalia, the cochlea is larger in relation to the femi-circular canals than it is in the human fubjeft. It is, likewife, fo in the dog, el-ephant, and horse. On the contrary, the relative fize of the cochlea to the canals, is lefs in the mole and hare than in man.

In general, the cochlea forms two turns and a half in mammalia, as in man. But the guinea-pig, cony, and por-cupine, have three turns and a half. Their cochlea has a pyramidal figure, and makes a projicution into the cavity of the tympanum.

The cochlea of cetacea is very peculiar. It is large, but only forms one turn and a half, which is nearly in the plane of its axis. The offceous lamina spiralis is divided throughout its length by a very narrow fiffure into two parts. That which touches the axis is three times larger than the other. The fiffure is only completed in the recent fkel by a membrane.

The offceous part of this feptum also, which touches the axis, has under its bafe, and in the scala of the tympanum, a small canal, which follows the fame curvature from one extremity of the cochlea to the other. This canal appears like a third fcala to the cochlea, but it differs in the circumference of its capacity increasing as it proceeds in the cochlea; it is widest at the apex. Cuvier obferves, that there is a fimilar canal, though much smaller, in the eleven-loofed quadrupeds. In the other mammalia, only the part of the lamina spiralis which touches the axis is offceous, as in man.

According to Cuvier, the dog, sloth, el-ephant, horfe, dol-phine, &c. refemble man in having the fcala of the cochlea that goes to the tympanum rather larger than the other. It is much greater in the bat. The fcala that leads to the veftibulum, is the larger in the elf, geat, foep, hare, cat, guinea-pig, rat, &c.

The aquiludus, as they are called, appear to exift in all mammalia. They have been obferved to be very large in the dol-phine.
The figures which illustrate the organ of hearing, are found in Plate XIII. of the Anatomy of Mammalia.

Fig. 5. represents the under surface of the skull in the mol., the lower jaw being removed: a is the flat dilatation of the cavity of the tympanum, analogous to the mastoid cells, seen externally on the left hand side: b is the round, level, membrana tympani, exposed on the other side by the bone being cut away: e, the ossa incisus and auditory. Fig. 6. shews an undivided view of the bone, containing the organ of hearing in the grampus, removed from its connections with the skull: d, the bone which forms the tympanum: b, the extensive flat-shaped opening into the cavity of the tympanum, and which has been compared to the aperture of the bulla shell: c, the irregular trihedral space left for the attachment of the membrane tympani: d, the part of the petrous bone containing the labyrinth. Fig. 7. is a view of the malleus of the mol., Fig. 8. shews the same bone in the fee. Fig. 9. is the short, thick malleus of the grampus, with the membrane tympani attached to it: a, the ossiculum: b, the infundibular membrane tympani, with its elongated point inserted into the neck of the malleus. Fig. 10. gives the shape of the incus in the mol.: a is the hollow proc. of the bone. Fig. 11. is the incus of the grampus. Fig. 12. exhibits the flaps of the incus in situ: a, the ossiculum: b, the ossae incisi ve. Fig. 13. gives a side view of the flaps in the grampus, in which is shown the small aperture that corresponds to the space left between the limits of that bone in other mammals. Fig. 14. is a view of the lower part of the interior of the cranium in the mol.: a indicates the labyrinth as it appears, without any division of the bones of the cranium: b, the semi-circular canals and cochlea exposed, by cutting away some part of the cranium, which is very loose and cellular in its texture, adjoining the ossae labyrinthi in this animal. Fig. 15. is a representation of the ossae labyrinthi of the bat, removed from the skull, and a little magnified: a, the semi-circular canal: b, the very large cochlea: c, the foramen cochleae fenestra: d, the vestibular fenestra. Fig. 16. exhibits the turriculated cochlea of the guinea-pig, laid open on one side, to expose the three turns and a half made by it in this animal. Fig. 17. shews the cochlea and part of the semi-circular canals of the grampus, excavated from the petraus bone: a, b, the two tubes which form the cochlea: c, d, parts of the semi-circular canals exposed and laid open in making the sections of the bone in which they are inclosed: e is the portion of the petrous bone left in the section. Fig. 18. shews the entire cochlea of the whale, abstracted from all surrounding bone; at the extremity are seen the openings into the two tubes of the organ. Fig. 19. is a lateral view of the same cochleae: a, b, are the two small openings of the cochlea: c is the beginning of a ridge which divides the entrance of the cochlea: d, the tube, which appeared to Camper to contain a nerve.

Organ of Vission.—The eye is composed of the same coats and humours in mammalia as in the human subject. The comparative anatomy of the organs of vision in this class, relates to varieties in the structure of particular parts, with a description of a few appendages to the eye, that do not exist in man.

There is some diversity in the external figure of the eye-ball in different mammalia. Agreeable to a general principle already laid down, it is more globular, or the anterior part is more gibbous, in proportion to the tenuity of the medium, through which the animal beholds objects. We therefore find that eyes of the aquatic mammalia are more flat upon the anterior side, in which circumstance they approach in form the eyes of fishes.

The departure from the spherical form of the eye is indicated by a table published in Cuvier's 'Comparative Anatomy,' in which the length of the axis is compared with that of the transversal diameter of the eye. We shall extract the following examples.

Both the permanent and changeable forms of the eye-ball depend necessarily upon its external particulars, which are the sclerotic coat and cornea.

The sclerotic coat has the same texture, and proportionate thickness of its different parts, in mammalia generally as in man. There are, nevertheless, some striking exceptions to this observation in the aquatic tribes. The sclerotic of the fab is thick and firm at the anterior, and still more so at the posterior parts of the eye; but around the middle this coat is very thin and pliant. This change of the strength of the coat is not, however, abrupt. Blumenbach attributes to this structure the power of accommodating the form of the organ to the different media in which these animals reside. The cornea of the fab is also thin and yielding, and the muscles which act upon the eyeball are strong. The result of all these circumstances is, that the creature can elongate and shorten the axis of the eye according to the occasion, and thereby adapt it to vision in the two media of air and water.

D'Albeus has discovered a similar conformation of the sclerotic in the cyclus, in which it is also obviously intended to answer the same purposes.

The sclerotic coat of the eye in ocellus or the aquatic mammalia is very peculiar. It is prodigiously thick at the posterior part; in the larger species about an inch and a half; in the grampus about 2/3 of an inch; and in the porpois two or three lines thick.

It gradually declines until it arrives at the corneal, where it polishes the ordinary thickness of the sclerotic, in proportion to the size of the animal. The composition of this coat is equally curious with its form. Upon dividing it, we find a multitude of ligamentous fibres passing through it in all directions, and forming an inextricable plexus, which contains in its meshes a brown glistening clastic substance. A section of the sclerotic has very much the appearance of that of tanned leather, only that it is paler. The coat is looser in its texture, and fonder quite at the back part, than on the sides of the eye-ball. The meshes there contain an oily substance. The sheath of the dura mater, which contains the optic nerve, is necessarily very long, and is very easily demonstrated in the cyclus. The fibres which enter into the composition of the sclerotic are seen to depart from the external part of the sheath, which fact has been taken as the proof of the sclerotic coat being, in all cases, a production of the dura mater, as supposed by the ancient anatomists. The sclerotic of the cycloidea kind, by its great firmness, defends the internal parts of the eye from pressure, to which they would otherwise be subject, from the shallowness of the orbit. The form of the internal part of the organ is also

Also
Mammalia.

also altered to nearly an oval, although the external figure is spherical.

The transparent cornea generally resembles that of the human subject in the clasps of mammalia. The porcupine and opisphium have this part large, and forming the same sphere with the sclerotic. Blumenbach says the cornea of the porcupine extends over half the globe of the eye.

The definition between the cornea and the sclerotic, which is generally but an apparent change of structure, is very clearly to be traced in some of the large animals, in which these two coats can be separated. In the rhinoceros and the rhinoceros, the attachment of the sclerotic to the cornea is by the fibres of the former passing into the latter. In the ox, &c. the line of separation can be seen to be oblique, the cornea passing a little under the edge of the sclerotic. In the bare and others, the edge of the sclerotic is double, and embraces on both sides the margin of the cornea.

The tunica conjunctiva is, especially in the large quadrupeds, less adherent to the eye-ball than in man. Mr. Pierce Smith has professed to trace not only the conjunctiva, but the expansion of the straight muscles over the cornea. The plainest evidence of the continuation of the conjunctiva over the front of the cornea is found in the xenini rat (mus typhlus), which has the conjunctiva retaining the structure of the true skin, and even covered with hair, so that the eye is altogether useless, or at most can faintly discern the difference between light and darkness. The eye of this animal is said to be not larger than a poppy seed. In the mole, also, the eye is extremely minute, and so much shut in by the hair on the eyelids, that it does not appear to be capable of seeing any object distinctly; indeed the eyes of the mole are so much concealed, that they are supposed by common people to be wanting altogether.

In the sabale and the large quadrupeds, the definition of the two layers of the choroid coat is very perceptible. The internal layer, or membrana Ruyfchiana, is particularly plain in the sabale.

Mr. Thomas has discovered a most curious apparatus connected with the choroides in the Esot Indian rhinoceros. Four tenacious processes arise from the back part of the sclerotic coat, expand anteriorly, and form a species of muscular membra, which is loll in the choroides at the broadest diameter of the eye-ball. It is easy to conceive that this structure can produce material alterations in the figure of the eye, and in the distance of the crystalline lens from the retina, but we cannot conceive why so great a power of adjustment in the eye to different distances should belong exclusively to this animal.

The pigment of the internal surface of the membrana Ruyfchiana is of various colours in mammalia, particularly on the back of the eye. The monkey has it dark coloured. The bare, rabbit, and hog, have it a brown: but in many other mammalia the pigment upon the back of the eye has light and vivid colours. It is called, in those cases, the tagetum lucidum. The ox has the back of the eye a green, which is lost in an azure blue. In the sheep it is a pale yellow-green, or sometimes bluish. Some anatomists, who seem to have confined these observations to those two cases, have conjectured that the use of the tapetum is to reflect the natural colour of the animal's food. But the absurdity of this opinion is shown by the varieties of the colour of the back of the eye in other animals.

The tapetum is a silvery blue, changing to violet in the hare, goat, buffalo, and fleg. It is a pale golden yellow in the lion, cat, bear, and dolphin. It is a pure white, terminating in blue, in the dog, wolf, and lynx.

The shape of the coloured portion of the Ruyfchian coat is irregular, and is situated chiefly upon the temporal side of the entrance of the optic nerve: but in the sabale the whole of the Ruyfchian is a silver colour; the ciliary processes and back of the iris alone being dark. The ule of the tapetum is not very obvious. The most probable opinion respecting it, is, that it enables animals to see better in the dark.

The ciliary processes do not appear to differ in their structure in this class and in the human subject. It is true they are very prominent in the large species, and the denticulation of their edges is so much increased, as to form a rich fringed appearance, particularly in the rhinoceros and sabale. The laminae of these processes are long and narrow in the cat kind, more especially in the lion.

Mammalia have the irix usually of a more uniform colour than in man. In domestic quadrupeds, however, there is considerable variety in this respect. The colour of the iris corresponds so much with that of the hair, that in spotted dogs, &c. the iris is often of a mixed colour.

In the large mammalia the iris is of considerable thickness, but no difference of structure has been perceived.

The uvex is found much more plain in the ox, rhinoceros, and sabale, &c. than in man, and the lirre that are continued upon the uvex from the ciliary processes, are very distinct in these species. They extend in the rhinoceros nearly to the edge of the pupil.

The pupil of the eye has various forms in some mammalia. It is in the cat kind a vertical slit, over which these animals have great command, sometimes contracing it to a mere line, and at others dilating it to nearly a round figure. In the cloven-hoofed order, the pupil is a transverse slit, with the ends of the slit wider than the middle. In the bare it is also transverse, but the superior edge projects a little way. This has been compared to the curtain that hangs over the pupil in the feline by Swammerdam, although there is but little resemblance between the two parts.

It is a transverse oblong aperture in the true sabale, and in the genus delphinus it is a heart shape.

The retina is formed usually in the same manner in mammalia as in man. It sometimes happens that the optic nerve, immediately on entering the cavity of the eye, forms a slight projection. In the bare and rabbit, this projection is described as producing a kind of oval cupola, which is highly concave in the middle. The retina arises from the edge of it. The fibres of the nerve are condoned on each side by two fronds or pencils, which are a more opaque white than the other parts of the retina. In almost all mammalia the retina has at its origin the appearance of its substance being collected into folds, or fibres, which arise in a radiated manner.

Comparati flates, that the optic nerve of the bat perforates the sclerotic coat by a number of foramina. The filaments, thus formed, unite to produce the retina.

The foramen of the retina, which usually takes the name of Sömmering, has not been found in any of these clasps, except the monkey tribe. Cuvier flates, that he found it in the synocepclus considerably larger than in man, and of an oval shape.

It is singular, that although this foramen does not exist in the lemurs, yet the fold which contains it in man and the monkey is found. The use of the foramen of Sömmering are not yet determined. Mr. Home imagined that it gave exit to an absorbent vessel; but it is much more probable that its existence is connected with the position of the eye, as it is only met with in those that have the eyes placed in
that their axes are parallel. Blumenbach observes, upon this subject, that when the two eyes are situated, as in man and the monkey, they are liable to be both dazzled at the same time, by an exposure to a strong light, as the rays fall upon the corresponding principal focus of both eyes at once. He concludes, that the foramen of Schmincke being in the principal focus, the rays pass through it, and are focused in the pigment of the choroid coat. But to produce such an effect, without weakening vision at all times, would require a muscular power to open and shut the foramen according to circumstances, nothing of which kind appears to be provided.

The aqueous humour of the eye would appear to be in less quantity, according to the bulk of the organ in mammalia, than in man.

The crystalline, on the contrary, occupies less space in proportion to the other parts in man than any of the mammalia. It is also more of a spherical figure in all this class than it is in the human subject. Blumenbach states, that he found the crystalline to be larger in relation to the vitreous humour in the Virginia opussem. We select the following instances from a table founded on the observations of Petit and Cuvier, to show that there is a scale, from man to the cetacea, with respect to the form of the crystalline, by which it will be found, that the lens is half spherical in the human subject, and half so in the aquatic mammalia.

The axis of the crystalline is to the transverse diameter,

In Man, 

1 to 2 generally.

In the cetacea, therefore, the lens is nearly a perfect sphere, as in fishes.

The vitreous humour of man is more abundant, in proportion, than that of mammalia. Thus, the human vitreous humour is twenty times larger than the aqueous, while, in the ox, it is only ten times as large, and in the sheep but nine times the size of the aqueous humour. The oblique muscles of the eye-ball do not differ from those of the human subject; but the straight muscles are more numerous, except in the monkey kind. In many there is but one additional muscle, which enclodes the back of the eye and the optic nerve, as if in a funnel. It arises, like the other recti muscles, from around the optic foramen, and is inserted into the sclerotic behind them. This muscle is called the suilpenfory, oblongor, or rector of the eye.

The lifpenfory muscle is divided into four slips, or, as some might flate it, there are four additional straight muscles in most of the carnivorous mammalia, and the cetacea.

In the rhinoceros there are only two portions corresponding to the lifpenfory muscles.

In all mammalia, we find the four recti muscles as in man, independently of the lifpenfory above-mentioned.

In the third eye-lid is e/4, liberally developed in many quadupeds. It is usually found near in its figure. In the horse, rat, agouti, &c. its free edge is convex. In many cases, it contains a thin cartilage, which, from a fupposed resemblance to a nail, is called unguis. This cartilaginous plate is broad and triangular in the third eye-lid of the bare. There is almost always a row of pores upon this eye-lid, which discharge an unctuous fluid. The third eye-lid is large in the
cut genus, the opussum, the seal, and particularly so in the elephant.

There is no trace of the third eye-lid in the cetacea, and the two usual eye-lids are so much thickened by the adipofol frumentation, that they have fearlessly any motion. They seem half closed, but, we believe, are never completely shut, the constant residence of these animals in water not making it necessary.

The lacrymal gland exists in mammalia, except the cetacea. In the hare and rabbit it is extremely large. It nearly envelopes the eye, and even paffes out of the orbit on the flde of the nolc. Cuvier thinks it has but one excretory duct.

The lacrymal gland in the eleven-bofed quadrupeds is divided into two or three muffs. Some separate grains have each a very short excretory duct.

The pantha lacrymalis, and the nafal duct, for carrying off the tears, have been observed in the bifurca, kozz, floth, and antelopes, &c. and probably are to be found generally. Camper, however, denies the pantha lacrymalis, lacrymalis jacc, and even the sa unguis to the elephant. Some anatomists have considered cells below the internal angle of the eye in the deer and antelope genera as receptacles for the tears; but these follicles, as already mentioned, in delifying the excretory glands, have no connection with the lacrymal piafferes and contain an unicous matter.

In the hare and rabbit, the pantha lacrymalis are supplied by a semi-lunar fissure, which is placed under the inferior edge of the third eye. The border of this slit is provided with cartilages to keep it open. There is a single lacrymal duct, and a small valve in the canal, to prevent the tears returning upon the eye. There is no apparatus for the secretion of tears in the cetacea. Thus, constant residence in the water is sufficient to keep their eyes moist.

In many mammalia there is an additional gland to the eye, which, from an anatomist that described it, has been called glandula Harderi. It is placed near the inner angle of the eye-lids, and discharges its secretion, which is a thick unctuous fluid, through an opening under the third eye-lid. The glandula Harderi consists of small lobes, and resembles very much the true lacrymal gland in its structure. There would seem to be two glands of this description in the hare, one is a white colour, the other red; but both apparently have the same structure. They are connected by cellular subflubine. This gland is large and double in the water rat. It is single, oblong, and hard in its texture in the eleven-bofed quadrupeds. It has been found oval in many others. There are some cetaceous follicles under the upper eye-lid of cetaceus mammalia, which probably fulfill the same purpofes as the glandula Harderi.

In Plate XIV. of the Anatomy of Mammalia, fig. 1, exhibits a section of the eye of the fin, in the direction of the optic nerve: a is the anterior part of the sclerotic coat, which is thick; b, the posterior part, still thicker; c, the middle portion, which is thin; d, the cornea; e, the optic nerve; f, the vitreous humour; g, is the crystalline lens, which is seen to approach the figure of a true sphere. Fig. 2, represents a similar section of the eye in the grampus: a is the optic nerve passing in the canal formed in the sclerotic coat at bb. That coat is also shown to derive its white fibres from the thraight of the optic nerve; e, the cornea; d, the ciliary processes; e, the membra Ruykhiara; f, the choroides. Its two layers are a little separated, to show them more distinctly. Fig. 3, is a view of the interior of the front of the eye in the ox, produced by the vertical section of the organ: a, the divided coats; b, b, the fringed ciliary processes; e, e, the fibers of the uvea; d, the trans-
Mammalia.

The eyeball. Fig. 4, is the front of the eye in the cat, with the cornea removed, to shew the vertical slit produced by the pupil in this genus. Fig. 5, is a similar preparation of the eye of the porpoise, to shew the figure of its pupil. Fig. 6, is a view of the eye-lids in the hare, with the aperture into the lacrimal duct; a, b, the upper and lower eye-lids; c, the third eye-lid; d, the fissure corresponding to the puncta lacrimalis. Fig. 7, exhibits the glans of the eye in the hare: a is the lacrimal gland; b, the white glandula Harderii; c, is the red-coloured one.

Weapons and Organs of Defence.—There is no animal so unprovided with the natural means of protection or defence as man. His strength and his security depend upon the social institutions established by his species. It is true many of the mammals are not furnished with natural arms, but in place of them, they are endowed with great swiftness of foot, and an acute sense of hearing, as may be observed in almost all the fastigiate quadrupeds, and others which are pursued by the beaks of prey. Some fugaline animals seek security in concealment, as the digging and diving quadrupeds, for example the mole, the duck-billed animal, &c.

The various coverings of mammalia, such as hair, hoofs, scales, spines, &c. not only serve to shelter quadrupeds from the inclemency of the weather, but from the attacks of hostile animals. The strong tough hair of the ant-eaters and sloths, the scales of the pangolin, the spines of the hedgehog and porcupine, and, most of all, the bands of the armadillo, are well calculated for this purpose.

Those quadrupeds that have defensive integuments, have generally the power of rolling themselves up, fo as to conceal the head, feet, and under parts of the body, which are commonly unarmed. The muscles that are designed for the contraction of the body, are described with the other organs of motion.

The most powerful weapons of mammalia are their horns, teeth, and the hard subduces with which their toes are armed. The structure and growth of each of these parts are described in their proper place.

The horns are generally employed as the means of defence, and chiefly belong to quadrupeds that are gregarious and insinuative, unless much irritated, or during those periods in which they are under the excitement of the sexual or parental instincts.

The teeth are the weapons most commonly employed by animals; almost every quadruped may be provoked to make use of them; even man himself, in those states of society where rules of combat are not acknowledged, always refers to his teeth, when pressed by an adversary. As the teeth are the most general weapons of animals, they are also the most destructive in the operation; when any animal kills another, it is most commonly by means of its teeth. The large teeth called tusks, although generally incapable of being employed in any other way than as weapons, are less dangerous than the small front teeth of many animals. Some tusks, although formidable in their appearance, are very harmless in fact. The tusks of the babirouss are so much turned backward, that they cannot inflict a wound, and those of the elephant and mammoth seem incapable of injuring a small animal. The tusks of the narwhal are said to be terrible weapons, which their direction, length, and pointed figure render very probable; there being also few of them wanting, it is likely that it may have been lost in combat.

The feet of quadrupeds are amongst their most effectual weapons when they are furnished with claws, as in most of the beaks of prey. The strength of the limbs in all predaceous quadrupeds has already been remarked. The mechanism of their feet, by which the claws are inverted by the very act of grasping any object, is singularly useful to those animals.

Some of the mammalia possess a great security from the assaults of others, in certain exertions produced by peculiar glands, situated commonly in the neighbourhood of the anus. These exertions have a disagreeable smell, which is probably particularly offensive to those animals they are intended to repel. Some of the American species of *opisurus* are said to occasion fo strong a factor by the expulsion of the contents of their anal glands, that it is discerned at a distance of two miles, and cannot be immediately approached by any person without the greatest danger. The organs which furnish these fecidal matters are described along with other excretory glands.

Organs of Voice.—The monkey tribe, which have in most parts of their anatomy so strongly a likeness to the human body, have many striking and important peculiarities in the organs of voice, some of which are even poled by the *ourang-outang*.

This animal has the *arytenoid cartilages* smaller, and the *cuneiform* ones larger than in man. The *corda vocale* are long and sharp upon the edge. The ventricles of the glottis are large oval cavities, and partially divided by a partition. The superior part of each ventricle leads into a hole, which is situated between the thyroid cartilage and the os hyoideum, and is the opening of a large membranous sac. These two sacs lie under the skin of the throat, and are in contact with each other, and defend towards the mouth. These sacs, in some individuals, are of different sizes according to Camper’s observations. Blumenbach found the right sac three inches long and two inches round, and the left only the bulk of a nutmeg in the *pigmy ape* (*fumia fuscicornis*).

In many other monkeys there is one large pouch or membranous sac, which communicates with the glottis. This sac has been described by Camper in the *Barbary ape* (*fumia inuus*), and the common *baboon* (*fumia fuscincus*). The opening from the glottis in these cases is in the middle, at the root of the epiglottis, immediately above the thyroid cartilage. Vic d’Azir also discovered the same kind of sac in the *ribbed-nose ape* (*fumia mainas*), in which it is very large, and has a round opening under the epiglottis. Cuvier found a similar laryngeal sac in the *bare-lipped ape* (*fumia cynamolagus*), and a very large one in the *fumia water*. It has been described in the *varied ape* (*fumia mona*); but Cuvier denies there being any appearance of it in this species, and even of the hole or depression at the base of the epiglottis, which exists in some *monkeys* that do not possess a laryngeal sac, as in the *great baboon* (*fumia harmadryas*), the *red ape* (*fumia rubra*), and the *Chinese ape* (*fumia finica*).

In the *jolly monkey* (*fumia mariniis*), the laryngeal sac has its opening between the cricoid and thyroid cartilages.

The *bowling baboon* (*fumia belzeboul*), and the *fumia senicula*, have the laryngeal sac inclosed in a bony case, which is hollowed out in the os hyoideum. Camper described but one sac, which he flated to communicate with the larynx by an aperture between the os hyoideum and the thyroid cartilage. Vic d’Azir also found but one sac, which he described as being of an irregular pyramidal figure, situated under the tongue between the two branches of the lower jaw, with its pointed part forwards, and divided internally by several thin projections of bone. It had a wide opening posteriorly, above which was placed a bony plate, with two projections at its two extremities. The opening
of the face communicate with a large, firm, membranous tube, which proceeding horizontally backwards, terminated in the larynx between the apex of the thyroid cartilage, so as to form a communication with both the ventricles of the glottis. The thyroid cartilage was remarkably large, and projected downwards: from its cornu on each side there passed a ligament to the two projections of the bone face. The thyroid cartilage had a projection where it terminated, which seemed to divide the channel leading from the bone fac into two channels: such is the description given by Vie d'Azer of the organ of voice in the baboon. Cuvier, however, states, that in the fumer fibinicus each ventricle leads into a membranous fac, which divides the epi- glottis and contiguous ala of the thyroid cartilage, and proceeds towards the os hyoide. In the individual which he described, the right face alone occupied almost the whole of the cavity in the os hyoide; the left terminated at the moment when it was to enter that bone: but he conceives, that in other individuals, the faces were of equal size, or that the left might even be the larger of the two.

The effect of all these cavities connected with the larynx is to increase the resonance of the voice. The cartilaginous framework of the larynx and trachea in all animals has the same operation in a greater or less degree; for the corda vocales could only occasion the parts immediately adjoining them to vibrate, the sound which they produced would scarcely be audible. The power of hollow parts in multiplying sound, or rendering it loud by a secondary vibration, is strikingly exemplified in the difference observed between the common and the mute fide. The body of the latter is a narrow fold piece of wood, and although the tones are the same as those of the common fiddle, they are faint as scarcely to be heard. The influence of the laryngeal cavities upon the voice is clearly shown in those animals which possess them. The baboon, that have the best contrived apparatus for increasing the voice, are said to utter a cry which is really terrific.

One species of monkey, the fumer paniceus, has a different kind of dilatation than is found in the rest of this tribe. It is a very considerable enlargement of the membranous part of the trachea immediately behind the cricoid cartilage. The muscles which go from the larynx to the pharynx compress this face, and urge the air it contains in a stronger current through the parts that immediately produce the voice. Cuvier describes in this monkey, and in all those of the continent of America, a peculiarity in the structure of their larynx, by which their voice is rendered soft, like the tone of a flute, and are therefore called whistling monkeys. This peculiarity consists in the smallness of the arytenoid cartilages, and the great bulk of the cuneiform cartilages, which, increased by some fat cellular substance, form before the superior extremity of the ventricle of the glottis a large cushion, having the figure of a segment of a sphere on each side. It follows from this structure, that the air which has vibrated in the ventricles has to go through a narrow canal, curved in the figure of an S, which is occupied by the formation of these cushions and the concavity of the epiglottis.

In the fumer jacchus, and the fumer midas, the cuneiform cartilages are so large, that their superior projection even divides the upper part of the larynx into two, so as to give it apparently a resemblance to the larynx of birds.

The os hyoide is large and round on the front, even in those monkeys which do not possess laryngeal facs, as in the fumer apella and the fumer capucina.

In the lemurs, the superior ligaments of the glottis are very prominent, and there are between them and the epiglottis deprellions, which might be considered perhaps as superior corda: vocales and ventricles.

The epiglottis of the hares is soft and hardly perceptible. Its existence has been denied by Vie d'Azer. The corda vocales also are very indistinct. In the vampire bat, there is a slight membranous projection in place of epiglottis.

In the dog genus the corda: vocales are prominent, thin, and free; the ventricles are deep; and the membrane which lines them is wider than they are. The cuneiform cartilages have the shape of an italic S. The loftiness of the corda vocales and the membrane of the ventricles, no doubt tends to produce the barking voice of these quadrupeds.

In the cat genus, the anterior ligaments of the glottis are, as in the dog, contiguous to the internal parietes of the epiglottis, but are separated by a wide deep groove on each side. The posterior ligaments, or corda vocales, are not loose or sharp. There are two small thin membranes near them, which, when they vibrate, produce the purring sound of the cat's voice. Cuvier thinks, that the anterior ligaments of the epiglottis constitute the corda vocales of the cat, the ventricles being so very shallow.

The ichneumon and civet have the organs of voice similar to those of the cat genus.

In the bager, the ventricle is open, and leads into two pouches, one of which extends forwards under the root of the tongue, where it is only separated from that of the opposite side by the hyoepiglottic muscles; the other goes backwards between the thyroid and cricoid cartilages. The found of the voice in this animal appears to be occasioned by the vibration of the breath against the posterior edge of the anterior ligament, when it is driven with force into these two pouches. There are similar pouches in the several, but the anterior has the least extent.

The marsupial animals have the larynx peculiarly formed.

In the kangaroo the arytenoid cartilages are very large, their superior edge forms the two-thirds of that of the glottis. The cuneiform cartilages, the anterior ligaments, and the ventricles of the glottis, do not exist in this animal, and it can scarcely be said that there is even any posterior ligament or corda vocales. Cuvier is disposed to think that the kangaroo is very nearly mute.

The American opipium has also the arytenoid cartilages of great size, and the thyroid cartilage concave. The superior ligament of the glottis is wanting, as in the kangaroo. The corda vocales are very small, and scarcely to be distinguished from the surrounding membrane. There is an oval epiglottis, with two little folds of membrane at its root, which are susceptible of vibration.

The long-tailed phalangers of Cook have a membrane, which serves at once for a vocal ligament and the edge of the glottis, between which, and the cricoid cartilage, there is a groove which might be considered as a ventricle in an unusual situation. This ventricle has also been observed in the glottis of the ornithorhynchus, in which animal it is very deep. Both the ornithorhynchus and echidna have the edge of the glottis formed by the arytenoid cartilage, and a single vocal ligament. There is no ventricle in the glottis of the echidna.

In the didelphic orientalis there is no distinct ligament, and the epiglottis is deeply notched.

In the fahigara mammal, Cuvier has derived two different kinds of structure in the organs of voice. In the one, of which he gives the porcupine as an instance, the corda vocales and ventricles are not found, or scarcely discernible: in the other, which seems to belong to the great majority of the
the order, the vocal ligaments are dilatant, and the ventricles often deep. The glottis in the *bears* and *rabbits* is peculiar. It wants the superior ligament, and the cartilaginous cartilages; nevertheless, the arytenoid cartilages are pyramidal, and afford attachment to two cordae vocales, which are very free and thin edged, and are separated from the base of the epiglottis by a deep narrow groove. Between their commissures, at the base of the epiglottis, there are two little cartilaginous tubercles projecting inwards. They do not give any attachment to the anterior extremities of the vocal ligaments, which are fixed externally to them.

Amongst the *edentata*, Cuvier describes the organs of voice as differing in each genus. In the *Cape ant-eater* (orycteropus), the cordae vocales form the edge of the glottis; there is but a slight groove in place of the ventricle. In the *armadillo* the larynx is smooth internally, and the epiglottis is in two lobes.

The *tardi grade* quadrupeds have a singularly formed larynx. The free edges of the *corda* vocales are the inferior ones; they hang down against the inner side of the cricoid cartilage, like triangular valves. There are no ventricles or anterioal ligaments.

Amongst the *many-hoofed* tribe of quadrupeds, the *elephant* has a simply formed larynx. The inferior ligaments of the glottis or corda vocales are prominent, and sharp edged. They ascend in proceeding to their anterior attachment much more than in the *pig*. The ventricles are mere grooves.

In the *pig*, the direction of the corda* vocales is peculiar: they defend anteriorly. They are long and sharp edged; and capable of being rendered extremely tense by the actions of the larynx, which enable this animal to utter the thrill cry it is so remarkable for. The ventricle opens posteriorly into an oblong sinus, that ascends between the internal membrane and the thyroid cartilage. The magnitude of this sinus has been over-rated by some anatomists. Its real size, according to Cuvier's observations and our own, is about sufficient to admit the end of the little finger. It is this cavity which enables the *pig* to produce the *grunting* sound, the corda vocales being at the same time in the relaxed state.

In the *eleven-hoofed* quadrupeds, a superior angle of the arytenoid cartilages bends backwards, and makes the two thirds of the end of the glottis; and an inferior angle of the arytenoid bends forwards, and gives attachment to the corda vocales. This last has the anterior part more or less free, sharp, and thin, according to the species, but its posterior edge is blunt, and continued into the membrane lining the rest of the glottis. The anterior ligaments are not found, and the place of the ventricle is supplied by the furrow arising from the projection of the corda vocales. There are no cuneiform cartilages in this tribe. The thyroid cartilage swells out anteriorly, where the corda vocales are attached in the *fallow deer*, and still more in the *cerveau antilope*, in which the projection is nearly pyramidal. The swelling under the throat in the *antilope gutturosa*, is occasioned by this enlargement of the thyroid cartilage.

There is a membranous sac in the front of the thyroid cartilage in several of the *antilope genus* and the *rein deers*. The opening into it is at the root of the epiglottis. The face of the *rein deers* is very large, extending under the neck, as in the *mamillar* (*femina mordax*).

Cuvier has given a full description of the organs of voice in the *solid-hoofed* quadrupeds, in which he has corrected many errors in the account of the larynx of the *bores* and *afs* by Herissant. The chief peculiarities of the vocal organs of these animals, consist in the faces connected with the larynx. There are three of these: one is situated anteriory, under the vault formed by the anterior boundary of the thyroid cartilage; the opening into it is under the root of the epiglottis. The two others are oblong flaps contained between the lateral paries of the glottis and the thyroid cartilage, and covered, in a great measure, by the thyro-arytenoidei muscles, by which they are compressed. There is no anterior ligament of the glottis, nor any ventricle, properly speaking; but above the corda vocales, on each side, there is a foramen which leads into the lateral face.

In the *bores* the apertures of the lateral faces are long and wide, and bear some resemblance to the usual ventricles of the glottis. The opening into the anterior cavity is very wide in the *bores*, in which all this cavity is a shallow depression. On the contrary, in the *afs*, the opening into each of the three faces is a small and round hole, and the anterior face is a real bag of considerable size.

Cuvier states that the *mule*, which is generated by the *male* *afs* and the *mare*, has the openings into the laryngeal faces wide, and the structure of the organs of voice altogether approaching that found in the *bores*, and he concludes that the account published by Herissant was taken from the description of the offspring of the *fallow deers*, and the *female* *afs*. Binenbach has, however, followed many other anatomists in attributing similar organs of voice to the *common mule* and the *afs*. We are not enabled to decide the point, not having dissected these organs in the *mule*.

Cuvier further adds, that in the *bores* and the *mare* there is at the commissure of the two corda vocales a slight fold of the membrane, which is not visible in the *afs*. The size of this fold has been greatly exaggerated by Herissant; he has also attributed to it important offices which it does not seem to perform.

The peculiar sound called a *bray*, is uttered by the *afs* in consequence of the extent of the laryngeal faces, and their being so much separated from the cavity of the larynx, by thus having small apertures. The *bray* seems to be a compound discordant sound, produced from the resonance of different fixed cavities.

Cuvier found in the *cownagga* the larynx organized as in the *bores*, except that the membrane extending from one corda, which in the other did not.

The larynx is very peculiarly formed in the *cretases*. The arytenoid cartilages and the epiglottis have the figure of very elongated triangles. These three cartilages are united to each other by the membrane of the glottis, and have a degree and kind of motion somewhat familiar to that of the parts about the mouth of a mule. The top of the larynx, which is composed of these three cartilages, has a pyramidal figure, and is invested into the common origin of the posterior nare. It is retained in that situation by the circular muscles of the fleasy tube which forms the common passage to the nare. The usual office of the epiglottis is, therefore, lost in *cretases*, and instead of making an orifice to the rima of the glottis, it enters into the composition of that aperture, which is thence rendered wider in the tranverse direction, and resembles very much, in appearance, the mouth of a mule. The advantage of having the air-tube immediately connected with the nasal passages in the whole kind, shall be obvious. These animals catch their prey by swimming with their mouths open, and below the surface of the sea, at which times, the water and small fish are carried through the hairs on each side of the pyramid formed by the larynx. When, however, the latter is withdrawn from the posterior nare, in order to eject the water through the spiracles, the rima glottidis is shut; but rather by the edges being closely applied to each other, than by being covered by the epiglottis.
The interior part of the larynx in *cetacea*, exhibits no true cordeae vocales or ventricles. The membrane, at the anterior part of the cavity, forms some very irregular folds, or rather a corded appearance, resembling, in a degree, the internal surfaces of the heart. Cuvier says, he only perceived some longitudinal rugae. The inequalities on the interior part of the larynx, in these animals, do not, however, appear capable of vibrating sufficiently to produce any voice; or if the whole tribe do utter any sound, it must, we conceive, be a kind of brrra, occasioned by the forcible emission of the air through the aperture of the glottis.

In Plate XIV. and XV. of the Anatomy of Mammalia, the figures are found which illustrate the structure of the organs of voice.

In Plate XIV. fig. 8 represents the entire larynx and face of the macacid (firma mammon), as it appears when dissected out: a, the root of the tongue left with the larynx; b, the os hyoides; c, the larvyngeal sac dilated with air; d, the trachea seen beyond it. Fig. 9, of the same plate, shows the larynx opened from behind; and the hole which leads into the laryngeal sac, as it usually appears in these monkeys, that have these dilatations connected with the organ of voice: a, the epiglottis; b, the tendons at its base, opening into the laryngeal sac, which has been cut off in this preparation; c, d, the cordae vocales; d, d, the two ventricles.

In Plate XV. fig. 1 is a view of the larynx, and bony face attached to it, divided longitudinally to shew their internal formation in the *boiling calabash*. This figure is copied from one of Vic d'Azir's, and of course agrees with his description of the organs of voice in this animal: a, is the tongue, divided lengthwise through its middle; b, c, pharynx and oesophagus laid open; d, the ligament between the bony face and the thyroid cartilage; g, o, p, b, larynx and trachea laid open; d, epiglottis; f, b, bony fac laid open; i, k, the course of the tube leading from the face to the larynx; m, a projection of the thyroid cartilage dividing the tube into two; p, the corda vocalis of that side; g, the ventricle of the glottis. Fig. 2 exhibits a view of the larynx, similar to the last, in the *firma papionis*: a, the tongue; b, the epiglottis; c, the thyroid cartilage; d, the arytenoide cartilage; f, the ventricle of the glottis; g, the cartilage; b, the face, which in this animal is placed at the membraneous part of the beginning of the trachea: it is laid open. Fig. 3 represents the interior of the larynx in the cat: a, the epiglottis; b, b, the cordae vocales; c, c, the two membranes, which are thought to produce, by their vibration, the purring sound made by this animal. Fig. 4 shews the internal parts in the larynx of the fig. a, a, the ligaments of the glottis seen descending towards the thyroid cartilage; b, b, the ventricles; c, c, their opening into the finusae connected with them. Fig. 5 is the larynx of the *pojas* laid open behind: a, the epiglottis; b, b, the arytenoid cartilages; c, the wrinkled or corded appearance, which seems to correspond with the cordae vocales and ventricles of other mammals. Fig. 6 gives a view of the interior of the larynx in the *bore* to shew the opening into the three larvyngeal faces: a, the aperture of the anterior face; b, b, the openings of the lateral cavities; c, the tracheo-laryngeal membrane found in the *bore* at the commencement of the corda vocales. Fig. 7 is a lateral view of the larynx and faces in the 90, with the parts laid open: a, the anterior face, which has a considerable capacity, although so small an opening into the larynx; b, the aperture of the lateral face on one side; c, part of the face of the other side, which is not removed in the dissection.

MAMMÁRIA, in Natural History, a genus of the class Vermes, and order Mollusca. The generic character is, body smooth; without cirri or rays; aperture single. There are three species.

**MAMMILLA.** In this the body is conic, ventricofe, white: it is found in the Northern seas.

**VARIA.** Body ovate, varied with white and purple: inhabits the northern ocean.

**GLOBULUS.** Body globular, cincereous, and not fixed. Found on the Greenland shores, among the roots of fuc. The body is very simple, soft, smooth, gelatinous, with a thin skin about the eights of an inch in diameter.

**MAMMARY, in Anatomy,** an epithet applied to various parts belonging to, or connected with, the breast. The internal mammary artery is a branch of the fibulavian situated within the ched. (See Art.) There is a vein corresponding to it. The mammary gland is the organ secreting the milk. See Breast.

Gen. Ch. Cal. Perianth inferior, of one leaf, cloven into two, roundish, concave, leathery, coloured, widely spreading, deciduous segments. *Cer.* Petals four, roundish, concave, widely spreading, somewhat leathery, longer than the calyces. *Stam.* Filaments numerous, brittle-shaped, erect, very short, inserted into the receptacle; anthers oblong, obtuse, erect. *Pist.* Germin roundish, depressed; style cylinndrical, erect, longer than the lamens, permanent; stigma capitata, convex. *Pero.* Fruit spherical, fibrous, of one cell, very large, pointed with a part of the style, its rind leathery. *Seeds* four, nearly ovate, rough, separated from each other by the pulp.

Eff. Ch. Corolla of four petals. Calyx of two leaves. Fruit very large, inferior, with four seeds.

Obif. The flowers of this genus, instead of being always perfect, are occasionally found to be only male ones on the same or on a different plant. This was observed by Jacquin, and Browne in his history of Jamaica takes occasion from this circumstance to make different species of such as have perfect, and such as have only male flowers; Swartz also observes that the former trees are larger and loftier than the latter.

1. *M. americana*. American Mammea apple. Linn. Sp. Pl. 731. Plum. Gen. t. 170.—A native of Jamaica, Hispaniola, and the Caribbean Islands. A tall, handsome tree, with a thick spreading, elegant head. Branches quadrangular when young. *Leaves* opposite, on short footstalks, oval, or obovate, entire, blunt, very smooth and shining, leathery, firm, from five to eight inches in length. *Flower* small, short, scattered over the frater branches, bearing a solitary, fragrant, white flower an inch and half in diameter. The *calyx* is occasionally trid, and the *carolla* five or fix-petalled. *Fruit* slightly angular, generally having one or two abortive seeds, from three to five inches in diameter; its rind double, the outer leathery, tough, brownish; the inner thin, yellow, adhering closely to the pulp which is firm, bright yellow, of a pleasant, though angular flavour, and a sweet aromatic smell. The *skin* and *seeds* are bitter.
bitter and resinous. Jacquin tells us that the Mammee fruit is eaten raw and alone, or cut into slices with wine and fugar, or preferred in fyrop. In Martinico, the flowers are distilled with spirits, making a liquor which is called Eau-Créole. The French term this plant Abricot-sauvage, the yellowness of its pulp resembling that of an Apricot. Browne informs us that this is one of the largest trees in Jamaica, that it abounds with a resinous gum, and is esteemed one of the best timber-trees. From Miller we learn that it rises to the height of sixty or seventy feet, and that its fruit, which is of a yellowish-green colour, and highly esteemed, is commonly to be purchased in the markets of the Spanish West Indies.

This tree having a long downright tap-root, is of course very difficult to transplant, so that the belt mode of propagating it is by setting the stumps or roots, as fresh as possible, in pots filled with light earth, and then to plunge them into a hot-bed of bark.

M. africana of Linnæus Sp. Pl. 731, is now called Barringtonia; see that article in this work, and in Mart. Mill. Dict. I. v.

Wilkenow describes another species which he calls bunius, the fruit of which contains only three seeds; but he says that Vahl takes it to be nothing else than Rhoea lateriflora of Linnæus.

Mammee, in Gardening, contains plants of the evergreen exotic tree kind, of which the species most cultivated is, the American mammee, (M. americana.)

Method of Culture.—This tree may be increased from seeds procured from America, which should be sown in the early spring, in pots filled with light fresh mould, plunging them in a bark hot-bed, keeping the mould moist by occasional watering, when they will soon come up. The young plants should be often watered in dry weather. When they have attained some growth, they should be removed, with earth about them, into other pots a little larger, being placed in the hot-bed, till fresh rooted, filling up the pots with fresh mould; due shade, air, and water being given. In the autumn they should be removed into the house, where they must be kept, being shifted into other pots in the following spring; having regard not to over-pot them.

And they may also be raised by placing the stumps of the fruit under the pots upon the turl, more expeditiously than when planted in the mould of the pots.

These plants afford a fine variety among the others of the flow kind.

MAMMEE BAY, in Geography, a bay on the north coast of the island of Jamaica. N. lat. 18°35'. W. long. 77°.

Mammillaris Processus, in Anatomy, the same as the maitdor procves. This term, mammillary, has been sometimes applied to the unevenness of substance of the kidney. See Kidney.

MAMMOTH’S TEETH, or Mammoth Bones and Mam- mon Horti, in Natural History, names given by travellers and other writers to certain hofl teeth, and other bones, found in Russia and some other parts of the world, and that usually at great depth in the earth. The Russians and other people give them this name, supposing them to have belonged to an animal, which they describe as being of a monstrous size, and living in caverns under ground. But the true account of them is, that they are in reality the teeth and other bones of an animal now unknown, there being no such beast as these people describe. The mammoth of America, whose enormous bones are found particularly near the salt springs upon the Ohio, though armed with tusks of ivory, has been supposured to be even five or six times larger than the elephant; but the bones are probably the same with those of the supposed elephant found in Siberia. In Siberia the bones of the mammoth are thrown ashore from the frozen ocean; and it is probable that these and other similar remains may have been driven by currents from very distant parts of the globe, and deposited on the banks of rivers by the tide, when a great part of the north of Siberia was covered by the sea. The tusks of the mammoth are equal to elephants’ teeth in whiteness and beauty, but very different in their shape, being all bent spirally, forming about one round and a half; and eight feet form their greatest length. See Elephant’s Bones, Ivory, &c.

MAM茅OJOO, in Geography, a town on the west coast of the island of Celebes. S. lat. 2°18'. E. long. 119°12'.

MAMORA. See MAMMORA.

MAMOS, a town of South America, in the audience of Quito; 110 miles E.N.E. of Archidona.

MAMOSA, LA, a town of Naples, in Basilicata; 10 miles S.W. of Turi.

MAMOUTRAN, a town of Aftic Turkey, in the province of Caramania; 12 miles S.E. of Erkhi.

MAMPATA, in Botany, according to Justfau, is the Senegale name of a tree, belonging to the Adansonia, which the former conceives to be of the same genus with Aublet’s Parinari, Aubl. Guian. t. 294—295, the Persevera of Schreber, though its nut is less deeply furrowed, and the fruits appear to be fifteen instead of fourteen. The germs, moreover, is laterally attached to the calyx. See Persevera and Neou.

MAMTRASNA, in Geography, a mountain of Ireland, in the county of Galway; 15 miles S. of Callinbar.

MAMUD, an island in the Sooloo Archipelage. N. lat. 6°14'. E. long. 121°42'.

MAMUL, a town of Walachia; 51 miles N.E. of Krajova.

MAMUN, a town of Africa, in the country of Sugulmecha; 25 miles S.E. of Sugulmecha.

MAN. To write a complete history of man, it is necessary that we should describe both the individual and the species: that we should, with reference to the former, relate the phenomena of his first production, examine his anatomical structure, his bodily and intellectual functions, and his disaeees, and pursue his progress from the time of his birth to the grave: in respect to the latter, it would be necessary to point out the circumstances that distinguish him from other animals, to delineate the physical and moral characters of the people inhabiting the different portions of the globe, and trace their progress from the first rudiments of civil society to the state at which they are now arrived. (See on the latter subject, Condorcet Tableau du Progrès de l’Esprit humain; Ithelin, Geschichte der menschlichen; Ferguson’s History of Civil Society; Adelung Verfuch einer Geschichte der Cultur des menschlichen Gefeichts, &c.) To treat the subject in this way would demand a familiar acquaintance with almost the whole circle of human knowledge, and a combination of the most opposite pursuits and talents: of the knowledge of nature posseed by a Buffon, a Cuvier, or a Blumenbach; the insight into the operations of the human mind and passions of a Hume, a Rousseau, and a Condorcet; and a knowledge of history and antinomies in their most extensive sense: a cyclopædian would be necessary, rather than a single article. This extensive labour, which could not be properly executed by any individual, is divided into several subordinate branches. The anatomist and physiologist unfold the structure and functions of the body; the surgeon and physician describe its diseases; and the metaphysician and moralist employ themselves with the functions
M A N.

that constitute the mind, and with the moral sentiments. We refer, therefore, to the different articles of the Cyclo- 

pedia on these subjects; giving only, what could not be entirely omitted in a view of the history of man, a short 

general sketch of his passage through the various periods of his existence. Man in society, his progress in the various 
countries and ages of the world, his multiplication, &c. &c. are the province of the historian and political economist. Our 

object, in the following article, is the description of the species. We shall speak, in the first place, of the situations 

which man occupies on the globe, of his food, intoxicating 

drinks, dwellings, and dress: we shall endeavour to explain 

the distinctions, more particularly in bodily structure, be- 

tween man and animals; to describe the principal dif- 

ferences between the various races of mankind, and to con- 

consider the causes by which these have been accounted for. 

This, indeed, is rather what our limits and the confined 

knowledge of an individual restrain us to, than a discussion of 

all the points which the history of man should involve. We 

think it should contain, moreover, a consideration of the 

original abode and distribution of the species, of the varieties 
of intellectual power, and mental dispositions. The remark- 
able manners and customs, the employments and pleasures, 

the notions of decency and elegance, honour and shame, the 

religious opinions, forms of government and laws, particu- 
larly among uncivilized nations, are very interesting subjects, 

when considered in general, but are not included in the la- 

bourers of the historian or moralist. The education of chil- 
dren, and treatment of women, in all parts of the world; the 

various degrees of cultivation; the opinions of savages 

people concerning the most important works and phenomena 
of nature; the origin of the most necessary sciences, as arithmetic, measure of time, and medicine, are not less interesting than important topics, which are not considered at all, as the historian, the geographer, the moralist, and the man of science, occupied with other pursuits, consider them, each, as not belonging to his department. These, together with the subjects of the present article, would constitute a pecu- 

lar science, or branch of science, under the name of the history of man, which, in point of instruction or entertain- 

ment, would not be inferior to the narratives of intrigue and treachery, of war, conquest, and defolation, that compose 

general history.

The natural history of man is yet in its infancy; in fact, we cannot pretend to give anything like a com- 
plete view of the subject. The description and arrange- 
ment of the various productions of the globe have occupied 
numerous observers in all ages of the world. Every plant 

and every insect has had its historian, and has been described with minute accuracy, while the human subject has been comparatively neglected. In a very voluminous work on 

the history of the animal kingdom, now publishing in this 
country, ("General Zoology, or Systmatic Natural His- 
tory,"*) man is entirely omitted. Does the learned author 
deem him more or less than an animal? Whether we investigate the physical or the moral nature of man, we 
recognize, at every step, the limited extent of our know- 

ledge, and are obliged to confess that ignorance, which a Rous- 

cau and a Buffon have not been ashamed to avow. "The most useful and the least successfully cultivated of all 

human knowledge, is that of man; and the inscription on 

the temple of Delphi contained a more important and diffi- 
cult precept, than all the books of the moralists." (Dif- 
cours sur l'Inegalité, prefixed.) The immortal historian of 

nature gives his testimony to the same effect. "Quelque 

interet nous ayes a nous connaitre nousmesmes, je ne 

fais it nous ne connaissons pas mieux toute ce qui n'elit pas 
os." (De la Nature de l'Homme.) It is only of late, and 

principally through the excellent writings of Blumenbach, 

that the natural history of man has begun to receive its due 

share of attention; and we shall venture to assert, that 

whether we regard the intrinsic importance of the questions 

of art and morality, or their relation to the affinities and 
history of nations, or advert Novelty to the pleasure of the 

research, no subject is found more worthy of minute in- 

vestigation.

The sources from which the history of man must be 

derived, are human and comparative anatomy; the natural 

history of organized beings in general, and of the animal 

kingdom in particular. These branches of knowledge 

are of the greatest importance: comparative anatomy, 

and the analogies afforded by the natural history of ani-

mals, will often afford us more assistance than the most 

learned labourers of the historian. We must not be content 

with noting the more striking varieties of the human species, 

but must investigate all the intermediate gradations. The 

tell fources of information in books, particularly of travels, 
must not be employed too indiscriminately; a disposition 

to doubt, and a critical examination and balancing of authorities, 

are essentially necessary to prevent us from being led into 

error by the ignorance or credulity, the inaccuracy or the 

pre-conceived notions of the writers. Certain parts of 

physiological science are connected with the subject, as an acquaintance with the face of the globe, climates, &c. History, in the common acceptance of the word; that of the human race in its early periods; of particular people and their 

changes of situation, when they have emerged from the 

thick cloud that covers the first ages of the world, so as to 

admit of being distinctly traced, will very considerably aid our investigations. The subject full labours under diffi-

culties, from our imperfect knowledge of the habits and 

anatomy of those animals which most nearly resemble man; from the impenetrable darkness that involves the infancy of the species; the uncertainty of the ancient geography in gen-

eral, and of the modern geography of many remote re-

gions; and our defective acquaintance with the wild races.

Progress of Man through the various Stages of his Exis-
tence. — The differences in structure and functions between the male and female are explained in the article Generation, under the head of sexual disjunctions; the mode in which repro- 
duction is effected in the human subject, as well as the dif-

tereutrical theories concerning this highly interrelling and im-
portant, but obscure function, are considered in the same 

article. Under Embrroyo, we have described the formation and development of the new being, and the circumstances in which its organization and mode of existence differ from those of the individual after birth.

Petal Exisience. — The precife period at which the future 

man begins to exist, and the form under which his rudii-

ments appear, are not yet known. For many days after 

conception, the cavity of the uterus contains nothing in 

which we can conceive organization to refuse: the lord of the creation is loll in a drop of liquor. A soft subllance, 

not refilling the slightest touch, and unfolding to our ob-

ervation no arrangement of different parts, assumes a round-

ish shape about the second week after a fruitful cotion, and 

may be regarded as the first appearance of the ovum; a 

fetus cannot be seen in that till towards the end of the third 

week. Poffessing at this time the most simple kind of vitality, 

very similar indeed to that of the vegetable, it has true 

blood about the fourth week. Now the motion of the heart is 

visible; in some very rare instances (Blumenbach, Infltr.

Physiol.
Phy. § 641.) it has been seen in the human embryo, but it was observed even by Aristotle in the incubated chick: its motion could not fail to be noticed from the contrail it afforded to the quiescence of the other parts, and hence the explication of *pontium fallax*. The formation of bone commences at the seventh or eighth week; bone nuclei are first visible in the clavicles, ribs, vertebrae, the larger cylindrical bones of the extremities, the lower jaw, and some other bones of the face; a most delicate bony network is developed at the same time in the flat bones of the cranium, as the frontal and occipital, later in the parietal, &c.

The nearer the embryo, and indeed the animal both before and after birth, is to the epocha of its first production, the more rapid is its growth. That the first germ, when hidden in the ovum, must be exceedingly small, is clear, because it escapes our closest observation, even when assisted by the microscope: from this minuteness it increases in nine months to the weight of six or eight pounds. It grows in the first month to 500,000 times its first size; in the second month to 45 times; and in each of the remaining months of utero-gestation, one with the other, to 15 times. At the end of three years the child has grown from 105 to 261 ounces, or nearly in the ratio of five to fourteen; and in the 22 followings, from 281 to 2,250 ounces, which is an increase of about 5,000 times.

About the middle of pregnancy, motions of the child are first perceived by the mother; in common language it is said to *quicken*, and the popular notion is that it receives life at this time. The judicial questions concerning abortion, and the execution of pregnant criminals, render it important that right views should be entertained upon this point. By the Roman law the punishment of death was inflicted, when a formed and animated fetus perished by abortion intentionally produced; and it was held that the fetus perceive animation on the fortieth day. In this country a condemned criminal is reprieved, if she is found to be quick with child. It seems to be implied in both cases, and such we believe to be the general opinion, that the child is not alive until a certain period of gestation. This is most erroneous, physiologically: vital processes, as an exceedingly rapid growth and development of parts, are carried on with great activity from the earliest time, at which the germ can be discerned, and the heart actually beats at the fourth week. Hence, if abortion be procured at the end of a month, or a woman be executed at the same time, a child is destroyed in either case, just as much as if these things happen after the ordinary period of quickening. Our physiological views of fetal existence lead us to suppose that the creature in utero has no sensations, and is unconscious of its own life; its destruction, therefore, cannot be charged with the infliction of cruelty on a sentient being.

Divines are much intertied in a point allied to this; namely, at what time the new being has a soul. Very nice questions have been roused in the Roman church concerning the propriety of baptizing, administering the sacrament of extreme unction, and performing the funeral service at particular ages; and these must be equally interesting topics to all, as such ceremonies are ordained for the benefit of these animals only which have souls. Physiologicals, in general, have not acted very fairly in refuting their influence towards elucidating so important a subject. "De his mysteriis," says Haller, "et de animae humanae origine, posterior a cum Galeno adhibita pronuntiante." He adds, however, immediately after, that, he supposes the fetus to have a soul, when it performs spontaneous motion. (Lib. 20, f. i. v. § 21.) To ascertain the meaning of the word soul, is a very important preliminary in settling our notions on this subject. We are fully convinced that the fetus has no sensations, and consequently can have no will, nor any intellectual functions (see EMBRYO): this is equivalent to saying that it has no soul. For an account of the different opinions concerning the nature and faculties of the soul, see SOUL.

Fat and bile are formed about the middle of utero-gestation. In the remaining part of the time, the hair of the head and the nails appear; the external ear becomes firm and elastic; and the teeth defined in the male.

The fetus is lodged in the uterus, until its organization is arrived at such a degree of development, as will enable it to assume independent existence. During its residence in this organ, it may be regarded as a part of the body of the mother: although it has brains, organs of sense and voice, these are yet inactive, and do not give rise to any relations between it and surrounding objects: its organs of digestion, secretion, and locomotion, are equally inert, and calculated, like the former, for the succeeding stage of existence. It has all the organs that enable it to exist by itself, although their functions are not necessary while it continues in the womb of the mother. (See MONSTER.) The chief peculiarities of the fetal life are the simplicity of its life, the budding of little more than the function of nutritive, and the inactivity of almost all the important organs; its confinement, surrounded by the fluid of the amnion, in the uterus, where no external impressions can reach it, and the exercise of the moving powers is impracticable, even if volition could take place: the connection with the mother through the umbilical chord and placenta (see EMBRYO): the uniform colour of the blood in all the vessels, and the communications between the two sides of the heart. (See HEART AND CIRCULATION.) As respiration has never taken place, the lungs sink in water. (See LUNGS.) The cœcum is very different from that of the adult, and the large intestine, in general, is diffused with a peculiar dark green semi-fluid substance, called meconium. (See INTESTINE.) The urachus, the membrana papillaris, and the delicacy of the teles, are important peculiarities in the fetal state, as nothing like a rational conjecture concerning their use or purpose can be formed. (See the description of the bladder, in the article KIDNEY; of the iris, in EYE; and of the teats, in GENERATION.) Three organs, in the approach of more nearly to that of glands than to any other, appear by their superior size in the unborn child to belong particularly to its economy, although here, as in the parts just noticed, we are entirely ignorant of the uses to which they are subservient. The two former are not only much larger in the fetus than in the adult, but they also contain a considerable quantity of fluid in their texture; the thyrmus, although as large as the heart in the fetus, is entirely loit in the adult; the two other organs are much smaller comparatively after birth. See THYMUS, LARYNX, and KIDNEY.

Birth.—Towards the end of the tenth lunar month, when the child has arrived at a weight varying from four to eleven pounds, though generally between five and eight, and is from eighteen to twenty-one inches long, parturition takes place; several very important changes occur in the animal economy, and a state of being, altogether new, commences. "Nothing," says Buffon, "exhibits such a striking picture of weakness, of pain, and of misery, as the condition of an infant immediately after birth. Incapable of employing its organs or its senses, the infant requires every kind of assistance; it is more helpless than the young of any other animal; its uncertain life seems every moment to vibrate on the borders of death. It can neither move nor support
support its body; it has hardly strength enough to exit, and to announce, by groans, the pain which it suffers, as if nature intended to apprise the little innocent, that it is born to misery, and that it is to be ranked among human creatures only to partake of their infirmities and afflictions."

History of Man, c. ii.

The navel-sling being tied and divided, the connection between the mother and child is separated. In animals, this cord is severed by the teeth; if it were not tied in the human subject, fatal hemorrhage would ensue. The child, from the warm medium of the amniotic fluid, is introduced into a new and more stimulating element, the air, and draws it into his lungs: thus respiration begins, and produces changes in the blood, which seem to make up for the loss of the placental circulation. A healthy and strong child generally cries as soon as it comes out of the vagina, and respiration is necessary to this action. We usually wash the body with warm water and soap, in order to remove the greasy substance that covers the skin, and are very careful to keep the child warm; but there are whole nations, inhabiting climates colder than our's, where the infants are plunged into cold water as soon as they are born, without receiving the slightest injury. The desire for food seems to be coeval with the commencement of the new existence: sucking is performed at once in a perfect manner, as soon as the mouth is brought to the nipple.

Within a few hours after birth, meconium and urine are discharged. The infant sleeps much, and feems to awake only for the purpose of taking food: the gratification of the latter want, and sleep, are the great employments of the first months.

Infancy.—As we remember nothing of what passes at this early period of our existence, we cannot discover the feelings produced by the first impressions of the air; but the cries uttered immediately after birth seem to indicate that the action of the atmosphere causes painful impressions. The fetuses at first act very imperfectly; the newly born creatures have a stupid appearance, and give hardly any proof that their organs of sense act. The eyes are fixed and dull, and have not the motions which accompany distinct vision; yet they feel the impression of light, and the pupil contracts or dilates in proportion to its quantity. When any thing is suddenly brought near to the eye, neither the lids nor the head are moved. The other senses are in an equally imperfect state. All the other parts of the body are extremely feeble, and their motions awkward and ill directed. The thighs and legs are bent, from the habit contracted while in the womb of the mother; there is not strength enough to have any thing with the hands; if abandoned in this condition, the child would remain on its back, without being able to turn to one side or the other. See Life.

The pulsation of the brain is felt at the fontanelles.

Besides the commencement of the functions that connect us to the external world, as well as those of the digestive apparatus, and the modifications of the circulating organs consequent on the ligature of the cord, and the beginning of respiration, various alterations in the external habit of the body are discernible after parturition. The downy covering of the skin gradually disappears, the wrinkles are obliterated, the nates are developed, and hide the opening of the anus.

A newly born infant discovers pain by its cries; but it has no expression indicating pleasure. It smiles about the fifth or seventh week, and it begins to weep about the same time; for its former cries were not accompanied with tears.

Newly born children sleep much, but only for short periods; they require very frequent nourishment, and express this want by crying, which generally terminates their sleep. This indication should always be carefully attended to. Nothing is required in addition to what nature has provided in the mother's milk; no substitute is equal to this, though the milk of other animals may be employed in cases of necessity: the teat of the animal may be substituted for that of the mother. Buffon says that he has known several peafants, who had no other nurseries than ewes; and yet they were equally vigorous as those who had been nursed by their mothers.

As soon as the infant had escaped from the uterus, and enjoyed the liberty of stretching its limbs, it was again condemned, while the use of swaddling clothes prevailed, to a more cruel and unnatural bondage. The head and limbs were fixed, and the whole body was tied and fettered, that hardly a joint could be moved. People now begin to find out that the development of the body will be accomplished without this artificial assistance. Perhaps they are hardly yet aware, that the efforts of the little prisoners to disentangle themselves have a more direct tendency to disfart their members, than any positions they could assume, if left in the full possession of liberty. Swaddling bands may be compared to the flays worn by young girls, which occasion many more deformities and difficulties than they are intended to prevent. The practices of savage nations have been much more rational than those of the civilized; they lay their infants naked in hanging beds of cotton, or cradles lined with fur, in which they are at perfect liberty to move themselves as they are inclined, and provide at the same time very carefully for absorbing the moisture of their discharges. No improvement can be forgotten on this plan.

As the child becomes accustomed to external objects, it gradually learns the use of its senses, and looses the apparent fluidity that characterizes it for the first months of existence. It is fond of light, and directs its eyes always to the lightest part of a room; hence the propriety of placing it so that both eyes may receive the light at the same time, and consequently acquire by exercise an equal degree of strength. It is attracted by any shining object, and endeavours to seize them; when pleased, it smiles; and cries and attempts to refit, when it is hurt or vexed: it recognizes individuals, and is frightened by strangers. The organs of the external senses are more perfectly formed, as the external ear, the nostrils, the supraventricular arches and eye-brows, &c. At the same time, the mental functions, dependent on the operation of these organs, as attention, perception, memory, the will, &c. are gradually developed: hence dreams are observed in a few months after birth. The bones of the cranum become more firmly united, and the fontanelles are gradually closed.

Dentition, which begins about the sixth or seventh month, is a most important era in the life of the infant. The process is always painful, and not unfrequently fatal. For the description of the teeth and the history of their development, see CANINES: the dangers with which it is accompanied are described under INFANTS. Diff. of. This change points out the natural time for weaning: the newly acquired instruments, which injure the nipple of the mother, enable the infant to use firmer food, and thus make it independent of the breast.

As conception does not usually take place again, while suckling is continued, mothers, who with not to have a numerous family, often keep the child at the breast long after this time, although there is no advantage to be derived to the child from the practice.

Obliteration goes on with great activity, and covers on all parts of the skeleton that firmness which is essential to the execution of their functions. Bony nuclei are seen in the cartilages, which are afterwards to form the bones of the
The urine contains little or no phosphat of lime, as that substance is all employed in the completion of the bones. Towards the beginning or middle of the second year, they have become strong enough to support the weight of the body, hence the infant at this time begins to learn the use of his feet, and to assume the erect attitude, one of the most remarkable prerogatives of the human species. The smalls of the lower limbs and pelvis, in comparison to the head and upper part of the trunk; the soft state of the bones, as well as the want of power in the muscles, which, like the organs of sense, require the flow education of frequent exercise; and the very complicated exertion necessary to maintain the body erect (see Muscles, towards the end), pollute the power of going alone to this late period after birth, and render all the motions and positions connected with it very unsteady and unsafe for a still longer time; although animals in general can maintain themselves in their natural attitudes tolerably well from the day of birth. Attempts to make the child assume the erect attitude before the epochs we have mentioned, are dangerous, as the flexible bones, unequal to the burden, give way under it, and thus deformity is produced.

Removal from the mother's breast, and the power of going alone, are two very important steps, and the progress towards independent existence is greatly aided by another remarkable privilege of the human species, the use of speech, which begins in children of lively minds far after the first year. The power is uttered in the careless of the mother are attended to, and eagerly imitated; and every faculty is strained to the utmost, for the purpose of acquiring the use of an instrument so important towards attaining the gratification of its daily increasing desires, and establishing its communications with surrounding beings. The power of speech, however, like the use of the senses, and of the moving organs, is not possefled perfectly at once; it is the offspring of laborious and repeated efforts. The vowel A (broad) is the most easily pronounced, as it requires only the opening of the mouth and forcing out the air; the consonants, B, P, and M require the least motion of the organs, and are most easily articulated. The other sounds are formed in proportion as the organs learn their offices. (See Articulation.) Some can articulate distinctly, and repeat whatever is said to them, at two years of age, but a longer time is generally necessary.

While the infant is thus slowly advancing in the development of its powers, it is exposed to numerous and destructive diseases, which render its life very precarious for the three first years. (See Infants, Digest of.) Half of the children produced die in the first few years of life, and the work of destruction proceeds still more rapidly, when they are crowded together in considerable numbers. Camper informs us, that of 5989 admitted into the establishments for foundlings at Paris, in one year, 405 died in the first month, and 673 more in the remaining eleven months; only 874 were alive at the end of five years. Ludwig Grundris der Naturgeschichte der Menschenfpecies, p. 293. See Mortality.

About the seventh year, the deciduous or milk teeth begin to fall out, and a second dentition ensues. Of the thirty-two permanent teeth, which are designed to remain through life, the greatest number have come into the vacancies left by the deciduous discharge of the temporary ones, by the twelfth year; but the whole set is not complete till the 18th or 20th year.

Childhood, or Adolescence.—In the age of infancy, memory seems to excel the other faculties of the mind, and affords a most commodious instrument for retaining the signs of surrounding objects. It hardly continues in its original strength beyond the fifteenth year. The imagination is developed after it, and begins to predominate when the memory is weakened; its exercise is aided by the happy memory of this age, which supplies it with materials. The judgment is developed at a later age; children pass rapidly from one object to another, without bellowing the time for accurate comparison and enquiry, which judgment requires.

The nervous system is early affected in childhood, and grief and joy are excited by flight cauæs. Much time is pulled in sleep.

A considerable stratum of fat covers the body under the integuments, hides the muscles and bones, and beffows a roundness and softness of outline on the whole frame. See Membrane, Cellular, and Muscle, under the head of development of those tiffues.

The fluids undergo a considerable change: in the fetus, or in a young child, the urine, faces, and perforation are not fixed; the bile is not bitter; all the secretions indeed are mild. But the urine soon acquires its distinguishing smell; the kidneys, which form an agreeable food in the calf, are rejected on account of their strong taste in the bullock; the faces become more confident, and have a powerful odour. The food and mode of life are not the cauæs of these alterations; for the faces, perfpiration, &c. have their strong sensible properties in the adult, even when the diet consists of milk or vegetables.

Puberty.—The great development of the imagination is about the age of puberty, when man is prepared, by various and important changes of his organization, for the exercise of the generative functions. Nature hitherto seems to have had nothing further in view than the growth and preservation of her work. The child enjoys an existence confined to itself, which it cannot communicate; but the principles of life soon multiply beyond what is sufficient for our own being, and enable us to bestowed existence on others.

When the mammary enlarge in the female, the beard grows itself in the male, and the other phenomena of approaching puberty are exhibited in both sexes, as the development of hair on the external organs, &c. the former begins to have the menstrual discharge, which is accompanied, amongst other appearances, with increased lustre of the eyes, redness of the lips, and more sensible properties in the perforation; the latter secretes true semen, having at the same time a more copious growth of the beard, and a memorable change of the voice into a deeper tone. The latter, for a confiderable time, is rough and unequal; after which it becomes more full, articulate, and strong. This change is very conspicuous in boys; but it is less distinguishable in girls, whose voices are naturally more sharp. A very remarkable enlargement of the vocal organ, covered with puberty, is the source of the alteration just mentioned. There is hardly a sensible difference of size in the larynx, between a child of three, and another of twelve years: there is at least nothing corresponding to the diversity of stature. But at puberty, in the space of a year, the opening of the male glottis is doubled, both in length and breadth. This increase in the female is only in the proportion of seven to five. (Richerand, Elem. de Physiology, ed. 3. § 226.) These marks are not always uniform. The beard, for example, does not always appear precisely at the age of puberty: there are even whole nations, who have hardly any beard. On the contrary, there is no country where the age of puberty in women is not distinguished by the enlargement of the breasts. At the same time the sexual instinct is awakened by what we may call the pampula.
neous internal voice of nature, and both sexes, in this spring of their existence, become capable of exercising that important function of all animated beings, the propagation of the species. For the detailed consideration of this subject, see Generation. In that article the reader will find a view of the changes occurring in the generative organs at this age, and of the effects, which they exert in the body in general, of menstruation, and of the phenomena observed where unusual organizations exit, constituting what have been often called hermaphrodites.

Virginity, impotency, circumcision, castration, infibulation, &c. are articles so important in the history of man, either on account of the interest attached to some of the subjects, or of the general prevalence of some of the practices, that we should consider it afacility of what is essential to false notions of delicacy, if we passed them over entirely unnoticed. On the subject of virginity, see the account of the hymen, in the description of the vagina, in the article Generation, and Buffon's History of Man, sect. 3 respecting Circumcision and Impotence, see those articles; and concerning the latter, Mr. Hunter's Treatise on the Verebral Diseases, pt. iii. ch. 11 and 12. Boys are induced by drawing the prepuce forwards, piercing it, and putting through the holes a small cord, which remains until the cicatrix is formed; the cord is then removed, and a ring subordinated in its place, which is made of sufficient strength to halt as long as the performer, who ordered the operation, pleases; and it sometimes remains for life. The Eastern monks, who took the vow of chastity, used to employ a large ring, which rendered a breach of their oath impossible. On this subject hardly anything can be imagined to ridiculous that it has not been practised by some men, either from motives of passion or of superstition.

The practice of castration is of great antiquity, and has prevailed very extensively. It is employed in Afa, to procure guards for the chastity of the women; in Italy, this infamous, this cruel operation, has for its object only the improvement of the voice. Besides destroying the faculty of propagation, it prevents, or very signally modifies, the changes that usually occur at the time of puberty, and remarkably influences the voice. (See Generation and Eunuchus.) The species of castration varies according to the object in view; the testicles only are removed, when the improvement of the voice is intended. But men, whose minds are possessed with jealousy, would not believe their females safe in the custody of such eunuchs; they employ none but those who have been deprived of all the external organs of generation. Sometimes the texture of the organs has been destroyed by piercing and rubbing them for a long time; but the effect of this process cannot be so securely depended on as that of removal. Infancy is always preferable for these operations. The amputation of the testicles is not very dangerous; but the more complete removal is often fatal, especially if performed after the age of fifteen; even in the most favourable time, from seven to ten years, there is always great danger. The difficulty of preferring such eunuchs renders them exceedingly precious. Tavernier informs us, that in Turkey and Persia, they bring five or six times the price of the other kind. Chardin observes, that the total amputation is performed pretty safely upon young children, and is exceedingly dangerous after the age of fifteen; that hardly a fourth part escape with life, and that the wound is never cured in less than six weeks. On the other hand, Pietro della Valle affirms, that those who suffer this punishment in Persia for rape, and other crimes of that nature, recover easily, though advanced in years; and that they apply nothing but ashes to the wound. According to Thevenot, vast numbers of negroes, who are forced by the Turks to submit to this operation, perish, even when it is performed on individuals eight or ten years old.

The arrival of puberty differs according to climate, temperament, way of life, &c. so that no particular age can be set down for its general occurrence. It is earlier in women than in men; the former, in our climate, show the phenomena of puberty at about the age of fifteen, the latter at that of eighteen.

Infancies are not very uncommon, of considerable development of the body, with the changes that usually occur at puberty, such as the appearance of the beard, enlargement of the generative organs, secretion of semen, expansion of the breasts, flow of the menses, and formation of hair on the pubes, at a much earlier age than we have mentioned. Besides the infancies related in the article Generation, a considerable number may be found in Haller's Elements Physiologici, lib. xxx. fept. i. § 15. Puer triennis pubefcens, virili in pudendis robore, altii 37 uncias. Journ. de Medecine, 1757. Puella quatuor annorum mammis con- fpecia et pupe, ut etiam menues pateterunt. Vallinieri Op. t. iii. p. 309. Puer quatuor annorum nudulis, feminarum cupidus, voce gravi, tanto robore, ut libras 50 elevarit. Journ.de Medecine, 1759. Many other examples are mentioned of children younger than thefe, who exhibited signs of puberty, such as the growth of the beard, and of the hair on the pubes; and there are numerous instances of others from four years upwards, who have been able to perform all the sexual functions. The termination of the growth of the body in length is fixed a little after this time; the epiphyses of the bones, hitherto distinct from the bodies, now coalesce, and are completely consolidated to them.

\textit{Nature of} Man — There is no fixed law, determining invariably the human nature, although there is a standard, as in other species of animals, from which the deviations, independently of disease or accident, are not very considerable in either direction. In the temperate climates of Europe, the height of the human race may be fixed at five feet two inches to five feet ten. Schreber gives to the human species a height of from two feet four inches, to five feet eight inches. (Mammalia, t. i. p. 27.) Individuals of six feet, and even as high as six feet three and four, are not uncommon in this and other European countries. Occasional infancies have been known in various parts of the world, of men reaching the height of seven and eight feet; and ancient as well as modern authors speak of the human nature reaching nine, ten, and even eighteen feet. The latter representations are generally grounded on bones dug out of the earth; these, together with the common propensity to believe and report what is marvellous, and the notion that mankind have undergone
undergone a degeneracy since their first formation, have led 
to a very common belief that the human stature in general, 
is at this period less than it was in remote ages. We are 
warranted in ascertaining the accounts of such great elevation 
above the ordinary stature, in the human species, by observing 
that nature, within the time of which we have any authentic 
records, exhibits no such disproportions in other species. 
We find, too, that the height of these giants is reduced, as 
we approach to modern times, to what we have opportunities 
of observing now; so that we may probably affirm, that no 
sufficiently authenticated example can be adduced of a man 
higher than eight or nine feet. The large bones on which 
the notions about giants have been, in many instances, 
founded, have been discovered, by the accurate examinations 
of modern science, to belong to extinct species of animals 
of the elephant and other allied kinds. Of the loofe and 
unphilosophical mode in which these matters have generally 
been inquired into, we have a specimen in the funsped bones 
of a barbarian king. Hubert, an anatomist, in a work en-
titled "Gigantoloege," describes some huge bones, found 
under the ruins of the castle of Chaumont in Dauphiny, in a 
leper-hospital, which was a great infirmary, of the DURO-
Roces Rex. This skeleton, he says, was 25} feet long, 
and to broad at the shoulders. Riolan, in his "Giganto-
machie," disputes the measurements, and affirms that 
the bones belong to the elephant. In the long controversy 
which ensued, it is remarkable that no exact description 
or representations of the bones should have been given. It 
is very surprizing that such a philosopher as Buffon should 
have figured and described the fossil bones of large animals as re-
manis of human giants, in the 5th vol. of the supplemen-
tary on the human species. Among others he has those dug up at 
Lucerne, in the 16th century, and still preserved there. 
Blumenbach found these, on the firft view, to be elephants' 
bones. Felix Plater, an excellent physician and anatomift of his 
time, after carefully examining and measuring these bones, 
declared that they belonged to a human giant of seventeen 
feet, and had a drawing made of this skeleton, according to 
his opinion of its dimensions, which is still preserved in the 
Jehuit's college at Lucerne. (Blumenbach de Gen. Human. 
Varit. Nat., p. 253, note.) That men in general were taller in 
the ancient ages than in the world at present, or that ex-
amples of very tall men were then more frequent than now, 
had been afferted without any proof. The remains of human 
bones, and particularly the teeth, which are unchangeable in 
the moft ancient urns and burial places, the mummies, and 
the sarcophagus of the great pyramid of Egipt (Norden's 
Travels), demonstrate this point clearly; and every fact 
which we can collect from ancient works of art, from ar-
mour, as helmets and breast plates, or from buildings de-
signated for the accommodation of men, concurs in strenghten-
ing the proof. Blumenbach has the skull and bones of an 
old perfon, taken out of a burial place of the moft remote 
antiqutity in Denmark (in antiquimonial tumulo Cimbren), 
and correponding in size to the modern standard. (Ibid, 
p. 252, note.) That we cannot have degenerated in con-
sequence of the habits of civilized society is clear, because the 
individuals of nations living in a way fo different from us as 
the Americans, Africans, Southern inhabitants, &c. do not 
exceed us in stature. Indeed it has been generally observed 
that the Americans are shorter than the Europeans. 
We frequently meet with examples of individuals below, 
as well as above the ordinary stature; but when the deviation 
is considerable, they are rarely well made. 

Giants and Dwarfs.—In mentioning individuals who have 
exceeded the ordinary height, it is necessary to confine our-
theselves, in order to avoid what may be fabulous or exag-
gerated, to inferences in our own times. One of the king of 
 Pruflia's gigantic guards, a Swede, was 8½ feet, and a 
youman of the duke John Frederic, at Brunswick-Hanover, 
who lived the measure, was 8 feet (Swedish). I. H. Hartmann Reichardt of Fried-
berg, near Frankfort, was 8½ sin. his father was a giant, 
and his fifer a giantes. A female of Stargard, named La 
Pierre, was 7 feet. (Danish.) Ludwig, Grundriffe der Na-
turgeschichte, &c. p. 150. See also Haller, Elem. Phy-
fiol. lib. xxx. sect. 1. § 17. Martin Salmeron, the Mexi-
can giant, is the fon of a Meftizo by an Indian woman, 
and measures 7 ft. 3¾ in. (English.) He is very well propor-
tioned. Humboldt's Political Essay, b. ii. ch. 6. Several 
Irishmen, of from 7 to 8 feet, have been exhibited in this 
country, Behe, the dwarf of Staniflaus king of Poland, 
was 23 in. (French), and well proportioned. His spine 
became curved as he approached manhood; he grew weak, 

The Polish nobleman Borwalski measured 28 Paris inches; 
was well made, clever, and skilled in languages. He had a 
brother of 34 in. and a fifer of 21. Memoirs of the cele-
brated bor B. of Borwalski, &c. Lond. 1788. 

A Fricland peafant of two years of age had reached 29 
Amsterdam inches. C. H. Stöber in Nürnberg was 
early 3 feet high at 20, well proportioned, and full of talents. 
Her parents, brothers, and fifers, were dwarfs. 
Lavater Phyfiognomische Fragmente iv. p. 72. 

Of numerous other inftrances on record, most seem to have 
been defcribed, and particularly rickey, individuals; fo that 
they may rather be classed among pathological phenomena. 
The men who have considerably exceeded the ordinary 
standard, have neither polynomial these proportions in their 
form, which we account elegant; nor has their ftrength by 
any means corresponded to their fize. The head, in these 
cafs, is below the ratio which it fhould bear to the body, 
according to what we deduce from men of ordinary ftrength; 
hence the brain must be comparatively smaller. It is a ge-
eral obervation that very large men are feldom diftinguifh-
ed by extent or force of mental power. The dwarfs, again, are 
generally ill made; the head, in particular, is too large. 
There are very few inftrances of what We could deem healthy 
well made men, with all the proper attributes of the race, 
more than below the general average; those, by the ap-
pearance of the face, are pfenions of the common race.
that the whole is changed in the course of a few years. There are no accurate data for calculating the time in which all the particles are renewed; probably, however, this is different in the different tissues. The hair and nails are rapidly renewed; the fat is often increased or removed within a very short time; on the contrary, the marks in the skin produced by puncturing it, and rubbing in various coloured substances, continue through life.

Towards the latter half of the age of manhood, there is a disposition to the deposition of fat over the whole body; indeed such depositions take place at any part of this period, when tranquility of mind and insufficiency of body are joined with copious food. Fat is particularly formed about the abdomen. (See CONFORMATION.) As the growth of the frame isfinished, and all the functions are carried on with vigour, there is a reductance of nutritive particles, by which we can account for this occurrence.

Temperaments.—We avail ourselves of this age, in which the characters of the human species, roughly sketched in infancy and youth, are fixed and drawn in indelible colours, in order to delineate the distinctive traits of individuals. We designate by the word temperament the physical and moral differences of men, depending on the various proportions and relations of the part entering into their organization, as well as on the various degrees of energy in certain organs. Thus, the collection of circumstances in the organization or functions of the body, that characterise a number of individuals, constitutes their temperament. Again, each person has a mode of being peculiar to himself, distinguishing his temperament from that of all others, to some of whom he may, however, bear in general a considerable resemblance. The four individual temperaments, of which the knowledge is highly important in the practice of medicine, are called idiocracies.

- The predominance of a particular system of organs modifies the whole economy, impresses striking differences on the results of organization, and exerts no less influence on the moral and intellectual than on the physical powers. This predominance establishes temperament, of which it is the cause and essence.

Since the construction of the body follows the same model in all, it seems strange, at first sight, that each individual should be different from all others, and should posses a character peculiar to himself. Let the number of tissues, or elementary ingredients of the body, be considered; let the number of organs composed by these be taken into the view; let us remember the various vital properties which these posses, and the very numerous functions which they exercise. The original component structure may differ, the organs, which they build up, may vary; the vital forces exist in every possible degree from the highest pitch to the lowest plane; the functions are modified by innumerable causes, as climate, food, clothing, way of life, exercice, labour of mind and body, &c. &c. By the various combinations produced by all these differences, individual temperaments or idiocracies are sufficiently accounted for. It seems probable, however, that these diversities are in a great measure insignificant; all wild animals are alike; the differences between individuals are not considerable in the domesticated races; and there is much greater general resemblance between individual men in savage than in civilized life.

When we ascribe temperaments to differences of organization, we are aware that the truth of the proposition cannot be easily proved, that the anatomist cannot trace in the material fabric the causes of these phenomena, which at present must be regarded rather as characters of the vital functions than of the organization. The operation of moral causes, too, must greatly obscure this intricate question. Education, acquired habits, situation, and fortune in life, and a long list of causes, have so great an influence on the character and many of the bodily functions, that we are at a great loss in pointing out what ought to be ascribed to original conformation or disposition, and what flows from subsequent agency. We wish, therefore, the following sketch of temperaments which we have borrowed from a French writer (RicheAUD, Elemens de Physiologie, chap. 11.) not to be received in a very rigorous sense, as founded on the basis of anatomy, but rather to be regarded as a statement of the views generally entertained on the subject, to the truth of which, anatomically, we would not be confined as pledged.

When the agents of circulation, the heart and blood-vessels, enjoy a predominant activity, the pulse will be strong, frequent, and regular, the skin highly coloured, the physis or carriage animated, the forms soft but well expressed, the flesh tolerably firm, the emboupoint moderate, the hair light coloured; the nervous susceptibility lively and rapid, united with quick conception, good memory, and prompt imagination. Such individuals sacrifice freely to Bacchus and Venus, and have their health rarely interrupted by disease. The latter is generally situated in the circulating fylhen, (inflammatory fever, inflammatiows, active hemorrhages,) and requires the use of antiphlogistic remedies, particularly of blood-letting. The ancients gave the name of fangium temperament to this disposition of body: they had very correctly observed that it was to be noticed generally in young persons of both sexes, and that its characters are most clearly developed in spring.

The physical traits of this temperament may be seen in the beautiful statues of Antony, and the Apollo of Belvedere: its moral physiognomy is delineated in the lives of Marc Antony and Alcibiades. Inconstancy is a characteristic attribute of this temperament; great variety is necessary as well as agreeable to the individuals whom it marks. Generous, sensible, and passionat, but inconsistent, they are too soon tired after possession, and free themselves from the dominion of Beauty at the very instant when the fancies they has secured them by a durable chain. He, on whom nature has bestowed a fangium temperament, vainly endeavours to renounce sensual enjoyment, and arrive, by deep meditation, at abstract truth; overpowered by his physical dispositions, he is constantly forced back to the pleasures which he avoids; his mind is better calculated for the brilliant productions of wit, than the sublime conceptions of genius.

When a man of this temperament is forced, by his condition, to undergo labours, which exercize considerably his organs of motion, the muscles acquire a development proportioned to that of the circulating organs, and increase in size; the muscular or athletic temperament, characterised by all the external signs of vigour, is the result. The head is small, the neck powerful, particularly behind, the shoulders broad, the calf wide, the hips firm, and the muscular forms strongly marked. The hands, the feet, the knees, and all the joints not much covered by muscles, appear small; the tendons display themselves under the skin. The fusceptibility is not considerable, but when the calm is once disturbed, the greatest resistances are overcome. The Iarnache Hercules affords a model of the physical attributes of this constitution, and the exploits of this demi-god, as recorded in fabulous antiquity, give us a tolerably just notion of the concomitant moral dispositions. We see him performing his twelve labours without calculation, without reflection, and, as it were by instinct, courageous because he is strong, seeking obstacles that he may overcome, certain of overwhelming
cholic individuals of a different character: endowed with an exquisitely sensitive, enthralledly fond of the beautiful, and capable of realizing it in their conceptions, living in society in a state of reverie bordering on drift, simulating most carefully the actions of men, perceiving in matters of sentiment even the most delicate shades, but disposed to unfavourable interpretations, and seeing all objects through the distorting medium of melancholy. It would be extremely difficult to describe this temperament in a general or abstract manner. Although the ground of the picture is the same, the fining is susceptible of infinite variations: it is better therefore to refer to the history of the illusory characters in which it is exhibited. Of these, Taffe, Pafcal, Rousier, Gilbert, and Zimmermann, furnish remarkable illustrations. In the philosopher of Geneva particularly, the melancholic temperament existed in a high degree of energy: numerous passages of his well-known writings, and especially the two last parts of the Confessions and the Reveries de Promeneur solitaire, give us an instructive picture of its workings.

When the liquids are abundant, they distend and develope the cellular tissue, and give to the whole body a considerable volume. The skin is soft, the countenance dull, the hair of some light tint, the pulse feeble, the forms rounded and inexpressive, all the vital actions more or less languid, the memory treacherous, and the power of attention weak. The individuals of this temperament, called, by the ancients, pituitous, and which we term phlegmatic, have, generally, a strong disposition to idleness, and an invincible repugnance to exercise of the mind as well as of the body: hence, we are not to be surprised that no examples occur among the illusory men of Plutarch: little fitted for business, they have exerted dominion over their species, nor altered the surface of the globe by negotiation or conquest. Attilius, the friend of Cicero, who lived on good terms with all the parties who successively harassed the Roman republic in the civil wars of Cesar and Pompey, is an example of this temperament. The circulation is tranquil, the imagination cool, and the passions moderate. From this moderation of the desires arise often the virtues of temperament, as they are called; virtues, by the bye, of which the poissieurs ought to be the least proud.

The property, by virtue of which we are more or less sensible to impressions on our organs, which is weak in the phlegmatic, very inconsiderable in the muscular, moderate in the fanguine temperament, and tolerably lively in the bilious, constitutes, when it is excessive, the nervous temperament. This is seldom original, but more commonly acquired, and arising from a sedentary life, habits of pleasure, and an unnatural state of mind, kept up by reading works of imagination, &c. Soft and small muscles, and consequently inconsiderable size of body, lively sensations, tremor and varicose veins, white surfaces, and sunken eyes, are marks of this temperament: it is often exhibited in vapourous women, in whom, however, it frequently exils with tolerable embounoint, the predominance of the nervous system being connected with a moderate development of the lymphatic system. Convulsions are not unfrequent in such individuals. Antispasmodics succeed well in the treatment of their difficulties, which always borrow their hue, more or less, from the temperament. This, like the melancholic, is not so much a natural constitution of the body, as the first image of a disease. It exils only, as the nervous affections, to which it dissolves, in societies arrived at a high pitch of civilization, when man is as remote as possible from the state of nature. The Roman women were not subject to nervous disorders.
MAN.

disorders until the commencement of those depraved manners, which signaled the downfall of the empire. Vapours were extremely common in France during the 18th century, in the times that preceded the ruin of the monarchy, and numerous works appeared on the subject within a short time. Tronchin of Geneva acquired very extensive reputation and a large fortune by his skill in treating these disorders: he made idle women exercise themselves habitually, till they were fatigued, and restricted them to simple and wholesome food.

We cannot doubt, that the peculiar bodily dispositions, on which the differences of temperament are grounded, are constant at birth; but they appear to be modified, or even entirely changed by education, mode of life, climate, and contracted habits. The prevalence of particular temperaments in certain countries shows us the influence of climate. The bilious characterizes the inhabitants of southern climates; the sanguine those of the north; the phlegmatic constitution prevails in cold and wet countries, as Holland, &c. We rarely meet with individuals, who present the characters assigned to the various temperaments in all their purity, consequently the sketches here given of them are abstractions, which it is difficult to realize. The sanguine constitution is directly opposite to the melancholic, and never unites with it: we may make the same observation of the bilious and phlegmatic: yet a person, who is sanguine in his youth, may become melancholic at a subsequent period of life; for man never remains as he came from the hand of nature: modified by every thing that surrounds him, his physical properties, as well as his character, present numerous differences at the different periods of life.

Proportion.—The proportions which the parts of the body bear to each other, when its growth is completed, must also be considered in this division of our subject. We have very little exact knowledge concerning these; they are hardly the same in any two individuals. Repeated observations alone can ascertain a standard, by which we may be enabled to form a perfect idea of the natural and fault proportions of the human figure. The ancients made statues so exquisitely beautiful, that they have uniformly been regarded as exact representations of the most perfect human forms. These, which were only copies, are now considered as originals, because they were not imitated from an individual, but from the whole species, so attentively compared, and diligently observed, that it is impossible to find an equal degree of symmetry and proportion in any one man that ever existed. We shall, therefore, relate the dimensions of the different parts which these artists have fixed as standards of perfection. The height of the body is ten times the length of the face; and each face, or tenth of the body, is divided into three equal parts; the first commences at the springing of the hair on the forehead, and terminates at the root of the nose; the nose is the second division; and the third extends from the nose to the end of the chin. The term nose, or length of a nose, is used to denote the third of a face, or the third part of the body. The first face begins at the root of the hair, above the forehead, and extends to the end of the chin; but, from the top of the forehead to the crown, there is full a third of a face or a nose in height. Thus, from the top of the head to the end of the chin, there is a face and a third; from the chin to the juncture of the clavicles, two-thirds of a face; and, therefore, from the top of the head to the breast is twice the length of the face, or the fifth of the body. From the joining of the clavicles to the under part of the breasts, they reckon one face; from this to the

navel is a fourth face; and the fifth extends from the navel to the division of the inferior extremities, which should complete half the length of the body. Two faces are extended between the thigh and knee, to the half of which they allow half a face, being the fifth part of the eighth face; two faces are assigned between the knee and the top of the foot, and from that to the sole half a face, which completes the ten faces, or the length of the body. This division has been established from men of ordinary size; but in those of higher stature, they allow half a face additional between the breasts and the commencement of the thighs, which, in tall men, is not the middle of the body.

When the arms are fully extended in a horizontal line, the space between the tops of the middle fingers is equal to the length of the body. The space between the two great toes, when the feet are separated as widely as possible, is the same length. From the pubes to the heel is one-half of this length.

From the joining of the collar bones, to the articulation of the shoulder bone with that of the arm, is one face. When the arm hangs down, or is bent forwards, it is four faces in length; two between the shoulder and elbow, and two between the elbow and the root of the little finger. Five faces, therefore, from the joining of the collar bones, and the face number for the other arm, make up the length of the body: about half a face remains for the length of the fingers, but it must be remarked, that this is lost in the elbows and shoulders, when the arms are extended. The hand is about a face in length, the thumb a third of a face, or a nose, and the longest toe is of the same length with the thumb. The under part of the foot is equal in length to the fifth part of the length of the body; of this the tarfus composes three, the metatarsus five, and the toes four.

It is very difficult to fix the proportional thickness of the different parts of the body. The changes are so great when the same man is thin or fat, and the action of the muscles, in different positions, creates so much variety in the dimensions of the parts, that it is almost impossible to set down any fixed rules on the subject. The circumference of the trunk, about the chest or abdomen, equals half the length of the body.

Strength of the Body.—It is difficult to form any satisfactory comparison between the strength of men and of animals. The habit of exertion, the kind and quantity of food, the state of health, and many other causes, have such effect on the vital powers of the muscles, that it is hardly possible to perform experiments under circumstances in all respects similar. Delugnelli tells us, that by means of a certain harness, by which every part of a man's body was simultaneously loaded, the person employed in the experiment could support, in the erect position, a weight not less than 2000 pounds. A horse, which is about six times the size of an ordinary man, ought, therefore, when managed in the same manner, to bear 12 or 14,000 pounds, a much greater weight than that an animal can support, even when it is distributed with every possible advantage.

The strength of animals may likewise be estimated by agility, and perseverance in labour. Men, when accustomed to running, are able to outrun horses in the long run: a man will accomplish a long journey sooner, and be less fatigued, than the bell road horses. The royal mullengers of Tiphani, who are trained to running, go thirty-six leagues in fourteen or fifteen hours; we are assured by travelers, that the Hotentotes outrun lions in the chase; and that those savages, who live by hunting, pursue and even catch deer, and other animals of equal swiftness. Many other
other stories are told of the amazing nimbleness of savages, of the long journeys they accomplish on foot over the most craggy mountains, where there is no path to direct, but every obstacle to obstruct their progress. These people are said to travel 1000 leagues in six weeks, or at most in two months. If we except birds, whose muscles are proportionally stronger than those of any other animals, no creature could support such long continued fatigue. Civilized man is ignorant of his own strength; nor is he sensible how much he is weakened by ennui, nor to what extent he might recover his native force by an habitual and vigorous exercise of his powers.

Age of Decline.—Every object in nature must change and decay; the bodies of men, when arrived at full maturity, begin to decline. The waste is at first insensible, and several years frequently revolve before we perceive any considerable alteration. The deposition of fat may perhaps be regarded as the first step towards decay; it is an addition of superfluous matter, loading the body with an useless weight. As the quantity of it augments, the body loses its former lightness and freedom of motion; the members become unsteady, and extenuation is acquired at the expense of strength and activity. But the most unequivocal signs of approaching old age are the caffation of the catamenia in women, often attended with a development of the beard, diminished sexual appetite in men, the approach in both of what has been called the dryness of old age, (ficcitas senilis,) and a sensible diminution of the vital forces. The epocha of these changes is from forty to forty-five in women; from forty-five to fifty in men; peculiar causes may either accelerate or retard the period. The individuals of both sexes are now no longer capable of exercising that most important function, the propagation of the species; their sexual life is at an end. Diminished activity of the muscles and brain, impaired vigour in the moving organs, and leffened energy of all the internal functions, gradually come on after this great revolution in the animal economy. Considerable organic changes are gradually developed; the motion of decomposition begins to predominate in the internal functions, and the volume of the whole body is reduced. The cellular subfatt, soft and flexible in the youth, is converted into long and hard threads; it undergoes, over the whole body, a change that cannot but impair the mobility of the organs. The yielding skin of the infant, which has the softness of velvet in the young woman, grows rough and harsh; a tawny and disfiguring hue takes place of its fresh redness; its contracility is destroyed, the absorption of the fat leaves it unsupported, and hence wrinkles are produced. They are first seen in the eye-lids, and extend over the whole body; but we notice them more particularly in the face, on the wrinkled front of which approaching decrepitude is marked in mostlegible characters. So hard does the texture of the skin become in very old individuals, that considerable force must sometimes be used to penetrate it with a knife. The hair partakes of the same changes with the skin; it turns grey, becomes much thinner, then assumes a white colour, and is at last entirely lost.

The cornea of the eye is rendered flatter, so that its power of refracting the rays of light, that come from near objects, is diminished. The vision of distant objects, however, is still perfect; and the use of convex glasses supplies the imperfection in the sight of what is near. A white circle is often developed in the cornea, near its attachment to the sclerotica, and has been called arcus senilis.

The arteries are not exempt from the general decay; the larger trunks are dilated, their coats are more or less converted into a substance of cartilaginous or bony hardness, and assume a brittle texture. The process of ossification in the smaller tubes reduces their calibre. The capillaries are greatly diminished in number. Hence injections, particularly minute ones, succeed very imperfectly in old bodies. This change affects organs of every description; the same parts which exhibited innumerable blood-vessels in the growing body, poofs now but few and scattered ramifications. The veins are enlarged and various.

The muscles become tough, and are rendered unfit in animals for the purposes of the table; fat is deposited among their fibres, and the tendinous parts increase in their proportion. They feel, however, at this time actually soft and flabby.

The bones receive an undue deposition of earthy matter, lose their coherence, break very easily, and unite after fractures very slowly and imperfectly. The cartilages become brittle, and in many instances are ossified, the ligaments are rendered harder, but are less capable of resuming extension. The teeth fall out.

Analogous changes take place in all parts of the body, but are not equally obvious in all. Yet all the organs have something peculiar in their characters at this time, by which we can easily distinguish them from those of young individuals.

But the most important alterations are those which affect the vital properties, and consequently, the functions of the body. These changes are often seen when the above-mentioned alterations of structure are not visible to any very great degree. The external fences decay; vision becomes dim, and hearing dull; the operations of the intellect are affected in the same manner, attention and perception are weakened, the memory becomes confused. Thus, the relations of the old man to the external world are gradually destroyed; he sinks into second infancy, becomes incapable of judging and willing, and has his intellectual world confined to a few confused recollections, which soon disappear. When he is thus shut out from new impressions, he sleeps most of his time, awakening only for the purpose of taking food; thus he is reduced to a kind of vegetative existence.

The organs of motion lose their vitality in an equal degree with those of sensation and volition. The movements are slow, tremulous, and uncertain. The creator muscles of the trunk can no longer support it in the upright posture, hence the body is bent forwards, and the legs become unable to sustain and move the body. The intervertebral fibro-cartilages are compressed and reduced in size, and the stature, consequently, experiences a real diminution.

Digestion, and the other parts of the assimilating procce, are executed slowly and imperfectly: the loss of the teeth is disadvantageous to the former. Food is taken at longer intervals; the bowels become torpid; and the feces and urine are longer retained.

The vigour of the circulation is impaired; the pulse becomes slower; the extremities of the body are soon rendered cold, and their vitality is so weak, that they easily freeze. For a statement of the number of the pulse at different ages, see the article Circulation.

Decrepitude.—From the end of manhood to death, there is a gradual progress in which no stages can be very distinctly marked. Yet the first years of decay are sometimes included under the term of green old age; in which all the functions are still performed, but with leaffened energy. This may reach, with considerable latitude, however, to the fiftieth year. In this time the memory grows dull; former events are remembered, but the more recent soon escape. This is succeeded by decrepitude. The nervous system is now rendered nearly useless: the old impressions are effaced, and no new ones received. No desire remains but that of food, which
which is the last to leave us; in the end food is not taken, unless it is offered. The irritation of the face in the large intestine is not perceived before death; and sleep is almost constant. A. de Mollevre, who died at the age of eightyeight, slept twenty hours in the twenty-four during the last year of his life. Complete deafness and blindness come on. The muscles are first exceedingly weak, and then lose their power entirely, so that old people are obliged to lie constantly in bed. Excessive emaciation takes place. The heart at last fails; its pulsations are reduced to fifty, forty, thirty; and become intermittent; and the heat of the frame is no longer kept up.

Death.—For a more particular account of the changes preceding death, and of death itself, we refer to that article. We have only to add here a few observations concerning the apprehensions generally entertained of this event. We have shewn, in the preceding sketch, that life both commences and terminates by imperceptible degrees. Why then should we be afraid of death, if we have no reasonable apprehensions of its consequences? why dread this single moment, which has been preceded by so many others of the same order? since death is fully as natural as life, and both arrive in the same manner, without our being able to perceive their approach. If we inquire of those who are accustomed to observe the actions and sentiments of the dying, we shall find that, except in a few acute diseases, attended with agitations and convulsions, which exhibit only the appearances of pain, most men expire quietly, and without the smallest indication of uneasiness. Even when persons seem to be afflicted with the most dreadful agonies, these have no existence but in the imagination of the spectator; the truth of this has been repeatedly attested by many persons who have recovered after the most violent commotions and convulsions, yet were unable to recollect anything they had felt during this seemingly distressful situation. The greatest part of mankind die, therefore, without being sensible of the fatal stroke; and of those who preserve their senses to the last hour, there are very few who do not entertain some hope of recovery.

Death is a spectre which terrifies us at a distance, but disappears when we approach it more closely. That the sensation of ideas may be so rapid as to give to a moment the appearance of an age, and thus to subject our departure from existence to excruciating torture, has been supposed without a single proof in its favour, and against all probability and analogy. Excessive pain extinguishes all reflection; yet symptoms of the latter have sometimes appeared in the very moment of violent death. When Charles XII. received the blow, which terminated, in an infant, both his enterprises and his existence, he clapped his hand upon his sword. This mortal pang, since it excluded not reflection, could not be excursive. He found himself attacked, and determined to defend himself; it is evident, therefore, that he felt no greater pain than he would have suffered from an ordinary stroke.

If it were as easy to dissipate the terrors caused by the anticipation of what is to happen after death, and to quiet the minds of men concerning the undiscovered country beyond the grave, the Tartar, with its judges and furies, its lakes of liquid fire, and the other hellish apparatus, as it is to prove that the termination of existence is not physically painful, the human race would be more gladly benefited, and would no longer have to envy brutes their peaceful death.

Rigidity of the body, joined with coldness, flaccidity of the cornea, open state of the anus, lividity of the back, and a cadaverous odour, where they exist together, prove very satisfactorily that death has taken place.

It is hardly possible to fix down any age as the natural period of life, as the most common and regular limit of advanced old age. Blumenbach observes, however, that a careful inspection of several bills of mortality has shown him, that a comparatively considerable number of Europeans reach their eighty-fourth year, while very few sur vive it.

On the whole, although the human race is destroyed in such numbers, among other causes, from the weakness of the thread of life in the early years, by the intemperance of mankind, by disease and accident, that not more than seventy-eight out of a thousand die a natural death; yet, where human longevity is compared to the period of life of the other mammals under similar circumstances, it will be found discovered, that of all the complaints concerning the misery of human life, none is more unfair than that of its shortness.

On the very interesting subjects of the probabilities of life at different ages, the annual mortality in different countries and situations, the number of marriages, deaths, and births, the rate of increase of population, and the proportions destroyed in the different ways by which existence is terminated, see Expectation of Life, Life-Annuities, and an excellent table by M. Dupré de St. Maur, drawn up from the bills of twelve country parishes in France, and three in Paris, and published by Buffon, in his History of Man, sect. 5. Mortality, Marriage, and Population. For an account of individuals who have reached an unusual age, and of the circumstances, under which this has happened, see Haller's Elementa Physiologiae, lib. xxx. section 3; the article Longevity in this Cyclopaedia; and Sir John Sinclair on Health and Longevity, 4 vols. 8vo.

II. History of the Species.

In the diversity of the regions which he is capable of inhabiting, the lord of the creation naturally holds the first place among animals. His frame and nature are stronger and more flexible than those of any other creature; and he dwells, without injury, in all situations on the surface of the globe. The neighbourhood of the pole and the equator, the highest mountains and the deepest rivers are occupied by him: his strong but pliant body bears cold, heat, moisture, light or heavy air; he can thrive anywhere, and runs into less remarkable varieties than any other animals which occupy so great a diversity of abodes;—a prerogative so singular, that it is not to be overlooked.

What climates, what degrees of heat and cold can man bear? where does he live? and how is he able to endure such various abodes? Is he indebted for this privilege to the strength and flexibility of his organization, or, as Buffon affirms, merely to his reason? Does he constitute a distinct species; or is he allied in kind to the curang-outang? How do climate, food, and similar causes operate on him? Are these sufficient to account for all the diversities hitherto observed; or must we suppose that several individuals were originally created, each for its own climate? What country did he first inhabit, and what was the appearance of the original man? Did he go erect, or on all fours? was he a Patagian, or an Eskimo, Negro, or Georgian? Such are the important questions which we have to consider in the present division of the article;—questions, of which a full discussion would require a much greater extent and variety of knowledge than the writer can lay the leaf claim to, as well as much a larger portion of space than the limits of this work will allow. We must, therefore, be contented with exhibiting a few hints, rather than a complete view of the matter.

Abode of the Human Species.—The situations occupied by man in the present times, extend as far as the known surface of the earth. The Greenlander and Eskimo live in the eightieth, and even, perhaps, in still higher degrees of north latitude.
MAN.

Latitude. Nooagack, a Danish settlement, lies in 72° north latitude; and the Greenlanders themselves go much higher. Three Russians lived between fix and seven years on Spitzbergen, in latitude between 77° and 78°. See Dr. Aikin in the Manchester Society's Memoirs, vol. i. p. 96. The Negro lives under the equator, and all America is inhabited even to Terra del Fuego. Cook discovered land about the 58th and 60th degrees of south latitude, which he called Sandwich land; and a cluster of islands as far as the 66th degree, on which he saw no men. Very probably there are no human habitations here; but it is sufficiently proved that places at least as cold are habitable. Perhaps we are not quite warranted in asserting that there are men in the interior of Africa; yet the accounts received from those on the coasts induce us to believe that these regions are in some degree peopled. Hence we find that man is capable of exist- ing and propagating his species in the hottest and coldest countries of the earth.

The greatest natural cold which has been ascertained by thermometrical measurement, was that experienced by the elder Gmelin in the year 1753 at Jenischik in 58° north latitude, and 110° east longitude (from Ferro). The mercury fell to 126° below 0. (Flora Siberica, pref.) The sparrows and jays were killed. When Pallas was at Krasniairik, 56° north latitude, and 110° east longitude, the thermometer fell to 85° below 0; and the quicksilver froze in the bulb. A mafs of pure mercury, exposed in the open air, was frozen. (Travels in Russia, pt. 3.) Our own countrymen experienced apparently as severe a degree of cold on the Churchill river in Hudson's Bay. Brandy was frozen in the rooms where they had their fires. (Phil. Trans. N. 465.) Yet the Canadian fowls and the Eskimau go to the chase in this temperature; and the inhabitants of the countries visited by Gmelin and Pallas cannot remain constantly in their houses during their winters. Even Europeans, accustomed to warmer climates, can undergo such cold as we have just mentioned, and escape unhurt, if they take exercise enough.

The Danes have lived in Greenland in the 72° north latitude; and the Dutch, under Heemskerk, wintered at Nova Zembla in 1597, in 75° north latitude. Some of them perished; but those who moved enough, and were in found health at first, withstood the dreadful cold, which the polar bear (ursus maritimus), apparently born for these climates, seems to have been incapable of supporting; for the journal states that, as soon as the sun sank below the horizon, the cold is so intense, that the bears are no longer seen, and the white fox (canis lagopus), alone braves the weather. (Voy. de la Comp. des Indes, part 1.) For an account of other examples, and particularly of one, in which three men remained for between six and seven years in 78° north latitude, see Dr. Aikin's Memoir, already quoted, concerning the attempts to winter in high northern latitudes.

The power of the human body to withstand severe degrees of cold will appear in a more remarkable light, when we observe what heat it is capable of bearing. Boerhaave asserted, that a heat of 66° to 100° would be fatal to man. Adamson saw the thermometer in the shade at 108° at Senegal in 17° north latitude; and Buffon cites an insistance of its being seen at 117°. Probably the country to the west of the great defect is still hotter from the effect of the winds which have blown over the whole tract of its burning sands. When the sirocco blows in Sicily, the thermometer rises to 112°, according to Brydone. Dr. Chalmers observed a heat of 115° in South Carolina, in the shade; (On the Weather and Diseases of South Carolina;) and Humboldt experienced a temperature from 110° to 115° in the Llanos or deseins near the Orinoco, in South America. (Tableau Physique des Regions Equatoriales.) Much greater degrees of artificial heat have been supported. See Heat, Animal.

Thus we see that man can sustain all possible degrees of atmospheric heat and cold. He has an equal power of supporting varieties of prehure. We may reckon the ordinary prehure of the air, at the level of the sea, at 33,235 lbs. for the whole surface of the body; supposing the barometer to stand at 30 inches. If we ascend to a height of 13,000 feet, (extensive tracts in South America, inhabited by thousands, have this height,) the barometer stands at 20 inches, and the prehure is 21,750. Condamne and Bouguer, with their attendants, lived three weeks at a height where the barometer stood at 15 inches; the prehure is 16,920. (Mem. de l'Acad. des Sciences, 1744.) In the Peruvian territory, extensive plains occur at an altitude of 9000 feet; and three-fifths of the vicereignty of Mexico, comprehending the interior provinces, present a surface of half a million of square miles, which runs nearly level at an elevation of from 6000 to 8000 feet. Mexico is 7475, and Quito 9550 feet above the sea. The hamlet of Antaiana, 13,500 feet above the level of the sea, is the highest inhabited spot on the surface of our globe; but Humboldt ascended to 19,300 feet. (Tableau Physique des Regions Equatoriales; et Tableaux de la Nature.) There are no influences of men living under a prehure much greater than we have just mentioned: the depths to which the earth has been penetrated, in the operations of mining, are trifling in this point of view. In diving, however, the body is subject to, and can bear several atmospheres; as, on the contrary, in balloons, men have ascended beyond any point of elevation on the surface of the earth, and have consequently been exposed to a much more considerable diminution of the ordinary prehure than what we have hitherto.

Food.—The great variety of substances, which man is not only capable of digesting, but from which his organs can extract wholesome nourishment, contribute very essentially to his wide extension over the surface of the earth. We have already explained, under the article Digestion, that almost the whole animal and vegetable kingdom afford food to man. Under particular circumstances, he can not only derive his nutriment exclusively from the animal kingdom, as in New South Wales, and in the Archipelago between Asia and America, from fish; in the islands to the south of Iceland, from fish and puffins (see Sir G. Mackenzie's Travels in Iceland;) but can confume what appears to us the most filthy and disgusting objects. The Greenlander and the inhabitants of Alaska eat the whale, and can digest this hard and revolting food without the assistance of cookery. The former bury a seal, when they catch one, under the grafs in summer, and the snow in winter, and eat the half-frozen half-purrid flesh with as keen a relish as the European finds in his greatest dainties. (Cranz Hist. of Greenland.) They drink the blood of the seall white warm, and eat dried harring miiftened with whale oil. They mix fresh, purrid, and half-incubated eggs, whortle berries, and angelica, in a bag of seal-kin, pour whale-blubber on it, and revise the infernal mixture as a delicacy for the winter. The people of admiral Monk, and some Russians, cast away on one of the Aleutian islands, greedily consumed the purrid remains of a whale; and the Greenlanders always dispoze of the whales stranded on their coasts in this way, not defiling, however far puteaification may have proceeded, till the whole is gone.

Even the earth, impregnated with the relicue of animal and vegetable matter, affords food to some favages. The Ottomases, on the banks of the Meta and the Orinoco, feed
fed on a fat unctuous earth, or a species of pipe-clay tinged with a little oxyd of iron. They collect this clay very carefully, distinguishing it by the taste: they knead it into balls of four or six inches in diameter, which they bake slightly before a slow fire. Whole flakes of such provisions are seen piled up in their huts. These clods are soaked in water, when about to be used; and each individual eats nearly a pound of the material every day. The only addition which they occasionally make to this unnatural fare, consists in small fish, lizards, and fern roots. The quantity of clay that the Ottomans confume, and the greediness with which they devour it, seem to prove that it does more than merely defend their hungry stomachs, and that the organs of digestion have the power of extracting from it something convertible into animal substance. Humboldt Tableau Physique des Regions Equatoriales.

The researches of Menes respecting food seem to have accomplished every accessible authority on the subject: his deductions, supported by an almost infinite number of quotations, exhibit a complete view of the matter, that we present them to the reader in his own words. "The common positions concerning the earlier use of vegetables, and the effects of vegetable and animal food on the dispositions of people, have been brought forwards by men not acquainted with all the facts which history pretends. There were formerly, and still are, many people, particularly among the dark coloured nations, who eat nothing, or almost nothing but flesh; and that with little or no preparation. Examples of this are afforded in Aina, by the Huns, Calmucks, and people of Thibet; by the Burates, Tungoofes, Kaffchatians, and eastern idlers; by the Ottomans and Sameedes, whom the Kuffians were obliged to imitate in Nova Zembia, and the Eastern ocean; by the Wogubs, Circfaithans, Mongrellas, and Abscafs; and lastly, by some tribes in Babylon: in Europe, by the Alani, all the Celtic people, the Tartars of the Crimea, and even the inhabitants of St. Kilda: in America, by the Efequeins, the Greenlanders, the North American savages, the Persians, and the inhabitants of Terra del Fuego: in Africa, by the Ethiopians and Gallas: in the southern countries, and the islands of the South Sea, by the New Hollanders, New Zealanders, and the inhabitants of the Friendly and Society islands."

"On the contrary, there have been, and still are, many people who live almost exclusively, or wholly on vegetables. Such are the Cretans, Spartans, and Romans, in certain periods; most of the Slavonic tribes; the Turks, Arabinians, and Persians; the Mahometans, and still more the Brahmins in Hindooftan; the Chinefe, Japaneze, and certain of the Javanese; most of the Otaheiteans, and inhabitants of the Marian islands; lastly, the Egyptians, Moors, Negroes, Hottentots, and inhabitants of Sennaar."

"The most common animal food is fish, which, in the warm climates of Aina and Africa, is seldom eaten except in a flinking or putrid state. Fish are eaten pigs and dogs; then camels, mules, horses, and locusts. The southern people prefer smoked and salted, the northern fresh meat. The modes of preparation are various: very few boil; most either dry or roast their flesh, and this in very different ways."

"Of vegetable foods, maize deferves the first place; then bananas, potatoes, yams, and other roots; rice, and millet. The history of our European corn is very obscure. Originally the corn was eaten either raw or roasted; or else it was pounded or bruised, and the meal taken, either raw, or roasted or boiled. Examples of these methods are still found. The viete, as well as some of our kinds of corn, are produced in much more southern countries than is commonly supposed."

"Of trees that produce fruits, those of the palm kind should be first mentioned; the fago and bread-fruit trees are much less widely extended. Many people eat acorns or chestnuts, or the rind or exuded juices of well known trees; or the pitch, fruit, or roots of trees that we know little of. In other situations, moss or berries, or the roots and bulbs of known plants, have been employed. The fruit trees of our climates grow neither in the torrid nor in the frigid zones. The use of hot spices generally increases with the heat of the climate. The perfectly irregular meals of savages are less remarkable than the quick eating of the orientals."

"The orientals are the most moderate; all of Mongolian or mixed origin, in all climates, and even in the torrid zone, are the most voracious. Respectable writers bear testimony to this voracity in the Negros, Tun-goofes, Bafchiks, and Kirgiaces; in the Greenlanders, Laplanders, and Fins; in the Hindoes, Tunquines, and the inhabitants of Laos; in the Negroes and Hottentots; in the North and South Americans. There are situations, in which the appetite of new comers is much increased, or a greater quantity of food is required to support the bodily powers."

"The voracious people swallow with brutal avidity the most disgusting and difficultly digestible substances. The Calmucks devour putrid and flinking matters, the afterbirth of animals, marmots, mice, otters, birds of prey, foxes, and wolves; but not dogs nor weasels. The Jakuts eat carnivorous animals; and the after-birth of their women is a delicious morfel, to which they invite their friends: they will not, however, touch frogs or pigs. The Tungoofes and Olhaks swallow slimy mud: the former also eat lice and the foot of their children. The Sameedes eat putrid relics of hoffa, cats, dogs, whales, &c.; and the Kaffchatians indigestible fungi. The women of the former used to eat the after-birth, that they might conceive again sooner. The Tchufuks and their guests drink the urine of the women; and the inhabitants of the Fox islands, besides lice, eat raw whale-blubber: they also lick themselves dry, after washing with urine. The Laplanders chew tobacco; flick it behind their ears, and then chew it again. The Tunquinefe eat tigers, lions, snakes, bats, elephants, flinking and uncleaned fish; the Chinefe, dead dogs, horsef, and rats; the Arracanefe, Siamefe, and Formofans, besides such things, devour entrails, with all their contents. The inhabitants of the Bangoo islands in the Indian ocean, who are in other respects cleanly, consider the contents of a goat's foimach as a great luxury. Crocodiles, eagles, oifiches, hippopotamis, serpents, raw and putrid buffaloes and elephants, uncleaned entrails, toads, rats, and worms, the most flinking carcases, chalk, and earths, are eaten by the Negroes. The Bojeafmef make themselves fat with ants, and maggots of wood; and, like the Negroes, are fond of elephants' flesh, which they eat in pieces, and dry in the sun. The women of the Americans free each other from vermin, and eat them; and the contents of a rein-deer's foimach, mixed up with whale-oil or bear's-grease, is deemed a bonne bouche by the Greenlanders. They also cook fish with blubber, chewing them, and spitting them into the vessels, that nothing may be wafted: they broke off the sweat with their fingers, and swallowed it. The Californians not only consume lice, uncleaned entrails, serpents, lizards, infects of all kind, maggots from rotten wood, spoiled corn full of worms, but also dry leather and clay; undigefted grains of the pitchoias, which they get from human excrement; and lastly, rats and mice, which they put on the fire for
for a short time, and then swallow quite bloody. Besides other matters, the Brazilians and Chilote eat the bleeding hearts of their enemies; and the former also the bodies and broken bones of their children and leaders. The Caribs, and other people on the Orinoco, like the Negroes, eat chalk and clay; and make with them, and spoiled maize, balls which they moisten with turtle fat, and swallow with great delight.

"Almost all people, even the wildest and most stupid, have devised methods for intoxicating or stupefying themselves. For this purpose they either smoked or chewed leaves or herbs, in some instances. The orientals, who possessed the western half of southern Asia, and the north-west side of Africa, have from early times preferred the use of opium; and the south-east nations, and their colonies, that of betel. The orientals and the East Indians drink wine to excess; but they prefer the spirit extracted from sugar or rice, or still stronger liquor. The Russians in Siberia, and the European colonists in the torrid zone, drink brandy in great quantities. Palm and honey wine are very common in hot countries. There is scarcely any herb or vegetable production, and much less any article of vegetable food, from which intoxicating drinks have not been extracted. Bread, malt, meal, fruit, fago, caffa (jaca dulce et amarga), potatoes, the aloe (agave americana), millet, and maras' milk, have been used for this purpose. The chics of the Americans, of which maize is the base, is the most disgusting liquor. Very few people have been entirely unacquainted with holling liquors: the love of these, however, seems particularly strong in the ugly races of Asia and America." Meiners' Grundris, p. 140-162.

On the subject of eating human flesh, see the articles CANNIBAL AND ANTHROPOPHAGI.

In almost all ages there have been disputes concerning the food suited to the nature of man; whether a mixed diet, or one purely animal or vegetable, is most favourable to the development of the bodily and mental powers. "The Pythagorean diet," says Buffon, "though extolled by ancient and modern philosophers, and even recommended by certain physicians, was never indicated by nature. If man were obliged to abstain totally from flesh, he could not at least in our climates, either exist or multiply. An entire abstinence from flesh can have no effect but to enervate nature. To preserve himself in proper plight, man requires not only the use of this food nourishment, but even to vary it. To obtain complete vigour, he must choose that species of food which is the most agreeable to his constitution; and as he cannot preserve himself in a state of activity but by procuring new formations, he must give his senses their full stretch, and eat a variety of meats, to prevent the disgust arising from an uniformity of nourishment." We are told, on the other side, that, in the golden age, man was innocent as the dove; his food was acorns, and his beverage pure water from the fountain; finding everywhere abundant subsistence he felt no anxieties, but lived independent, and always in peace both with himself and the other animals. But he no sooner forgot his native dignity, and sacrificed his liberty to the bonds of society, than war and the iron age succeeded that of gold and of peace. Cruelty and an invariable appetite for flesh and blood were the first fruits of a depraved nature, the corruption of which was completed by the inventions of manners and arts. Either immediately, or remotely, all the physical and moral evil, by which individuals are afflicted and society laid waste, arise from these carnivorous practices.

We cannot give our approbation to either of these representations, both of which are contradicted by the only criterion in such questions, an appeal to experience. That man can be perfectly nourished, and that their physical and intellectual capabilities can be fully developed in any climate, by a diet purely vegetable, has been proved by such abundant experience, that it will not be necessary to adduce any formal arguments on the subject. The representations of the Pythagoreans are the mere offspring of imagination. We have not the shadow of a proof that this state of ideal innocence, of exalted temperance, of entire abstinence from flesh, of perfect tranquility, of profound peace, ever existed, or that it is more than a fable designed to convey to us moral instruction. If the experience of every individual were not sufficient to convince us, that the use of animal food is quite sufficient with the greatest strength of body and of mind, the truth of this point is proclaimed by the voice of all history. A few hundreds of Europeans hold in bondage the vegetable eating millions of the East. We see the carnivorous Romans winning their way, from a beginning so inconsiderable, that it is lost in the obscurity of fable, to the empire of the world; we see them, by the power of intellect, establishing that dominion which they had acquired by the sword, and furnishing such compositions in poetry, oratory, philosophy, and history, as are at once the admiration and despair of succeeding ages: we see our own countrymen rivalling them in arts and in arms, exhibiting no less signal bravery in the field and on the ocean, and displaying in a Milton and Shakspere, in a Newton, Bacon, and Locke, in a Chatham, Erkine, and Fox, no less mental energy: yet, with these proofs before their eyes, men are actually found, who would have us believe, on the faith of some inflated, exaggerated, or misrepresented facts, and still more miserable hypotheses, that the development, form, and powers of the body are impaired and lefened, and the intellectual and moral faculties injured and perverted by animal diet.

The present demands a very proper place for considering a question, that is frequently agitated on this subject; whether man approaches most nearly to the carnivorous or herbivorous animals in his structure? We naturally expect to find, in the figure and construction of the teeth, a relation to the kind of food which an animal subsists on. The carnivorous have very long and pointed cuspidi or canine teeth, which are employed as weapons of offence and defence, and are very serviceable in seizing and lacerating their prey; these are three or four times as long as the other teeth in some animals, as the lion, tiger, &c. and constitute very formidable weapons. The grinding teeth have their bases elevated into pointed prominences; and those of the lower flux within those of the upper jaw. In the herbivorous animals, these terrible canine teeth are not found, and the grinders have broad surfaces, opposed in a vertical line to each other in the two jaws: enamel is generally internitened with the bone of the teeth in the latter, and thus produces ridges on the grinding surface, by which their operation on the food is increased: in the former, it is confined altogether to the surface. For further details on this subject, see MAMMALIA. The articulation of the lower jaw differs very remarkably in the two kinds of animals: in the carnivorous, it can only move forwards and backwards; in the herbivorous it has, moreover, motion from side to side. Thus we observe, in the ffeft eater, teeth calculated only for tearing, and subcutaneous, in part at least, to the procure of food, as well as to purposes of defence, and an articulation of the lower jaw that precludes all lateral motion: in those which live on vegetables, the form of the teeth, and the nature of the joint, are calculated for the lateral
r al or grinding motion: the former swallow the food in manifess; while in the latter it undergoes considerable commination before it is swallowed. The teeth of man have not the slightest resemblance to those of the carnivorous animals, except that their enamel is confined to the external surface; he polishes, indeed, teeth called canine, but they do not exceed the level of the others, and are obviously unsuited to the purposes which the corresponding teeth execute in carnivorous animals. These organs, in short, very closely resemble the teeth of monkeys, except that the canine are much longer and stronger in the latter animals. In the freedom of lateral motion, the lower jaw of the human subject resembles that of herbivorous animals. In the form of the flotnach again, and, indeed, in the structure of the whole alimentary canal, man comes much nearer to the monkey than to any other animal. The length and divisions of the intestinal tube are very different according to the kind of food employed. In the proper carnivorous animals the canal is very short, and the large intestine is cylindrical; in the herbivora, the former is very long, and there is either a complicated flotnach, or a very large cæcum and a facellated colon. In comparing the length of the intestines to that of the body in man, and in other animals, a difficulty arises on account of the legs, which are included in the former, and left out in the latter: hence the comparative length of the intestinal tube is slanted at less than it ought to be in man. If allowance be made for this circumstance, man will be placed on nearly the same line with the monkey race, and will be removed to a considerable distance from the proper carnivora. Soemmerring states that the intestinal canal of man varies from three to eight times the length of the body. (De Corp. Hum. Fab. t. 6.) In Tyron's chimpanzee of 26 inches, the canal measured 179 inches, which is about six times the length of the body; in two lapajons and two monkeys, the intestines were respectively 52 and 96 inches, which must be considerably shorter in proportion, although the length of the body is not mentioned. p. 32.

The following are the comparative lengths of the canal and body in several animals, according to Cuvier, t. 3 p. 448. As the hind limbs are not included in the length of the body, it will be immediately apparent that the alimentary canal of these herbivorous animals is generally shorter than that of man.

Man possessing a tolerably large cæcum, and a cellular colon, which we believe is found in no carnivorous animal. In general, then, the human teeth and joint of the jaw resemble most those of herbivorous animals; and man approaches most nearly in these, as well as in other points, to the monkey race, which are, in their natural state, completely herbivorous.

In fating these circumstances, we do not with our readers to draw the inference, that man is designed by nature to feed on vegetables. The differences between him and other animals, render it difficult to apply to him reasonings drawn from them. The hands of man, and particularly his arts, procure for him the food which carnivorous animals can by their teeth. The processes of cookery bring what he eats into a different state from that in which it is employed by either carnivorous or herbivorous animals. Hence the analogy is too loose for us to place much confidence on the results of these comparative views. We must therefore experience alone for elucidating the great problem of diet: but the experimental mode of investigation is so difficult; mankind are too averse to relinquish long habits, and there are so many other causes affecting human health, that we are by no means fain to turn the expectations of important results. Before we can venture to draw any inferences on a subject, beset with so many obstacles, we want to know the effects of a purely animal diet on several individuals of different. habits. We must have accurate reports of their state, both bodily and mental, and must learn the condition of two or three succeeding generations fed in the same way. A similar statement will be necessary on the operation of a strictly vegetable diet. The drink, too, is an important consideration. For further remarks on this subject, see Corpulence and Diet.

Abode and Drefs of various Nations.—We shall employ on this subject the observations of Meiners, who has collected his materials from every accessible source of information, both ancient and modern, and subjoined the numerous authorities from which they are derived.

Abode.—There have been more people than is commonly supposed, without any, or at least without any fecund and protecting dwelling; and these were, without exception, dark coloured or ugly nations; such were the Femi of Tacitus, the favages about Hudson's Bay, northwards from the river St. Laurence, and in North America in general, the Californians, Peruvians, the Indians near Garcia de Dios, the Brazilians, those on the Oronoco and Maranon, the New Hollanders, some of the New Zealanders, some favages near Abiylinia; and the lowest inhabitants of Sumatra, Arabia, and Hindoostan, have such huts.

More solid and perfect edifices were constructed with beams, or stones, or woodwork; the walls covered with earth. In this way the Greeks, Germans, and Slavons of ancient times built; the same method is adopted still by the Mochchasins, the inhabitants of several German and Turkish provinces; the Finnic and mixed races in Europe and Asia; the Ruffians and Icelanders; several favages in America; most of the Negroes; the Cabyles and Moors in Africa, several of the Arabsians, and Perians, Hindoos, Ceylonese, Chineese, and Japanese.

The mode of building is modified by various causes. Conduit danger taught the nations of the middle ages, the Greeks of the iflands, the Mingrelians, the inhabitants of Sumatra, the Baffee islands, New Zealand, &c. to provide themselves with the means of safety. Those who are exposed to earthquakes, inundations, vermin, rapacious animals, will build differently from such as know nothing of these evils. Extreme heat and cold of the climate require different methods; pastoral and agricultural people will lodge themselves very differently. There are many reasons why
rings, not only in the ears and nose, but also about the neck, arms, legs, body, &c. prevails still chiefly in Africa and Asia, where it has existed from the earliest times. The Europeans also, in the dark ages, took pleasure in founding and heavy ornaments. The decoration of the female head was formerly, and still continues, the most complex and heavy, in the oriental nations of Asia, and the mixed people of Siberia. The attention of ornaments made of feathers are among the peculiarities of the Americans.

The inhabitants of cold climates prefer some order of the ancient economy, for some, and nearly so; and this is the case at present with the Magyrians, the inhabitants of Terra del Fuego and their neighbours, and the New Hollander. The savages of California, Louisiana, the island of Darien, Guiana, Brazil, and Paraguay, several islands of the South Sea, and several negroes, go also naked.

The art of clothing is supplied in the naked people by favoring the body with oil or grease, generally mixed with colored earths or plants. Painting of the whole body, or of parts, and particularly of the face, has been a chief object of employment of vanity with nearly all the savage people of the world. One or the other was practiced by the Celts, Perians, and Medes: the custom still prevails in Asia among the Brahmins, Hindoos, and their women; among the females of the Arabian, Perian, Turks, Armenians, Egyptians, and Magyrians, to whom we may add those of the Greeks, Walachians, and Ruffians: also the Chinese, Peguans and Siamee, the New Hollander, New Zealanders, inhabitants of several South Sea islands, and the Kamchats, among the Negros and Hottentots, and all the wild Americans, both north and south. The practice of puncturing and tattooing the skin, performed with very various objects, and on very different parts, has not been lost universal; we find, at least, that it has existed among the Celts, the Egyptians, Syrians, Brahmins, and Arracanees, the Turks, Armenians, Moors, and the Formosans, the Tsungofoes, Oliaks, Creelander, and eastern indians, the North and South Americans, and the South sea indians. Instead of punctures and lines incisions with a knife were made in some instances.

Great attention has generally been paid to decorating the hair, to changing its colour by powders and grease, to curling it in various ways, or adorning it with feathers and other articles. The women of the Greeks and Romans, even in their times of simplicity, were distinguished in this way, so the Turks and Moors and their women, the southern indians, most of the negroes, and nearly all the American savages. Several people, from their notions of beauty, have employed themselves in staining, filing, and otherwise decorating their teeth; also in colouring and encouraging the growth of their nails. Still more extraordinary attempts at personal decoration have been made by the Garga women, several negroes of both sexes, the Carib women, the Gallas, and the natives of Natal.

With the view of beautifying the person, the ears and nose have been perforated, and the lips and cheeks either slit up, or perforated. The latter practice has been observed chiefly in the inhabitants of the eastern islands, and the savages of Paraguay and Brazil; but it was much more common to make holes in the ears or nose, to hold rings or other ornaments. This was carried no where so far as in South America, the eastern islands, and those of the south sea. The taste for

**Vol. XXII.**
race dispersée aincennement dans les bois n’avait eu occasion de développer aucune de ses facultés virtuelles, n’avoir acquis aucun degré de perfection, et le trouver encore dans l’état primitif de nature."

Other writers, who have pleased themselves with describing what they call a regular gradation or chain of beings, represent man only as a superior kind of monkey; and place the unfortunate African as the connecting link between the superior races of mankind and the orang-outang. (White’s account of the regular gradation in man and animals, &c. 4to. London 1779.) The precise meaning of the word gradation, in this mode of employing it, we do not understand, nor do those who use it favour us with any definition of a term so very important in settling the question: we conceive the meaning to be that man is not a race originally distinct from monkeys. That the slave merchant, who traffics in human blood, and the negro-driver, who uses his fellow creatures worse than brutes, should endeavour to justify their conduct by depressing the African to a level with the brute, is what we might reasonably expect, as well as to hear the slave traffic commended because it imparts to the negroes the blessings of Christianity: but we should not have expected to find such opinions defended by the natural historian; and we shall not hesitate to assert that they are as false philosophically, as the moral and political consequences, to which they would lead, are shocking and detestable. We set out with this position that man has numerous distinctive marks, by which, under every circumstance of roughness and uncivilization, and every variety of country and race, he is separated by a broad and most clearly defined interval from every other animal, even of those species which, from their general resemblance to the human subject, have been called anthropo-morphous. We cannot, indeed, by any means coincide with those moderns who have indulged their imaginations in painting a certain continuity or gradation of created beings; and who fancy they have discovered great wisdom of the creator, and great wisdom of the creation in this respect; that nature makes no leaps, but has connected the various objects of the three kingdoms with each other like the steps of a stair-case, or the links of a chain. The candid and unprejudiced observer must allow, that in the animal kingdom there are whole classes, as birds, and particular genera, as the cuttlefish, which cannot find a place in such a scheme of arrangement without a very forced and unnatural introduction; and again, that there are certain genera, as the corvids, where the two sexes are so different from each other, that the male and female must be separated, and occupy different parts of the scale in this artificial plan of gradation.

The completely unsupported assertions of Monboddo and Roufeau only show that they are equally ignorant of the structure and characters of men and monkeys, and that they know nothing of the laws, according to which the deviations of an animal from the original stock take place. We should not waste a moment in refuting what is not defended by a single proof. But the subject is important and very interesting; and we shall therefore consider at some length what are the specific characters of man.

In this part of our subject we shall have frequent occasion to mention the orang-outang, and therefore think it necessary to observe, that two distinct species have been confounded under this common appellation. Linnaeus, Buffon, and Erxleben, have not rectified this mistake; although Blumenbach had long ago pointed it out. The latter author, in his manual of natural history, describes, under the name of Simia troglodytes, the animal of which Tyfon, in his anatomy of the pigmy, has given so excellent an anatomical description. It is found in Angola, Congo, and the interior of Africa, and, as well as the following, reaches about the size of a boy eight years old. It is called chimpanzee, and has been described by the names pongo, jockko, and barris. It is distinguished by its black hair and very large ears; and has a nail on the thumb of the hind hand. The Simia fayurus is the proper orang-outang (which word, in the Malay language, means man of the woods), is found in the island of Borneo, and is the animal deified by Camper. It has reddish-brown hair, and no nail on the thumbs of the hind hands.

**Differences between Man and Animals.**—The circumstances which distinguish man from other animals, may be considered under the divisions of 1. external construction; 2. internal structure; 3. functions of the animal economy; 4. faculties of the mind; 5. differences; 6. alleged, but not well-grounded differences.

1. **External Conformation:** erect Stature.—Under the first head we remark, as the most distinguishing peculiarity of man, his erect stature: that majestic attitude which announces his superiority over all the other inhabitants of the globe. He is the only being adapted by his natural formation to the upright position. Enlaved to their senses, and partaking merely of physical enjoyments, other animals have the head directed towards the earth: "que natura prona atque ventriculi obedientia maxit." Man, whose more elevated nature is connected to surrounding objects by moral relations, who can embrace in his mind the system of the universe, and follow the connections of causes and effects, boldly regards the heavens, and can direct his flight even into the starry regions.

"Prumaque cum specie animalia cetera terrarum, Os homini sublimine dedit; cælumque tueri Jufit; et creatus ad sidera tollere vultus."

In considering this distinction, it will be necessary for us to prove two points: 1, that the erect stature is suited to the organization of the human subject; 2, that it is peculiar to man.

**Erect Attitude suited to the human Organisation.**—The former is clear from what we shall observe afterwards, concerning the arrangement of certain parts of the human frame; it is not less evinced by the invariable practice of all nations in all ages of the world. The individuals of no nation, even in the wilder state, have ever gone on all fours; and no animal has ever altered its frame. The chief function of this relation concerning the human subject being designed to support the body on four limbs, has been derived from the examples of children loll in woods and growing up in a wild state. Can we conceive any thing more widely removed from the natural condition of man than these wretched individuals? and might we not as well adopt any monstrous birth for a model of the human form, as draw our notions of attitude and way of life from these specimens? Moreover, if we look attentively into the most authentic accounts of these wild men, we shall find, that in the least fupicious influences they were erect; as for instance, Peter the wild boy (Blumenbach in Voigt’s Magazin für Physik, &c. iv. pt. 3. p. 91. Monboddo Ancient Metaphysics, v. iii. p. 57 and 367.), the girl described by Condamin (Histoire d’une jeune fille Sauvage, Paris, 1761, 12mo.), a man found in the Pyrenees (Leroy l’Exploitation de la Nature dans les Pyrenees, London, 1776. 4to. p. 81; and the young savage of Aveyron (Historical Account of the young Savage of Aveyron, London, 12mo.) On the other hand, where they have been described as going on all-fours, many circumstances of a very fupicious kind will be detected in the narrative, as in the account.
of the juvenis ovinus Hibernus of Linnæus: we cannot therefore help suspecting that Linnæus’s homo fapiens ferus has no more claim to the epithet tetrapus than to that of bir-futus.

That the structure of the human body is adapted to the erect attitude, may be deemed so clear as to need no proof: but two respectable authors have defended the contrary paradox (Mofcati von der körperlichen wentsflichen unter-fehiede zwischen der Struktur der Thiere und der Menfchen; Göttingen, 1771, 8vo. and Schrage in a Dutch Jour-nal.)

Structure of the lower Limbs.—The support of the trunk upon the two lower limbs, and its being moved by the muscles of those limbs, lead us to expect great peculiarities in their structure. We find accordingly, that man is distin-guished by the great length of the legs in comparison to the trunk and to the arms. Daubenton’s assertion, that no animal but man has lower extremities equaling the trunk and head together in length, is nearly correct: (the kangaroo, jerbooa, &c. form exceptions, but do not invalidate the assertion fo far as regards our present purpose.) The hind limbs of the gorilla and orang-outang fall very far short of this proportion. This length of the legs, which is so convenient in our erect attitude, makes us altogether unfit for going on all fours, as any perfon will immediately discern by making or observing a trial: the limbs in such an experiment must be thrown obliquely backwards, or the articulations held in a bent and very insecure position. Even children, before they can walk, in whom the lower limbs are comparatively shorter than in adults, crawl upon their knees, or else drag the lower extremi-ties after them on the ground. The feet of men are much broader than those of any animal, and admit of being sepa-rated more widely from each other. The features of the lat-ter prerogative reside in the superior breadth of the human pelvis, and in the length and obliquity of the neck of the femur, which, by throwing the body of the bone outwards, disengages it from the hip-joint. The whole tarsus, meta-tarsus, and toes, rest on the ground in the human subject, and afford an ample bafe of support for the body. The fimiie and the bear have the end of the os calcis raised from the surface; while, on the contrary, it projects in man, and its prominent portion has a most important share in supporting the back of the foot: it is larger and more prominent in man than in any animal. The thigh-bone is straight, and its two condyles of equal length in the orang-outang. The thigh is placed in the same line with the trunk in man; it always forms an angle with the spine in animals; and this is often even an acute one: the unfeated of the erect attitude, and the difficulty of maintaining the equilibrium under such an arrangement, are too obvious to need any particular explanation.

Not only the length, but also the remarkable strength of the legs, when contralined with the slender arms, clearly shew that the foremer are designed for supporting and moving the body. And here we may adduce a further argument drawn from the progress of ossification. The bones of the tarfus, and particularly the os calcis, ossify at an earlier period, and advance more rapidly in their development than those of the corpus. Very little strength of hand is required in the first years of life, while the feet, at the end of twelve months, begin to be employed in sustaining the body, and advancing it by progreffeive motion.

The Muscles.—The extensor muscles of the ankle joint, and chiefly those which form the calf of the legs, are very small in the mammalia, even in the genus simia. The peculiar mode of progression of the human subiect accounts sufficiently for their vaffy superior magnitude in man. By elevating the os calcis, they raise the whole body in the act of progression; and, by extending the leg on the foot, they counteract that tendency, which the weight of the body has to bend the leg in standing. Hence Ariosto, and others after him, very juflly observed, that true calves of the legs can be ascribed to man only. See GASTRONEMIUS and MUSCLE, under the head of Standing and walking.

The extensors of the knee are much stronger in the hu-man subiect than in other mammalia; as their double effect of extending the leg on the thigh, and of bringing the thigh forwards on the leg, forms a very essential part in the human mode of progression. The flexors of the knee are, on the contrary, stronger in animals; and are inferted so much lower down in the tibia (even in the simia) than in the hu-man subiect, that the support of the body on the hind legs must be very insecure, since the thigh and leg form an angle, instead of being continued in a straight line. Upper Limbs.—A very curious inspection of the upper limbs will convince us, that, whether we regard the situation and mode of their connection to the trunk, or the di-rection and arrangement of the articulations throughout, they are entirely unfitted to the office of suppotting the body, and as well calculated for the use to which we put them, of seizing and holding objects, and thereby executing, besides all the processes of the arts, a thousand minute but most serviceable actions of confitant recurrence. The arms, instead of falling perpendicularly under the anterior part of the trunk, are thrust outwards by the clavicles; the glenoid cavities of the scapula, instead of being directed downwards, as in quadrupeds, look outwards: the elbows bend outwards, instead of forwards, &c.

Thorax.—The whole arrangement of the thorax shews man to be a biped. Those quadrupeds which have long legs, have a thorax comprifed at the sides, narrow and keel-shaped in front, confequently deep from the spine to the ilium, but confined in the transverse dimension, and they are defitute of clavicles, fo that the front legs come together, and suport with greater firmnefs and facility the front of the trunk. They poffefs moreover a longer ilium, or a greater number of ribs (18 in the horse), which advance nearer to the crifla of the os innominatum, for the purpose of supporting the abdominal viscera in the horizontal po-ition of the trunk. Even in the ouan-outang, the mea-surement of the thorax from the spine to the ilium exceeds that from side to side. (Œuvres de P. Camper, p. 115.) All thefe particulars are different in man. His thorax is flattened in front, very broad, but flawful from before back-wards: the humeri are thrown to the fides of the trunk, and thus acquire a more extensive range in their motions: the ilium is short, and the abdoamen unprovided with bony supports in a very great share of its surface. Thefe, with other points which cannot escape observation, when the skeleton of any rather long-legged quadruped is compared to that of man, shew how unfit he is for the attitude on all fours, which in his cafe can never be otherwife than unfeady, irklome, and fatiguing in the highest degree.

Pelvis.—The peculiarities of the human pelvis afford a strong confirmation of what we have already flated. The form of this part is very characteristic in man, and enables us to distinguish him from the anthropo-morphous finte, and indeed from all the other mammalia. Although it might found paradoxical and affected, yet we could defend the affertion that the human skeleton alone has a proper pelvis that is, such a connection of the fcinum and coccyx with the osa innominata, as forms a cavity resembling a before, from which the elongated osa innominata of other mammalia dif-fer toto coelo. In the ouan-outang and elephant we find the

near
The nearest approach to the human formation: in the former, however, the upper part of the skull is narrow and elongated, stretching upwards in the direction of the spine, and its length exceeds its breadth, so that the relations of these two dimensions are very different in man and this animal. The height of the whole pelvis, from the tuber ischii to the anterior spine of the ilium, is 7 in. 5 in. in man, and 6 in. in the orang-outang; its breadth between the two anterior spines in the former 10 in. 6 in.; in the latter 6 in. 6 in.: in the latter the symphysis pubis is very deep: and in both, there is neither that incurvation of the sacrum from its prominence downwards, nor that direction of the coccyx towards the front, which, with the broad, horizontal extension of the ilis, and the blearer size of the symphysis pubis are peculiar to the human frame, and confer a broad and firm basis for the trunk, on which the weight of the abdominal contents is supported. The sacrum of the orang-outang is flat and contracted, and continued in a straight line with the vertebral column.

Further Proofs.—Such then are the supports by which the trunk of the human body is firmly maintained in the erect position, and fuel are the properties of the trunk contributing to the same end. The breadth of the human pelvis affords a firm basis, on all the superior parts rest securely; the same part is so narrow in other animals, that the trunk represents an inverted pyramid: there must consequently be great difficulty in maintaining it in a state of equilibrium, if it were possible for the animal to assume the erect position. In those instances where the pelvis is broader, the other conditions of the upright stature are absent: the bear, however, forms an exception to this observation, and consequently may be taught to stand and walk erect, although the posture is manifestly inconvenient and irksome to the animal. When quadrupeds endeavor to support themselves on the hind extremities, as, for instance, for the purpose of seizing any objects with the fore-feet, they rather sit down than assume the erect position. For they rest on the thighs as well as on the feet, and this can only be done where the fore-part of the body is small, as in the simiae, the gibbon, &c.: in other cases the animal is obliged to support itself by the fore-feet also, as in the dog, cat, &c.

The perpendicular position of the vertebral column under the centre of the basin cranium, and the direction of the eyes and mouth forwards, would be as inconvenient to man, if he went on all fours, as they are well adapted to his erect stature. In the former case he would not be able to look before him; and the great weight of the head, with the comparative weakness of the extensor muscles, and the want of ligamentum nuchae, would render the elevation of that organ almost impossible. See Cranium, under the head of "comparison of the human skull with that of animals," and Head.

Every part of the skeleton would lead to the same inference on this subject: but we forbear to enter into further detail, as being unnecessary. The reader will meet with some observations on this subject in the articles Extremities and Muscle.

The relation of the neighboring soft parts to the pelvis deserves our consideration. Its posterior surface gives origin to the glutis muscles, of which the exterior (glutis magni), exceeding in size all others in the body, and covered by a remarkable pratum of fat, form the buttocks, which, by their ample, bulky, and convex protuberances, conceal the anus, and are accounted, both by the classical authors in natural history, as Aristotle and Buffon, and by the greatest physiologists, as Galen and Haller, as the chief character by which man is distinguished from the buttock's limbus. "Les fesses," says the great historian of nature, "n'appartient qu'à l'espèce humaine." The final cause of this prerogative has been aligned by an anatomist: "Solus homo ex omnibus animalibus commode pedest, cui carnose et magnae nates contigere, et pro subtermuculo pulvinarique, tomento repetito, inferi, ut estra moletiliam fedendo, cognitiobus rerum divinarum animam recte applicare possit." Spigel de Hum. Corp. Fab. p. 9.

The use of the glutei, however, is not confined solely to what the pious Spigelus has imagined, eis. the forming a cushion on which the body may be softly supported for the purpose of dividing cogitation; but they serve in extending the pelvis on the thighs, and maintaining it in that state in the erect position of the trunk. (See Glutei.) Thus the muscles are particularly connected with the attitude of man; and hence the gluteus maximus, which is the largest muscle of the human body, is so small and insignificant in animals, that it may be almost said not to exist. F. Cuvier says of the orang-outang "les fesses estoient presque nulles, ainsi que les mollets." Annales du Museum, t. 16. p. 47.

Direction of the Vagina.—The peculiar curvature of the human vulva and os coccygis gives rise to the particular direction of the organs of generation, and especially of the vagina. That canal, which in the other female mammals nearly follows the axis of the pelvis, is placed almost at right angles to that axis in the woman; hence parturition is more difficult; but many inconveniences, to which she would have been otherwise exposed, particularly during pregnancy, are obviated.

From this direction of the vagina we explain why the human female is not, like that of brutes, rectum ingenti; and there is this further difference, that the orifice of the uterus in brutes, instead of being placed as in woman, within in the labia pudendi, opens into the vagina itself: such at least is the case, according to Blumenbach, in the papio species, and simiae eumolopigus.

The same circumstances concerning the direction of the vagina will enable us to determine the question agitated from the time of Lucretius, about the most natural posture for the act of copulation, and &c. The vagina, as it were, would be the organ log thence to be the object of the female, in such a way that the male might, without any exertion, hold the vagina, and incline the body through the same. This is the case, according to Blumenbach, in the Papio species, and simiae eumolopigus.

The same circumstanee concerning the direction of the vagina will enable us to determine the question agitated from the time of Lucretius, about the most natural posture for the act of copulation, and &c. The vagina, as it were, would be the organ log thence to be the object of the female, in such a way that the male might, without any exertion, hold the vagina, and incline the body through the same. This is the case, according to Blumenbach, in the Papio species, and simiae eumolopigus.

The same circumstances concerning the direction of the vagina will enable us to determine the question agitated from the time of Lucretius, about the most natural posture for the act of copulation, and &c. The vagina, as it were, would be the organ log thence to be the object of the female, in such a way that the male might, without any exertion, hold the vagina, and incline the body through the same. This is the case, according to Blumenbach, in the Papio species, and simiae eumolopigus.
the female frame, and one for which no rational use has been hitherto assigned. See Generation.

The nymphæ and ciliæ, which have been supposed, like the hymen, to be peculiar to the human subject, are certainly found in many animals.

Man is a two-handed Animal.—From the erect attitude of man arises another very distinguishing prerogative; viz. the molt free use of his two very perfect hands. So greatly does he excel other animals in the conformation of these parts, that Anaxagoras was hence induced to make an observation, which Helvetius has again brought forwards in our time, "that man is the wife of animals, because he pol- letter hands." This indeed is too much, yet Aritotle is well justified in observing that man alone poliuss hands really deserving that name. Several genera of the mammalia pol- lute hands; but they are much less complete, and con- cequently less useful than that of the human subject, which well deserves the name given to it by the Stagyrites, of the organ of all organs. The great superiority of that molt perfect instrument, the human hand, arises from the size and strength of the thumb, which can be brought into a flake of opposition to the fingers, and is hence of the greatest use in enabling us to grasp spherical bodies, and take up any object in the hand, in giving a firm hold on whatever we seize, in executing all the mechanical processes of the arts, in short, in a thousand offices, which occur every moment of our lives, and which either could not be accom- plished at all, if the thumb were absent, or would require the concurrence of both hands, instead of being done by one only. All the improve fields hands; but the molt distin- guishing part, namely the thumb, is slenher, short, and weak, even in the molt anthropo-morphous; regarded as an imitation of the human structure, it would almost warrant the term employed by Euthachus, ridiculous: and the other fingers are elongated and slenher. The thumb reached to the first articulation of the index in the ourang-outang described by F. Olivier, Annales du Museum. t. 15. p. 178.

Monkeys are be-headed. —The monkeys, ape, and other anthropo-morphous animals can, in fact, he called neither bipeds nor quadrupeds; but they are quadrumanous, or four- handed. Their posterior limbs are furnished with a thumb, instead of a great toe; which latter part belongs only to man, and arises from the manner in which his body is sup- ported in the erect position.

By a thumb we mean a member, not placed in a parallel direction to the other fingers, but slanding off from them laterally, enjoying a free power of separative motion, and, therefore, capable of being brought into opposition to the other fingers, so as to give to the member the power of grasping or prehension. A great toe, in its direction, articulations, and extent of motion, corresponds entirely to the other toes; whereas, the joints and muscles must be altogether different in the thumb. It is hardly necessary to point out how entirely unfit the human feet are for all purposes of prehension; but the hind limbs of the human really deserve the name of hands more than the front; and are more advantageously contructed for holding. There is, too, a kind of monkey (simia panipus, Linn. Costa, Buff.) without any thumb to the fore limb; but no species has been discovered without the thumbs on the hind limbs.

Hence the dispute concerning the mode of progression of the ourang-outang and other simæ; viz. whether they go on all fours, or are supported by the posterior limbs only, will be easily settled. Neither of these representations is correct. Since the hands of these animals are not formed for walking, but for seizing and holding objects, it is clear that nature has designed them to live chiefly in trees. They climb thence, and seek their food in them; and one pair of hands is employed in fixing and supporting the body, while the other gathers their food, or serves for other offices. Hence some, who have left perfect hands, are furnished with prehensile tails, by which they can be more securely sup- ported in trees.

It is hardly necessary to add, that when we fee monkeys walking erect, it is to be ascribed to instruction and discipline. The delineations of the ourang-outang, taken accurately from the life, shew how inconvenient and unnatural the erect posture is to these animals; they are drawn with the front hand hanging on a chock, while the posterior ones are gathered up into the appearance of a ball. No imitation has ever been produced of a monkey, nor of any other animal, except man, who could preserve his body in a state of equilibrium, when standing on one foot only. All these considerations render it very clear, that the erect stature not only arises out of the structure and conformation of the human body, but also that it is peculiar to man: and that the differences in the form and arrangements of parts, de- rived from this source only, are abundantly sufficient to distinguish man by a wide interval from other animals.

Monkeys not contrived for the erect Attitude. —The circum- stances in the structure of the monkey kind, which render them unfitted for the erect attitude, have been already in part explained; viz. the narrowness of the pelvis, short and weak lower limbs, small size of the muscles composing the buttocks and calves, and flight prominence of the os calcis, which does not come to the ground. We may add, that the exterior margin of the foot chiefly rests on the ground in the simæ, which circumstance, while it leaves them a freer use of their thumb and long toes in seizing the branches of trees, &c. renders the organ so much the less adapted to support the body on level ground. The plantaris muscle, instead of terminating in the os calcis, expands into the plantar fascia, in animals of the monkey kind; and in other quadrupeds it holds the place of the flexor perforatus digi- torum pedis, passing over the os calcis in such a direction, that its tendon would be compresed, and its action impeded if the heel rested on the ground.

It is rather singular, since perfons have been found to con- tend that man ought to go on all-fours, that there should have been others, who undertake to prove, that the ourang- outang, and the monkey tribe in general, have an organiza- tion suited to biped progression. Buffon even states, that one which he saw always went on two feet, and he ascribes the erect attitude to him without any hesitation. We do not doubt that he can fullan this posture for some time, and when in the unnatural condition of confinement, he may fre- quently fit: hence, perhaps, we may account for the nu- merous observations in which he is said to go erect. But the circumstances of structure already explained, shew most clearly that he is not calculated, like man, for that attitude; and we find, in some of the most authentic accounts, that he is said to go on all-fours. Altmann, who saw one (simia satyrus) in Holland, gives us the following account of its motions and attitudes. "Its usual attitude was fit- ting, with its thighs and knees raised; it walked nearly in the same posture, its rump being very near the ground. It never saw it perfectly upright, except when it wished to reach something; and even then its knees were always a little on the bend, and it tottered." (Buffon, by Wood, vol. x. p. 79.) Vosmaer, who has described the same individual, says, "This animal generally walked on all-fours, like the other monkeys, but it could, likewise, walk erect on its hind feet, and, provided with a thick, it would often sup-
port itself for a considerable time. However, it never re fled its feet flat on the ground, as a man would do, but bent backwards in such a manner, that it supported itself on the external edge of its hind feet, with the toes drawn inwards, which denotes a polture for climbing trees." (Ibid. p. 84.) The testimony of Camper, concerning one which lived for some time at the menagerie of the fladholder at Petit Loo, is to the same effect: "L'orang vivant courroit a quatre pattes, et lorfqu'il fe tennit debout (ce qu'il lit le plus, dans les premiers tems de fon arrivé) et lorfqu'il jouiflait encore de toute la vigueur) il tennoit les genoux ployés." (Œuvres, tom. i. p. 60.) The bent knees, and general attitude of the figure represented by Tyfon, shew clearly that the animal was not designed for a biped: "Being weak," says the author, "the better to support him, I have given him a stick in his right hand." (P. 16.) Several pages fhave that this animal often went on all-fours, and thus concur with the representation given in the report of the directors of the Sierra Leone company, p. 164: in describing a young one, they say, "at first he crawled on all-fours, always walking on the outside of his hands; but when grown larger, he endeavoured to go erect, supporting himself by a stick, which he carried in his hand." The description of the individual observed by F. Cuvier, corroborates these observations: he climbed excellently, but walked as imperfectly. In the latter operation, he re fled hisclothed hands on the ground, and dragged forward his hind parts. If one hand was held, he could walk on his feet; but then he supported himself partly by resting the other hand on the ground. The outer edge of the foot alone touched the ground, and the toes were bent. Annales du Mueum, vol. xvi. p. 40.

That the gibbon (fimia longimana), another of the anthropo-morphous Simiae, is not futed for the erect attitude, appears from the testimony of Dauben ton. It could carry itself almost erect on its feet, but the legs and thighs were rather bent, and sometimes the hand touched the ground to support the reeling body; it was unsteady whenever it flopped while in an upright posture; it re led on the heel only, and raised the sole of the foot; it remained but a short time in this attitude, which appeared unnatural. (Bullon, by Wood, vol. x. p. 80.) We muft, therefore, set down as incorrect the following affertion of Linneus: "Dar filias creto corpore binis ac homo pedibus incedente, et pedum et manuum mimifurto humano referentes fpecis." The relative fize of the cranium and face, the nearly vertical direction of a line drawn in front of the forehead and face, and the position and direction of the great occipital foramen and condyles, are points in which man differs from all animals. See Cranium.

Teeth. — The teeth of man are diftinguished by the circumstance of their being arranged in an uniform, unbroken feries: there are intervals, and some teeth project beyond the others in all animals. The canine teeth are longer than the others in mon fies; in some genera very considerably so; and there are intervals in each jaw to receive the teeth of the other. The lower incisors are placed perpendicularly, which is a principal characteristic of the human frame: the cutidilats neither project beyond the neighbouring teeth, nor are separated from them by any interval. The molares are clearly differentiated by their obfolute prominences from thofe of all the Simiae. The lower jaw is remarkable for three circumstances; viz its frontness, the prominence of the chin, which corresponds to the perpendicularity of the in- cisor teeth, and the form, direction, and articulation of the condyles. The lower incisors of man and the front of his jaw are placed in the fame vertical line; in animals the former plant very considerably backwards, the jaw slopes backwards directly from the alveoli, and there is consequently no chin.

Smoothness of the Skin.—Paffing over fome circumstances of its confection, ordinarily enumerated among the dif- tinctive characters of man, as the lobules of the ear, the tymid lips, particularly the inferior one, &c. we have a few remarks to make on the smoothnefs of the human integuments. "Dantus," says Linneus, "alabici terrarum timor minus quam homo pilosius:" but he does not tell us in what part of the world they are to be found. The unanimous reports of all travellers, as well as the fpecimens of fuch animals exhibited in Europe, prove incontestibly that the man-like fimir, called orang-ouangans, whether the fpecies from Angola, or that from Borneo, as well as the long-armed monkey or gibbon, are naturally much more hairy than the human fubject. Although the individuals brought into these countries have been under the adult age, and generally very fickly, their body has been in all cafes univer- fally hairy. We have, indeed, fome accounts of people, particularly in the islands of the South fea, remarkable for their hairiness: but they are not completely fatisfactory. Spanberg relates, that he found fuch a race in one of the Southern Kurile islands (lat. 43° 50'), on his return from Japan to Kamtchatka. (Mühler Sammlung Ruffiicher Gcichtete, tom. iii. p. 174.) And J. R. Forster observed individual fpecies in the islands of Tana, Mallicolo, and New Caledonia. (Obfervations on a Voyage round the World.) Such a race is faid to be found in the interior of Sumatra. Martden, History of Sumatra, p. 35, note.

While man is remarkable for the smoothnefs of his skin on the whole, some parts of his body are even moie hairy than they are in animals, as, for example, the pubes and axilla, which the ancients confequently regarded as peculiar characters of man.

Comparative Proportions of the Body in Man and the Orang-ouangans.—To this divifion we fhall subjoin a short fatement of the comparative fize of parts in the human fubject and in the orang-ouangans: it is an important point in illustrating the fpecific differences of the two animals, and cannot be fo conveniently introduced in any other part.

The difference of fature is remarkable: none of thofe lither to brought into Europe has been more than three feet high, and moll have been under that fize. Of eight feen by Camper, none exceeded 2½ feet. (Rhyland meafure): (Œuvres, vol. i. p. 51.) From obferving the flate of the teeth, and progress of offification, and effimating, according to the human fubject, the additions which the fature might be expected to receive, he thinks that their adult height may be fett down at 4 feet (Rhyland meafure); and F. Cuvier makes it confiderably lefs. (Annales du Mueum, vol. xvi. p. 51.) Yet travellers speak of them as 5 and 6 feet high, and even more: what they fay of their erect gait, of their violating women, &c. &c. is probably of equal accuracy.

Tyfon's chimpanfe (fimia troglodytes) was 26 inches from the top of the head to the heel: the arm, from the fhoulder to the end of the fingers, 17 inches; the hand, 5½ inches: the middle finger 2¾ inches. From the head of the thigh-bone to the heel, 12 inches; from the heel to the end of the middle toe, which was the longest, 52 inches. femur, 7: Tyfon's Anatomy of a Pigmy, p. 15.

In the true orang-ouang (S. fatyus), according to Camper, the whole length was lefs than 32 inches: the arm, 5½: the fore-arm, 9: the hand, 7: the fingers, 3: the femur, 7: the tibias, 7: the foot, 7½: the toes, 2½.

In the orang-ouang defcribed by F. Cuvier, the height
MAN.

was between 26 and 30 inches: the arm, from the axilla to the end of the fingers, measured 18; and the lower extremity, from the top of the thigh to the tarsus, 8 or 9.

The important differences will be perceived by comparing these measures with the proportions of the human frame, as given in a former part of this article: we shall, in parallel lines, two or three of the most striking.

Length of the whole body - 8 heads. 6 heads.
Length, from the end of one middle finger to that of other, when the arms are extended - 8 - 8
Length of the hand - 4 - 4
Length of the foot - 5½ - 5½

In the following table we have placed together the dimensions of some parts of a male skeleton, of the sine fatuus (orang-outang, Camper); and of the sine troglodytes, (chimpanzee, Tyfon.)

* This length seems excessive: Camper's measures are, arm 8½, fore-arm 9, hand 7. In another, rather smaller individual, the same parts measured respectively, 6½, 6, and 5½ inches. Cœuvres, vol. i. p. 49.

The comparative lengths of the upper arm and fore-arm, exhibit also a striking difference in man and the monkey kind. In a male skeleton measuring 5 feet 8 inches, the os humerum was 13, and the ulna 9½; in a living man of 5 feet 9½ inches, these bones were respectively 14 and 11. In Tyfon's chimpanzee of 26 inches, the humerus was little more than 5, the ulna 5, and the radius 5½: in a monkey of 2 feet 2 inches, the humerus was 4½, the ulna 5, and the radius 5½.

Other Differences.—We may observe further, with respect to the comparison of man and the orang-outangs, that one species of the latter (sine fatuus) has no nail on the thumb of the hind hand; and the other (troglodytes), according to Tyfon, has 13 ribs. Both of them have a fornix composed of three pieces only, instead of five, as in the human subject; and one at least (fatuus) has a large membranous pouch communicating with the larynx. The orang-outang has no ligamentum teres (Camper, l. c. p. 112.); it has a membranous canal running along the spermatic chord from the abdomen to the tunica vaginalis, as other monkeys and quadrupeds have (ibid. p. 109.); but this does not exist in the chimpanzee. (Tyfon, p. 82.) We venture to assert that these differences, even without any others, would be sufficient to establish the distinction of species; that no example can be adduced of animal structure deviating from its original model in this way; and consequently that the difference can be accounted for only by referring the animals to species originally distinct.

II. Dissections of Internal Structure.

1. Parts that man alone, or with a few other mammals, does not possess. Most of these, which are found chiefly in the domesticated kinds, were formerly attributed to man, when human dissections were rare, from the want of opportunity, or greater attachment to zootomy.

The Paniceus carnosus, or subcutaneous flratum of fibres, described by Galen and his followers, even by Vesalius, the great restorer of anatomy, and exposcer of Galen's errors, as a part of the human body, does not exist in man, nor, according to Tyfon, in the chimpanzee. It is found in the monkeys.

The rate mirabile of the head, the seventh or supenorius muscle of the eye, the membrana allantois, and ligamentum nuchae, are parts not found in the human subject.

1. The foramen incisivum is common to man with animals; but it is small and single: most other mammals have it double and large.

On the subject of the intermaxillary bone, see the comparison of the human head with that of animals, in the article Cranium; and the article Mammalia, in Comparative Anatomy.

2. Differences between Man and Animals, in certain internal parts: the Brain.—Paffing over in silence some less important parts, as, for instance, that the human crystalline is proportionally smaller than that of any animals, excepting the cetacea, and left convex in the adult, that the foramen occipitale is placed further forwards in the head (see Cranium), &c. we find in the brain a very striking difference between man and other animals. He has the largest brain, not, according to the opinion which has been generally received since the time of Ariftotle, in proportion to the rest of the body, but to the fize of the nerves, which proceed from it. Hence, if we divide the nervous system into two parts, one consisting of the nerves, and that part of the brain, from which they arise, which is to be considered as appropriate to the functions of a merely animal life; the other, comprehending the remainder of the brain, and connecting the functions of the nerves with the faculties of the mind, man will possess the greatest proportion of the latter more important part. See Soemmerring, Diff. de l'Esprit, etc., pp. 17. I. G. Ehel: Of: Neurologicae ex Anatome comparatae, 1788. Soemmerring von der kérperlichen Verschiedenheit des Mohren vom Europäer, 1795.

From the latter work of Soemmerring, to whom we owe the discovery of this very interesting circumstance, we extract his own account of the matter. "The careful and accurate comparison of the brains of animals of various orders, for which my opportunities have been very considerable, conducted me at last to the following position, first discovered by myself: that man possesses with the largest brain the smallest nerves; or, that the assertion that man has the largest brain will hold good only in comparing that organ to its nerves. That acute physiologist Monro seems to be the first who adopted and confirmed this opinion. (On the Nerv. Sytem, Edinb. fol. chap. 8.) It was formerly conceived, indeed, that man has the largest brain; but how was this proved by weighing the brain and the body in man, and in the most common domestic animals? The present observation confirmed it. But these physiologists who carried their investigations further, were more perplexed at finding that birds exceed man in the proportion which their brain bears to the rest of the body, and that the dolphin, seals, and the smaller mammals, as the moun, squirrel, &c. have, in proportion to their small bodies, (but certainly
certainly not in proportion to their head and organs of sense, or to that part which the face forms, compared with the cranium) a very large brain.

"It is a very loose mode of proceeding to compare the body of which the weight varies considerably according to fatness, illness, emaciation, or embolism, with the brain, which is affected by none of these circumstances, and seems to remain constantly the same; an easier and much less deceptive comparison is that of the brain to its own nerves.

"I do not conceive that the nerves are related to this organ, as exertory ducts are to a gland; but I think it probable that a very small proportion of its mass is sufficient for their connection; so far as more animal existence is concerned. Consequently, the being which possesthe greatest quantity of brain over and above this portion, will probably posses the greatest intellectual capacity. Man, who holds only a middle rank in respect to his bodily properties, is raised in this point of view far above other animals; he is the first of beings. All the finie (for I have been fortunate enough to procure specimens of the four principal divisions) came after him; for, although the proportion of their brain to the body, particularly in the small species with prehensile tails, is equal to that of man, their very large eyes, ears, tongue, and jaws, require a much larger mass of brain than the corresponding parts in the human subject; and if you remove the head, be that the ratio of the brain to the body is much diminished.

"Animals of various kinds seem to me to possest a larger or smaller quantity of this superabundant portion of brain, according to the degree of their sagacity and docility.

"The largest brain of a horse, which I possest, weighs one pound seven ounces; the smallest human brain that I have met with in an adult, two pounds five ounces and a quarter. But the nerves on the basis of the horse's brain are ten times larger than in the other instance, although it weighs less by fourteen ounces and a quarter.

"But we are not hasty to conclude that the human species have smaller nerves than any other animal. In order that my ideas may be better understood, I shall state the following imaginary case. Suppose the hall of the eye to require 600 nervous fibrils in one infiance, and 300 in another, though only half the fize of the former; further, that the animal ver's 600 fibrils possest a brain of seven and a half, with 300 a brain of only five drums; to the latter we ought to afcribe the larger brain, and a more ample capacity of rendering the impressions made on the organ of vision; for, allowing one drum of encephalon to 150 fibrils, the brain which is absolutely the least will have a superabundant quantity of two drums, while the larger has only one. That the eye, which is supplied with a double quantity of fibrils, may be a more complete organ of sense, will be readily admitted; but the remark is inapplicable to the subject in dispute."

P. 59-67.

The brain of the monkey is easily distinguished from that of man, independently of its size and weight; Soemmerring found no less than fifteen visible material anatomical differences between the human brain and that of the common ape. Ibid. p. 77.

Soemmerring has also shown that the earthy matter of the pineal gland does not exist in any animal besides man. He found it once in the brain of a deer, and Caldaen informed Bluemberch that it did not exist in an old man, whom he dissected. De Gen. Hum. Variae. p. 44.

"The situation of the heart, which rests not on the sternum, as in quadrupeds, but, according to the erect attitude of man, on the diaphragm, is peculiar. Its bails does not look towards the head, as in the former, but towards the dorsal vertebra; while the apex is turned to the left breast. There are very few mammalia, besides man, which have the pericardium fixed to the diaphragm.

The appendix vermiformis ceci belongs to the chimpanzee and orang-outang, the gibbon according to Daubenton, the phaseoloum of New Holland, and man.

In addition to what we have said about female organs, the parenchyma of the uterus is unlike that of any animal; the texture of the placenta, the length of the chord, and the single umbilical are peculiar to man. The umbilical cords, found in all human conceptions before the fourth month, has been observed in no other animal.

3. Functions of the animal Economy. Gravity of the human Frame.—The most important prerogaive under this head, according to Bluemberch, is the loss of the plancky (tenenritudo et obsequio multitidini) of the cellular substance. Zinn observed that this tisue is more fine and tender in man than in any animal. To this circumstance Bluemberch ascribes the singular power of adaptation to every climate on the globe. "Utergo natura hominem respectu cuneorum fecit; ia respecto habitations eum omnis foli et clima constitu; ideaque homo in multis obsequio contextu mucro fabricatum est, ut eo facilius ad multiterias diverfiforum climatum impressio fe aptare et ac commodiore pollut."

If we adopt this view, it will afford an answer to a question stated in the outset, whether the existence of men in such various climates can be ascribed to physical constitution or reason? In what way do the Greenlander, the Eskiman, and the Canadian employ remarkable talents or invention to protect themselves against the cold? They brave the winter with open breast and uncovered limbs, and devour their whales and feeds droll, raw, or putrid. The negro is healthy and strong under a vertical sun, with the folks of his feet bare on the burning sands. The fox, the beaver, the marmot, and the hammer, dig dwellings for themselves, where then is the prerogative of man? The mind indeed employs the excellent structure of the body, lifts man above the veil of the creation, accommodates him to all places, gives him iron, fire, and arms, furs, and sereens from the fun, &c.; but with all this he could never make him what he now is. The climate, if he did not possest the most enduring and flexible body. The lower animals have no defence aginst the evils of a new climate, but the force of nature. The arts of human ingenuity furnish a defence to man against the dangers that surround him in every region. Accordingly we see the same nation pass into every climate of the earth; reside whole winters at the pole; plant colonies beneath the equator; pursue their commerce, and establish their factories in Africa, Asia, and America. They can equally live under a burning and a frozen sky, and inhabit regions, where the hardiest animals cannot exist. Such great changes indeed ought not to be hazarded suddenly, and without precaution. The greatest evils that have arisen from change of climate, have been occasioned by the preoccupation of health that refutes to the necessary precautions, or the neglect of ignorance that knows not what precautions to use. But when changes are gradually and prudently effected, habit from accommodates the constitution to a new situation, and human ingenuity discovers the means of guarding against the dangers of every fregion, and of every climate. The superiority of man appears more striking, when we compare him to the animals which most resemble him in form and properties. The most anthropo-morphous fenne inhabit only a few small southern districts and islands of the old world; are subject to numerous diseases, lose all their vivacity, strength, and natural character, and perish after lingering
lingering in a miserable way, when removed from their native abodes. An orang-outang brought to Paris, never recovered the exposure to cold in crossing the Pyrenees, and died at the age of fifteen months, with most of the viceria "déformée et remplis d’obliquités." (Annales du Muséum, t. xvi. p. 53.) The monkeys in general are confined within very narrow limits; they exist with difficulty in temperate countries, and can propagate only in warm climates. One which was impregnated in this country, and attended with all possible care, brought forth a young one, which died immediately. (Hunter on the Animal Economy, p. 137.) Probably the species could not be continued here, with all the aid of art; and it certainly could not be effected, if the animals were wild. When they are introduced into the north (indeed into the greater part) of Europe, and very carefully managed in their food, temperature, &c., they die very quickly, and, in almost all cases of diversified viceria, particularly the hogs.

Slow Development.—Other circumstances in the economy correspond with this power of adaptation; such are, the flow growth, long infancy, and late puberty of man. In no animal but man do the futures of the cranium close, or the teeth come out at so late a period; none is so long before it can support the body on the legs, before it arrives at the complete adult stature, and capacity for exercising the sexual functions. If we add to these circumstances, that man is not provided with nature with means of defence, and, consequently, requires affluence; and that his great distinctions, reason, and speech, are only germis, which are not developed of themselves, but are brought to maturity by extraneous affluence, cultivation, and education, we shall infer that he is designed, by nature, for social union. Such a condition appears more consonant to the structure, properties, and functions of our frame, even if it were not supported by the concurrent voice of actual experience in all ages and nations, than the imaginary and most absurdly named "state of nature," of some philosophers. Roufeau, the great apostle of this doctrine, informs us, in direct words, that the state of nature never has existed; and he sets aside all facts as foreign to the question. With these admonitions before us, we are required to believe that we have degenerated from our natural state; that speech, society, arts, inventions, sciences, agriculture, commerce, property, civil government, and inequality of conditions, have introduced all possible misery, and have debilitated our physical being; that we should live in the woods scattered and solitary to get food enough, protect life by flight and force, satisfy our desires and sleep. Buffon has reasoned so well on this subject, that we employ his words. "In this condition of nature, the first education requires an equal time as in the civilized state; for, in both, the infant is equally feeble, and equally slow in its growth; and, consequently, demands the care of its parents during an equal period. In a word, if abandoned before the age of three years, it would infallibly perish. Now, this necessary and long-continued intercourse between mother and child is sufficient to communicate to it all that the possesseis and through it should receive from nature that a mother, in a state of nature, possessis nothing, not even the faculty of speech; would not this long intercourse with her infant produce a language? Hence a state of pure nature, in which man is supposed neither to think nor speak, is imaginary, and never had an existence. This necessity of a long intercourse between parents and children produces society in the midst of a desert. The family understand each other both by signs and sounds; and thus first ray of intelligence; when cherished, cultivated, and communicated, unfolds, in process of time, all the germis of cognition. As this habitual intercourse could not habitually so long, without producing mutual signs and sounds, these, always repeated and gradually engraven on the memory of the child, would become permanent expressions. The catalogue of words, though short, forms a language, which will join extend as the family augments, and will always follow, in its improvement, the progress of society. As soon as society begins to form, the education of the infant is no longer individual, since the parents communicate to it, not only what they derive from nature, but likewise what they have received from their progenitors, and from the society to which they belong. It is no longer a communication between detached individuals, which, as in the animals, would be limited to the transmission of simple faculties, but are inclusions of which the whole species participates, and whose produce constitutes the laws and bond of society." Buffon, by Wood, vol. x. p. 30.

Some other Characters.—No other of the classes mammalia enjoys so long a life as man in proportion to his size; the duration of life is in proportion to the time spent in arriving at the full growth, there is every reason to suppose that the monkies will fall very far short of man in this respect: in this climate they are cut off so quickly, that we cannot form a judgment.

The celebration of the rites of Venus is not confined to any particular season of the year; although the author of a work "de Amore," dedicated to Joanna of Arragon, fo highly celebrated for her personal charms, enquires why "silata puella finit libidinosiores & amantiores; virt autem contra hymen." Nocturnal discharges of the femial fluid are peculiar to man. See Generation, in the phylogeny of the male organs.

Menstr.—The menstrual discharges are peculiar to women, and belong to the whole sex in all countries: so that Pliny is right in regarding woman as the only "animal menstruae." "I know indeed," says Blumenbach, "that the same discharge has been ascribed to other animals, particularly of the order quadrupedae. I have carefully enquired about all the female monkies, which I have seen for these twenty years, either in menageries or carried about for public exhibition, and have found some of them liable to uterine hemorrhage, which observed no period, and was regarded by the more intelligent keepers as a circumstance arising from disease, although they acknowledged, that in order to excite the admiration of the speculators, they often represented it as true menstruation" De Gen. Hum. Var. note. p. 51.

4. Faculties of the Mind: Reason.—All philosophers refer with one accord to the enjoyment of reason, as the chief and most important prerogative of the human species. If we enquire, however, more particularly into the meaning of this word, we shall be surprized to find what various fancies different individuals affix to the same expression, or, as Blumenbach observes, "quaime longe daturismas de rationis notabile reddunt rationes philofophi maxime rationales." According to some, reason is a peculiar faculty of the mind, belonging exclusively to man: others consider it as a more enlarged and complete knowledge of a power, which exists, in a less degree, in other animals: some deride it as a combination of all the higher faculties of the mind; while others assert that it is only a peculiar direction of the powers of the human mind, &c. "Non solum inter hos tantas composere lites." The subject may perhaps be more shortly and safely dispatched by considering it a pollentiori. In the enumeration of natural existences we are obliged to rank man in the class of
class of animals: but the analogies on which we do this are external, and authorize us not to pronounce that the nature of man is similar to that of the brute. In order to acquire a distinct idea concerning the nature of each, it is necessary that we should have as complete a knowledge of the internal qualities of animals, as we have of our own. But, as it is impossible to know what passes within them, or how to rank and estimate their sensations, in relation to those of man, we can only judge by comparing the effects which result from the natural operations of both.

Let us, therefore, consider the faculties; and, while we acknowledge the species of the mss of general distinctions. The mss stupid man is able to manage the most alert and sagacious animal: he governs it, and makes it subservient to his purposes. This he effects not so much by strength or address, as by the superiority of his nature. He compels the animal to obey him, by his being possessed of reason, which enables him to project and to act in a systematic manner. Quiqvis es, iniquus aminator fortis humanae, cogita quanta nobis tribuerit parens nolter, quanto valerientors animalia sub jugum mifererrimus, quanto velociora alqueamur, quam nihil fit mortale non sub eto nolore potitum. Seneca. The sagacious and mss sagacious animals have not the capacity of commanding the inferior tribes, or of reducing them to a state of servitude. The stronger, indeed, devour the weaker: but this action implies an urgent necessity only, and a voracious appetite, qualities very different from that which produces a train of actions all directed to one common design. If animals be endued with this faculty, why do not some of them assume the reins of government over others, and force them to furnish their food, to watch over them, and to relieve the sick or wounded? But, among animals there is no mark of subordination, nor the least trace of any of them being able to recognize or feel a superiority in his nature above that of other species. We should therefore conclude, that all animals are of the same nature, and that the nature of man is not only far superior, but likewise of a very different kind from that of the brute.

Man uses all kinds of food, and inhabits every climate of the globe. The unlimited power, which he possesses in these respects, gives rise to various wants, from the infinite variety of climate, soil, and other circumstances.

Pater ipse colendi
Haud facilem esse viam voluit, primusque per artem
Movit agros, curis aequos mortalia corda.

Man exhibits, by external signs, what passes within him: he communicates his sentiments by words; and this sign is universal. The savage and the civilized man have the same powers of utterance; both speak naturally, and are equally understood. It is not owing, as some have imagined, to any defect in their organs, that animals are denied the faculty of speech. The tongue of a monkey is as perfect as that of a man: Camper asserts that the laryngeal pouch renders it impossible for the orang-outang to speak; we do not understand how this is ascertained; but, allowing its truth, there are other monkeys who have no pouches, and yet cannot speak.

There are infinite subtleties both in the ancient and modern scholastics concerning the speech of brutes. We cite, as an example, Albertus, signified the great, who allows to a monkey the privilege of speech, but with a memorable restriction: "Pygmaeus loquitur quidem, cum tamen fit irrationali animal, verum non difputat; nec loquitur de universalibus rerum, sed potius fus voces diriguntur ad res particulares de quibus loquitur."

Several animals may be taught to pronounce words, and even to repeat sentences; which proves clearly that the want of speech is not owing to any defect in their organs; but to make them conceive the ideas which these words express, is beyond the power of art. They articulate and repeat like an echo or machine.

Language implies a train of thinking; and for this reason brute animals are incapable of speech. For though we should allow them to possess something similar to our first apprehensions, and to our most grofs and mechanical sensations, it is certain that they are unable to form that association of ideas in which alone the efficacy of thought consists. They can neither think nor speak, because they can neither join nor separate ideas; and, for the same reason, they neither invent nor bring any thing to perfection.

With the operations of animals, who always perform the same work in the very same manner, the execution of any individual being neither better nor worse than that of any other, in whom the individual, at the end of some months, is what he will remain through life, and the species, after a thousand years, just what it was in the first year; contrast the results of human industry and invention, and the fruits of that perfection, which characterizes both the species and the individual; by the intelligence of man the animals have been fudued, tamed, and reduced to perpetual flavery. By his labours marines have been drained, rivers confined, their cataracts effaced, forests cleared, and the earth cultivated. By his reflection, time has been computed, space measured, the celestial motions recognized and represented, the heavens and the earth compared, and the Creator worshiply adored. By his art, which is an emanation of science, the seas have been traversed, and mountains overcome; nations have been united; a new world has been discovered; a thousand other detached lands have been reduced under his dominion; lastly, the whole face of the earth at present exhibits the works of his power, which, though subordinate to that of nature, often exceeds, at least, if wonderfully secords her operations, that, by the aid of his hands, her whole extent is unfolded, and she has gradually arrived at that point of perfection and magnificence in which we now behold her.

In the point of view which we have just considered, man stands alone; his reason, and what he has effected by it, place him at a wide interval from all animals; at an interval, which no animal hitherto known to us can fill up. The man-like monkey, the almost reasonable elephant, the docile dog, the sagacious beaver, the bee have no reason. In none
none of these infinences is there any progress either in the
individuals or the species. See the article INSTINCT.

Laughter and Weeping.—Whether these are peculiar to man
may admit of some doubt; they were not, like speech, in-
vented by him, but seem rather born with him, and are
more connected with the passions than with reason. Many
animals secrete tears; but the question is, do they weep
grief? The fact has been affected by some reprehensible
instances, as by Steller of the seal, and Pallas of the camel.
It is more doubtful whether they manifest tears by laughter,
though this has been affected. Le Cat says, that he saw
the chimpanzee both laugh and weep.

5. Diseases.—There are many diseases peculiar to man,
which may be thought a more fit subject for pathology
than natural history; but as these unnatural phenomena
arise out of the natural organization and habit of the body,
and dispositions of the animal economy, they undoubtedly
deferve a place in the discussion.

While the causes of disease in general are so obscure, it is
hazardous to fet down any particular affections as exclusively
belonging to man; they might affect other animals also, if
they were exposed to the same causes. Wild animals, we
believe, have no diseases; domesticated ones have several;
and they are more numerous in proportion as the subjugation
is more complete, and the way of life differs more widely
from the natural one. The diseases of our more
valuable domestic animals, are sufficiently numerous to em-
ploy a particular order of men; and the horse alone has a
fet of furies or physicians to his own share. The misera-
able canary birds seem to be equally in want of profecional
affinities: among the disorders to which they are exposed,
Buffon enumerates inflammation of the bowels, asthma,
epilepsy, abscess, thakers on the bill, and febras. (Vol. xiv.
p. 87.) In man, the most artificial of all animals, the moat
exposed to all the circumstances that can act unfavour-
ably on his frame, diseases are the most numerous, and so
abundant and diversified, as to exercise the ingenuity of
the nofologist, and fatigue the memory of the phy-
sician. Perhaps nofological catalogues afford the most
convincing proof, that man has departed from his natu-
ral habits, or has deserted that way of life to which
nature had designed him; unless, indeed, it should be
contended that these afflictions are a part of his nature, a
distinction from animals of which he will not be very likely
to boast. This, however, we apprehend, will be too much
even for the sons of Galen to defend, and it would certainly
bring the theologians on their backs, as leading to inferences
not very favourable to the benevolence of the Deity.
The following sentiments of a most eloquent writer, and great
philosopher, deserve attention, although he was no phy-
sician.

"Have we any foul reason to suppose, that in coun-
tries where medicine is most neglected, the life of man is
to be entered than where this art is the most carefully culti-
vated? And how should it be so, if the evils we bring on ourselves
are more numerous than the remedies which medicine fur-
nishes. The extreme inequality in the mode of living, the
excessive labours which consume the bodies and break down
the strength of the poor, the still more dangerous softness,
which enfeebles the rich, destroying the one by their wants,
and the others by their excess; the cafe with which fen-
suality can be excited and gratified, the too luxurious food
of the rich, the monstrous mixtures, the pernicious fea-
dings which stimulate and overwhelm them with indigefion;
the bad and often insufficient nourishment of the poor; the
spoiled provisions, the apothecary's drugs; the knavery
of those who sell, the errors of those who administer them;
the want of red, the violent passions which agitate and ex-
halt us, the chagrins and vexations incidental to all con-
ditions; are so many fatal proofs that most of our ills are
our own work, and might have been avoided by adhering
to the simple, uniform, and solitary life preferred by nature.
If the deigned that we should be healthy, I would almost
affirm that reflection is a flate contrary to nature, and that
the man, who meditates, is already a depraved animal.
Consider the epidemic diseases engendered among multitudes
collected together, the disorders caused by the delicacy in
our mode of living, by palling from our heated rooms into
the open air, by increasing or lessening our clothing without
sufficient precaution, and all the cares converted by our ex-
cessive finenity into necessary habits, and the neglect or
privation of which then very frequently coasts us our life or
health; add to the account the fires and earthquakes, which
consume and overturn whole cities, and sweep off the inna-
britants by thousands; in short, bring together the dangers,
which all these causes constantly surfeit over our heads,
and you will feel how deeply nature makes us pay for
defying her lessons. When we reflect on the healthy con-
stitutions of savages, at least of those whom we have not
corrupted by our spirituous liquors, and remember that they
know no other ailments than wounds and old age, we are
led to suppose, that the history of disease would be easily
written by following that of civil societies."—D'Ingehih, p. 69, and note 8.

The history of the youngavage of Aveyron strikingly
illuminates several of the foregoing remarks. In his wild
state, he bore the cold of the winter without any
clothing, and could remain, when he was first taken, for
several hours together, in the winter, exposed half naked to
wind and rain on the wet turf. He refused high-priced dines
and strong liquors, even when very hungry, and ate at
first only potatoes, acorns, and raw cheftnuts. His civili-
zation went on so rapidly and successffully, that in a few
months he had had three severe colds, and fom after the
same affection to epileptic fits. An observation of Humboldt
trands to confirm the position, that the individuals, whole
bodies are strengthened by healthy habits in respect to food,
exercise, &c. are enabled to refist those caufes which pro-
cuce diseases in other men. Humboldt paints to us the
Indians of New Spain as a fet of peaceful cultivators, ac-
customad to uniform nourishment, of an almost entirely ve-
getable nature, that of their maize and cereals grains; they
are fubject to no deformity: he never saw a lunch-backad
Indian, and it is extremely rare to fee any who squat, or
are lame in the arm or leg. "In the countries where the
inhabitants fuffer from the goitre, this affection of the thy-
roid gland is never observed among the Indians, and seldom
among the Mefitios." (Political Essay on the Kingdom of
New Spain, book ii, ch. 6.) Similar obervations on the free-
dom from deformity occur in the descriptions of molt
savages.

This comparison of diseases is difficult, since the nofology
of brutes mult by its very nature be cultivated under the
molt feroius obstacles. The diseases in the following list,
derived from Blumenbach, may be considered, in all pro-
ability, as peculiar to man.

Nearly all the exanthemat, at leaft

Varieget*,
Morillis,
Scarlatina,
Mihtures,
Pettechie,
Pellis.

* A monkey at Amsterdam, contracted a local ulcer
from the contagion of small-pox, but had no fever.
Of the Hemorrhagies.

Epistaxis.
Hemorrhoids.
Menorrhagia.

Of nervous affections.

Hysteria.
Mental affections, properly so called, as melancholia, nothalmia, &c. probably also fatyriasis and psychomania.

Of the cachexias.

Rheuma.
Struma.
Luces Venerea.
Lepro and Elephantiasis.

Of the Locubs.

Amenorrhoea.
Cancer.
Clavus.
Hernia congenita.

The various kinds of prolapsus, particularly that congenital one of the urinary bladder.

Herpes.
Tinea capitis.

6. In the preceding remarks, we have adverted to some of the points, in which man has been erroneously supposed to differ from animals; a few only remain. The approximation of the two eyes is not peculiar; they are much nearer to each other in the feline.

Many other mammals, particularly among the quadrupeds, have eye-lashes in both eye-lids: this is the case in the cheetah.

The long-nosed monkey (fimia rostrata or nasalis) exceeds man in the length of the nose.

The external ears are not moveable in all men, nor movable in all other mammals, as in the anteaters for example.

Many quadrupeds have an organ of touch, and an uvula, as well as man.

Varieties of the human Species.—Our next point is the consideration of the varieties of the human species, and their causes.

The differences which exist between inhabitants of different regions of the globe, both in bodily conformation and in the faculties of the mind, are so striking, that they must have attracted the notice of civilized observers. There are two ways of explaining these; first, by referring the different races of men to different original families, according to which supposition they will form in the language of naturalists, different species; or we may suppose them all to have descended from one family, and account for the diversity, which is observable in them, by the influence of physical and moral causes; in which case they will only form different varieties of the same species.

This disquisition will perhaps appear superfluous to the devout believer, whose philosophy on this point will be derived from the writings composed with the assistance of divine inspiration, and therefore commanding our implicit assent. The account of the creation of the human race, and of its dispersion over the face of the globe, contained in the book of Genesis, will supercede in mind the necessity of having recourse to any argument on the subject. We shall venture to submit, that the Moslem account does not make it quite clear that the inhabitants of all the world descend from Adam and Eve; we are told indeed, that "Adam called his wife’s name Eve, because she was the mother of all living." But in the first chapter of Genesis we learn, that God created man, male and female; and this seems to have been previously to the formation of Eve, which did not take place until after the garden of Eden had been made. Again, we are informed in the fifth chapter of Genesis, that "in the day that God created man, in the likeness of God made he him; male and female created he them; and blessed them, and called their name Adam, in the day when they were created." We find also that Cain, after slaying his brother, was married, although it does not appear that Eve had produced any daughters before this time. "Cain went out from the presence of the Lord, and dwelt in the land of Nod, on the exit of Eden. And Cain knew his wife, and she conceived and bare Enoch." Indeed it is said (ch. 5, v. 4.), that "the days of Adam, after he had begotten Seth, were eight hundred years, and he begat sons and daughters." This it seems took place after the birth of Seth, and consequent, long after Cain had his wife; for Seth was not born till after the death of Abel. If Cain had fillers prior to that period, from amongst whom he might have taken a wife, it is singular, as some persons may allege, that Moses should not have noticed them. But we refer the solution of these difficulties to the biblical critic and commentator, in whose judgment they will not materially affect the general credibility of the Scripture history.

It appears, therefore, that the field is open for discussion on this subject; and at all events, if the defect of mankind from one flock can be proved independently of the holy writings, the conclusion will establish the authority of those inspired annals.

If we fail in tracing the succession of the human race from above downwards, much less are we able to trace back any particular tribe to their first origin from the present flock. To use the words of an elegant modern historian: 'neither the annals nor traditions of nations reach back to those remote ages, in which the different descendants of the first pair took possession of the different countries where they are now settled. We cannot trace the branches of this first family, nor point out with certainty, the time and manner in which they divided and spread over the face of the globe. Even among the most enlightened people, the period of authentic history is extremely short, and every thing prior to that period is fabulous and obscure.' In considering the present question, we must, therefore, be contented to proceed in the flow and humble, but sure method of observation; to ascertain carefully all the differences that actually exist between the various races of men; to compare these with the diversities observed among animals; and to draw our inferences concerning the causes from the analogies which these considerations may unfold. Above all things, we must enter our protest against arguments a priori on this subject. One philosopher tells us, that nature does nothing in vain; that the world would not give herself the trouble to create several different flocks, when one family would be sufficient to colonize the world in a short space of time. Another, with equal speculations, dilates on the absurdity of supposing, that immense regions should remain for ages an unoccupied and dreary waste, while the offspring of a single pair was slowly extending over the face of the earth; or that such an admirable variety of islands should display their charms in vain, till a shipwreck or some other casual occurrence may supply them with inhabitants. He pleads how much more consonant to the wisdom and benevolence of the Deity it would be, for the earth to have teemed, from the first moment of its production, with trees and fruits, and to have been occupied by all kinds of animals
We therefore, necessary in zoology and hold it to be important that we prevent our readers with our own words. 

"Hae quanquam ia est speciea videatur, omnia ut, si velut horum argumentorum munus infcerta sunt. Q1 qua magna loquax, et tamen igitur ex Discori concilia defcendent, neque ut humiles minusia, ut qui intem interpretes oporet, rarum lumine quantulosque ejus absdita illustrant. Illi quidem dixerunt quodam mundum constituto, sic hoc etiam curationi sufficit commodum; sed quas rationes re ipsa constitutis fuit, tabibus sui piciis, et latet, et fomer Latibit." P. 5.

What is Species?—Before we proceed to the chief object of this division of our article, it is necessary to consider what constitutes a species in zoology; and how varieties arise out of species. We should answer, in the abstract, to the first question; that all animals, which differ in such points only as might arise in the natural course of degeneration, belong to the same species; while those differences, which could not be accounted for on this supposition, would lead us to clas the animals, which exhibit them, in different species. But the chief difficulty, is to point out the characters, by which, in actual practice, we can distinguish mere varieties from genuine specific differences.

Of Breeding as a Criterion of Species.—In the sixteenth century, and consequently long before the time of Buffon, Ray referred to one and the same species those animals which copulated together, and produce a fertile offspring, ascribing the differences which may exist between them to adventitious causes. The high authority of the great French naturalist, who adopted the same opinion, has occasioned this criterion to be very generally relied on; Mr. Hunter, on the faith of it, included the dog, the wolf, and the jackal in one species, and excluded the fox. If we adopt this, our present question would be immediately solved; for all the races breed together, and their progeny is prolific, either with each other, or with any of the original races. Indeed we know no difference in productiveness between such unions and those of the same race.

We apprehend that this rule involves a pettico principle; has it been proved, that animals of different species never produce together a fertile offspring? On the contrary, there are instances, both among the mammalia and birds, of individuals belonging to species universally held to be distinct, uniting and producing young, which were prolific. That the mule can engender with the mare, and that the he-mule can conceive, was known to Aristotle. The circumstance is said to occur most frequently in warm countries, but it has happened in Scotland. (Buffon, vol. iv, p. 209. 265.) The offspring of the he-goat and ewe feem to possess perfect powers of reproduction. The cock and hen canary birds produce with the hen and cock finch and goldfinch (ibid. v. xiv, p. 65, et seq.) : the hen canary produces with the cock chaffinch, bullfinch, yellowhammer, and sparrow. The progeny in all these cafes is prolific, and breeds not only with both the species, from which they spring, but likewise with each other. (Ibid. p. 70.) It appears also that the common cock and the hen partridge, as well as the cock and the guinea-hen, can produce together. (Ibid. v. xxii. 61.) It is true, that all these unnatural unions take place in anima's under the power of man, and that they generally require an attention to several preliminary circumstances: it is also found that unions of different species may take place without fecundation, as of the bull and mare (Buffon, v. iv. p. 221.) : but they prove sufficiently, that this affair of generation will not afford the criterion we are in search of.

It was soon found that this rule of reproduction could not be applied to domesticated animals, on account of their unnatural way of life, and hence Frisch, towards the beginning of the last century, confined it entirely to the wild ones. And here it is of little service; for how can we expect ever to bring together those wild species, particularly where they inhabit distinct countries, as for instance the chim-pansie of Angola and the orang-outang of Borneo? Nor are there so many doubts about these, as about the domesticated animals, which are thus excluded.

The different breeds of dogs, for example, are referred by some to different species; others consider, that they have all descended from the shepherd's dog; others derive them from the juckal; and all the dogs with the latter animal, owe their origin, according to others, to the wolf.

Of other Marks.—Nor is the conformity of any particular character to be deemed a mark of difference in species. The white hair and red pupils of the white variety of the rabbit are as constant an specific characters; and we see breeds of animals, produced under our own eyes, discriminated by marks transmitted regularly to the offspring.

The Criterion of Analogy.—We must therefore resort at last to the criterion adopted by Buffon, and draw our notions of species in zoology from analogy and probability. (Dr. Gen. Hist. Variet. Nat. p. 76.) If we see two races of animals resembling each other in general, and differing only in certain respects, according to laws, which we have found to hold good in other instances, we refer them to the same species without hesitation. "I say" this mark acute and judicious naturalist, "a remarkable difference between the Asian and African elephants in the structure of the molar teeth. Whether these inhabitants of such distant regions will ever be brought to copulate together, and whether this formation be universal is uncertain; but it exists in all the species I have seen or heard of, and I know no example of molar teeth changed in such a manner by degeneration (or the action of adventitious causes): therefore, I conjecture from analogy, that these animals are not mere varieties but truly different species. On the other hand, I hold the ferret (mustela furo) to be only a variety of the pole-cat (m. putorius), nor to much because they produce together, but because it has red pupils, and the analogy of numerous other instances induces me to regard all the mammalia, which are definite of the colouring pigment of the eye, as varieties degenerated from their original stocks."

It is very clear that this analomical method is the only one that we can adopt for solving the quæfion concerning the varieties of the human species; we must explain the bodily diversities of man upon the same principle, as those of all other domestic animals; and if we find these causes adequate to the solution of the phenomena, it will be unnecessary to resort to the supposition of originally different species.

A very superficial consideration will shew, that there is no point of difference between the several races of mankind, which has not been found to arise, in at least an equal degree, among other animals as a mere variety, from the usual causes of degeneration. The influences of this kind are derived chiefly from domesticated animals, as they are exposed to all those causes which can produce such effects; by living with men they had an artificial and unnatural kind of life, and are taken with him into climates and reations, and exposed to various other circumstances altogether different from
from their original delineation; hence they run into numerous varieties of colour, form, size, &c. which, when they are established as permanent breeds, would be considered by a person uninform'd on these subjects, to be originally different species. Wild animals, on the contrary, remaining constantly in the state for which they were originally framed, retain permanently their first character. Man, the inhabitant of every climate and soil, partaking of every kind of food, and of every variety in mode of life, must be exposed still more than any animal to the causes of degeneration.

Differences of Colour.—The various colours of the skin form very conflant hereditary characters, most clearly influenced by that of both parents in the hybrid offspring of different varieties, having a close and nearly uniform relation to that of the hair and iris, and indeed to the whole temperament of the individual; and for all these reasons attracting most immediately the attention of a curious observer.

The feat of this colour is in a thin mucous stratum, interposed between the cuticle, or dead surface of the body, and the true skin, and called rete mucous or Malpighii. The native reddish white of the real skin appears through this, which is very thin and almost colourless, in the white races of mankind. But in the darker varieties the rete mucous is much thicker, and contains throughout its substance a black pigment; while the cuticle and cutis deviate but little from the colour which they have in fair persons.

See Integuments.

The various varieties of mankind exhibit every possible shade between the snowy whitefenes of the Albino or of the most delicate European female and the jet black of the Negro. Although none of these gradations obtain so universally, as to be found in all the individuals of any particular nation, nor are so peculiar to one race, as not to occur occasionally in other widely different ones, the national varieties of colour may be referred on the whole, with sufficient accuracy, to the five following principal classes:

1. White, to which redness of the cheeks is almost wholly confined, being observed at least very rarely, if at all, in the other varieties. This is most in most of the European nations, in the Turks, Georgians, Circassians, Mingrelians, Armenians, Persians, &c. and in the inhabitants of the north of Africa.

Considerable variety, however, will be found to exist in the colour known by the general epithet-white. That singular race of men, the Albino, possesses a milk-white or red skin and yellowish-white hair, with red eyes. In the natural history of our species they have not met with much better treatment than the poor Negroes; for some have doubted whether they, as well as the latter, belonged to the same species with us. The Negroes were thought to be too black, the Albino too white. Their skin has an unnatural whitefenes, often seeming to approach to a flight degree of lepra, and the hair of all parts of the body has the same character. The latter has not the snowy whitefenes of old age, nor the elegant light yellow or flaxen appearance of the fair-haired in our climates (blondins, Fr.) but is rather to be compared to the appearance of cream; neither is the colour of the skin like that of the European, but it approaches to that of milk, or of a white horse. The eye is deprived of its colouring matter; and hence the iris is of a pale rose colour, and the pupil intensely red, in consequence of the blood contained in the numerous vessels, which almost entirely make up the subsistence of those parts. Thus, the colouring matter of the body, as well that of the skin (rete mucous), and hair, as that of the eye, (pigmentum nigrum, or more properly fulceum) is deficient.

These affections of the skin and eye are always concomitant. This peculiarity always exists from the time of birth; it never changes afterwards, and it is sometimes hereditary. The notion, that Albino are incapable of propagation, is completely unfounded. They are in truth not numerous enough for them to breed together, and thus produce a permanent variety; but there are scattered instances to prove, that they can beget and conceive. A white negro bore a perfect negro to a negro father; and another produced with an European father three true Malattos, but with light hair. Blumenbach Beyträge zur Naturgeschichte, p. 125. See Albino, Eye, under the description of the Iris, and Integuments.

This variety was first observed in the African, as the great difference of colour would render the variation more striking; and hence the individuals were termed Leucæthiopes or white negroes; their peculiar constitution, for the deviation is by no means confined to the surface of the body, may be conveniently termed, after some modern authors, Leucæthispin. From their avoiding the light, the Dutch gave them (in the island of Java) the contemptuous appellation of Kakkerlaken (infects humming the light); the Spaniards called them Albinos, and the French Blafards. So far is this variety from being peculiar to the Negro, or even to the torrid zone, that there is no race of men, nor any part of the globe, in which it may not occur. Blumenbach has seen sixteen examples of it in various parts of Germany, and he refers to authors who have seen it in Denmark, England, Ireland, France, Switzerland, Italy, the Grecian Archipelago, and Hungary; in Arabia, on the coast of Malabar, in Madagascar, among the Caffres and Negroes, (as well those born in Africa, as the descendants of the individuals conveyed to America); in the islands of Darien and Brazil; in the islands of the Indian ocean and of the Pacific. De Gen. Hum. Var. fæc. ii. § 78.

There is another description of men with a very white skin, and often a rose tint, particularly in the face, with yellow (flaxen) or red hair, and generally blue or whitish eyes (iris). The Germans, and nations descended from them, are of this kind.

Lastly. There is a most extensive race, including nearly all the nations enumerated in the first division, with the skin, although white, possess'd more or less of a brown tint, with black hair and dark eyes.

2. Yellow or olive (gilvus feu buscus, a middle tint between that of wheat and the boiled quince or dried lemon peel), which characterizes the Mongolian tribes, usually called, together with the inhabitants of great part of Asia, Tartars (Tatars).

3. Red or copper colour (bronze, Fr. an obscure orange, or ruddy iron colour, not unlike the bark of the cinnamon tree) almost confined to the Americans.

4. Tawny or brown (badius, bafanc, Fr. a middle tint between that of sreth mahogany and cloves or chefnuts), which belongs to the Malays, and the inhabitants of the South sea islands.

5. Black, in various shades from the footy colour or tawny black, to that of pitch, or jet black. This is well known to prevail very extensively on the continent of Africa; it is found also in other very different and distant varieties of the human race, mingled with the national colour, as in the natives of Brazil, California, India, and some South sea islands, as New Holland and New Guinea. The New Caledonians constitute an insensible transition, with the chefnut coloured islanders of Tongataboo, from the tawny or brown Otaheitians to the black New Hol-

Intermediate Shades.—In describing these varieties, we fix
on the most strongly marked tints, between which there is
every conceivable intermediate shade of colour. The oppo-
site extremes run into each other by the nicest and most de-
licate gradations, in every other particular in which the
human species differs. This forms no flight objection to the
hypothesis of different species: for, on that supposition, we
cannot define the number of species, nor can we point out
the boundaries that divide them; whereas, in animals most
resembling each other, the different species are preferred
pure and unmixed. Neither does the colour, which we de-
scribe in general terms as belonging to any particular race,
prevail so universally in all the individuals of that race as to
constitute an invariable character, as we should expect, if it
aroie from such an uniform cause as an original specific dif-
fERENCE: its varieties, on the contrary, point out the action
of other circumstances. Thus, although the red colour is
very prevalent on the American continent, travellers have
observed fair tribes in several parts: as Bouguer, in Peru;
Cook, at Nootka Sound; Humboldt, near the sources of the
Orinoco; and Weld, near the United States. The na-
tives of New Zealand vary from a deep ind to an olive
or yellowish tinge. In the Friendly Islands, they are of a
complexion deeper than the copper-brown; but several of
both sexes are of the olive colour, and some of the women
are much fairer.

Various Colours of Animals.—The domestic animals ex-
hibit varieties entirely analogous to those which we have just
enumerated; a fact so familiarly known, with respect to the
sheep, pig, horse, and cow, that it cannot be necessary to
support the assertion by any details. The leucanthropic con-
stitution, too, occurs in them as well as in the human sub-
ject: it has been observed (not to mention the well-known
examples of the rabbit, ferret, mole, and horfe) in the
monkey, squirrel, rat, hamster, guinea-pig, mole, opolpfum,
ｍartini, weasel, and roe. The crow, black-bird, canine
bird, partridge, common fowl, and peacock, are sometimes
the subjects of it; but it has never been seen in any cold-
blooded animals. Blumenbach, i. e.

Classification and Denominations of the mixed Breeds.—When two
varieties coalesce together, the offspring resembles neither
parent wholly, but partakes of the form and other peculiar-
ities of both. This cannot with propriety be termed
hybrid generation; as authors apply that expression to the
produce of the copulation of different species, as of the
horse and ass, the canary bird and gold-finch, &c. In this
sense, hybrids are never produced in the human species.
We read, indeed, various instances of this unnatural com-
merce, either where men, from depraved passions, solitary
life, or mistaken notions of sanctity, have been connected
with animals: see J. Barton, in a note on Theocr. Idyll. i.
88. p. 19. "Audivi ex docto quodam amico, qui per Si-
ciliam infumam iter faciens, ibidem cum vetera monumenta,
tum populi moris accuratus investigavert, inter confessionalis
articulos a Sicilis caprarius apud montes vitafo solitariae de-
genius, etiamnum per facerdoes proprios rite foleri
exigi ad rem cum hircis fuis habuerunt: " and M. Baum-
garten, Peregriatio in Egyptum, Arabiam, &c. p. 73.

"Ibi vidimus fentum unum Saracenicum, inter arenarum
cursum planam, sustinuerat altero matris profut, nundam fedezent.
Audivimus fentum illum, quem do lacto vidimus, publicitus
apprimo commendari; cum effe lomemem fentum, divinum,
as intregate prsecipuum, eo quod nec feminarum uel quam
eft effe juvenum, sed tantummodo adfellarum concusor
atque mularum: " or with the view of deriving benefit when
ill, as Pallas states: "Perfas ifchiae laborantes onagra
inire, " Neuen Nordfichen Beytragen, vol. 2. p. 38: or
where women, from luft or religious motives, have solicited
the embraces of male animals, Steller of the Kamtchatkan
Women, in Beschreibung von Kamtchatka, p. 289; and
the Mendeian women with the sacred goat, D'Hancarville
Recherches sur l'Origine des Arts de la Grece, tom. i.
p. 320. The laws of various countries, too, have directed
that the fruit of such intercourse should be burned, or other-
wise destroyed. Yet there is no infalce, related by wit-
nesses worthy of credit, or with circumstances sufficient to
authenticate it, of any offspring being produced. We only
spake of such hybrids as result from the union of different
varieties, as of the green and white canary birds; which
unions have a most remarkable effect on the progeny, and
are employed with wonderful advantage in improving the
breeds of the domestic animals, particularly the horse and
sheep.

Children, produced from the copulation of different races,
exhibit in their colour the middle between the two tints of
their parents. From a refinement of vanity, the inhabitants
of the Spanish colonies in America have enriched their lan-
guage with terms for the finest shades, which result from
the degeneration of the primitive colour.

In the first generation, the offspring of Europeans and
Negroes are called Mulattos. The word Creole (Criollo)
has been frequently confounded with this, even by good
writers; but that name (originally applied by the first
Negroes, conveyed to America in the sixteenth century,
to their children born in that country, and borrowed by the
Spaniards from them to denote their own offspring in the
New World; Garcilasso del Origen de los Incas) belongs
properly to the children of European parents born in the
East or West Indies. The offspring of Europeans and
Indians are called Mestizos; of Europeans and Americans,
Mestizos, also Melinda, Mitfi, and Mameluco; of Ne-
egros and Americans, Zambos or Sambos, also Mulattos,
Lobos, Curibocos, and Kabbogos.

"The descendants of Negroes and Indian women bear at
Mexico, Lima, and even at the Havannah, the strange name
of Chino, Chinese. On the coast of Caraccas, and, as ap-
ppears from the laws, even in New Spain, they are called
Zambos. This last denomination is now principally limited
to the descendants of a Negro and a female Mulatto, or a
Negro and a Chinefe female." Humboldt's political Lefly
on New Spain, vol. i. p. 244.

All the above enumerated descriptions of persons have the
middle countenance and colour, formed by the union of
those of both parents; the latter is mere or less brown or
tawny, with hardly any visible redness of the cheek. The
hair of the Mulattos is curled; in the other influences straigt,
and almost invariably black: the iris is dark. "A Mel-
tizo," says Humboldt, "is in colour almost a pure white;
The skin is of a particular transparency. The small beard,
and small hands and feet, and a certain obliquity of the
eyes, are more frequent indications of the mixture of
Indian blood, than the nature of the hair." Ibid.

In the second generation, two Mulattos produce Caf-
quos: Europeans and Mulattos, Terceros, called by some
authors Quarteros, Moricos, and even Meltizos. The
hair and countenance of these resemble the European: the
skin has a very light brown tint, and the cheeks are red.
The scrotum is blackish in the male, and the labia pudendi
rather purple in the female.

Negroes with Mulattos produce Grisios (Zambos de
Mutlata, or Cabros): an European and Indian Meltize,
Cadinos. "If a Meltiza marry a white man, the second
generation differs hardly in any thing from the European
race." (Humboldt; ibid.) From an European and Ame-
rican
The two latter are respectively white and black; the former are white by law, and consequently free in our West India islands. They are not distinguishable from pure whites in complexion, features, or hair.

Thus, in obedience to that principle, by which the properties of the offspring depend on those of the parents, we have the power of changing one species into another by repeated intermixture. If the offspring of a white woman and a black be matched with a black man, and this procés be repeated two or three times, the form of the original mother is entirely lost, and that of the father substituded; or, vice versâ: and the same may be done with plants.

Exceptions to the Law concerning the Colour of the mixed Breeds.—Although the children generally partake of the character of both parents, they sometimes resemble one only; and in such a case, the influence of the other is often observed in the second or third generation. We see children like their grandfathers, and unlike the father and mother.

"It fit quoque, ut interdum feminis exsistere avorum Pollini, et referant provarum fore figuras."

"Inde Venus variis product forte figuris, Mejorunquique refert volutis, vocofigur, comafique."

Lucertins, lib. ii.

Thus, a white Negress (Albinos) married an Englishman, and brought forth three true Mulattoes, but with light hair. (Blumenbach, Beiträge, p. 125.) The offspring of a black and white may be either black or white, instead of being mixed; and in some rare cases it has been spotted.

A black man married a white woman in York, who in due course of time had a child that was entirely black, and very much like the father both in colour and features, without the least participation of the features or colour of the mother. A black man married a white woman in London, who afterwards had a daughter as fair as any one born of white parents, and like the mother in features; but her right buttock and thigh were as black as the skin of the father. A Negro woman had a white daughter by a man of her own race: white children had been frequently born in his family, and his own father was one of these; but his grandfather and grandmother were black. Parsons in Phil. Trans. vol. iv.

A Negress had twins by an Englishman: the one was perfectly black, with short, woolly, curled hair; the other was white, with long hair. White on the regular Gradation, p. 122.

Production of Varieties.—It is a general law, that animals produce their like; and thus species and races preserve uniformity of character. But this resemblance between children and their parents is not constant: the former, under certain circumstances, differ from the latter; and thus we have persons in each race, with characters approaching to those of the other races. In European countries, scattered instances of individuals, with skins nearly as dark as those of the Mongols or South Sea islanders, are not unfrequent. Forther, in his voyage round the world, saw a man with fair skin and red hair in an island, where the inhabitants in general are nearly black. Among the Otahiteans, who are descanted from the Malay race, light complexions and linen hair are not very uncommon; and red-haired individuals have been observed in most of the dark coloured nations, as the Wotakis, Esquimaux, islanders of New Guinea and New Zealand, and the Negroes (Blumenbach, p. 169.) Again, the origin of Albinos, particularly in the black nations, is a remarkable example of native variety of colour.

Inflans analogous to these are of daily occurrence among animals, as in the production of black sheep, cats, horses, foxes, &c. White sheep produce black lambs; and grey rabbits may bring forth either white (leucocithope) or black ones. Two common peacocks produced fourteen young; two of them were white, and the rest resembled their parents. (Buffon, vol. xii. p. 286, note.) Leucocithope animals are constantly produced from those of the ordinary characters.

The native varieties, thus produced, are propagated by generation,
MAN.

The skin differs in some other properties besides its colour. Travellers have described it as remarkably soft and smooth, and as it were silky, in the Carib, Negro, Otaheitean, and Turf. It secretes a matter of peculiar colour in some races. "The Peruvian Indians," says Humboldt, "who, in the middle of the night, distinguish the different races by their quick sense of fineness, have formed three words to express the

Vol. XXII.

colour of the European, the Indian American, and the Negro: they call the first pezuna, the second poico, and the third grao." Humboldt, p. 245.

The hairs, as it grows and is nourished from the common integuments, is connected with them in many points by a close kind of sympathy. Hence the spotted Africans have white hairs growing out of a white patch on the head. The four

ject in the description of the colours of men, have black hair; and in the first, or the white, every gradation from the fair to the dark, is accompanied by correspondent alterations in the hair. This is true, not only of nations, but also of individuals in the white races.

A light complexion and thin skin are accompanied with redder

hair; a dark one, and thick skin, with black hair, almost invariably, even in individuals of the same family; a difference, which, according to the philosophy of some writers, would be a sufficient ground for classing them in different species. The other properties of the hair vary, as well as its colour; and these changes may be brought under the four following varieties:

1. Brownish, deviating into red on one side and black on

the other; this is copious, soft, and long, and slightly un-}

8ulated. It obtains in most of the temperate climates of

Europe, and formerly attracted particular notice in the

ancient Germans. The thin and white skinned Alhino has the

softer and thinna hair, of a white colour: in the Germanic

race it is also very soft; and red hair is usually found in con-

junction with a thin and soft skin. The Celtico and Slavo-

nic races, which make up the chief population of Europe,

and the eastern Asiatics and northern Africans have generally, in a rather thicker and darker skin, stronger, black, or
dark russet brown, and often males or less curling hair.

2. Black, strong, straight, and thin; occurring in the

Mongolian and American races.

3. Black, softer, denser, and curlier; observable in

most of the South Sea islanders.

4. Black, and crisp, so as generally to be called woolly;

common to all the Ethiopians.

The analogy, on which the covering of the Africans has

thus been called wool, is quite a loose one, and goes no

further than a slight resemblance in appearance. The

filament in wool is rough on its surface, in the hair it is smooth;

the latter is of uniform thickness throughout, or rather

denser towards the point, while the former is unequal in size,

and rather larger towards its end. The wool is detached al-

together, while the hairs fall off separately. In none of

these characters does the hair of the African agree with

wool.

The above division, although sufficient for general pur-

poses, is not uniformly true. For the woolly hair is not

confined entirely to the Ethiopians, nor is the black colour

invariably found in all the three last varieties. Some tribes of

Africans have long hair, (Bruce of the Gallas) and other

red coloured people, as those of the Duke of York's island,

have it strongly curled. The New Hollanders form to com-

plete a medium between the woolly haired African, and the

copious curling hair of the other South Sea islanders, that

we are completely puzzled how to class them. Individual

influences of red hair occur in all the three last varieties.

The soft white hair of the Alhino may be produced in any

race of mankind; and is most widely different from the

black hair of the dark varieties.

The animal kingdom furnishes us with numerous parallel

influences of varieties in the colour and texture of the hair;

as, for example, in the black sheep, black and white horset,

&c. The sheep exhibit every kind of covering, from the

X

delicate
delicate fleeces of Thibet or Spain, to the ears and rough hair which takes the place of wool in many warm countries.

The hair of the pig is soft and fine: kind, as in Normandy, that they are not applicable to the manufacture of the ordinary instruments. The wild pig has a soft curling hair interspersed between its bristles, which is entirely felt in the domesticated animal.

Sheep, rabbits and cats in Angora, a small district of Asia Minor, are remarkable for the length and softness, as well as snowy whiteness, of their coverings.

The sheep of some of the Tartar tribes have hairs mixed with the wool; such a mixture is observed even in this country, where the breed is neglected; and it occurs in the Ayrshire, the furred wild origin of our flocks. In these cases, if the animals with the wool fibres are selected to breed from, and this rule be observed constantly, the wool would be gradually improved, and the hairs disappear; or vice versa, the sheep would become entirely hairy.

A child born in Yorkshire of European parents, had the woolly hair; and this is the only example. Prichard de Generis Hum. Varior. p. 26.

It may appear very clearly, from these analogies, that the differences of the hair will not warrant us in establishing distinct species of men.

Together, with the differences of the hair we may mention those of the beard. This growth is small in quantity, and thin in many tribes of the Mongolian, African and American races. "One of the most general characters of the ugly nations," says Meiners, "is either an entire want of beard, or a very thin one, developed at a later period than usual: on the contrary, a copious beard has always been the pride of the handsome races. Dark coloured nations, with strong beards, are not much more numerous than individuals of handsome people with a weak growth." Grundris. p. 98.

Unfounded reports have been generally received of its entire absence in the Americans, and this circumstance has been represented as a characteristic peculiarity of the race. The concurring testimonies of all accurate modern travellers prove clearly that the Americans have naturally beards; that it is a very general custom with them, as it has been with several Mongolian and Malay tribes, carefully to eradicate this excellence; but that various hordes in different parts of the continent prefer it as other men do. Gmelin found this practice in Asia. "It is not easy to find a Tunguso, nor any man of the neighbouring tribes, with a beard. For they extract the hairs as soon as they appear, and repeat this process until at last no more are formed." (Reise durch Sibirien. t. 2. p. 125.) The same circumstance is reported of the Sumatra by Marrden; of the Mundanoo aborigines by Forrest; of the Pelew aborigines by Wilkson; the inhabitants of New Guinea by Carteret; and those of Navigator's Riles, by Bougainville. From a cloud of unanimous testimonies concerning the Americans, we extract the following statement of Cook respecting the inhabitants of Nootka Sound: "Some have no beards at all, and others only a thin one on the point of the chin. This does not arise from an original deficiency of hair in those parts, but from their plucking it out by the roots; for those, who do not destroy it, have not only considerable beard on every part of the chin, but also whiskers, or moustachios, running from the upper lip to the lower jaw obliquely downwards." (Lett. Voyage, v. 2. p. 243.) The testimony of Humboldt concerning the South Americans is to the same effect: "The Mexicans, particularly those of the Aztecs and Otomi race, have more beard than I ever saw in any other Indians of South America. Almost all the Indians in the neighbourhood of the capital wear small moustachios."—"I can affirm that the Indians, who inhabit the torrid zone of South America, have generally some beard; and that this beard increases when they shave themselves."—Mr. de Galvez, in the account of the last Spanish expedition to the Straits of Magellan, informs us that there are many old men among the Patagonians with beards, though they are short, and by no means bushy." (Political Essay on the Kingdom of New Spain, v. 1. p. 137.) The existence of a beard, and the habit of extirpating it, are mentioned of the Greenlanders, by Cranz, Geschichte von Grönland; by Charlevoix of the Eskimans, Nouvelle France, iii. p. 179; by Oldendorp of the Curibs, Geschledte der Mission auf den Karabibischen Inseln; p. 22: By Wafer of the Americans at Panama, Thesaurus of America, p. 165; by Bougainville of the Patagonians, Voyage autour du Monde; and by Parkinlon, of the inhabitants of Terra del Fuero, voyage v. 1. Commeron speaks of the whiskers of the Patagonians, Journal Encyclop. 1772.

Colour of the Hair.--We have just explained how the hair is connected with the skin; that a similar connexion is in the animal of colour exists between the latter organ and the eyes, was noticed by Aritotole, who observed that white perfons have blue eyes, and black ones black. Thus, in Germany, Blumenbach says that newly-born children have generally blue eyes and light hair, and that both grow gradually dark together in individuals who become dark. Again, the pigment of the eye loses much of its colour in proportion as the hair grows grey in the old subject. With their peculiar hair and skin, the Albinos have an entire deficiency of the pigment, and consequently a pale red iris. Those animals only which vary in the colour of the skin and hair, have differently coloured irides; and this is true, not only of men and horses, according to the opinion of the ancients, but of other animals, particularly in the domesticated state. Moreover, the iris is often variegated in animals which have a spotted skin. This has been noticed in dogs (Comment. Ist. Bonon. t. iii. p. 291.). Blumenbach has observed something of it in horses and sheep, but more particularly in rabbits: the grey, or those which have the native colour of their wild state, have dark irides; the spotted have them marked with different colours; and the white, like other Leucoplastics animals, have them of a pale rose colour.

The three principal colours of the human eye were well laid down by Aritotle: 1. blue, palling, in its lighter tints, to what we call grey; 2. an obflcure orange, which he calls the colour of the eye in the goat (Gall. Yeux de Chevre); 3. a kind of middle tint, between blue and orange, and sometimes remarkably green in men with red hair and freckled skin; and 3. blackish brown.

These may all occur in different individuals of the same race; and again, they are sometimes confined to the different tribes of the same country, within the boundaries of a few degrees. Thus Linnaeus describes in Sweden the Gotlander with light hair and greyish-blue eyes; the Fin with yellow hair and brown iris; and the Laplander with black hair and iris. Blue eyes, as well as yellow hair (rutila), denote the resemblance to gold, whence auricani Batavi, Silus, Saxoni, Gr. were formerly set down among the characters of the Germans (cerulii oculi, rutile corne, Tactus); and the same combination is met with in scattered influences, in the most remote nations. The iris of the negro is the most intensely black, so that very close inspection is necessary, in living individuals, to distinguish it from the pupil.

Differences of Form.—The existence of great variations in the
the conformation and proportions of the body in all animals, and particularly of the features of the human countenance, subject, however, to certain fixed rules as to the general model, accords entirely with what we observe throughout all nature.

“Preterea genus humanum, mutuque natantes
Quamquamserum pecudes, et lata armenta, ferreux,
Et varie volucres; latantia qux loca aquarum
Concelebrant, circum ripas, fontecquis, lucueque;
Et qux pervolgent nemoras avia pavolvarentes;
Horum inum quodvis generatim surnore pergex;
Invenies tamen inter fe diffare figuras.
Nec ratione alia prolés cognoscere matrem,
Nec mater poléf problem; quod poléf videmus,
Nec minus atque homines inter fe nota clure.”

National Features.—Although it is a common and very just observation, that two individuals hardly are to be met with possessing exactly the same features, yet there is generally a certain call of countenance common to the particular races of men, and often to the inhabitants of particular countries. The five following varieties are established by Blumenbach, and are a careful comparison of numerous drawings, and of the various races themselves, in situations, where commerce attracts them from all parts of the globe, as at London and Amsterdam.

1. An oval and slanting face, with the different parts moderately different from each other; forehead rather flattened, nose narrow, and slightly aquiline, or at least with the dorsum somewhat convex; no prominence of the cheek-bones; small mouth, with lips slightly turned out, particularly the lower one; a full and rounded chin.

This is the kind of countenance which accords most with our ideas of beauty: it may be considered as a middle, departing into two extremes, exactly opposed to each other; of which one consists in a lateral expansion of the face, and the other in its being extended downwards. Each of these includes two varieties, which are most readily distinguished by a profile view; one, in which the nose and other parts run together, and the other, in which they are more prominent and separate.

2. Broad and flattened face, with the parts slightly different, and as it were running together; the space between the eyes flat and very broad; flat nose, rounded projecting cheeks; narrow and linear aperture of the eye-lids, extending towards the temples (Yeux brûles, Fr.) chin slightly prominent.

This is the face of the Mongolian tribes; commonly called in English the Tartar face, from the confusion of the Tartars (Tatars) with the Mongols.

3. Face broad, but not flat and depressed, with prominent cheek-bones, and the parts, when viewed in profile, as if they were, more deeply and distinctly cut out. Short forehead; eyes deeply set; nose flatish, but prominent. Such is the countenance of most of the Americans.

4. Narrow face, projecting towards its lower part; arched forehead; eyes prominent (a fleur de tête); a thick nose, conflued on either side with the projecting cheeks (nez épine); the lips, particularly the upper one, very thick; the jaws prominent; and the chin retraced. This is the countenance of the Negroes, the Guinea face.

5. The face not so narrow as in the preceding, rather projecting downwards, with the different parts in a fade-view, riding more freely and dilluminly. The nose rather full and broad, and thicker towards its apex (bottle-nosed). The mouth large. This is the face of the Malays, particularly of the South Sea islands. Excellent representations of celebrated individuals of these five varieties may be seen in Blumenbach's Abbildungen Naturhistorischer Gegenstände, part 1, also, in his Beyträg zur Naturgeschichte.

Intermediate Gradations and Varieties in the different Races.—In this respect, as in colour, the different characters run into each other by the most gentle gradations; so that, although any two extremes, when contrasted, appear strikingly different, they are connected by numerous intermediate and very slightly differing shades; and no formation is exhibited so constantly in all the individuals of one race, as not to admit of numerous exceptions.

In the Africans.—We see, indeed, an astonishing difference, when we place an ugly Negro (for there are such as well as ugly Europeans), against a specimen of the Grecian ideal model; but, when we trace the intermediate gradations, this striking diversity vanishes. “Of the Negroes of both sexes,” says Blumenbach, “who I have attentively examined, in every considerable number, as well as in the portraits and profiles of others, and in the numerous Negro crania, which I possess, or have seen, there are not two completely resembling each other in their very minute and by intermedium differing points, of the other races, and approach to the other varieties even in their most pleasing modifications. A Creole, whom I saw at Yverdon, born of parents from Congo, and brought from St. Domingo by the chevalier Treytorrens, had a countenance, of which no part, not even the nose, and rather strongly marked lips, were very striking, much less displeasing: the same features, with an European complexion, would certainly have been generally agreeable.” (Beytrag zur Naturgeschichte, p. 89.) The testimony of Le Maire, in his journey to Senegal and Gambia, is to the same effect; that there are Negroes, except in colour, as handsome as European women. Vaillant says of the Cafhrre women, that, setting aside the prejudice which operates against their colour, many might be accounted handsome, even in an European country. The accurate Adamson confirms this statement, in his description of the Senegambians. “Les femmes font a peu près de la taille des hommes, également bien faite. Leur form est d'un fine et d'une douceur extrême. Elles ont les yeux noirs, bien fendus, la bouche et les levres petites, et forme agréable. Tout se combine et d'une beauté parfaite. Elles ont beaucoup de vivacité, et fur tout un air aisé de liberté qui fait plaisir.” (Hilt. Nat. du Senegal, p. 22.)

The Jaloifs, according to Mungo Park, have not the protruberant lip, nor flat nose of the African countenance. We have also the testimony of another traveller, concerning this tribe, to the same effect: the Jaloifs, according to Moore, have handsome features, and neither broad noses nor thick lips. (Zimmermann Geographische Geschicichte, &c. vol. i. p. 99.) Pagetau states, that the Congo Negroes have not the thick lips of the Nubiens, and that, except in colour, they are very like the Portuguese. (Relazione del Reame di Congo, Roma, p. 12.) Dampier, in his account of Natal, describes the natives as having curled hair, but a long face, well-proportioned nose, and agreeable countenance. The fix Negro crania engraved in the two first decades of Blumenbach, exhibit very clearly this diversity of character in the African race; and prove, most unequivocally, that the variety among individuals is certainly not less, than greater than the difference between forms of them and many Europeans. See Decas Cranorum, p. 23., and Decas Altera, p. 13.

In the Americans.—The same observations hold good of the American race. The most accurate observers treat with contempt the hyperbolical affirmtion of some, that all the inhabitants of the New World have one and the same countenance, so that he who has seen one may say that he has seen X x 2 all,
all. "Rido fra me stesso," says Molina, "quando leggo in certi scrittori moderni riportati diligentissimi osservatori, che tutti gli Americani hanno un medesimo aspetto, e che quando ne abbia veduto uno, si possa dire di avergli veduti tutti. Codesti autori si lasciarono troppo facilmente sì certe vage apparenze di somiglianza procedenti per lo più dal colorito, le quali fanno noto tal che si confrontano gl' individui di una nazione con quelli dell'altra. Un Chilen non si differenziava meno nell' aspetto da un Peruviano, che un Italiano da un Tedesco. Io ho veduto pur dei Paraguanis, de' Cuyanis, e dei Magellanicis, i quali tutti hanno dei lineamenti peculiari, che li distinguono notabilmente gli uni dagli altri." (Storia Naturale del Chili, p. 336. We have further unexceptionable testimony to prove that the same variety of countenance is found in the Americans as in other races; although generally the countenance follows the model above described. In South America only we have the Cassaguas with flat noses, observed by Nic. del Tacho; the neighbouring Abipons, of whom many individuals have aquiline noses, by Martin Dobrichhoff; the Peruvians with narrow and aquiline noses by Ulloa; the Chileans with rather a broad nose by Molina; and the inhabitants of Terra del Fuego with a very depressed one by G. Forster. The truth of this representation is most fully attested by Humboldt, whose accuracy and extensive opportunities entitle his observations to the most implicit deference. "In the faithful portrait, which an excellent observer, Mr. Volney, has drawn of the Canadian Indians, we undoubtedly recognize the tribes scattered in the meadows of the Rio de la Plata and the Carony. The same file of feature exists, no doubt, in both America; but those Europeans who have failed on the great rivers Ornoco and Amazonas, and have had occasion to see a great number of tribes assembled under the monarchical hierarchy in the missions, must have observed that the American race contains natives, whose features differ as essentially from one another, as the numerous varieties of the race of Caucasus, the Circassians, Moors, and Persians, differ from one another. The tall form of the Patagonians is again found by us, as it were, among the Caribs, who dwell in the plains from the delta of the Orinoco, to the sources of the Rio Blanco. What a difference between the figure, phylogonomy and physical constitution of these Caribs, who ought to be accounted one of the most robust nations on the face of the earth, and are not to be confounded with the degenerate Zambos, formerly called Caribs of the island St. Vincent, and the squat bodies of the Chaymas Indians of the province of Cumaca! What a difference of form between the Indians of Tlascala and the Lipans and the Chichimecs of the northern part of Mexico." Political Essay on the Kingdom of New Spain, v. 1. p. 142.

In the South Sea Islands.—An analogous variety has been noticed in the features of the Friendly islands: "their features are very various; inhomoch, that it is scarcely possible to fix on any general likeness by which to characterize them, unless it be a flatness at the point of the nose, which is very common. But, on the other hand, we met with hundreds of truly European faces, and many genuine Roman noses amongst them." Cook's Last Voyage, v. 1. p. 385.

In Europeans.—Again, particular individuals in Europe often have the countenance exactly resembling the Negro, or Mongoil face.

Differences in the Skull.—The form of the cranium in the different varieties of man has been described in the article CRANIUM ; in which the causes of the diversities of its figure are also considered. We have one or two additional remarks to make, particularly concerning the Negro. "The bony apparatus," says Soemmering, "concerned in malleation, as well as the part of the face containing the organs of sense, are, whether considered generally or particularly, stronger, thicker, and more advantageously disposed for this strength in the Negro, than in the race where more extensive use of experience and reason, and greater cultivation supply the place of what is deficient in animal strength. Should we take the bones of the face in the Negro, as a basis, and add to them a cranium, according to the proportions observed in European heads, the space allotted for the reception of the organ of thinking would exceed the size that it has in us. Von der körpفل. Verfchiedenheit, § 12. The ridge that bounds the origin of the temporal muscle is more prominent, and rises much higher on the side of the head in the Negro, than in the European; consequently, the muscle is considerably larger, and the bony arch surrounding it (the zygoma), is larger, stronger, and more capacious. (Ibid. § 16 and 17.) Both openings of the nose are more ample, and the cavity itself considerably more capacious than in the European. The thin convoluted plates of the ethmoid bone are larger, and consequently increase the extent of the pituitary membrane; the cribiform plate is remarkably large. These circumstances of anatomical structure are not, however, peculiar to the Negro: Soemmering finds the nasal cavity in the cranium of a North American savage still more ample than in most Negroes. (Ibid. § 21 and 22.) The influences related of the mienes of smell in these people, such as their being able to distinguish Europeans from Negroes and Americans, &c. correspond to what we observe in their organs.

"The nerves," says this anatomist, "connected with the basis of the brain, appear to me, in comparison with an European brain of the same size, to be, in proportion, rather larger; at least the olfactory, the fifth, and the facial nerves, are remarkably large, as we might have expected, from the greater size of the nose and face." § 56.

The relation between the cranium and face is best seen in a vertical section carried from before backwards: the area of the face, independently of the lower jaw, is about one-fourth of the cranium in the European; in the Negro, the cranium remaining the same, the face increases by about one-fifth. The proportion fills in places in the orang-outang; in the apes, in the mandrills, and most of the carnivora, the face and cranium are about equal.

The oss nasi of the Negro, instead of forming the bridge-like convexity which we see in the European, are nearly flat, and run together into an acute angle above, which makes them very much resemble the simple triangular nasal bone of the ape. But in one cranium they exactly resemble the European. Ibid. § 19.

The varieties in the form of the teeth are also considered in the article CRANIUM.

Supposed Causes of Difference of Features: Climate.—That the national differences of features owe their origin to climate, has been the opinion of many philosophers; and some have even attempted to shew how the effect is produced. "En effet," says Volney, "j'observe que la figure des Negres représente presque tout et de contraction que prend notre visage, lorsqu'il est fraisé par la lumière et une forte réverberation de chaleur. Alors le fourcil se forme; la pomme des joues s'élève; la paupière se ferme; la bouche fait la moue. Cette contraction, qui a lieu partiellement dans le pays nui et chaud des Negres, n'est-elle pas dû devenir le caractère propre de leur figure?" Volney, Voy. en Syrie et en Egypte, t. i. p. 74. It is unfortunate for these speculations that the most opposite kinds of features occur under similar climates in different parts of the world; and that there are races with flattened countenances, as well
as with prominent ones in hot countries. These causes, too, could only affect the soft parts: a negro might "faire la main" to eternity, without altering the whole bony com-
pages of his head. Indeed, the whole account is so fanciful, that it hardly deserves serious attention. If there were any foundation for the supposition, we might expect Mr. Vol-
ney's countrymen, from their well-known habit of shrugg-
ing the shoulders, to have become long ago the highest
shouldered race in the world.

Artificial Prejudice.—The custom of carrying the children
on the back has been referred to by others, in order to ex-
plain the flat nose of the Negro: in the violent motions re-
quired for their hard labour, as in beating or pounding the
millet, &c. the face of the young one is said to be constantly
beating against the back of the mother. The testimonies
concerning the employment of prenure, with a view to flatten
the mone, are so numerous and respectable, that we cannot
refuse to believe that it is attempted. (See Blumenbach,
d Variate, p. 193.) But two reasons prevent us from
ascribing any efficacy to these practices in producing the
national varieties of the cranium. The diversities extend to
the whole bony fabric of the head, and are observable in so many parts, where external prenure
could have no influence, not to mention that they confilt, in
many instances, of formations just the reverse of what pre-
ure would effect, that we may ascribe them to native variety.
This determination is confirmed by the discovery, that all
the peculiarities of the Negro cranium exist in the fetus.
The researches of Blumenbach, Camper, Soemmerring, Lud-
wig, and Luider, have proved this fact concerning Negro
features of various ages, in which they find the same promo-
nis of the jaws, flat nose, &c. as in the adult. (Soemmen-
ing von der Körperr. Verfichenheit, p. 4. Ludwig
Grundrisf der Naturgeschichte der Menfchen Spezies,
p. 121.) The children of Negro parents in Europe, Ame-
rica, and other situations, where there are opportunities of
knowing that no means are used to flatten the face, resemble,
in all respects, those born in Africa. These arguments re-
cieve a further confirmation from three of the crania engraved
by Blumenbach, of a Jewith girl, five years old, a Mongo-
lian child, a year and a half, and a newly born Negro, in
which the characters of the Caucasian, Mongolian, and
Ethiopian varieties are as strongly represented as in the heads
In the form and proportions of other parts, there are
not fewer differences than in the composition of the fea-
tures.

Differences in the Form and Proportions of other Parts.—
Connection of the Head and Trunk.—In consequence of the
foramen magnum being placed further back in the head in
the Negro than in the European (see CRANIUM), and of
the head of the former being consequently placed further
forwards on the vertebral column, the occiput projects less
behind the spine. Hence, a line drawn from the occiput
along the nape of the neck, is nearly straight in the Negro,
but it dips in considerably under the head in the European;
as if a part of the cranium had been fixed off in the former.
The same circumstance may be observed in a much more
striking degree in the Simite.

Body and Limbs.—The body is large, square, and robust;
the extremities thick, short, and nervous; and the shoulders
high in the Mongols. They are well described in a letter
inferred in the Hildra Major of Matthew Paris, London,
1686, p. 530, under the name of Tartars (Tatars). “Ha-
bent antem Tartari pecora dura et robusta, facies macras
et pallidas, facellas rigidas et erectas, natos dilateros et
breves, menta proeminientia et acuta, superimem mandi-
bulam humilem et profundam, dentes longos et raros, pal-
pebras a crinis usque ad naium preterea, oculos incon-
flantes et niger, apulicis obliquos et torvos, extremitatis
offisas et nervofas, crura quoque grofa, fed tibias breviores,
flatura tamen nobis equales; quo quid catrn in tibias deficit,
in superiori corpore compenfatur.”

In the negro the body is more slender, particularly about
the loins and pelvis. The dimensions of the latter cavity
are actually smaller than in the European: in the skeleton
of a negro, twenty years old,

Camper found that the great diameter (from one os inno-
minatum to the other) was to the smaller (from the facrum
of the symphysa pubis)

In the negro as 39 to 27 1/2 |
In the European as 41 27

Yet the stature of the negro exceeded considerably that of
the European. In another European the proportions were
as 44 to 28. (See Soemmering über die Körperliche Verfich-
chenheit, p. 43.) Not only is the cavity smaller, but the
bones composing it are slenderer; and the circumstance has
been noticed by travellers and others.

The fame slendernees of the trunk may be observed in
some of the Indians: it is at least apparent in the Laffars,
who come to this country with the East India ships. Their
legs are long.

Proportionate Length of the Arm and Fore-arm.—The limbs
are smaller in the negro, and some differences are observable
in particular parts. “I measured,” says Mr. White, “the
arms of about fifty negroes, men, women, and children, born
in very different climates, and found the lower arm longer
than in Europeans, in proportion to the upper arm, and to
the height of the body. The first negro on the list is one in
the Lunate hospital at Liverpool; his fore-arm measures
13 3/4 inches, and his stature is only 5 feet 10 1/2 inches. I
have measured a great number of white people, from that
size up to 6 feet 4 1/2 inches, and among them one who
was paid to have the longest arms of any man in England,
but none had a fore-arm equal to that of the black
lunatic.

“I have measured the arms of a great number of Eu-
ropean skeletons, and have found that the os humeri, or
upper arm, exceeds in length the ulna, which is the longer
bone of the fore-arm by two or three inches; in none by
less than two, and in one by not less than 3 1/2 inches. In my
negro skeleton, the os humeri is only one inch and one-eighth
longer than the ulna. In Dr. Tyn’s Pigmy (Emin fatymus),
the os humeri and ulna were of the same length; and in my
skelton of a common monkey, the ulna is 2 3/4 inches
longer than the os humeri.” White, on the Regular Grad-
ation, p. 52, et seq.

As the comparison just mentioned leads to some intere-

ing insula, we subjoin a tabular view of the chief particulars.

Legs of the Negro, and other Races.—The ancients noticed, what they regarded as defects in the form of the lower limbs in the Egyptians, Ethiopians, and Negro slaves. Sumermering observes, that the bones of the leg are directed outwards from the knee, so that the knees appear farther apart, and the feet rather bent outwards; he found the same circumstance in numerous living negroes. The femur and tibia are flated, both by him and White (who has given a comparative view of the bones of the negro and European leg and foot, pl. 1.), to be more convex in front than in the European. The calves of the leg are very high, so as to encroach upon the hands. The feet and hands, but particularly the former, are flat; the os calcis, instead of forming an arch, is continued in nearly a straight line with the other bones of the foot, which is remarkably broad. They both terminate in beautiful, but remarkably long fingers and toes, which, in that respect approach to those of the monkey; and they all polished, what is not common among Europeans, felamoid bones. (Von der körperlichen Verhältniss, p. 39.) Uneemly thickness of the legs is not uncommon among the negroes; and the feet are marked with numerous chinks and furrows, which, as they occur principally in the soles, must probably be referred to the operation of the burning sands on the epidermis. In the sole of a perfectly healthy negro leg, Blumenbach found this covering "mirum in medium crania, rimola, et in multi-fidas lamellas delucentes." De Gen. Hum. Var. Nat. p. 245, note 6.

It has been observed, that the Indians of the peninsula and the New Hollanders have long and slender limbs; that the Hottentots have meagre bodies and small limbs, &c. The crooked legs so common among the Calmucks, &c., have been ascribed by others to the mode of treating the children, and the practice of riding, to which they are accustomed from their tenderest years. Tallas über die Mongolischen Völkerschaften, p. 98, tom. 1.

The lower limbs are very ill formed in the inhabitants of Terra del Fuego, according to Forster; he says that they bear no proportion to the body; that the thighs are meagre and thin, the legs bowed, the knees prominent, the toes turned inwards. Obi. on a Journey round the World.

Ear.—It is well known that the ears stand out farther from the head, and are moveable in savages, and that the appendix is enlarged and monstrously elongated by various artificial means in many tribes, particularly in the East Indies and the Pacific. These practices have given rise to the fables of some older writers concerning the enormous ears of certain people.

Mammæ.—Many travellers have spoken of the prolix and pendulous mammae of the females of certain barbarous tribes, particularly in Africa, and in the South Sea Islands. We cannot help supposing that many of these narratives are exaggerated; as, for example, in Hakluyt's Collection, vol. ii. p. 26, where it is said, that "divers of the women have such exceeding long breasts, that some of them will lay the same upon the ground, and lie down by them;" in Bruce's Travels, where he says, that they hang down to the knees in some of the Shangallas; or in Montezibus, Beschreibungs des Vorgebärges der guten Holland, tom. ii. p. 570, where it is said, that purfes are made in great numbers from the breasts of the Hottentot females, and sold at the Cape of Good Hope. It is also certain that this conformation is not universal in the tribes alluded to, and that many negroes, who may be seen in the great European emporia, as well as numerous females in the isles of the Great Pacific (Forster's Observations, &c.), have very beautifully shaped breasts, and that it exists also in several European countries. "I saw," says Lithgow, "in Ireland's North parts women travailing the way, or toying at home, carry their infants about their necks, and laying the daggers over their shoulders, would give suck to the babies behind their backs, without taking them in their arms: such kind of breasts, me thinketh, were very fit to be made money-bags for East or West Indian merchants, being more than halfe a yard long, and as well wrought, as any tanner, in the like charge, could ever manifeate such leather." (Rare Adventures and Painfulle Peregrinations, p. 433.) An unliminably large size of these parts has been observed in the Morlachian women, by Fortis, (Viaggio in Dalmazia, vol. i. p. 81.) and the Greenland women are said to fuckle their children at their back.

Long continued fuckling, and the habit of suckling the children on the back of the mother, seem to be the principal causes of this state of the mammae. In some instances artificial means of elongation have been employed from peculiar notions of beauty.

A large and swelling state of the breast, is mentioned by Juvenal of the Egyptians, as a well-known fact. "In Meroe crasso majoræ infantis papilla." The Portuguese women, of modern days, are said to be remarkable in the same way; while the breasts are small in the Spaniards, as in the last century at least they took pains to compress them in order to prevent too great a luxuriance.

To the disgrace of London, even in this truly pious age of societies for suppressing vice and distributing bibles, a philo-sofaphic foreigner has found in her streets a proof of the effects of too early venereal excitement in enlarging the breast; and has commemorated the fact in a classical work, which must convey the scandal over the whole learned world, "Contraria cura ambitum mammam aegri poiffe nullum dubium esse; quantum vero praterea Venus quoque prae- nutra eo conserver posse memorabilis fame exemplo impuberex et nondum adulter pulcher mercenaria docet que Londina, praestantimum ex vicinis maxime suburbiis, confuquent, & quidem
MAN.

quintum corpore facientes ingenti numero plateas noceu per-

Organ of Generation.—Negros are particularly famous for their organs of generation; and specimens preferred in anatomical cabinets seem to justify their celebrity for the size of these parts; but it is doubtful whether this be a general character. The frunnnum prepustii does not exist in many of them. White, p. 62.

In the Hottentot women, and in some others, the nymphae are said to form growths of considerable size (in dactyliform aspects) in the vulva; but the former are more celebrated for what has been described as a natural covering of skin, hanging from the abdomen, and hiding the parts of generation. This, with other arguments of equal force, is brought forward by Voltaire, to prove that the Hottentots are not of the same species with Europeans. (Lettres d'Amad.) Blumenbach, who received from sir Joseph Banks, several views of these parts, drawn from the life, informs us that the peculiarity is an artificial elongation of the labia pudendii; in one representation they are 6½ inches long. Le Vaillant's testimony is to the same effect. Voyage dans l'Intérieur de l'Afrique, p. 371. See Generation.

Hands and Feet.—Smallness of the hands and feet has been mentioned as a character of some races, as the Indians, Chinefs, Kaffirdrakens, Eskimaux, Peruvians, New Hollanders, and Hottentots. “It has been observed,” says Hodges, “of the arms of the Hindoos frequently brought to England, that the girth of the fabre is too small for most European hands.” Travels in India, p. 3.

What art can produce in this way, is shown by the feet of the Chinese women.

Transmission of native Characters to the Children.—Peculiarities of form, like those of colour, are transmitted to the offspring; and this principle prevails so generally, that even these minute, and to our senses entirely imperceptible differences of organization or vital properties, which render men disposed to particular diseases, are conveyed from father to son for age after age. Hence we fee a general resemblance in persons of the same blood, and may frequently observe a peculiar feature running through a whole family. The thick lip introduced into the imperial house of Austria by the marriage of Maximilian to Mary of Burgundy, is visible in their descendants to this day. In small and secluded communities, where marriages take place within what we may regard only as a more extensive family, hereditary varieties are blended, and produce one form, which prevails through the whole circle. The operation of this principle may be clearly perceived in several small districts; it will act with more efficacy, and consequently be more discernible, in larger collections of men, where differences of manners, religion, and language, and mutual animosities, forbid all intermarriages with surrounding people. In the course of time the individual peculiarities are lost, and a natural characteristic countenance or form is established, which, it the restrictions of intercourse are rigidly adhered to, is constantly more and more strengthened. The ancient Gcrman, according to the description of Tacitus, were such a people, and his short, but expressive sketch of their character, most aptly confirms the preceding view: “Iep: eorum opinionibus accedt, qui Germaniae populus nullis aliarum nationum canibus infectos, propriam & sinceram, et tantum fum filiam gentem exultit arbitrantur. Unde habitas quoque corporum, quanquam in tanto hominum numero, idem omnibus; traces cærulii ochli, rutilis comit, magna corpora.” De Morb. Germ. 4. The gipsey afford another example of a people spread over all Europe for the last four centuries, and nearly confined in marriages to their own race, by their peculiar way of life. In Transylvania, where there is a great number of them, and the race remains perfectly pure, their features can consequently be more accurately observed: in every country and climate, however, which they have inhabited, they preserve their distinctive character so perfectly that they are recognized at a glance, and cannot be confounded with the natives: see the description and figure of the cranium of a Transylvanian Gipsey, in Blumenbach, Decas Altera, p. 3. But, above all, the Jews exhibit the most striking instance of a peculiar national countenance, so strongly marked in almost every individual, that persons the least versed in phthognomical observations detect its influence, yet not easily understood or described. Religion has, in this case, most successfully exerted its power in preventing communication with other races; and this exclusion of intercourse with all others has preferred the Jewish countenance so completely in every foil and climate of the globe, that a miracle has been thought necessary to account for the appearance.

In what other way can we explain the difference between the Englith and Scotch? Would it be more reasonable to suppose that they descented from different rocks; or to ascribe the high cheek bones of the latter to soil or climate?

Alteration of Form by Breeding.—As, on the one hand, a particular form may be perpetuated by confining the intercourse of the sexes to individuals in whom it exists; so, again, it may be changed by introducing into the breed those remarkable for any other quality. Connections in marriage will generally be formed on the idea of human beauty in any country; an influence this, which will gradually approximate the countenance towards one common standard: If men, in the affair of marriage, were as much under management as some other animals, an abolished might as well accomplish, in his dominions, almost any idea of the human form. The great and noble have generally had it more in their power than others to select the beauty of nations in marriage; and thus, while, without system or design, they gratified merely their own taste, they have generally distinguished their order, as much by elegant proportions of person, and beautiful features, as by its prerogatives in society. “The fame superiority,” says Cook, “which is observable in the Eroes or nobles in all the other orbs, is found also here (Owbyhee.) Thoe, whom we saw, were, without exception, perfectly well formed; whereas, the lower sort, besides their general inferiority, are subject to all the variety of make and figure that is seen in the populace of other countries.” (Third Voyage, hook iii. chap. 6.) In no instance, perhaps, has the personal beauty of a people been more improved, by introducing handomne individuals to breed from, than in the Persians, of whom the nobility have, by this means, completely succeeded in walking out the blood of their Mongolian origin. “That the blood of the Perians,” says Chardin, “is naturally grofs, appears from the Guebres, who are a remnant of the ancient Perians, and are an ugly, ill-made, rough-hinned people. This is also apparent from the inhabitants of the provinces in the neighbourhood of India, who are nearly as clumsy and deformed as the Guebres, because they never formed alliances with any other tribes. But, in the other parts of the kingdom, the Persian blood is now highly refined by frequent intermixtures with the Georgians and Circassians, two nations which surprize all the world in personal beauty. There is hardly a man of rank in Persia, who is not born of a Georgian or Circassian mother; and even the king himself is commonly sprung, on the female side, from one or other of these countries: so it is long
MAN.

since this mixture commenced, the Perisan women have become very handsome and beautiful, though they do not rival the ladies of Georgia. The men are generally tall and erect: their complexion is ruddy and vigorous, and they have a graceful air, and an engaging deportment. The mildness of the climate, joined to their temperance in living, has a great influence in improving their personal beauty. This quality they inherit not from their fathers; for, without the mixture mentioned above, the men of rank in Persia, who are descendants of the Parthas, would be extremely ugly and deformed." Voyage en Perse, &c. tom. ii. p. 54.

The transmission of natural peculiarities, by generation, is remarkably illustrated by some instances of unusual formation: such is the family of the porcepine men, and of the fix-legged and six-toed pervers, both produced from individuals of the common form. (See, for the former, the article Monster, and for the latter, Generation.) There is no reason to doubt, that if the individuals, with these peculiarities, had been carefully matched together, that a permanent variety might have been established.

Let us suppose that the porcepine family had been exiled from human society, and obliged to take up their abode in some solitary spot, or desert island; by matching with each other a race would have been produced, more widely removed from us in external appearance than the negro. If they had been discovered at some remote period, our philosophers would have explained to us how the foil, air, or climate, had produced so strange an organization; or would have demonstrated that they must have sprung from an originally different race: for who would acknowledge such brilly beings for brothers?

We learn that the giants, collected with such pains by Frederic William I. for his regiment of guards, produced, in a town of Germany, where they were quartered, a very tall race of men: in the language of Dr. Johnfon, they " propagated progeny."

Corresponding Varieties in Animals.—There is none of the varieties above enumerated, which does not exist in a still greater degree in animals confessedly of the same species. What differences in the figure and proportion of parts in the various breeds of horses; in the Arabian, the Barb, and the German! How striking the contrast between the long-legged cattle of the Cape of Good Hope, and the short-legged of England! The same difference is observed in fowls. The cattle have no horns in some breeds of England and Ireland; in Sicily, on the contrary, they have very large ones. A breed of sheep, with an extraordinary number of horns, as three, four, or five, occur in some northern countries, and is accounted a mere variety (ovis polycera); the Cretan breed of the same animal, has long, large, and twisted horns. We may also point out the solidungular swine, with undivided hoof, as well as others, with three divisions of that part; the five-toed fowl (gallus penadrytis); the broad-tailed sheep of Tartary, Thibet, &c, in which the tail grows so large that it is placed on a board, supported by wheels, for the convenience of the animal; and the rumpless fowl (gallus eucaudatus), of America, and particularly Virginia, which has undoubtedly descended from the English breed. The common fowl, in different situations, runs into almost every conceivable variety. "E volucris albitibus varietatem nuncupat, inignis discrepantia certe eminent gallinae. Habentur magno, minuta, procer, pulmonibus, crififarium parvitate vel multiplicitate, ant thira plumaceis infignes, uropygio carentes, flavedpes, plumipes; habentur toto corpore reverteris pluminis hiefuta; immo in India naticatur varietas, plumis lanuginosis albis velrita, et cutre per totem corpus nigra. Et lux omnes, exceptis Indicis, innumerabur colorum diversitate Judaut." Pallas, Spicileg. Zooll. fac. 4.

The formation of new varieties by breeding from individuals, in which the desirable properties exist in the greatest degree, is much more difficult in our domestic animals, than in our own species, since the former are entirely in our power. The great object is to preserve the race pure; by selecting for propagation the animals most conspicuous for the size, colour, form, proportion, or any other property we may fix on, and excluding most carefully all others. In this way we may gain sheep valuable for their fleece, or for their carcase; large or small; with thick or thin legs; just such, in short, as we choose, within certain limits. (See Breeding and Cattle.) The importance of this principle is fully understood in rearing horses and cocks. The Arabian prefers the pedigree of his horse more carefully than his own, and never allows any ignoble blood to be mixed with that of his valued breed: he attests their unfilled nobility by formal depictions and numerous witnesses. (See Buffon on the Horse.) The English breeder knows equally well that he must vary his stallions and mares according as he wishes for a cart horse, a riding horse, or a racer; and that a mflake in this point would immediately frustrate his views. Blood is equally important in the cock; and the introduction of an inferior individual would inevitably deteriorate the properties of the offspring.

Species.—No part of our subject has been more disgraced by fables and hyperbolical exaggeration than the present division. Not to mention the pignies and giants of antiquity; the bones of different large animals, ascribed to human subjects of immoderate stature, even by such men as Buffon, sufficiently prove our assertion. The accuracy of modern investigation has, however, so completely exposed the extravagance of such suppositions, that we are relieved from the necessity of a detailed confutation. All the remains of antiquity, which afford us any inferences on the subject of stature, such as mummies, human bones, and particularly teeth taken from the oldest burial places and urns, armour, &c, in concur in proving that the ancients did not exceed the moderns in this respect. Yet amongst the latter there are obvious national differences. Of European nations some parts of Sweden and Switzerland are distinguished for tallness, as Lapland is in the contrary respect. The Abipons in the new world are of large size, and the Esquimaux of small; but neither are very remarkable: and there is no difference between any two modern nations, but what admits of easy explanation from the common causes of degeneration, and the analogous phenomena furnished by the natural history of other animals.

The Patagonians (so called from its being supposed that they were allied to a neighbouring people, the Chones, and from their resembling hair-yfooted animals, called in Spanish Patas, through their practice of wearing the rough skin of the guanaco) or, according to their own indigenous name, the Tchuels, which occupy the south-west part of the extremity of South America, seem to be the talllest of the human race; but their height has been much exaggerated. Pigafetta, who accompanied Magalhães on his voyage round the world, alleged that they were twice as tall as Europeans, (Viaggio attorno al Mondo, in the collection of Ramusio, vol. i.) From that time for two centuries and a half, the narratives of European voyages into that part of the world, are so strangely contradictory and inconsistent with each other, on the subject of these Patagonians, that they afford a lesson inculcating most strongly the necessity of caution.
caution and diffidence in employing such reports. Blumen-
bach cites ten authors in illustration of this point (De Varie-
tate, p. 255). It is sufficient, for our present purpose, to
represent what appears the most probable state of the cafe,
after weighing and critically considering the most unexcep-
tionable testimonies. They seem in truth to be a tall,
though not gigantic race, and to possess a remarkably mul-
cular frame. Thus at least they are represented by the most
respectable observers. The only Patagonians ever seen
in Europe, were brought to Spain towards the end of the 16th
century, and seen at Seville by the truly classical traveller Van
Limdonen, who says that they were "well formed and large
in the body," (vel gessetenu ende grau van Ieden.) The va-
riety in the instance makes it impossible to assign any
large height; but they probably do not exceed six feet six
inches English. Bougainville says that none were under five
feet six inches, and none over five feet eleven inches. (Paris
measure, of which the foot is to that of England as 144 to
135.) (Voy. autour du Monde, 4to. p. 112.) Commenon,
however, makes some of the highest six feet four inches
(French). Journal Encyclopédique, 1772.) Byron repre-
"\n"sent them as seven feet high; but he did not measure them:
(Hakeworth's Collelion, vol. i. p. 28.) Wallis, who mea-
ured them carefully, found the general stature to be six feet,
(1bid. p. 374.) and the statement of Carteret coincides with
this; Phil. Transact. vol. 1x. The stature we have alligned
of these people is not so very remarkable, since other native
tribes of the same family have been noticed for their
height: for example, the Caribs of Cumana, seen by Hum-
boldt. As they are a wandering race, we cannot be fur-
priised at finding that Europeans visiting the coasts have not
always been able to see them. The accounts of travellers
prove, that the height of the Patagonians is not a peculiar
circumstance. Bartram represents the Mufcogules and Chero-
kees of North America, inhabiting between 31° and 35° of North latitude, as taller than Europeans; many
being above five feet, and few under five feet eight or ten
inches. (Travels, p. 482.) The Cafrres, according to
Barrow, are "tall, robust, and muscular, and distinguished
by a peculiar firmness of carriage; some of them were six
feet ten inches, and so elegantly proportioned that they
would not have disgraced the pedesta of the Farnee Her-
cules. We may perhaps regard the Patagonians, like the
antient Germans, as a peculiar and genuine race, not modi-
fied or disturbed by intermixture with others. Large body
and limbs, as well as undaunted courage, were the attributes
of this people, according to Pomponius Mela; "immunes
animis & corporibus," lib. iii. cap. 3. Casar and Tactitus
corroboration this statement. By collecting and comparing
all the notices concerning them in the writers of antiquity,
we should be warranted in ascribing to them a height of fix
feet three inches and a half (French), which at least equals
the stature of the Telmees. The Laplanders and Nova
Zemblians in Europe, the Samoieds, Olleaces, Yukuts, and
Tunganaes in Asia, and the Granadinas and Equinockial
of America, all, in short who inhabit high northern lati-
dudes, are short in stature, measuring from four to five feet;
and they agree remarkably in other characters, although
occupying such distant countries. It seems rather doubtful
whether the miserable Pecheriaus, who wander naked over
the rocks of Terra del Fuego, are also diminutive; but
Barrow informs us that the Bofhmen who adjoin the Cape,
scarcely exceed four feet nine inches.

The nation of dwarfs in the interior of Madagascar,
called Quimos or Kimos, seems to be only an exaggeration
founded on the observation of a morbid individual. Com-
meron mentions that he measured one who was only three
Vol. XXI.
naneous monkey, which, with other exotic animals, was seen in the journey. (De Varie, p. 271, note p.) Thus, instead of having any race of men with tails authenticated by credible witnesses, there is no example even of a single family displaying such an anomaly, although there are many well-known instances of families with six fingers.

Monstrous Varieties.—These occur only in individual instances, and are probably to be regarded as pathological phenomena: their description is referred altogether to the article Monster.

Faculties of the Mind; and moral Feelings.—The different progress of various nations in general civilization, and in the culture of the arts and sciences, the different characters and degrees of excellence in their literary productions, their varied forms of government, and many other considerations, must convince us beyond the possibility of doubt that the races of mankind are no less characterized by diversity of mental endowments, than by those differences of organization, which we have already enumerated and considered. Such however has been the effect of education, of laws, of peculiar habits and customs, and of the different forms of government in modifying the mind and character of men, that we can hardly now discern what should be ascribed to original difference, and what should be referred to the operation of these external causes. That climate will exert a powerful influence on the mind may be very reasonably expected; and it has an analogous influence on the animal creation. We are informed, that the dog in Kambeshatka, instead of being faithful and attached to its master, is malignant, treacherous, and full of deceit. He does not bark in the hot parts of Africa nor in Greenland; and in the latter country loses his docility so as not to be fit for hunting.

Yet, without denying that there are differences both in the extent and kind of mental power, we are decidedly of opinion that these differences are not sufficient in any instance to warrant us in referring a particular race to an originally different species; and we protest especially against the sentiments of those, who would either entirely deny to the Africans the enjoyment of reason; or who ascribe to them such vicious, malignant, and treacherous propensities as would degrade them, even below the level of the brute. It can be proved most clearly, and the preceding observations will suffice for this purpose, that there is no circumstance of bodily structure so peculiar to the Negro, as not to be found also in other far distant nations; no character which does not run into those of other races, by the same ineflable gradations as those which connect together all the varieties of mankind. We cannot but admire the reasoning and humanity of those, who, after tearing the African from his native soil, carrying him to the West Indies, and doomed him there to perpetual labour, complain that his understanding shows no signs of improvement, and that his temper and disposition are incorrigibly perverse, faithless, and treacherous. Let us however observe him in a somewhat more favourable state than in those dreadful receptacles of human misery, the crowded decks of the slave-ship, or in the leery openly thieving, but constrained and extorted, and therefore painful, labours of the sugar plantation. That the negroes are much like Europeans, and behave to others according to the treatment which they receive, may be easily gathered from the best sources of information. They have not indeed reached that sublime height, the "beau ideal" of morality, the returning good for evil, probably because their masters have not yet found leisure enough from the pursuit of riches to infil into them the true spirit of Christianity. "The feelings of the Negroes are extremely acute. According to the manner in which they are treated, they are gay or melancholy, laborious or slothful, friends or enemies. When well fed, and not maltreated, they are contented, joyous, ready for every enjoyment; and the satisfaction of their mind is painted in their countenance. But, when oppressed and abused, they grow pensive, and often die of melancholy. Of benefits and abuse they are extremely sensible, and against those who injure them they bear a mortal hatred. On the other hand, when they contract an affection to a master, there is no office, however hazardous, which they will not boldly execute, to demonstrate their zeal and attachment. They are naturally affectionate, and have an ardent love for their children, friends, and countrymen. The little they possess they freely distribute among the necessitous, without any other motive than that of pure compassion for the indigent." Hilt. des Antilles, p. 483.

The travels of Barrow, le Vaillant and Mango Park, abound with anecdotes favourable to the moral character of the Africans, and proving that they betray no deficiency in the amiable qualities of the heart. One of these gives us an interesting portrait of the chief of a tribe: "His countenance was strongly marked with the habit of reflection; vigorous in his mental, and amiable in his personal qualities. Gaika was at once the friend and ruler of a happy people, who uniformly pronounced his name with transport, and blessed his abode as the seat of felicity." Many highly polished European kings would appear to little advantage by the side of this savage. We see no reason to doubt that the negroes, taken altogether, are not inferior to any variety of the human race in natural goodness of heart. It is consonant to our experience of mankind in general, that the latter quality should be sharpened or completely extinguished in the slave ship or the plantation; indeed it is as little creditable to the head as to the heart of their white tormentors to expect affection and fidelity from slaves after such treatment.

The acute and accurate Barbé, in his large work on Africa, says, "The blacks have sufficient sense and understanding, their conceptions are quick and accurate, and their memory possesses extraordinary strength. For, although they can neither read nor write, they never fall into confusion or error in the greatest hurry of business and traffic. Their experience of the knavery of Europeans has put them completely on their guard in transactions of exchange; they carefully examined all our goods, piece by piece, to ascertain if their quality and measure are correctly listed; and shew as much sagacity and carelessness in all these transactions, as any European merchant could do." Of these initative arts, in which perfection can be attained only in an improved state of society, it is natural to suppose that the Negroes can have but little knowledge; but the fabric and colours of the Guinea cloths are proofs of their native ingenuity; and, that they are capable of learning all kinds of the more delicate manual labours, is proved by the facts, that nine-tenths of the artificers in the West Indies are Negroes: many are expert carpenters, and some watch-makers.

The drawings and bulks executed by the wild Bushman in the neighbourhood of the Cape are praised by Barrow for their accuracy of outline, and correctness of proportion.

Inferences are by no means rare, of negroes, who have distinguished themselves in literature and the arts, when favoured by fortune with opportunities of education and improvement. In proof of their musical talents, it may be mentioned that they have been known to earn so much in America, as to purchase their freedom with large sums. The younger Freidig in Vienna was an excellent performer both on the violin and violincello; he was also acapital draftman, and had made a very successful painting of himself.

The
The capacity of the negroes for the mathematical and physical sciences, is proved by Hannibal, a colonel in the Russian artillery, and Liliot of the Isle of France, who was named a corresponding member of the French Academy of Sciences, on account of his excellent meteorological observations. Fuller of Maryland was an extraordinary example of quickness in reckoning. Being asked in a company, for the purpose of trying his powers, how many fconds a person had lived who was 70 years and some months old, he gave the answer in a minute and a half. On reckoning it up after him, a different result was obtained; have not you forgotten the leap years? says the negro. This omission was supplied, and the number then agreed with his answer.

Boerhaave and De Haen have given the strongest testimony that our black brethren possess no mean insight into practical medicine; and several have been known as very dextrous surgeons. A negro at Yerusalem is mentioned by Blumenbach as a celebrated midwife of real knowledge and a fine experienced hand.

Omitting Madocks a methodist preacher, and not attempting to enumerate all the negroes who have written poems, we may mention that Blumenbach poled off English, Dutch, and Latin, wrote their different Negroes. In 1734, A. W. Amo, an African, from the coast of Guinea, took the degree of doctor in philosophy at the university of Wittenberg. Two of his dissertations, according to Blumenbach, exhibit much well digested knowledge of the highest physiological works of the time. In an account of his life, published at the time, by the academic council, his integrity, talents, industry, and erudition, are very highly commended.

Jesu Eliza Jos. Capitoine, who was bought by a slave dealer, when eight years old, studied theology at Leyden, and published several sermons and poems; his "Differtatio de Servitute Libertati Christiana non contraria," went through four editions very quickly. He was ordained in Amsterdam, and went to Elmina on the Gold coast, where he was either murdered, or exchanged for the life and faith of his countryman whose he had learned in Europe.

Ignatius Sancho, and Gualterus Vafa, the former born in a slave ship on its passage from Guinea to the West Indies, and the latter in the kingdom of Benin, have distinguished themselves as literary characters in this country in modern times; their works and lives are so well known, and so easily accessible, that it is not necessary for us to mention them.

Blumenbach, from whose "Beyträge zur Naturgeschichte," the preceding inferences are taken, factually observes, that entire and large provinces of Europe might be named, in which it would be difficult to meet with such good writers, poets, philologists, and correspondents of the French academy; and, on the other hand, that there is no savage people, which have distinguished themselves by such examples of perfectibility and even capacity for scientific cultivation; and consequently that none can approach more nearly to the polished nations of the globe, than the negro, p. 118.

The opportunities of observation, that fall to the lot of any individual, are so limited, and the remarks of travellers and historians so likely, from various causes, to be perverted by ignorance or misrepresentation, that it must be very difficult to produce anything satisfactory on the subject of the general characters of the various races in intellect, disposition, &c. We prefert therefore to the reader the conclusions which are drawn by Meiners, from an immense collection of authorities.

Providence bestowed on the white and handomne races, not only considerable prerogatives of bodily structure, but also of mental power; connecting however neither of them with the finest climates. The ancients observed that the most fruitful countries weakened the powers of the mind and the manly virtues. The favourable influence of climate on the intellect cannot be denied, and it is equally true that the noblest natures would be unavoidably corrupted and degraded in certain situations. The most dangerous are certain spots on the coast of Africa, Egypt, Hindoostan, the southern Asiatic kingdoms, particularly Siam, China, and several islands, the West Indies, and various spots in South America. An almost incredible acuteness of the external senses, which seems a gift of nature, is found in the dark and ugly nations. Among savages, as well as among the civilized, remarkable examples occur of men, who are not moved by the most violent impellions, and yet cannot bear the mildest perfume. In the ugly nations, an almost entire insensibility to beauty of form, order, and harmony, is united to the greatest acuteness of the senses. It seems that their imagination has a peculiar turn, which does not exist in the handomne nations.

The whole division of the ugly and dark coloured people is far below the white and handomne ones in the faculties of the mind; yet there are considerable differences between the various races in both. In Asia the Burates are the most elevated; the Calkmuck and more docile; and some southern people, as those of Pegu, the Malays, Chineses, and Japanese are much more so. This want of talents affects also the lower castes of the Hindoos. The original inhabitants of America possess still less intellect than the Mongolian tribes of Asia; and this is an incontrovertible proof that climate may rob the human race of genius and virtue. The rapidity of the Americans was so striking, and so generally known, that there was some trouble to convince the Spaniards, that they were men, and capable of becoming christians; yet these very Americans display, in certain points, a capability of learning, by which they exceed the most ingenious Europeans. The negroes indeed come above the Americans; but they are nearer to them than to the Europeans. Of the white people, the Celtic race has been much more richly endowed by nature, than the Slavonic or Oriental.

The dark people are again distinguished from the fair by a deplorable absence of virtues, and by several frightful excels. With an irritability arising from weakness, and an incredible sensibility to the slightest affronts, the black nation combine an astonishing quickness of the pains and joys of others, even their nearest relations, inflexible cruelty, filthiness, and disposition to cheat, and a want of all sympathetic impulses and feelings. With more than female cowardice, and fear of open approaching danger and death, they join inconceivable callousness and indifference under the most horrible tortures, diseases, and actual death; with want of affection towards their own children, an extraordinary degree of tenderness to animals, even the most disgusting vermin; with brutal obfervency, voracity, and flamehfevers, either an immoderate attachment to sensual love, or the greatest coldness, and contemptuous contempt of the female. Excessive irritability is found in all the Finnic races of Asia and America. The Burates are the world of all these savages, and are considerably excelled by the Tungooses, the Calkmucks and Mongols, the Carkiacs, the Tchufichis, the Kirikles, and particularly the Japaneese. The Kamtchitians are more contemptible, but less cruel than the Laplanders. The Chinese are one of the most wonderful people in Asia, and are exceeded in integrity at least, if in no other respect, by the Tjoquinees, Siamese and Hindoos. The Malays, and most of the people who descend from them, are feared, not only by the Afiatics, but even by the Europeans. The souls of the blacks in New Guinea, New Holland,
Holland, &c. are not less ugly than their bodies; on the contrary, the disposition alone of the inhabitants of the Nicobar and Bally islands would prove that they are of more noble origin than their neighbours. The worthless extened corruption of human nature is nowhere more universal, or has been more accurately observed, than in the Americans, the portraits of whom, fill the friend of humanity, by turns, with pity, horror, and indignation. The dispositions of the negroes are as different as their descent; hence the contradictory descriptions of their manners. Even the savage dealers fix their prices, not merely according to the bodily powers, but in proportion to the docility and good dispositions of their commodity. The white negroes of Malabar origin are the Jagas, the Aznies, those of Dahomey, and the Gallas, which, as well as all their black brethren, bear a remarkable resemblance in disposition to the Americans.

"The white and handsome nations may degenerate and be reduced to a state of barbarism by physical and moral causes, as we learn from the examples of the Greeks and Romans, of the modern inhabitants of Caucasus and almost all the European colonies in the torrid zone. But they have disting"uishing prerogatives in their wilder state, as a comparison of the ancient Germans, Spaniards, Scandinavians, and Syrian, and of the modern Highland Scotch and other Celtic people, with the African and American savages, will most abundantly prove. The Celtic people alone have possessed the bravery, love of liberty, and other passions and virtues of great souls. They alone have been as generous and mild towards the weak and the vanquished, as terrible to their enemies; and have constantly treated conquered nations and the female sex very differently from the Mongolians. Moll of the virtues, which adorn and ennoble man, have existed from early times in a higher degree among the Celtic than among the Slavonic and Oriental people. The white people are neither so debauched, nor so cold, nor so much addicted to unnatural enjoyments as the dark coloured. On the other hand, the Slavonic and Oriental people, which have a much stronger attachment to sensual love than the Celts; and of the latter, the southerm are more sensual than the northern. Some savages indeed have conceived themselves superior to Europeans; but, in general, they have acknowledged the excellence of these more noble races, and this consideration is most plainly implied in the practice of offering their wives and daughters to better men, in the attachment and fidelity, with which the women of the ugly nations display towards the more powerful Europeans, in preference to the men of their own race." Minares, Grundrifs, p. 111. 128.

Causes of the Varieties of the Human Species.—The causes which operate on the bodies of living animals, either modify the individual, or alter the offspring. The former are of great importance in the history of animals, and produce very astonishing alterations in their nature; but the latter are the most powerful, affect the species, and create the diversities of race or breed.

Climate.—That climate will exert a very powerful influence on all organized bodies, and particularly on warm-blooded animals, must naturally be expected, when we consider how constantly and completely these animals are exposed to the action of the atmosphere in which they live; how wonderfully the composition of this air, formerly supposed to be a simple element, varies, not only in its gaseous ingredients, but also in the excitable ones of light, heat, electricity, &c.; and what a variety of other circumstances is to be taken into consideration, as the geographical position of different countries, their elevation, mountains, rivers, vicinity to the sea, prevailing winds, &c. Let it be further remembered, that the blood exposed to this air in the chest must be variously changed according to its composition and nature, and thus that the secretions, as well as the function of nutrition, of which the materials are derived from this fluid, must be greatly influenced.

Although this confederate and confluent operation of climate on the animal economy, and the habit and form of the body has been noticed by attentive observers in all ages, it is rather difficult to define precisely what ought to be attributed to this cause only, and what arises from the other sources of degeneration, or from their concourse. We shall state one or two changes, which seem to depend unequivocally on this cause.

The whitening (bleaching or etiolation) of vegetables, when the sun's rays are excluded, demonstrates the agency of those rays on vegetable colours. In the same way, men who are much exposed to the air acquire a deeper tint in their skin than those who are more covered; and the tanning of the skin by the summer fun in parts of the body exposed to it, as the face and hands, is a phenomenon completely analogous. The ruddy and tawny hues of those who live in the country, and the pale yellow countenance of the inhabitants of towns owe their origin to this cause. Men of the same race are lighter or darker coloured according to the climate which they inhabit; the Moors, in their native colour, are not darker than the Spaniards, French, nor mob of the English; but their acquired tint is so much deeper, that we distinguish them infallibly. How swarthy do the Europeans become, who seek their fortunes under the tropics and equator, and have their skins parched by the burning funs of "Afric and of either Ind." The white colour, in the northern regions, of many animals which possess other colours in more temperate climates, as the fox, the hare, bealls of burden, the falcon, crow, jack-daw, chaffinch, &c. seems to arise entirely from climate. This opinion is strengthened by the analogy of those animals, which change their colour, in the same country at the winter season, to white or grey, as the ermine and weasel, hare, squirrel, rein deer, white game (tetra lagonus), snow bunting (emeriza rutila), &c. Lithinus Flora Lapponica; edit. of Smith, p. 55. 552. The common bear is differently coloured in different countries.

That the coverings of animals, as well as their colour, are much influenced by climate, is evinced in many instances. The sheep in Africa has a coarse hair substituted in the lace of its wool; and the dog, loses its coat entirely, and has a smooth and felt skin. The wool of the sheep is thicker and longer in the winter, and in hilly northern situations, than in the summer, and on warm plains. Much benefit is derived from the cultivation of this animal, by changing its pastures according to the seasons of the year, and protecting it from the severity of the climate. The influence of various causes, which may be comprehended under the general term of cultivation, is very striking in the sheep and goat; the great difference in the wool produced from the former, under various circumstances, is well known; and a person, who was acquainted with the covering of the goat in European climates, would hardly believe it possible that the material from which the precious flocks of Cashmere are manufactured, could be produced from the same animal.

Whether the long and silky coat of the goat, cat, sheep, and rabbits of Angora can be ascribed to the climate, we do not know; it is at least worthy of notice that this quality of the hair should exist in so many animals. It continues in they are removed into other countries, and is transmitted to the offspring; so that we may probably regard these animals as permanent breeds.
Mull we not refer to climate the constant and remarkable degeneracy of the horse in France. "In France," according to Buffon, "Spanish or Barbary horses, when the breed is not crossed, become French horses, sometimes in the second generation, and always in the third." V. iv. p. 126.

Food.—We naturally expect that food will produce considerable changes in the living body; its effect seems to be proved by the well-known fact that several fiding birds, chiefly of the hawk and fitch kinds, become gradually black, if they are fed on hempen food. (Blumenbach, de Variet. p. 94.) The texture of the hair has been changed, in an African style brought into England, from the coarse nature of that of the camel, to considerable fineness and softness, by one year's feeding in the pastures of this country. The influence of the same cause on the stature and proportion of the body is shown in the horse, which grows to a large size in the marshy grounds of Friesland, while on flinty soils, or dry heaths, they remain dwarfish. Oxen become very large and fat in rich soils, but are distinguishted by shortness of the legs; while in drier situations, their whole bulk is less, and the limbs are stronger and more fleshy. We say nothing of the well-known differences of flavour and weight produced by different kinds of food.

Changes caused by Climate are temporary.—Two very different opinions have been maintained concerning these changes, produced by the action of external causes on the bodies of animals. Some, as Buffon, Blumenbach, Zimmermann, (Geographische gehehle der Menschen, &c.) contend that they are transmitted to the offspring, and thus cause varieties; others argue that the effect terminates in the individual; that the young animal is not in the flighted degree modified by it, but is born with the original properties, and constitution of the parents, and a susceptibility only of the same changes when exposed to the same causes. The latter opinion has been most ably defended in the inaugural dissertation of Dr. Prichard, Edinburgh, 1808, and seems to us to rest upon the most incontrovertible grounds.

The change in the colour of the human skin, from exposure to sun and air, is obviously temporary; for it is diminished and even removed when the causes no longer act. The discolouration, which we term tanning or being sun-burnt, as well as the spots called freckles, are most incidental to fair skins, and disappear when the parts are covered, or no longer exposed to the sun. The children of the husbandman or of the sailor, whose countenances bear the marks of other climes, are just as fair as those of the most delicate and pale inhabitant of a city; may, in fact, be observed, by living for ages under a burning sun, still have white children; and the offspring of Europeans in the Indies have the original tint of their progenitors. Blumenbach has been led into a mistake on this point by an English author (Hawkeworth, in Collection of Voyages, v. iii. p. 374), who affirms that Creoles are born with a different complexion and cast of countenance, from the children of the same parents brought forth in their native country. In opposition to this statement, from one who was not an eye-witness, we shall place the authority of Long, who, in his history of Jamaica, affirms "that the children born in England have not, in general, lovelier or more transparent skins, than the offspring of white parents in Jamaica." The "aurum sparsum vultum & color," which this acute and learned naturalist ascribes to the Creole, is merely the acquired effect of the climate, and not a character existing at birth.

"Nothing," says Dr. Prichard, "seems to hold true more universally, than that all acquired conditions of body, whether produced by art or accident, end with the life of the individual in whom they are produced. Many nations mould their bodies into unnatural forms: the Indians flatten their foreheads (See Cranium); the Chinese women reduce their feet to one-third of their natural dimensions; savages elongate their ears; many races cut away the prepuce. We constantly mutilate our domestic animals by removing the tail or ears, and our own species are often obliged by dixsex to submit to the losses of limbs. That no deformity or mutilation of this kind is hereditary, is so plainly proved by every thing around us, that we wonder how the contrary opinion should have gained any advocates. After the operation of circumcision has prevailed for more than three thousand years, the Jews are still born with prepuces, and still obliged to submit to the painful rite. Docked horses and cropped dogs bring forth young with entire ears and tails. But for this halterian law, what a frightful spectacle would every race of animals exhibit! The niceties of all preceding times would overwhelm us with their united weight, and the catalogue would be continually increasing, until the universe, instead of displaying a spectacle of beauty and pleasure, would be filled with maimed, imperfect, and monstrous shapes."

The changes produced in the coverings of animals by external causes, and those brought about by food, are equally confined to the present race. If a breed with different qualities be required, other individuals, possessing those qualities, must be employed.

Varieties of Animals are only produced by Generation.—That the foregoing causes are not adequate to account for these more signal diversities, which constitute differences of race in animals, will be readily admitted. These can be explained only by native or congenital variety, as we have shown in enumerating those points, in which men and animals differ. In the present state of physiological knowledge, we cannot attempt to shew how it happens that an offspring is produced, differing from the parents in some characters, which are conveyed by hereditary succession; how a grey rabbit or cat shall bring forth at one birth, and from one father, yellow, black, white, and spotted young; how a white sheep shall have a black lamb; or the same parents, Luceathropie and ordinary children at different times. In short, in considering all the circumstances under which animal bodies are influenced by external agents, we must be contented with stating the facts that prove the influence of such causes, without attempting to explain how they produce their effects. As there is so little of a factitious nature ascertained on this head, we should be afraid of disputing the probable causes of the observable results, by substituting speculation in the place of more solid information.

Influence of Mode of Life in producing Varieties.—The state of domestication, or the artificial mode of life, which they lead under the dominion of man, is the most powerful cause in favouring the production of varieties in the animal kingdom. Wild animals, using always the same kind of food, being exposed to the action of the climate without fire or artificial covering, change, each of them according to its nature, their zone, and country; instead of differencing themselves, like men, they continue in those places, which are the most true to their constitutions. Hence their nature undergoes no change; their figure, colour, size, proportion, &c. are unaltered; and there is consequently no difficulty in determining their species. But, says Buffon, when forced by man, or by any revolution on the globe, to abandon their native soil, their nature undergoes changes so great, that, to recognize them, recourse must be had to accurate examination, and even to experiment and analogy. If to these natural causes of alteration in free animals, we add that of the empire of man over those which he has reduced to slavery, we shall
shall be abolished at the degree to which tyranny can degrade and disfigure nature; we shall perceive the meads of slavery, and the prints of her chains; we shall find that those wounds are deeper and more incurable in proportion to their antiquity: and that, in the present condition of domestic animals, it is, perhaps, impossible to restore their primitive form, and those attributes of nature, which we have taken from them." Vol. iv. p. 6.

To trace back our domestic animals to their wild originals, is in all cases difficult, in some impossible; long slavery has so degraded their nature, that the primitive animal may be said to be lost, and a degenerated being, running into endless varieties, is subducted in its place. The wild original of the sheep was for a long time unknown: Buffon conceived that he discovered it in the mouffon or argali (ovis ammon); and Pallas, who had an opportunity of studying this animal, adds the weight of his highly respectable authority to the opinion of the French naturalist. Yet, Blumenbach regards the argali as a distinct species. Should we allow the latter to be the parent of our sheep, and consequently admit that the differences are explicable by degeneration, no difficulty can any longer exist about the unity of the human species. An incomplete horn of the argali, in the academical museum at Göttingen, weighs nine pounds. Blumenbach, handbuch der Naturgeschichte. p. 111, note.

"Let us compare," says Buffon, "our pitiful sheep with the mouffon, from which they derived their origin. The mouffon is a large animal. He is fleet as a flag, armed with horns and thick hoofs, covered with coarse hair, and dreads neither the inclemency of the sky, nor the voracity of the wolf. He not only escapes from his enemies by the swiftness of his course, and feeding, with truly wonderful heaps, the most frightful precipices; but he resists them by the strength of his body, and the solidity of the arms with which his head and feet are fortified. How different from our sheep, which subsist with difficulty in flocks, who are unable to defend themselves by their numbers, who cannot endure the cold of our winters without shelter, and who would all perish, if man withdrew his protection. So completely are the frame and capabilities of this animal degraded by his association with us, that it is no longer able to subsist in a wild state, if turned loose, as the goat, pig, and cattle are. In the warmest climates of Asia and Africa, the mouffon, who is the common parent of all the races of this species, appears to be less degenerated than in any other region. Though reduced to a domestic state, he has preserved his nature and his hair, but the size of his horns is diminished. Of all domestic sheep, those of Senegal and India are the largest, and their nature has suffered least degradation. The sheep of Barbary, Egypt, Arabia, Peru, Tartary, &c. have undergone greater changes. In relation to man, they are improved in some articles, and vitiated in others; but, with regard to nature, improvement, and degeneration are the same thing; for they both imply an alteration of original constitution. Their coarse hair is changed into fine wool. Their tail, loaded with a mass of fat, (and sometimes reaching the weight of 40 pounds,) has acquired a magnitude so incommodious, that the animals trample it with pain. While swollen with superfluous matter, and adorned with a beautiful fleece, their strength, agility, magnitude, and arms are diminished; these long-tailed sheep are half the size only of the mouffon. They can neither fly from danger, nor resist it. To preserve and multiply the species, they require the constant care and support of man. The degeneration of the original species is still greater in our climates. Of all the qualities of the mouffon, our ewes and rams have retained nothing but a small portion of viracity, which yield to the crook of the shepherd. Timidity, weakness, resignation, and stupidity, are the only melancholy remains of their degraded nature." Vol. iv. p. 7.

It will naturally be expected that degeneration has operated most deeply and variously on those domestic animals which man has subjected for many ages, and to completely, that they propagate in their enslaved condition; not on those, of whom each individual is brought into captivity from his wild state, as the elephant; nor on such as have not been taken into foreign climates, as the rein-deer, which is confined to a very limited portion of the globe. The pig is a good example, because his descent is more clearly made out than that of many others. The dog indeed degenerates before our eyes, but it will hardly ever, perhaps, be ascertained whether there is one or more species. The extent of degeneration can be observed in the domestic pig, because, we believe, no natural has hitherto been sceptical enough to doubt whether he defended from the wild boar, and he was certainly first introduced by the Spaniards into the New World. The pigs introduced, in 1569, from Spain to the West India island Barbadoes, were celebrated for the pearl fishery, degenerated into a monstrous race with toes half a span long. Herrera, hechos de los Castellanos en las Islas, &c. (vol. i. p. 239-.) Those of Cuba became more than twice as large as their European progenitors; Clavigero, flora antigua del Mefico. (vol. iv. p. 145-.) How remarkably again have the domestic swine degenerated from the wild ones in the old world; in the lofs of the soft downy hair from between the bristles, in the vast accumulation of fat under the skin, in the form of the cranium, in the figure and growth of the whole body. The varieties of the domestic animal too are very numerous: in Piedmont they are almost invariably black; in Bavaria reddish-brown, in Normandy white, &c. The breed in England with straight back and large pendulous belly is just the reverse of that in the North of France, with high convex spine, and hanging head; and both are different from the German breed; to lay nothing of the solid-ungular race found in herds in Hungary and Sweden, and already known by Arilloite, and many other varieties.

The 46. in its wild state, is remarkably swift and lively, and still continues so in his native countries in the East; the bison, or wild ox, has a long flowing mane, hanging almost to the ground.

The original flock of our poultry cannot be determined, nor can the varieties into which they have run be enumerated. No wild bird in our climates resembles the domestic cock: he pheasant, grouse, and wood-hen, are the only analogous kinds; and it is uncertain whether those would intermix, and have prolific progeny. They have constituted distinct and separate species from the earliest times; and they want the combs, spurs, and pendulous membranes of the gallinaceous tribes. Buffon, vol. xii. p. 112.

There are twenty-nine varieties of canary birds known by name, all produced from the grey bird. Buffon, vol. xiv. p. 61.

Most of the mammals, which have been tamed by man, betray their subjugated state by having the ears and tail pendulous; a condition of the former parts which, we believe, belongs to no wild animal. In many of the very functions of the body, as the secretions, generation, &c. are greatly changed. The domestic cow produces young twice a year; the wild animal only once; it frequently brings forth monstrous fetuses, and is invaded by a new species of hydatids, forming what is called the mules in pork.

A good hen, well supplied with food, lays 100 eggs between...
MAN.

tween spring and autumn; in the wild state they only produce eighteen or twenty. Buffon, vol. ii. p. 30.:

The application of these facts to the question concerning the human species is very obvious. If domesticated animals vary, because they have been taken from their primitive condition, and exposed to the operation of many, to them unnatural, causes; if the pig is remarkable among these for its varieties, because it has been the most exposed to causes of degeneration; we shall be at no loss to account for the diversities in man, who is, in the true, though not ordinary sense of the word, more of a domesticated animal than any other. We know the wild state of most of them; but we are ignorant of the natural wild condition to which man was defined. Probably there is no such state; because nature, having limited him in no respect, having fitted him for every kind of life, every climate, and every variety of food, has given him the whole earth for his abode, and both the organized kingdoms for his nourishment.

The numerous varieties of domestic animals, which are incontestibly the offspring of domestication, may be regarded as a refutation of the general position, which we lately laid down, that no acquired condition is transmitted by generation. These diversities are undoubtedly the strongest argument in favour of the changes produced by the way of life being hereditary; and we are not hitherto warranted in positively denying this. They admit of explanation, however, on another principle; viz. that the domestic state causes a disposition to the production of native varieties, which, as we well know, are hereditary. We know no direct observations, by which it can be decided that modifications of colour, form, &c. produced by external causes, are in no instance transmitted to the offspring, and that they are all first produced as native varieties in the course of generation. Analogy, however, very much favours this notion.

Such, then, are the causes by which the varieties of man may be accounted for. Although we have acknowledged our entire ignorance of the manner in which these operate, we have proved that they exist, and have shown, by copious analogies, that they are sufficient to explain the phenomena. The tendency, under certain circumstances, to alterations of the original colour, form, and other properties of the body, and the law of transmission to the offspring, are the sources of varieties in man and animals, and thereby modify the species: climate, food, way of life, in a word, all the physical and moral causes that surround us, act indeed powerfully on the individual, but do not change the offspring, except in the indirect manner alluded to in the preceding paragraph. We should, therefore, openly violate the rules of philosophizing, which direct us to assign the same causes for natural effects of the same kind, and not to admit more causes than are sufficient for explaining the phenomena, if we recur, for the purpose of explaining the varieties of man, to the perfectly gratuitous assumption of originally different species, or called to our aid the operation of climate, &c.

Yet, if it be allowed that all men are of the same species, it does not follow that they all descend from the same family. Some contend that all parts of the globe were furnished at first with men and animals, and lay great stress on the difficulty which the race would experience in extending over wide tracts, and gaining access to remote regions and islands. A reference to facts will shew us that these difficulties have been overcome. The numerous islands of the Pacific, in many instances very distant from each other, and from the continent, are inhabited by men of the same race; and we meet in Madagascar and Easter island, separated by nearly half the globe, with men of the same origin, employing the same language. This view is confirmed by the very interesting facts first noticed by Buffon, that no animals are found in both continents, but such as are able to bear the cold of those regions where they probably join; and that not a single animal of the torrid zone is common to the old world and the new.

Confutation of the Opinion, which explains the Varieties of Mankind by the Operation of Climate. Statement of the Argument.—By the most intelligent and learned writers on the varieties of mankind, they have been explained altogether by the operation of adventitious causes, as climate, particularly the light and heat of the sun, food, and way of life. It has been considered that these, acting on men originally alike, produce various bodily diversities, and affect the colour of the skin especially; and that such alteration, transmitted to the offspring, and gradually increased through a long course of ages, account very sufficiently for all the differences observed at present in the inhabitants of the different regions of the globe. If we were inclined to submit in this question to authority, the number and celebrity of the philosophers, who have contended for the influence of climate, and other physical and moral causes, would certainly compel us to refer to their opinions. Buffon, Blumenbach, Smith (Essay on the Causes of the Variety of Complexion and Figure in the human Species, Philadelphia), Zimmermann (Geographische Geschichtliche des Mensichen, &c.) Ludwig (Grundriss der Naturgeschichte der Menschigen-Species, &c.), are only a few of those who have adopted and defended this view of the subject.

Opinion of Buffon.—"The heat of the climate," says Buffon, "is the chief cause of the blackness among the human species. When this heat is excessive, as in Senegal and Guinea, the men are perfectly black; when it is a little less violent, the blackness is not so deep; when it becomes somewhat temperate, as in Barbary, Mongolia, Arabia, &c., mankind are only brown; and lastly, when it is altogether temperate, as in Europe and Asia, men are white. Some varieties, indeed, are produced by the mode of living. All the Tartars (Mongols), for example, are swarthy, while the Europeans, who live under the same latitude, and other physical and moral causes, would certainly compel us to refer to their opinions. Buffon, Blumenbach, Smith (Essay on the Causes of the Variety of Complexion and Figure in the human Species, Philadelphia), Zimmermann (Geographische Geschichtliche des Mensichen, &c.), are only a few of those who have adopted and defended this view of the subject.

Climate may be regarded as the chief cause of the different colours of men; but food, though it has less influence than colour, greatly affects the form of our bodies. Coarse, unwholesome, and ill-prepared food makes the human species degenerate. All those people, who live miserably, are ugly and ill made. Even in France, the country people are not so beautiful as those who live in towns; and I have often remarked, that in those villages, where the people are richer and better fed than in others, the men are likewise more handsome, and have better countenances. The air and the soil have great influence on the figures of men, beasts, and plants.

Upon the whole, every circumstance concurs in proving that mankind are not composed of species essentially different.
MAN.

different from each other; that, on the contrary, there was originally but one species, which, after multiplying and spreading over the whole surface of the earth, have undergone various changes by the influence of climate, food, mode of living, epidemic diseases, and mixture of different individuals; that, at first, these changes were not so conspicuous, and produced only individual varieties; that these varieties became afterwards more specific, because they were rendered more general, more strongly marked, and more permanent, by the continual action of the same causes; that they are transmitted from generation to generation, as deformities or defects put from parents to children; and that, lastly, as they were originally produced by a train of external and accidental causes, and have only been perpetuated by time, and the constant operation of these causes, it is probable that they will gradually disappear, or, at least, that they will differ from what they are at present, if the causes which produced them should cease, or if their operation should be varied by other circumstances and combinations." Natural History, by Woud, vol. iii. pp. 445-446.

Opinion of Smith.—"In tracing the globe," says Smith, "from the pole to the equator, we observe a gradation in the complexion, nearly in proportion to the latitude of the country. Immediately below the arctic circle, a high and fanglike colour prevails: from this you descend to the mixture of red and white: afterwards succede the brown, the olive, the tawny, and, at length, the black, as you proceed to the line. The same distance from the sun, however, does not, in every region, indicate the same temperature of climate. Some secondary causes must be taken into consideration, as correcting and limiting its influence. The elevation of the land, its vicinity to the sea, the nature of the soil, the state of cultivation, the course of winds, and many other circumstances, enter into this view. Elevated and mountainous countries are cool, in proportion to their altitude above the level of the sea, &c. &c." Elys, p. 8-10.

Opinion of Blumenbach.—Blumenbach informs us how climate operates in modifying the colour of the skin. but does not attempt to explain its effects on the stature, proportions, &c. He states that the proximate cause of the dark colour of the integuments is an abundance of carbene, secreted by the skin with hydrogen, precipitated and fixed in the reticulum by the contact of the atmospheric oxygen. (De Variet. p. 124.) He observes further, that this abundance of carbene is most noticeably perceptible in persons of an irritable disposition; which fact, together with many others, proves the intimate connection between the biliary and the cutaneous organs; that hot climates exert a very signal influence on the liver; and thus, that an unnatural state of the biliary secretion, generated by heat, and increased through many generations, causes the veins of the skin to secrete that abundance of carbene, which produces the black colour of the Negro. Ibid. p. 126-137.

Certain superficial Vices favourable to this Opinion.—It cannot be supposed that men of undoubted talents and learning would take up these opinions without any foundation at all; and accordingly we find that there is a slender mixture of truth in these statements: but it is so enveloped in a thick cloud of error, and so concealed by misrepresentation and exaggeration, that we do not recognize it without difficulty. The colour of Europeans nearly follows the geographical positions of countries; this part of the world is occupied almost entirely by a white race, of which the individuals are fairer in cold latitudes, and more swarthy or sun-burnt in warm ones: thus, the French may be darker than the English, the Spaniards than the French, and the Moors than the Spaniards. In the same way, where different parts of a country differ much in latitude and in temperature, the inhabitants may be browner in the south than in the north: thus, the women of Granada are said to be more swarthy than those of Biscay, and the southern than the northern Chinees, &c. These diversities are produced by the climate, as we have already explained. The effect goes off if the cause be removed: it terminates in the individual, and is never transmitted to the offspring, as we shall prove most incontrovertibly presently.

On a superficial view again, we observe that temperate Europe is occupied by a white race, and that the blacks, of whom we see and hear most, dwell chiefly under the burning sun and on the parched sands of Africa and Asia: the numerous whites who live in hot, and the greater number of dark coloured people who are found in cold countries, are not taken into the account in these imperfect and partial comparisons.

We are particularly surprised that the acuteness and good sense of Blumenbach should have allowed him to return to an explanation grounded on such remote analogies, and so obviously weak and inadequate, as that by which he attempts to account for the black colour of the Negro. To require us to believe that all the dark coloured races labour under hepatic disease, when some of the opinions inform us that they are in perfect health, is really too much; the statement is too absurd to require serious refutation.

Arguments against it.—We proceed to shew that climate does not cause the diversities of mankind; and in this consideration, our remarks are chiefly directed to the colour of the skin, as that is the part in which its operation has been regarded, by all the defenders of its influence, as the most unequivocal: the reasoning, however, will apply in general to the other points of difference, as well as to this.

The uniform colour of all parts of the body is a strong argument against those who ascribe the blackness of the Negro to the effect of the sun's rays. The glans penis, the cavity of the axilla, the inside of the thigh are as black as any other parts; indeed, the organs of generation, which are always covered, are among the blackest parts of the body. Neither is the peculiar colour of the Negro confined to the skin; a small circle of the conjunctiva, round the cornea, is blackish, and the rest of the membrane has a yellowish-brown tinge. The fat has a deep yellow colour, at least in many of them, which could be distinguished by a very superficial inspection, from that of an European. On these points the testimony of Soemmering coincides with our own observation. (Ueber die kropel. Verf. §§ 47 and 48.) The species of domestic fowls in the East Indies, with black plumage, affords a further proof that the operation of the sun's rays is not the cause of colour in animal bodies.

On the other hand, a black slate of the skin is sometimes partially produced in individuals of the white races. In the fairest women, towards the end of pregnancy, spots of a more or less deep black colour have been often observed; they gradually disappear after parturition. "The dark colour of the skin," says White, "in some particular parts of the body, is not confined to either the torrid or frigid zones: for in England the nipple, the areola round the nipple, the pudenda, and the verge of the anus, are of a dark brown, and sometimes as black as in the Samoed women. It is to be remarked that the colour of these parts grows darker in women at the full period of gestation. One morning I examined the breasts of twenty women in the lying-in hospital in Manchester, and found that nineteen of them had dark-coloured nipples; some of them might be fair to be black, and the areola round the nipple, from one inch to
two inches and a half in diameter, was of the same colour. (On the regular Gradation, p. 114. Camper, Kleineere Schriften, vol. i. part i. p. 47.) Le Cat mentions a woman near Paris, in whom the abdomen became black at each pregnancy, and afterwards recovered its colour; in another the same change occurred in the leg. See Blumenbach de Varlet, page 156, note 2.

If we take the trouble of examining the races in any particular division of the world, we shall quickly find that the opinion, which ascribes their distinguishing characters to climate, must be given up; that the same race inhabits the most different regions, prevailing in all an uniformity of character; that different races are found in the same countries, and that those, who have changed their native abodes for situations, in which, according to the hypothesis, they ought to have undergone a complete metamorphosis, still retain their original distinctions.

Arguments from the Races that occupy Europe.—In the north of Europe, as also in the north of Asia and America, that is, in countries nearest to the pole, in which, according to the opinion above stated, the whitest races ought to be found, we have very brown and black people: they are much darker coloured than any other Europeans. The Moors in Africa, and the Arabs of the desert are born with a white skin, and continue so fair while adventitious causes are applied. But the Laplanders and Greenlanders, who hardly ever feel a moderate heat from the rays of the sun, are all very dark. "The Laplanders," says Buffon, "the inhabitants of Nova Zembla, the Boradians, the Sameoids, the northern Tartars, the natives of the cold continent, and the Greenlanders and the savages of the north of the Eskimans in the new continent, appear to be all the same race, who have extended and multiplied along the coasts of the North sea, in deserts, and under climates which could not be inhabited by other nations. All these people have broad large faces, and flat noses. Their eyes are of a yellowish-brown colour, inclining to black; their eyelids extend towards the temples: their cheek-bones are very prominent; their mouths are large, and their lips thick and reflected; the under part of their face is narrow; they have a squeaking voice; the head is large, the hair black and smooth, and the skin is of a tawny or swarthly hue. Their size is diminutive, but, though meagre, their form is equal. Mott of them are only four feet high, and their tallest men exceed not four feet and a half." Vol. iii. p. 302.

It is curious to observe how easily the ascerters of the power of climate in changing the human body get over an obstacle so fatal to their opinions; they tell us roundly that great cold has the same effect as great heat: "When the cold becomes extreme, it produces effects similar to those of violent heat. The Sameoids, Laplanders and natives of Greenland are very tawny; we are even assured that some of the Greenlanders are as black as the Africans; thus the two extremes approach each other: great cold and great heat produce the same effect upon the skin, because each of these causes acts by a quality common to both; and this quality is the dryness of the air, which, perhaps is equally great in extreme cold and extreme heat. Both cold and heat dry the skin, and give it that tawny hue which we find among the Laplanders. Cold contracts all the productions of nature. The Laplanders, accordingly, who are perpetually exposed to all the rigours of frost, are the smallest of the human species." Buffon, vol. iii. p. 443. See also Smith's Essay.

If this reasoning should not convince us, there are other arguments in reserve. The state of society is said to have great effect on the conformation and colour of the body. The nakedness of the savage, the filthy gore and paint with which he spears his body, his smoky hut, scanty diet, want of cleanliness, and the undrained and uncleared country which he inhabits, not only, according to Smith, darken his skin, but render it impossible that it ever should be fair. (p. 48—52.) On the other hand, the conveniences of clothing and lodging—the plenty and healthful quality of food—a country drained, cultivated, and freed from noxious effluvia—improved ideas of beauty—the constant study of elegance, and the infinite arts for attaining it, even in personal figure and appearance, give cultivated an immense advantage over savage society in its attempts to counteract the influence of climate, and to beautify the human form. (p. 53.) What false notions must mankind have hitherto entertained on this subject! We can no longer believe travellers, who tell us that the finest forms, and the greatest strength are to be seen in savage tribes, and that no ill-formed individuals can be met with amongst them; and as little can we trust the testimony of our own senses, concerning the frequency of deformity and disease in civilized society; since there are so many reasons why the former should be deformed, black, and ugly, and the latter well proportioned, fair, and handsome. Unluckily, however, this fine-pan theory does not correspond with a few plain facts. Most of the modern European nations excelled in a more or less complete state of barbarism within times of which we have the most authentic records: some of these were seen and described by philosophers; yet the permanence of their character is so remarkable after a greater progressive civilization than has happened in any other influence, that these descriptions are applicable with the greatest exactness to the same races of the present day. Instead therefore of accounting for the dark colour, peculiar features, and stature of the Greenlander, Laplander, and Sameoid, from their smoke, their dirt, their food, or the coldness of the climate, we can have no hesitation in ascribing them to the same cause that makes the Briton and the German of this day resemble the portraits of their ancestors, drawn by Cæsar and Tacitus; viz. their descent from a race marked by the same character as distinguish themselves. These tribes owe their origin to the Mongols, and retain in the north those marks of their descent, which we find as strongly expressed in the Chineses, under the widely different latitudes of the fourth. At the same time, the parent tribes live in the middle of Asia, equally removed from the former and the latter.

With slight exceptions, says Dr. Prichard, the different countries of Europe are now occupied by the same nations that have occupied them since the date of our earliest authentic accounts. Conquests have been made by small numbers, so that the races have been little changed by this cause. Thus when Clovis and his 30,000 Franks reduced the large and populous province of Gaul under their dominion, the bodily characters, and the language of the conquerors were lost in those of the conquered. The nations which have inhabited Europe for the last 2,500 years, consist of three great races, distinguished from each other by their bodily formation, character, and language.

1. The Celtic race, with black hair and eyes, and a white skin verging to brown, occupies the west of Europe; to this belong the ancient and modern inhabitants of France, Spain, Portugal, and the greatest part of Italy: the ancient Britons, Welsh, Bretons, Irish, Scotch, and Manks. The resemblance of the Silures to the Iberi was noticed by Tacitus; it is obvious to every observer in the present time; nor is the observation peculiar to the Welsh; it holds good

Vol. XXII.
MAN.

of all other Celtic nations. "Silurum colorati vulsas, et torti plerumque crines, et poftis contra Hifpania, India, vetere traiicte, caque fedes occupàse, idem facent." That black hair and a broader complexions belonged to all the Celts, is not only proved by many direct observations, but also because the marks of the fanguine conftitution were universally confidered as the definition of the German race.

2. The great German race, characterized by its blue eyes, yellow or reddifh hair, fair and red skin, occupies the middle of Europe, and includes the Swedes, Norwegians, Icelanders, Danes, ancient and modern Germans, Saxons and English, Caledonians or Picts, and the Lowland Scotch, who have sprung from them, the inhabitants of the Low Countries, the Vandals and Goths, &c. Historical records, and the fimilarity of language and character both of body and mind, prove that all these people belong to the fame race.

3. The eft of Europe contains the Sarmatian and Slavonic tribes, characterized by dark hair and eyes, and a darker skin than the German, with perhaps larger limbs than the Celts. To this division belong the Ruffians, Poles, Croats, Slavons, Bohemians, Bulgarians, Cofacks, and others who speak the Slavonic language. (Diff. Inaug. de Variet. p. 102—109.) He proceeds to fhow from Diodorus Siculus, that the Sarmatians defcended from the Medes, and were found on the banks of the Tanais, 700 years before the Christian era: by the authority of Herodotus, that they occupied the country between the Tanais and the Boryfhenes, when Darius Hyftaspes invaded Syria; and from Cluverius, that the coasts of the Baltic, the banks of the Vifula, Prufia, and the country as far as the fition of the Finni and Venedi, were the ancient feats of the Sarmatians. Since then a people of very different race have refided in the neighbourhhood of the Germans from the moft remote times, how can we explain the differences of the European nations, by the operation of climate, by heat and cold? How does the fame sky caufe the whitefefs of the German and Swede, and the comparatively dark complexions of the Pole and Ruffian?

But thefe European races are found also in Asia and Africa. All that part of the former region which lies to the weft of the river Ob, the Cafpian fea, and the Ganges; all the north of Africa, Abyffinia, and perhaps other parts till farther fouth, on the eft, are occupied by a race agreeing nearly in character with the Sarmatians and Celts. Thus it appears, that, excepting the Germans, and the Laplanders and Samoiedes, whom we deem of Mongolian origin, the fame native or congenital conftitution prevails over the whole of Europe, the weftem parts of Asia, and the north of Africa. Black hair, dark eyes, and a white skin, tending rather to a brownfih tint, than to the peculiar whitefefs of the German tribes, belong to the French, Spaniards, Portuguese, Italians, and all the Celts; to the Ruffians, Poles, and others of Slavonic origin; to the Tatars, commonly confounded with the Mongols, the Circassians and Georgians, the Turks, Greeks, Arabians, Abyffinians, Syrians, Jews, and the inhabitants of Tri- poli, Tunis, Algiers and Morocco. That climate cannot be the caufe of the identity of character in nations fpread over fifty degrees of latitude, and that food, drefs, flate of civilization, peculiar customs, &c. are equally inefficacious in accounting for this famefefs, when we confider how numerous and diverfified the nations are in whom it occurs, will be allowed by every unprejudiced observer.

Aftrian Races.—Two races are to be found in Asia, on the eft of the Ob and the Cafpian. "The vast tracts of mountains that fretch from the Cafpian to the remotest borders of the eft, have been occupied from time immemorial by the Mongolian tribes, diflincf in their conformation from all other races, and more different from the Europeans than any negroes. Their skin varies from yellow-white to olive colour. Their hair is perfectly black from the time of birth. In ftature they are fhort; they have round heads, large cars, oblique eyes, flat nofes. To this nation the name of Tartars (Tatars) has been very improperly applied, as they have nothing in common with the true Tatars, who altogether refeemble the Europeans. All the eft of Asia, except a few fots occupied by Tartars and Oftiaks, the Tichurfis, probably derived from the aborigines of America, and the Indians, contains ferveral nations very clofely refeembling the Monguls, and arising in all probability from the fame root. Among thefe we enumerate the Calmucks and Buriates, a part of the Mongolian nation itfelf, the Samoiedes, the Tungufes, the Manchou, who border on the Clinefe, the Chinese themselves, the Jakuts, the Japanefe, and the Kamtchatchans. "Calmuce propris," says Pallas, "Mongoli, Buriates, Kirghufes, Soulores Orientales, Tungufi Daurz, et Sienfes feptentrionales fbi invicem fimiilliunt." (Voy. en Siberie.) "Les Samoyèdes de l'Obf refemblent beaucoup aux Tungufes. Ils ont le vifage plat, rond et large. Ils ont peu de barbe, et les cheveux noirs et rudes. "On trouve les reltes de cette nation dans la partie orientale de la Sibérie près de l'Enifi. Les Koibals, les Kamaches, les Abbotors, les Soiotics, les Karagafles ont la meme figure que les Samoiedes, et parlent tout leur langue." (Ibid.) "Les Kamtchadales et Munguals (Mongols) are fwarthy, have black hair, little beard, broad faces, nofe short and flat, eyes small and fink, the belly protuberant, and the legs small. The language of the Kamtchadales refeemles the Mungul Clinefe." Steller's Voyage to Kamtchatcha.

The Japanefe in general, particularly the common people of Nipon, are ugły, short, ftrong, thick-legged, tawny, with flatthif nofes and thick eye-lids, though the eye stands not fo deep in the feadhead as in the Clinefe. The noble families are more majeftic in shape and countenance, and more like Europeans." Kæmpfer.

"The Mantchee Tatars are fcarcely diftinguifhable from the Clinefe by external appearances: the Clinefe are somewhat faller, but their features almost exactly refeemle. The natural colour, both of Clinefe and Tatars, feems to be that tint between a fair and a dark complexon, which we diftinguish by the word brunet or brunette; and the shades of this complexon are deeper or lighter, according as they have been more or less exposed to the influence of climate. The women of the lower cafes, who labour in the fields, or who dwell in veftels, are almofi invariably cofae, ill-featured, and of a deep brown complexon, like that of the Hottentots. We found women in China, though very few, who might pafs for beauties even in Europe. A small black or dark brown eye, a short rounded nofe, generally a little flattened, lips considerably thinner than in Europeans, and black hair, are univerfal." (Barrow's China.) "Befides the general fimilarity of the tribes occupying fuch vaf and diftant regions, it is curious to obferve that the Samoiedes, Kamtchatchans, and others towards the north, have a much darker skin than the Calmucks, Mantchees, and Clinefe in warmer countries." Prichard's Disputatio, p. 93—99.

"India is inhabited by a mixed race, made up of the aborigines, and of others whom the purfuits of war and conquest have at various times brought there. The religion of Brahma feems to have been conveyed there from the north;
In the midst of all these intermixture of races, the character of the Indians of the continent, as far as we can judge from this distance, is that of a race of men, differing in many respects. One of these approaches, and in some instances equals, the blackness of the Negro; the hair is curled and woolly, the body flender, the stature short, the disposition barbarous and cruel. The other is more like the Indians of the continent, has a fairer skin, larger limbs and stature, better proportions, and exhibits some marks of humanity and civilization. According to Forster, the former, who are aborigines, have occupied the middle and mountainous parts of many islands, leaving the coasts and plains to the more recent colonists. They occupy the highest parts of the Moluccas, the Philippines, Formose, and Borneo; all New Guinea, New Britain, Hibernia and Caledonia, Tanna, Malicello, New Holland, and Van Diemen's land. The more recent nation occupies Su- matra, and the other islands of the Indian sea, Othoheit, and the Society islands, the Friendly islands, Marquesas, Ladrones, Maricau and Caroline islands, New Zealand, Sand- wich and Eaker islands. The language of all the latter resembles the Malay, and there can be no doubt that they arise from that race, and have spread by their ships over these distant spots. The black people are everywhere barbarous, and, according to Forster, have languages not agreeing with each other. In neither can we perceive any traces of the influence of climate. The latter race, scattered in various parts of the vast island of New Holland, which has such variety of temperature, every where retains its black colour, although the climate at the English settlement is not much like that of England; and in Van Diemen's land, extending to 45° S. lat. (it is well understood that the cold is much more severe in the southern hemisphere, at an equal distance from the equator, than in the northern) they are of a deep black, and have curled hair like the negroes.

We may make the same remarks concerning the Malay race. The Sumatrans under a vertical fun are the fairest people of the Indian islands: and Maridin relates, that they sometimes approach the whiteness of Europeans. The inhabitants of Othoheit are very fair; yellow hair is not unfrequently seen amongst them; while those of New Zealand, twice as distant from the equator, are much darker. (Ibid, S. 87-89.) It is sufficiently obvious that in Asia, where we have countries with every variety of situation and temperature, at every distance from the equator, with every diversity of elevation, hills, valleys, plains, islands and continents, we can trace no effect of climate on the colour, or on any other character of the human race.

African Races.—On the hypothesis, which assigns the varieties of mankind to the operation of climate as their cause, we should expect to find in Africa all tribes under the equator of the most intensively black colour; the tinge should become lighter and lighter as we proceed thence towards the south, and the complexion ought to be white when we arrive at regions which enjoy an European climate. This, however, is by no means the case. The Abyssinians, on the east, with dark olive colour and long hair, are placed near the equator, and surrounded by negroes. In the same part also, the Gallas, a great and barbarous nation, having, according to Bruce, long black hair, and white skin verging to brown, occupy extensive regions under the equator itself.

On the other hand, as we proceed from the equator towards the south, through tribes of negroes, we find the black co-

lour continued with diminished intensity. It is known in the West Indies, that the Congo negroes in the blackness of their skin and woolly hair equal any race of Africans. Pateron affirms us that the Cafrres, within a few degrees of the Cape of Good Hope, where the climate is so far from being intolerably hot, that the corn is often hurt by the winter frosts, are of the deepest colour; and the same fact is familiarly known of the surrounding tribes.

The island of Madagascar, which is crossed by the mild breezes of the Indian ocean, and owing, therefore, to contain a white race, has two kinds of natives: one of olive colour with dark hair; the other true negroes.

The Hottentots, at one or two degrees from the deep black Cafrres, are of a brownish-yellow colour: this distance can hardly account for the difference. The observations of Barrow on the countenance and form of this race, render it probable that they owe their origin in part to the Chinefs, which circumstance will enable us to explain their colour very easily. He says that the eye-lids are joined towards the nose, by a rounded sweep without any angle; that the limbs and joints are small both in the Hottentots and the Chinese: that the voice and mode of speaking are nearly the same in both; that a broad nose, flaring eyes depressed towards the nose, and other features, are common to both. The hair has a middle character between that of the Negro and Chinese; it is fuch, in short, as the intermixture of the two races may be expected to produce.

When we consider how large an extent of Africa is occupied by the black woolly-haired negroes, and that these regions vary in their latitude, their elevation, and every other point; that they include sandy deserts, coasts, rivers, hills, valleys, and very great varieties of climate, the conclusion that these adventitious circumstances do not influence the colour or other properties of the race is irresistible.

American Races.—It only remains for us to examine the continent of America, which, as it stretches uninterruptedly from the neighbourhood of the north pole to 55° S. lat. and includes regions diversified in every possible way, affords the most ample opportunity for the development of all the changes that such causes can produce; and to examine whether the facts ascertained concerning its inhabitants are more favourable to the hypothesis of climate than what we have observed in the other three divisions of the world.

The reports of travellers are unanimous concerning the identity of character in the whole American race: copper-coloured skin, long and straight black hair, and a certain cast of features, are said to belong to all the inhabitants of this extensive continent. How remarkable this agreement is may be collected from the statements sometimes made, that a person who has seen one may consider that he has seen all; which, however, in its full extent, must be conceived as an exaggerated or partial view. The Esquimaux are not included in this account: their colour is more of the olive cast; in which, as well as in other points, they betray their Asiatic origin.

Herrara, Ulloa, and others who have visited the American continent, affirm, that all the native tribes, both of the northern and southern divisions, are of the same colour. We may cite the testimonies of Steedman, Hearm and Mackenzie, Wallis and Cook, who ascribe the copper colour respectively to the natives near Surinam, those in the regions farthest north, and to the Patagonians and inhabitants of Terra del Fuego. Humboldt, whose extensive opportunities of observation and philosophic spirit give great weight to his statements, confirms this representation in the most ample manner.

The Indians of New Spain bear a general resemblance...
Man.

They have the same swarthy and copper colour, flat and smooth hair, small beard, flat nose, long eye, with the corners directed upwards towards the temples, prominent cheek-bones, and expression of intelligence in the eyes. They are strongly contrasted with a gloomy and severe look. The American race, after the Hyperborean race, is the least numerous; but it occupies the greatest space in the globe. Over a million and a half of square leagues, from the Terra del Fuego island to the river St. Lawrence and Beering’s strait, we are struck at the first glance with the general resemblance in the features of the inhabitants. We think we perceive that they all descend from the same stock, notwithstanding the enormous diversity of language that separates them from each other. However, when we reflect more seriously on this family likeness, after living longer among the indigenous Americans, we discover that celebrated travellers, who could only observe a few individuals on the coasts, have singularly exaggerated the analogy of form among the Americans. The uniformity of the red complexions, and dark, coarse, and glossy hair, conceals for a long time the diversity of individual features.

The Indians of New Spain have a more swarthy complexion than the inhabitants of the warmest climates of South America. This fact is so much the more remarkable, as in the race of Caucasus, which may also be called the European Arab race, the people of the south have not so fair a skin as those of the north. Though many of the Asiatic nations, who invaded Europe in the sixth century, had a very dark complexion, it appears that the shades of colour observable among the white race, are less owing to their origin or mixture than to the local influence of the climate. This influence appears to have almost no effect on the Americans and Negroes. These races, in which there is abundant deposition of carburated hydrogen in the corpus mucosum or reticulum of Malpighi, reflect in a singular manner the impressions of the ambient air. The Negroes of the mountains of Upper Guinea are not less black than those who live on the coast. There are, no doubt, tribes of a colour by no means deep among the Indians of the new continent, whose complexion approaches to that of the Arabs or Moors. We found the people of the Rio Negro swarthy to those of the lower Orinoco, and yet the banks of the first of these rivers enjoy a much cooler climate than the more northern regions. In the forests of Guinea, especially near the sources of the Orinoco, are several tribes of a whitish complexion, the Gunacca, Gumbaros, and Argues, of whom several robust individuals, exhibiting no symptom of the albinoidal malady which characterizes Albinos, have the appearance of true Melizos. Yet these tribes have never mingled with Europeans, and are surrounded by other tribes of a dark brown hue. The Indians in the torrid zone, who inhabit the most elevated plains of the Cordillera of the Andes, and those who, under the 45° of S. lat. live by fishing among the islands of the Archipelago of Chocos, have as coppery a complexion as those who under a burning climate cultivate bananas in the narrowest and deepest valleys of the equinoctial region. We must add, that the Indians of the mountains are clothed, and were so long before the conquest, while the aborigines, who wander over the plains, go quite naked, and are consequently always exposed to the perpendicular rays of the sun. I could never observe that in the same individual these parts of the body which were covered were less dark than those in contact with a warm and humid air. We very nearly perceive that the colour of the American depends very little on the local position in which we see him." Political Essay on the Kingdom of New Spain, vol. i. p. 140—145.

How does it happen, that the same race, which makes the African black, tinges the American of a copper colour? and that the dark hue, which might possibly be produced by heat in the equatorial regions, should be found also in the cold and inhospitable tracts of Terra del Fuego, and the most northern part of the continent? The absence of white races can surely not be ascribed to the want of sufficiently cold climates. Bougainville found the thermometer, in the middle of summer, 54° 1/2 in lat. 62°; and Meffrs. Banks and Solander, and their attendants, had nearly perished all together from the cold, in an excursion in Terra del Fuego, in the middle of the summer. Two of the servants were actually loll.

Differences in the same regions.—A very curious survey of the globe will show us that the same regions have been occupied by men of different races, without any interchange of characters, in many instances, for several centuries. The Moors and Negroes are found together in Africa; Europeans, Negroes, and Americans in North and South America; Celts, Germans, and Slavons in Europe, and even in the same kingdoms of Europe, &c. &c. The distinctions of these different races, except where they have been confused by intermarriages, is just as easy now as it has been in any time, of which we have authentic records.

The establishments of the Europeans in Asia and America have now subsisted about three centuries. Vasquez de Gama landed at Calicut in 1498; and the Portuguese empire in India was founded in the beginning of the following century. Brazil was discovered and taken possession of by the same nation, under Alvaræs Cabral in 1500. Towards the end of the fifteenth, and the beginning of the sixteenth century, Columbus, Cortez, and Pizarro furbeggested for the Spaniards the West Indian islands, with the empires of Mexico and Peru. Sir Walter Raleigh planted an English colony in Virginia in 1584; and the French settlement of Canada has a rather later date. The colonists have, in no instance, approached to the natives of these countries; and their descendants, who have been kept pure, have, at this time, the same characters as the native Europeans. In the hotter situations indeed, as in the warmer countries of Europe, the skin is swarthy; but the children, at the time of birth, and women who are never exposed much to the sun's rays, have all their native whiteness. This observation admits of no exception: in the tint of the skin, the colour and other qualities of the hair, the features, the form of the cranium, the proportions and figure of the body, the European colonists retain all their original characters. The tawny complexion, with its blue eyes, yellow hair, and fair skin, which is so remarkably different from that of the natives, is nevertheless transmitted without the least alteration from generation to generation.

Negroes have been introduced into the new world for nearly an equal length of time: in the West Indian islands, in the United States, in the various parts of Spanish America, they live under new climates, and have adopted
new habits. Yet they have still woolly hair, black skins, flat noses, thick lips, and all the other characters of their race.

The Vandals passed from Spain into Africa about the middle of the fifth century; their descendants may be still traced, according to Shaw, in the mountains of Atlas, by their white and ruddy complexion, and yellow hair. The change, produced by climate, must be infinitely small, since it is not yet perceptible after a lapse of thirteen centuries.

The inhabitants of Persia, of Turkey, of Arabia, of Egypt, and of all Barbary, may be regarded as the same race of people, who, in the time of Mahomet and his successors, extended their dominions by invading immense territories. In all these situations the skin retains its native fairness, unless the tint be changed by exposure to the sun: and the children are invariably fair. "Il n'y a femme de laboureuse ou de payfan en Asie (A/s Minor) qui n'a le teint frais comme une rose, la peau délicate et blanche. fi pâle et si tendre, qu'il semble toucher du velours." (Obst. de Pierre Volon, p. 199.) The Arabians are fecundated by the heat of the sun, for most of them are either covered with a tattered shirt, or go entirely naked. Le Boullaye informs us, that the Arabian women of the desert are born fair, but that their Complexions are spoiled by being continually exposed to the sun. (Voyages de la Boullaye le Gouz, p. 318.) Another traveller remarks that the Arabian princesses and ladies, whom he was permitted to see, were extremely handsome, beautiful, and fair, because they are always covered from the rays of the sun; but that the common women are very much blackened by the sun. Voyage fait par Ordre du Roi dans la Paléistine, p. 260.

The Moors, who have lived in Africa since the seventh century, have not degenerated in their physical constitution from their Arabian progenitors: the sun exerts its full influence on their skin, but their children are just as white as those born in Europe. They are by no means confined to the northern coast, but have penetrated, as the prevalence of the Mahometan religion attests, deeply into the interior: here they dwell in countries, of which the woolly Negro is the native, but have not acquired, in six centuries of exposure to the same causes, any of his characters. The intelligent and accurate Shaw informs us that most of the Moorish women would be reckoned handsomc even in Europe; that the skin of their children is exceedingly fair and delicate, and though the boys, by being exposed to the sun, soon grow swarthy, yet the girls, who keep more within doors, preserve their beauty till the age of thirty, when they commonly give over childbearing. "Les Maures," says Pocet, "ne font pas naturellement noirs, malgré le poivre, et comme le penfent plusieurs écrivains; mais ils naissent blancs, et resteront blancs toute leur vie, quand leurs travaux ne les exposent pas aux ardeurs du soleil. Dans les villes les femmes ont une blancheur fi éclatante, qu'elle eclipsent la plupart de nos Européennes; mais les Maures montagnards, fans cellce bruées par le soleil et prêts toujours à monter nues, deviennent, même des Penfanes, d'une couleur brune qui approche beaucoup de celle de la fum. (Voy. en Barbare, tom. i. p. 31.)” The testimony of Bruce is to the same effect.

That the swarthsines of the Southern Europeans is merely the effect of the sun's action on the individual, whose children are born perfectly white, and continue so unless exposed to the operation of the climate, might be easily proved of the Spaniards and Portuguese, the Greeks, Turks, &c. but the fact is too well known to render this necessary.

The Jews exhibit one of the most striking instances of peculiar national formation, unaltered by the most various changes. They have been scattered, for ages, over the face of the whole earth; but their peculiar religious opinions and practices have kept the race uncommonly pure; accordingly their colour and their characteristic features are still the same under every diversity of climate and situation.

We consider it as sufficiently proved that native differences in general, and particularly that of colour, do not depend on extraneous causes: we have an observation or two to make on some other points. That the curled hair of the African is not produced by heat appears from its being found, in many situations, not remarkable for high temperature, as the Moluccas, New Guinea, Mallicollo, Borneo, New Holland, and even in the cold region of Van Diemen's land; as well as from the hot regions of Asia and America being inhabited by a long-haired race. The differences in stature, again, have been very confidently ascribed to adventitious causes. Temperate climate, pure air, copious food, &c. have been thought favourable to the full development of the human frame; while extreme cold, bad and unwholesome food, noxious air, and similar causes, have been thought capable of reducing the dimensions of the body below the ordinary standard. That these causes may have some effect on individuals we do not deny, although we believe that it is very slight; but the numerous examples of large people in cold countries, and diminutive men in warm climates, induce us to deny altogether its operation on the race. The tall and large-limbed Patagonians, the Tichuchtis, and the North Americans inhabit cold situations; the Mongols, who are small in stature, live in warm countries.

The foregoing facts and arguments warrant us, as we conceive, in drawing (with Dr. Prichard, Diff. p. 119.), the following conclusions.

1. That climate, manners, and other physical and moral causes, have some power in modifying the natural constitution of man, as well as of animals.

2. That the influence of such causes is confined to one generation; and that no alteration produced in this way, or brought about by art or chance, is transmitted to the offspring.

3. That all the diversities of mankind are examples of a propensity to the formation of natural varieties, common to all animals under certain circumstances, follow the same laws, and are to be ascribed to the same cause.

4. Therefore, that the hypothesis of different species having been originally formed, is unnecessary for the explanation of the phenomenon.

**Divisions of Mankind. Arrangement of Man as an Object of Natural History.**

**Varieties.** As we have shown, on the other hand, that there is no circumstance of difference between the varieties of the human race, which does not appear in a full greater degree among animals chiefly of the domesticated kinds, arising from the ordinary sources of degeneration: so there is no point, whether of colour, countenance, or stature, which does not pass by imperceptible gradations into the opposite character, rendering all these distinctions merely relative, and reducing them to differences in degree. Hence it is obvious, that any division of the varieties of the human race must be in a great measure arbitrary.

The single species then, which the genus Homo contains, is divided by Blumenbach into the five following varieties:
M A N.

1. Caucasian Variety.—White skin, inclining to brown, red cheeks, hair black, and of the various lighter colours, head of a somewhat globular form; oval and straight face, with features moderately separate from each other, expanded forehead, narrow and rather aquiline nose, and small mouth; front teeth of both jaws perpendicular; lips, particularly the lower, gently turned out; chin full and rounded. In short, that kind of countenance which accords with our notions of beauty.

It includes all the Europeans, except the Laplanders and the race of the Finn; the Wettens Alaities, as far as the river Ob, the Caspian sea, and the Ganges; that is, the proper Tartars, the Georgians, Circassians, Mingrelians, &c. the Persians, Arabsians, Syrians, the Turks; the Northern Africans, as the people of the Barbary states; the Egyptians and Abyssinians.

The name of this variety is derived from Mount Caucas, because in its neighbourhood, and particularly towards the south, we meet with the most beautiful race of men in the world, viz. the Georgians. From the accounts of numerous travellers, who all agree on this subject, we select the remark of Chardin: "The blood of Georgia is the finest in the east, and I may say in the world. I have not observed a single ugly countenance in that country in either sex; but have seen numerous angelic ones. Nature has bestowed on the women graces and charms, which we fee in no other place. It is impossible to look at them without loving them. More beautiful countenances, and finer figures, than those of the Georgian women, cannot even be imagined." Voyage en Perse, t. i. p. 171.

Many reasons induce us to believe, that the primitive form of the human race, was that which we have described as belonging to the Caucasian variety; and of which the Georgians, Turks, Greeks, and some Europeans, exhibit now the finest specimen. This race has the most beautifully formed cranium, (see Cranium, and Anatomy of the Cranium, Pl. 1. fig. 1.) from which, as from a middle and primitive configuration, the other forms descend by a most easy and simple gradation, on the one hand to the Mongolian, and on the other to the Ethiopian variety. The proportions of the body in general are the most beautiful in this race, and their minds are the most acute, so that nearly all the arts and sciences have been discovered by them. They occupy the middle regions of the globe, while the extreme

2. Mongolian Variety.— Olive colour; black, straight, long, and thin hair, scarcely ever curled; head of a square form; broad and flattened face, with the features running together; the glabella (interval between the eye-brows) flat and very broad; nose flat and small; round cheek projecting externally; narrow and linear aperture of the eyelids; eyes placed very obliquely; flight projection of the chin; large ears, thick lips. The stature, particularly in the countries near the north pole, is below that of the Europeans.

This includes the race of the Alaities (excepting the Malays); the Finnish races of the colder parts of Europe, as the Laplanders, &c.; and the tribes of Esquimaux, extending over the northern parts of America, from Beering's Strait to the extremity of Greenland.

The Mongolians, widely scattered over the continent of Asia, have generally, but erroneously, been included with some of very different origin and formation, under the name of Tartars; whereas the last-mentioned tribes, properly so called, belong to the first division of the human race. The Cimants, and other Mongolian nations, which overran the Saracen empire, under Zenghis Khan, about the middle of the thirteenth century, and had entered Europe, are described in the "Histoire Major" of Matthew Paris under the name of Tartars, whereas that name (or, as it should be, the Tartars) properly belongs to the western Alaities, whom we have been accustomed to the Mongols. The error, however, arising from this source, has been propagated down to the present day, so that in the works of the most approved naturalists, as Buffon and Erxleben, we find the characters of the Mongolian race ascribed to what they call the Tartars.

The Tartars indeed are connected by the Kirgizes, and neighbouring tribes, to the Mongols, in the same way as the latter are joined by the inhabitants of Thibet to the Indians; by the Esquimaux, to the Americans; and by the Philippine islands, with the Malays.

3. Ethiopian Variety.— Black skin and eyes; black and woolly hair; head narrow, and compressed laterally; arched forehead; cheek-bones ranging forwards; prominent eyes; thick

mities are filled by others. The most ancient, and most early civilized nations have belonged to this variety. To this form also, according to the observation of Blumenbach, there is a disposition to return in the other races; as may be observed in the South sea islands, and some parts of Africa; while this does not easily deviate into the dark coloured varieties.

If we admit the Caucasian to have been the primitive form of man, are we to suppose, that the eyes were blue, and the hair yellow or red, or that both were black? we can have little hesitation in adopting the latter opinion, since that formation belongs to all of this race except the Germans, which have occupied only the more distant regions. It forms, too, the middle colour of the human race, and appears often in scattered instances among the other varieties. Moreover, yellow or tawny breeds occur among animals, as in the rabbit and cat, by degeneration from the native colour.

In this Caucasian variety, Blumenbach and most others include the German race; but Dr. Pichard affirms it to have separate place under the name of "consititu Germanica aut faginaea." The form and proportions of the cranium, face, body and color in general, are the same as in the preceding; the features perhaps are rather less acute, and more rounded, and the eyes smaller. The whole stature and the limbs are rather larger. But the most prominent distinctions are in the very white skin, approaching to redness; in the yellow or red hair, and the blue eyes.

4. American Variety.— Black skin, straight, long, and thin hair, scarcely ever curled; head of a square form; broad and flattened face, with the features running together; the glabella (interval between the eye-brows) flat and very broad; nose flat and small; round cheek projecting externally; narrow and linear aperture of the eyelids; eyes placed very obliquely; flight projection of the chin; large ears, thick lips. The stature, particularly in the countries near the north pole, is below that of the Europeans.

This includes the race of the Esquimaux (excepting the Malays); the Finnish races of the colder parts of Europe, as the Laplanders, &c.; and the tribes of Esquimaux, extending over the northern parts of America, from Beering's Strait to the extremity of Greenland.

The Mongolians, widely scattered over the continent of Asia, have generally, but erroneously, been included with some of very different origin and formation, under the name of Tartars; whereas the last-mentioned tribes, properly so called, belong to the first division of the human race. The Cimants, and other Mongolian nations, which overran the Saracen empire, under Zenghis Khan, about the middle of the thirteenth century, and had entered Europe, are described in the "Histoire Major" of Matthew Paris under the name of Tartars, whereas that name (or, as it should be, the Tartars) properly belongs to the western Alaities, whom we have been accustomed to the Mongols. The error, however, arising from this source, has been propagated down to the present day, so that in the works of the most approved naturalists, as Buffon and Erxleben, we find the characters of the Mongolian race ascribed to what they call the Tartars.

The Tartars indeed are connected by the Kirgizes, and neighbouring tribes, to the Mongols, in the same way as the latter are joined by the inhabitants of Thibet to the Indians; by the Esquimaux, to the Americans; and by the Philippine islands, with the Malays.

5. Malay Variety.— Black skin and eyes; black and woolly hair; head narrow, and compressed laterally; arched forehead; cheek-bones ranging forwards; prominent eyes; thick
thick nose, confounded with the extended jaw; alveolar arch narrow, and elongated anteriorly; the upper front teeth projecting obliquely; the lips, and particularly the upper one, thick; the chin receding; knees turned in in many inferences. The remaining Africans, besides those classed in the first variety, belong to this.

The striking peculiarities of this variety, and particularly the very great difference between its colour and our own, have led many persons to adopt the opinion of Voltaire, who had not a sufficient knowledge of phytology and natural history to determine the question, that the Africans belong to a distinct species. We have shewn, in the preceding divisions of this article, that there is no one character so peculiar and common to the Africans, but that it is found frequently in the other varieties, and that negroes often want it; also, that the characters of this variety run by insensible gradations into those of the neighbouring races, as will be immediately perceived by comparing together different tribes of this race, as the Fonlahs, Wulufs, and Mandingoes, and carefully noting bow in these gradations they approach to the Moors, New Hollanders, &c.

Again, great stress has been laid on the fact, that the negroes resemble more nearly than the Europeans, the monkey tribe; the fear of being drawn into the family, even as distant relatives, has we believe induced many to place our black brethren in a distinct species; while others have brought forwards this approximation to the family, with the view of degrading the African below the standard of the human species, and thereby palliating the cruel hardships under which he groans in the islands and continent of the new world.

It is undoubtedly true, that in many of the points, wherein the Ethiopian differs from the Caucasian variety, it comes nearer to the monkeys; viz. in the greater size of the bones of the face, compared to those of the cranium; in the protuberance of the alveoli and teeth, reception of the chin, form of the opra na, position of the foramen magnum occipitale, outline of the union of the head and trunk, relative length of the humerus and ulna, &c. This resemblance is most unequivocally admitted by Soemmerring; über die körper. verficht, pref. p. 19, and $ 69. It appears to us, that this fact is not very important; if there are varieties of bodily formation among mankind, some one of these must approach nearer to the organization of the monkey than the others; but does this prove, that the variety in which the conformity occurs, is less man than the others? The solidingular variety of the common pig is more like the hâve than other swine; do we hence infer, that the nature of this animal in general is less porcine, or more like that of the hâve, than that of other pigs? The points in which the Negro differs from the European, are trivial and few, and do not touch upon those important characters which separate man in general from the animal world; the erect attitude, the two hands, the flow development of the body, the use of reafon, and consequently perfectibility, are attributes common to both.

That very little importance can be attached to the general observation of the resemblance of the negro and monkey, founded on external appearance, may be clearly inferred from this fact, that the same remark has been made, even by intelligent travelers, of particular people in the other varieties. Regnard concludes his description of the Laplanders with these words: voila la description de ce petit animal qu'on appelle Lapon, et l'on peut dire qu'il n'y en a point, aprés le finge, qui approche plus de l'homme. (Œuvres, t. i. p. 71.) An Esquimaux, who was brought to London by Cartwright, when he fir faw a monkey, asked "Is that an Esquimaux?" His companion adds, "I must confefs, that both the colour and contour of the countenance had considerable resemblance to the people of their nation." Nie. de Techo calls the Caiguas of South America, "tam similis similes, quam hominibus," Relat. de Caafir. gente, p. 31; and J. R. Forster, in the observations on his journey round the world, afferts "that the inhabitants of the island Malicello, of all the people whom I have seen, have the nearest relationship to the monkeys." 4 American Variety.—Red colour; black, straight, strong, and thin hair; short forehead; deep eyes; nose somewhat flattened, but prominent; a broad, but not flattened face, with the cheeks flanding out, and the different features projecting distinct and separately; the forehead and vertex often deformed by art. This variety includes all the Americans, with the exception of the Esquimaux.

Several idle tales have been propagated, concerning the disfiguring characters of this race. Some have denied the existence of a beard in the male, and that of the mental discharge in the female; and others have ascribed an uniform colour and countenance to all the inhabitants of this vast continent. The concurring testimonies of all accurate modern travellers, prove clearly that the Americans have naturally beards; and that the report of their deficiency has arisen from their practice of eradicating it. See the general observations in this article on the beard.

The fabulous report of the American women not being subject to the menstrual discharge, seems to have arisen from the European travellers, who saw numerous females almost naked, having observed nothing of it. Two circumstances will account for this, according to Blumenbach: "partim nempe quod apud illas America gentes feminæ quædam menstrualibus sint, fceli prejudicium pro venenas quas hæbantur, inque remotoribus tuguriolis et hominum coniecturus remote tamdui beneficio iphis oto fruantur; parsim vero etiam laudatum ipsum corporis munditiem et modellum crurum commiaturum eo conferre ut nulla catametricum vertigia in oculos incurrant, annotatum eft." De Variet. p. 313.

The redness of the skin is not so conflant, but that it varies in many inferences towards a brown, and approaches likewise in some temperate situations to the white colour. Cook states, that the natives about Nootka Sound are little inferior in fairness to Europeans; and Bouger makes the same observation of the Peruvians on the Andes. It is also fully ascertained at present, that the Americans poiffes the same variety of feature which are observed in the other races.

5 Malay Variety.—Brown colour; hair black, soft, curled, and abundant; head moderately narrow, and forehead slightly arched; nose full and broad towards the apex; large mouth; upper jaw rather prominent; the features, when viewed in profile, projecting and distinct. The inhabitants of the peninsula of Malacca, of the South sea, Ladrone, Philippine, Molucca, and Sunda islands, are arranged under this division.

As the Americans in their national characters, hold the middle place between that middle variety of the human race, which we have called the Caucasian, and one of the extremes, viz. the Mongolian; to the Malay forms the connecting link between the Caucasian and the Ethiopian. The name of Malay is given to it, because most of the tribes which it includes, as those which inhabit the Indian islands near Malacca, the Sandwich, Society, and Friendly islands, also, the islands of Madagascar, and thence to Easter island, use the Malay language. See Hawkefworth's collection. v. iii.

P. 373;
Cook's Voyage to the northern Hemisphere, v. iii.

**Arrangements of other Naturalists.**—The great number and diversity of the objects, the contradictory, imperfect, and confounded accounts which we poffefs of many of them, render all clasfifications very arbitrary; hence very different divisions have been adopted by different fhyfematic writers.

Of *Linius.*—This naturalift places the genus *Homo* in his order Primates, and gives him the company of the monkeys, lemurs, and bats; the characters of the order are, *"dentes primores incifores, superiores quatuor, paralleli; mammae pectorales bina."* He admits three species:

1. **Homo Sapiens:** Diurnus, vivans cultura, loco.
2. Corpus ercephum nudum, pilis raris remotifimos alperum, subfexpedale.

**Varieties.**

*Ferus:* Tetrapus, mutus, hirisutus.

*Americanus:* Rufus, cholericus, reftus.

Pilis nigris, rectis, craffis; naris patulis; facie epithelica; mento subfimberri.

Pertinax, contentus, liber.

Pungit fe lineis dextrae rubris.

Regitur confuetudine.

*Europaenus:* Albus, faugineus, torofus.

Pilis fauecentibus prolixis. Oculis caeruleis.

Levis, argutus, inventor.

Regitur vetinimis arcitis.

Regitur ritibus.

*Aficus:* Luridus, melancholicus, rigidus.

Pilis nigricantibus. Oculisfuscis.

Severus, faltufus, avarus.

Regitur indumentis laxis.

Regitur opinionibus.

*Af.;* Niger, phlegmaticus, laxus.

Vafar, fegus, negligentus.

Ungit fe pinguif.

Regitur arbitrio.

*Monstrofus:* Solo et arte variat:

Alpini parvi, agiles, timidi.

Patagonici, magni, fegnes.

Monochrides, ut minus fertiles; Hottentotti.

Juncae, pudefe abdomen attenuata; Europaenus.

Macrocephali capite conico: Chinenes.

Plagio-cephali capite antice comprefo: Canadenses.

II. **H. Throglodytes;** Nocturnus: habitat in Ethiopie conterminis, in Jave, Amboine, Ternateae fpeluncas, in monte Ophir Malaceae.

This feme to be a medley, compofed of the characters of the leucithiopes, and curuf-oblongae.

III. **Homo Lapé;** brachius longitudine corporis.

This is the gibbon, or long-armed monkey.

Var. 1. *Lapp:* Parvus, torofus, albus, macrocephalus, facie piana lata, maxilla inferiore prominula acuminata vix barbata, occuli parvis profundis negro fucis, nafo parvo ob-tulo, buccis inflatis, ore magnò, labiiis crassis, auriculis magnis, pilis reftis nigris crassis, brachiis longioribus, manibus plantifice minoribus.

**Habitat in borealibus Euraeus, Afia, America.**

At *Imao versus circularis arcum in Afia.*

3. *Afaticus:* Mediocris, luridus, rigidus, pilis nigricantibus, occuli parvis nigris, nafo depr effo, labis crassis, dentibus antorfoi versis.

Trans Gangen.

5. *Af.;* Magnus niger, cute holofericæ ex reticulo mucro Malpighiano crasifcre nigrcro, pilis atris, contortuplicatis, occuli nigris viridibus, nafo fimo, labis tumidi, ventre inflato, mannis laequantibus prolixis.

**Præcipu in Africa occidentali.**

Meiners adopts two chief divifions (haupt-flämme); the handfome and the ugly (fchöne und häfsliche); of which the former is white, the latter dark-coloured (dunkel fär- bige). The handfome divifion includes the Celtic, Slavonic, and Oriental people; the latter are the Armenians, Syrians, Arabsians, Egyptians, and others in the north-well of Africa, the Georgians, Circaffians, Perians, the inhabitants of Hindooftan, Bucharia, and the neighbouring parts, and a large part of Siberia; under the ugly divifion come all the reft of mankind. Grundrifs, chap. ii.

Of *J. R. Forster.*—1. Europeans, Aftatics on the zeft of the Ob, the Cafpian, and the Ganges, Aficans of Egypt, Nubia, Ethiopia, Cyrene, Tripoli, Tunis, Algiers, Fex, Mozraco, and all the country as far as the river Sanghara (Senegal?) in short the Caucaflian of Blumenbach.

White, yellow-fifth-brown, or even blackifth colour; long face with well-formed nose and lips; yellow-fifth-white, red-fifth-brown, or black hair, which is long and particularly curled in locks.

2. All the Aftatics beyond the Ob, the Cafpian and the Ganges; all the Americans from Unalfachka and Cook's river northwards to the northern icy ocean, and particularly Labrador and Greenland; all the inhabitants of the coasts in the Moluccas, Philippiannes, western South fee iflands, and New Zealand.

Yellow-fifth-brown colour nearly universal; broad flattened faces with high check bones. Narrow opening of the eyelids, and internal angle of the eyes depressed towards the nofe (that is situated lower down than the external). Hair universally black, long, and generally smooth and fiff.

3. Aficans or Negroes, and the inhabitants of the internal parts of various Indian and South fee iflands; and all New Holland.

Black with the under part of the face projecting: thick lips, broad flat nofes, and wolly curled hair.

4. Americans, except thofe in the fennent variety.

Copper red colour; nofe thin, long and pointed; hair black, smooth, and fiff.

Of *Dumeril.*—The firft family of his clafs of mammalia are the Bimanes, which have thofe characters: Mammiferes a membres
It would be desirable to investigate the original abode of mankind, to ascertain the situations of the different races from the earliest authentic accounts, and to follow their migrations until we could trace them to the situations which they now occupy. To accomplish anything satisfactory on this head, a very exact knowledge of the bodily characters of the races should be combined with exact historical information, and an acquaintance with languages, those living and unexceptionable testimonies of the affinities of people. On the former of these points, although it might at first appear that the facts are easily accessible, our data are still extremely imperfect; and history furnishes too feeble a light to guide us through the thick darkness that involves the origins of nations. We feel ourselves unable to bring forward anything sufficiently clear and well-grounded to the principal points, which we have endeavoured to illustrate in this article. A short sketch of the subject is given in Dr. Prichard's Differatation.

Principal Works on the Natural History of Man.—Buffon's natural history of man; his observations on mules, on the degeneration of animals, on wild and domestic animals, and indeed his natural history in general, contain a fund of most valuable information.

Blumenbach, de generis humani varietate nativa, ed. 3. Götting. 1793; his Decades craniorum diversarum gentium illustriatus, 1—4; 4to. Gött. 1790—1805; his Beyträ o zur naturgeschichte, Gött. 1790. 12mo.; his Hand- 

bacht der naturgeschiefte, ed. 6. Gött. 1799; and his Abbildungen naturhistorischer gegenflände; more particularly part I.

son of a king of Denmark and Norway, who, after reducing the Orescades and Hebrides, fixed his seat of government in the Isle of Man, where he reigned long and prosperously, as an independent king. In his reign, the house of Keys, which will be more particularly noticed hereafter, was established, as the constitutional parliament of the island. Gudred, the son of Otzy, was distinguished for the Nortland of his small kingdom, having devoted his whole attention to the civilization and welfare of his subjects. Reginald, who succeeded, was ails noted for his vices, which ultimately occasioned his assassination by the brothers of a lady whom he had dishonoured. Olave, the next prince of Man, unjustly suffered as a traitor, at the court of the king of Denmark, for having assumed the crown without his approbation. Olain, his brother, became his successor, and after an equitable reign, left his dominions to his son Allen, a tyrannical prince, who was poisoned. Macen took possession of the sovereignty, but having refused to pay homage to the English crown, he was deposed by Edgar, but was afterwards reinstated in his former dignity with additional power. The English monarch is likewise said to have appointed him admiral of an immense fleet, (amounting, according to Matthew of Weiltminder, to 4,200 sail, but this number is certainly incredible,) with which he sailed, twice a year, round the whole of the British islands, in order to protect their coasts from the pirates of the Danes and Normans. How long this great man continued to reign is uncertain, but towards the middle of the eleventh century we find Godrred, the son of Syra, upon the throne, whose barbarous conduct rendered him extremely abhorrent to his subjects. Fingal, his son, succeeded, who, on the other hand, was greatly beloved for his mildness and generosity. In his reign, Gudred Crovan, a Norwegian chief, arrived with a numerous fleet, and though twice defeated, at last obtained a decisive victory, the king and his principal officers being slain in the battle. This event occurred in the same year in which the conquest of England was effected by William of Normandy, and in consequence the whole island submitted to the superior fortune of Gudred. During his government the monks greatly distinguished themselves in war. He first made a successful predatory incursion into Ireland, and afterwards subdued the Hebrides, and so effectually kept the Scots in awe by the power of his navy, that, to use the metaphorical language of the Russian monks, "they durst not, when building a ship or boat, drive more than three nails into it." Gudred had three sons, the eldest of whom, named Lagman, succeeded to the throne. Harold, the second son, was king in rebellion against his brother, but being at last taken prisoner, had his eyes put out, and was otherwise mutilated. Lagman afterwards repeating of this cruel conduct, was overwhelmed with sorrow, renounced his kingdom, and as an expiation of his guilt, made a pilgrimage to Jerusalem, where he died in 1069. Olave, his youngest brother, being yet a minor, the inhabitants of Man sent a deputation to Marchand O'Brien, king of Ireland, requesting him to lend over some perfum of royal extraction to govern them till he should come of age. Accordingly this monarch nominated Donald Tadie, who governed with such barbarity and extremity, that the indigent natives excelled him from the island within three years. The chiefs then elected Maan, but that event, notwithstanding the clemency of his rule, gave birth to a conspiracy against him, and in the battle which it occasioned, both he and Earl Oughter, the leader of the conspirators, fell. According to the Man tradition, the northern men had nearly accomplished the victory, when the women of the south side flew with such resolution to the assailance of their husbands, as to turn the tide of fortune in their favour. The Chronicron-Henniac, however, attributes the victory to the inhabitants of the northern district. About this time, Magnus, king of Norway, having reigned his own throne on account of an absurd superstition, fitted out an army, with which he made himself master of the Orkneys and Hebrides, which latter, where he landed the day before the battle, and received the submission of the Manks without a contest. Here he established his seat of government, and after reigning six years, made a descent upon Ireland, where, having unwarily left his ship, he was surrounded and slain, in the year 1103. During these transactions, Olave, the son of Gudred, reigned in great favour at the court of Henry I. of England. Upon the death of Magnus, however, the chiefs of Man immediately dispatched messengers to offer him the crown, which he readily accepted. Ascending the throne, to the great satisfaction of the people, he concluded treaties with all the neighbouring monarchs, and enjoyed profound peace for forty years of his reign. In 1142, however, during the absence of his son Gudred, whom he had sent to Norway to do homage for the crown of Man, the three sons of his brother Harold landed on the island, and demanded his share of his kingdom. Olave, willing to pacify them, promised to submit the matter to his council and appointed a place of meeting for that purpose, near Ramsey. The king, with his retinue, placed himself on one side, while his nephews, with their followers, seated themselves on the other. At this moment, Reginald, one of the princes, pretending to salute the king, suddenly raised his shining battle axe, and cut off the head of his aged and venerable uncle at one blow. A general slaughter of the nobility ensued, and the subjugation of the whole island, which the three brothers divided among themselves. In the same year they collected a fleet, and landed in Galway, but were defeated with great slaughter. Just at this time Gudred returned from Norway, and the inhabitants crowning to his standard, the usurpers deemed it advisable to submit to his authority, without hazarding a battle, whereupon Reginald was condemned to death, and the other two had their eyes put out. Gudred, when he ascended the throne, was in the bloom of youth and manly intelligence, majestic in stature, magnanimous in his sentiments, and heroic in his actions. These qualities uniting with the recollection of his father's virtues, obtained him, not only the love of his own subjects, but the esteem of all the neighbouring nations. In the third year of his reign the fame of his merit induced the chief nobility of the province of Leinster to elect him their sovereign. Marchand, king of Ireland, opposed his accession, but being defeated, Gudred created himself on the throne to which the suffrages of the people had called him. His absence, however, excited considerable discontent in Man, which probably seduced him, upon his return, to act somewhat in a despotic manner towards several of his nobility. One of them, named Thorfinus, a powerful and ferocious chief, fled to Summerled, thence to Argyle, in Scotland, who had married one of the daughters of Olave, and prevailed upon him to invade the western isles, then part of the dominions of Gudred. Thence being reduced, he failed with a large fleet to attempt the conquest of Man, but being met at sea by his brother in law, also at the head of a powerful armament, a dreadful battle ensued, which terminated in a peace, by which Gudred retained Man, but ceded the other islands to Summerled. This event happened in 1156, but two years subsequent, the latter broke the treaty, and invaded Man with a fleet of 53 sail, defeated Gudred, who sought refuge in Norway, and compelled the whole isle to submit to his sovereignty. This success so puffed up the ambition of Summerled, that he projected
jected the conquest of Scotland, and accordingly made a de-

cent upon Ranulf with that intention, but was defeated in the

first engagement, himself and his son being among the num-

ber of the slain. About the same time, Reginald, one of the

illegitimate sons of Olave, having raised a party, invaded Man, and though opposed with great bravery by the

Manks people, succeeded in defeating them by the treachery of one of their generals. His power, however, was but of short duration, for only four days after the com-

mencement of his reign, Godred arrived from Norway with a

large army, attacked and took prisoner the usurper, and

was hailed by his subjects with the most cordial expres-

sions of attachment. In the residue of this monarch's reign,

mention is first made of the pope's influence in Man, the

apostolic majesty having sent over from Ireland his legate,

Vivian, who compelled the king to re-marry his queen, Piuhgola, according to the forms of the Roman church.

Godred died in 1187, the latter years of his life being spent

in perfect tranquillity, and left Olave, his only legitimate

son, heir to his kingdom. Reginald, one of his natural sons, however, was appointed king during Olave's minority.

This monarch, in 1192, foit a severe battle in the isles

with Engus, the son of Somerled, in which he was defeated

with considerable loss. In 1203, he invaded Ireland, but

was here unsuccessful also. In 1216, the Isle of Man was

plundered by an English earl, named Fulco, during his ab-

sence on a visit to his more northern dominions. But

notwithstanding these unfavourable circumstances, Reginald

was enabled to retain the government, even after Olave, the

rightful owner, had attained the years of maturity. But

battles ensued, and the latter ultimately ascended the throne,

and reigned till his death, which happened in 1237, when

his son Harold was fourteen years of age. Having re-

fused to appear at the court of the king of Norway, his ter-

ritories were invaded by a Norwegian army, under God-

patrick and Gillchrist, who converted the tributes of the coun-

ty to the service of their own sovereign; but Harold,

being at length induced to submit, sailed over to Norway,

and, performing the usual homage, was confirmed in the

possession of all the islands which his predecessors had enjoyed.

On his return home, he entered into treaties with the kings of England and Scotland. To the former he paid a viti,

and received from him the honour of knighthood, and other

distinguished marks of his royal favour. Soon after he

failed from Norway to eponge the daughter of that monarch,

offered to him in marriage by her father, but both he

and his princes perished by shipwreck, when on their way

back. His brother, Reginald, succeeded, who was slain

only a few days after his accension to the throne by Yvar, a

knight. Harold, the son of Godred Don, now assumed the

title of king, but was soon obliged to surrender his usurped

authority to Magnus, the son of Olave, who, as rightful

here, had obtained the function of the Norwegian monarch.

This prince was the last sovereign of the Norwegian race in

Man. His death happened in 1268. At this period,

the king of Norway finding himself unable to afford protec-

tion to his distant dominions, agreed to surrender the western

islands to Alexander III., king of Scotland, from the domi-

nions of whose ancestors they had been originally wrested by

the Norwegian arms. This enterprising monarch soon after

extended his authority over the island of Man also, and yel-

led the government in thanes, or lieutenants. Thence behav-

ing with great opprobrium towards the inhabitants, so exasper-

ated the Manks, that they formed the resolution of exterminating the Scots, or perishing in the attempt. From this bloody

purpose, however, they were restrained by the influence of

their bishop, who proposed, in imitation of the warriors of

Rome and Alba, that the future fate of their country should

be decided by a contest between selected combatants. This

proposal being eagerly embraced by both parties, thirty

heroes were chosen on each side, and a vote was appointed

as the scene of the conflict. The two nations covered the

opposite mountains in anxious expectation, the one of con-

firming their conquests, and the other of regaining their

former independence. The battle was long and terrifically

fought, but at length the Scots prevailed, though their

thanes, and five and twenty of their combatants, paid the for-

feit of their lives for the glory of their country. After this

period, no attempt seems to have been made by the Manks

to regain their liberty, but their island now became the

theatre of contests between Scotland and England. William

de Montacute, a defendant of one of the Manks monarchs,

having landed here with a body of English troops, forced

the Scots to retire to their own country. In the reign of

king Edward II. this island was bestowed on Gave-

ton, who was created earl of Cornwall. In 1340, it was

recovered to the Scots by their heroic king, Robert

Bruce, and continued in their possession till the earl of Saf-

bury, under the sanction of Edward III., wrested it again

from their authority, and sold it to William Scroop, who

was chamberlain to the king. On Henry's gaining posses-

sion of the throne, he granted the Isle of Man to the earl of

Percy, who afterwards rebelling against his sovereign, had

his elates forfeited by an act of attainder, but they were

all afterwards restored, with exception of this island, which

was bestowed on Sir John Stanley and his successors for ever.

In his reign, the laws of Man, which had hitherto been

concealed in the bosoms of the decemlers, or judges, were first

publicly promulgated, and committed to writing. For this

purpose, the sovereign convened the entire body of the

people at the Fynwald, where he himself attended, invested in

all the insignia of royalty. All things being in readiness, the

evenerable decemlers rose, and, with an audible voice, alter-

nately published to the assembly several laws, which, though

more favourable to the monarch than to his subjects, were

received with reiterated applauses. From this period,

the royalties and revenues of Man descended regularly, and

without molestation, from ancestor to heir, till the time of

William VI., earl of Derby, against whose title some ob-

jections were started and legally removed. To put the

question beyond doubt, however, a new grant was obtained

from James I., which afterwards received the function of

parliament. It should be observed, that the fifth descendant

of this line reigned the title of king, and assumed that of

lord of the island, conceiving it to be more honourable to be

eleeted a great baron than a petty and dependent monarch.

In the time of the civil wars, Man held out for the king till

near the close of that unhappy contest, when it was surren-

dered to the parliamentary forces. It was now granted to

Lord Fairfax, but upon the accession of Charles II., it was

recovered to the earl of Derby, son of him who had been be-

headed at Bolton. In the same family it continued till the

year 1755, when it became the inheritance of James, the

second duke of Athol, as grandson of Sophia, youngest sister

of that earl.

Before this period, the vast extent of the contraband trade

carried on between this island and Great Britain, attracted the

ferious attention of the government, and an act was passed

in 1766, authorizing the lord of Man to reign his royalties

for a pecuniary compensation; but no sale was effected till

the 7th of March, 1767, when John, duke of Athol, re-

igned all his regal privileges and immunities for the sum of

70,000l. An annuity has since been granted by parliament,

for the joint lives of himself and his duchess, as an additional

compensation
compensation for the loss he was supposed to have sustained by this transaction, which has, in no small degree, secured the revenues of the British islands. The condition and government may be partly inferred from the preceding narrative. About the fifth century the government became a despotic and feudal monarchy. In the tenth, the foundation was laid for a new dynasty called the House of Keys, whereby the inhabitants were allowed to choose sixteen representatives, who, with eight from the Isles, were to form the legislature. These representatives were called Taxiarms, but neither the period of their election, nor the precise power with which they were invested, can now be ascertained. It is probable, however, that their privileges were very limited, and that, in reality, they were mere nominal advisers, all substantial power being vested in the person of the monarch. Indeed, no mention is made of any interference on the part of this assembly in public affairs till the thirteenth century, when the island was taken by Alexander, king of Scotland. At this period, however, they appear to have exercised the right of enquiring into the existing laws and petitioning for new ones, but they possess no power of enactment. After the accession of the Stanley family the liberties of the people began to extend, and, in 1450, they obtained the exclusive privilege of electing the members of this assembly, who were increased to twenty-four in number for the 1le of Man alone. This dawn of liberty, however, was only of short duration, being destroyed by the Houfe of Keys itself, which, upon the death of any of its members, proceeded to elect another in his stead, in direct opposition to the democratic principle upon which the institution was founded. Constituted notwithstanding as it was, this assembly proved no incon siderable check upon the encroachments of the regal authority. In conjunction with the king, his council, and the deputies, it possessed the entire legislative authority of the isle. These four estates were denominated the Tywald Court. Since the purchase of the royalties by the British government, the power of this court has been considerably restricted, but it still retains the right of making certain ordinances, provided they agree with the general tenor of the ancient customs, which form what may be termed the Manx common law. The power of the Keys is judicial as well as legislative. Appeals may be made to them from the inferior courts, and in all such cases, as well as in actions, their decision is final, unless the cause be carried before the king in council. They always determine by a majority, and in their legislative capacity they conduct their deliberations in private. Foreigners, as well as natives, are eligible to seats in this house, the only requisite qualification being the possession of land. A grand court, consisting of the whole four estates of the island, continues to be held every year at the Tywald-Mount, where all new acts are publicly read, and thenceforth become binding on the people, who are compelled to give them their concurrence. The governor is nominated by the king. He is chancellor ex officio, and by himself or deputy is empowered to hear appeals from the decision of minor tribunals in all civil questions, except such as relate to the possession of land, which can only be entertained in the Keys. All arrests, both civil and criminal, are granted in his name, and he can, at pleasure, convene the different branches of the legislature; but there are some doubts respecting his powers of prosecution. He likewise possesses the prerogative of coming, as the representative of the ancient monarchs: but no money is legal till declared to be so by an act of Tywald. The council of the governor consists of five persons, who hold their seats ex officio. These are the lord bishop, the water-bailiff, the attorney-general, the clerk of the Rolls, and the archdeacon. Several other officers, both of the church and state, have likewise claimed this privilege, but their claims have not yet been recognized. The deputy, of whom there is one for the northern, and another for the southern district of the island, are judges both in common and criminal causes. They have each a distinct court, answering to those divisions where they preside, and give judgment without the intervention of a jury. The situation of deputies is of great dignity, and their influence over the people formerly reminded, in some degree, the civil authority of the ancient Druids, whose institutions were, in all probability, the original foundations of their authority. In the criminal courts, the usage observed by the Saxons before the conquest is still retained. The bishop, or his deputy, sits with the governor till sentence is to be pronounced, when, instead of the usual enquiry of guilty or not guilty, the deputies ask, "Vidit curiam?" signifying, "May the man of the charged, or be that ministers at the altar, continue to sit." If the question is answered in the affirmative, the bishop, or his substitute, continues sitting, but if sentence of death is to be pronounced he rises and leaves the court.

The other chief civil officers of the island, besides those already noticed, are the lieutenant-governor, who has little power, except in the absence of the governor; the high- bailiffs, one in each of the four towns, the coroners or sheriffs, the lock-men or bailiffs, coroner's officers, and the constables. The coroner is chief keeper of the peace, and is authorized to arrest any one who breaks it. He likewise sees that the governor's arrests are put in execution, has the impanelling of the juries, and the charge of enforcing the sentences of the courts of law.

Laws.—To give a detailed view of the laws of this island, would occupy a greater space than can with propriety be permitted in an article like the present. The more prominent features and characteristic peculiarities by which they are so distinguished seem, however, to have a more than ordinary claim to a distinct and ample exposition. At an early period, the Manx constitution and government being wholly arbitrary, the will of the sovereign, or his judges, was probably the only principle which regulated the decisions of their courts of justice. This much at least is certain, that no laws of any description were ever promulgated till towards the middle of the fifteenth century, when the independence of the House of Keys was fully established. Since that time, justice has been administered, generally, with strict impartiality, either according to the litigant's claim, or, in the event of the parents being old or decrepit. Servants refusing to work on the legal terms were imprisoned till they gave their compliance, and no person who had done a day's work for any compensation, could leave the island before he or she had arrived at the age of twenty-five years. On the subject of marriages, the laws were nearly silent till the year 1777, so that persons of any age or condition might marry without either licence or the publication of banns. Since that time, however, the marriage regulations have been, in some respects, similar to those of England, but, in others, they are yet essentially different. The ceremony is according to the forms prescribed by the Protestant church, but no person without a special licence from the ordinary can enter
the state of wedlock till he has received the sacrament. By the Manks law, the husband and wife are not so completely united into one person as they are by the English. Marriage is, indeed, regarded as a species of partnership, but it does not give an exclusive title to estates, either real or personal. In fact, the landed property of each always remains distinct, but the parties possess every thing else in common, with this difference, that the husband may bequeath his possessions to whom he pleases; but since the act passed in 1777, the wife can only leave her's to the children of the existing union. In case of either being found guilty of treason or felony, only the criminal's share is liable to forfeiture. Fathers are obliged to maintain their children till they reach the age of fourteen, when all legal obligation between them ceases. A child may then claim any legacy, and depart, if he is so inclined; but if he remains, his father is entitled to the interest or use of his money as a compensation for his maintenance. Upon the death of the husband without a will, the widow enters upon her share of the property only, but in the event of the woman's demise intestate, the husband enters upon the whole. Where there is only one child, and the father neglects to appoint a guardian, his kindred are entitled to the custody of it; but if there are two children, the mother takes care of the eldest, and the second is taken care of, as an only one would be. A child, though a bastard at the time of its birth, becomes legitimate by the marriage of the parents within three years after that period. At the decease of his father the eldest son succeeds to his heritable property, and if there are no sons, the eldest daughter, even though the estates are entailable. The origin of this custom, so different from the practice in other feudal countries, is attributed to the bravery of the Southern women in afflicting their husbands in a great battle, and enabling them to gain the victory.

All the lands of this island at an early period belonged to the lord or sovereign; even so lately as the sixteenth century, real property could not be alienated on any pretense without his special consent, or that of his three principal officers. The occupiers were figured the lord's tenants, and were subject to the payment of a fine or rental. Attempts were made about the middle of the seventeenth century to render all the tenures leasehold, either for three lives, or for twenty-one years. This produced a warm dispute between the sovereign and the land-holders, which was not terminated till the year 1703, when it was agreed that the latter should retain their possession so long as they continued to pay the fines and rentals settled between them and the carls of Derby's commissioners after the year 1643. The period of a lease is restricted to twenty-five years, and a mortgage, not redeemed within five years, renders the parties liable to the fine of alienation.

The whole island was formerly divided into six hundred portions, called quarter-haunds, but Fetham says, their number is now increased to seven hundred and fifty. All other estates are either allotments: out of, or encroachments upon, these. The titles to property are, as may be supposed, various and similar in their nature, though sometimes different in their limitations, to those acknowledged by the laws of England. Unmarried possession for ten years, till very lately, constituted a sufficient right to any species of property; but the term is now extended to twenty-one years. Every proprietor professes the privilege of feeding a certain number of cattle upon the commons, which abound in various parts of the isle, and every inhabitant has the privilege of quarrying flint and digging peat for his own use. All weeks not claimed within a year and a day, and all mines, belong to the lord by his prerogative. Game, likewise, was anciently his property. Goods taken in distress, or execution, must remain one month as a pawn, redeemable by the tenant, or defendant, on paying or of the rent, or of money recovered in an action at law.

But the most marked peculiarity in the Manks law is, that no arrest can be granted against a landed proprietor or native, to imprison or hold him to bail in a civil action, unless there appears some just cause to conclude that he intends leaving the island without making satisfaction to his creditors. Such persons as are prosecuted for a foreign debt can only be obliged to find bail for his personal appearance, and for the forthcoming of all his property on the island, except his clothes and money, which remain his own. It is from the operation of this latter law that the unfortunate, and too often the fraudulent sife, find an asylum here from the prosecution of their creditors. By converting the residue of the property into money, they are enabled to retire on this island in comfort, and without the danger of legal molestation. If, however, there is anything clearly shown to be criminal in the conduct of any individual as to infer the pains of law, the governor generally grants a warrant for delivering him over to the justice of the country to which he belongs.

By the laws relative to public wrongs, here no offender can be convicted of any capital crime, except by a jury at the court of general gaol delivery. Formerly, indeed, a person who made an attack upon the lord, or his lieutenant, could be condemned immediately, without any form of trial, but the practice has been long obsolete. This offence was deemed treason; so likewise was the striking of any of the lord's servants in his presence, robbing him in court, confirming him to hold a Tyndall court, relieving or concealing a rebel, counterfeiting the current coin of the island, and bringing in any false money and making payment with it. Thus, even copper coinage is treason, contrary to the law of England, which confines it to the counterfeiting of gold and silver money.

For bigamy, or polygamy, there is no punishment by the Manks law, even at the present day; but the second marriage, being illegal, is null and void, and the children are, consequently, regarded as ballards, and deprived of their rights to inherit the property of their parents. Suicide is punished by forfeiture. In the event of a rape on a married woman, there is no alternative but death; but if the woman is unmarried, she has her choice to hang, behead, or marry the offender. What is remarkable, there is no infraction of a conviction for this crime upon record, and only one traditionary, and in that case the lady is said to have adopted the last condition, just at the moment when her ravisher was about to be launched into eternity. Ailault and battery are punished by fine and imprisonment, according to the decision of the governor or deemster, without the intervention of a jury. It is felonious to enter a house with burglary in intention, even though it should be without a door, provided two licks are placed across the entrance. Forging is not accounted criminal, at least the offence is only regarded by the law as a civil debt. Theft, above the value of fifteenpence-halfpenny, is capital. Below that value the crime is termed petty larceny, and subjects the offender to corporal punishment and imprisonment at the discretion of the court. To convict for felony one respectable witness is now sufficient, if his evidence is supported by probable circumstances.

Religion.—The established religion of Man is the same with that of England. Toleration, however, having extended its beneficial influence here, as in other parts of the British empire, Diflfencers of almost every denomination are prevalent. Among these the most numerous feck is undoubtedly the
the Methodists, who form at least one-tenth of the whole population. The establishment is placed under the direction of a bishop, assisted by an archdeacon, two vicars-general, and an episcopal registrar. The patronage of the fee that devolves on the Atholl family, but the nomination of the superior clergy must be approved by his majesty. The bishop is consecrated by the archbishop of York as metropolitan of the diocese, and enjoys all the privileges and spiritual rights of other bishops; but his fee not being baronial, he is not entitled to vote in the house of lords.

He has, however, a seat, as Mr. Wood supposes, by courtesy, above the bar. The first bishop of Man was St. German, to whom the cathedral church is dedicated. At that time the diocese was limited to the boundaries of the island, nor did it extend beyond them till the conquest of the western isles by the Norwegians, about the commencement of the twelfth century. When the indivis Sodorvcs, so called from the bishopric of Sodor, a small village in Iona, and once the metropolis of learning and piety, was united to it; the whole formed one bishopric, called Sodor and Man. The metropolitan at that period was the archbishop of Drontheim. After the annexation of the island to the crown of England, the conjointed bishoprics were separated.

Surface and Rivers.—The general aspect of this island presents considerable diversity of hill and dale. A chain of mountains, moderately high, divides it nearly into two equal portions, in a direction from N.E. to S.W. This range is broken only at one place, between mount Kreevey and South Barrule. The most conspicuous summit of the whole is Snawfel, the height of which, as taken by the barometer, appears to be 580 yards above the level of the sea. The two Barrules, which form its northern and southern extremities, are nearly of the same elevation. Between North Barrule and mount Kreevey are several rivers, which empty themselves into the sea at Ramsey, at Laxey, and at Douglas. Of these rivers, that of Ramsey is by far the largest; being so much influenced by the tide, from the level nature of the district through which it flows, that it is navigable for vessels of considerable burthen at the distance of more than two miles from its mouth. The other rivers in the island are very shallow and inconsiderable streams. Here is a great deficiency of wood.

Soil and Climate.—The soil of this island is various. Towards the south parts the greater proportion is loam, but stiff clay; hickey abroad, and in some spots the surface exhibits a fine light sand. The northern district consists principally of a sandy loam, with a bottom of clay or marl. Here is an immense tract of land called the Carriagh, extending nearly across the whole island, from Ballaugh to Ramsey, which was formerly a bog, but is now drained and produces excellent grass crops. In a few places of this tract is a remarkable layer of peat, which stretches itself several miles under a stratum of gravel, or earth. The thickness of the layer varies from two to three feet, and that of the gravel, &c. from two to four feet. In other parts of the same tract the peat has been removed to the depth of ten feet. The climate is generally reckoned milder in winter than that either of England or Ireland in the same latitude, from the proximity of every part of the land to the sea, and snow are seldom of long continuance. The summers, however, are hot and warm, and grains of wind and falls of rain, during this period, are extremely frequent, often occasioning very considerable damage, not only to the fruit, but also to the grain-crops.

The mineralogy of the Isle of Man offers very few objects of interest or importance. More than two-thirds of the whole surface rests on strata of wacke-flate, or clay-flate. The hills, called North and South Barrule, are composed of mica-flate, covered with clay-flate; Mount Kreevey consists of the same materials, traversed by many large veins of quartz, two or three feet in thickness. On the north side of South Barrule appear some blocks of granite, containing a quantity of interfered mica, reddish feldspar, and grey quartz. In the neighbourhood of Castletown is found a blue-throst grey-flate, intermixed with impressions of shells and other marine exuviae, and interfaced by small veins of calcareous flate. This lime-flate lies above a stratum of wacke-flate, from which it is separated at some points by a thin layer of white clay, which does not in the slightest degree effervesce with acid. Near Pool-yar-lay this mineral becomes so highly indurated, that it is quarried below high-water mark, as a tolerable good marble for tomb-stones. Not far from Langslo a small quantity of compact brown iron-flate is found, lying under a breccia composed of pieces of quartz in a silaceous base, and bearing some resemblance to horn phyrty. The Calf of Man, which is separated about 100 yards from the main, consists entirely of a glossy blue-grey clay-flate, lying more inclined to the east, and more unevenly stratified than the flate-rock on the opposite shore.

At Kirk Arbovy are shafts of lead-mines now entirely deserted. Breda-head copper-mine is chiefly the sulphuret of that metal. The mines of Foxdale, celebrated for their fine lead-glance, are now entirely drowned by the tide; so that the only mines at present wrought on the island are those of Laxey, which produce a very considerable quantity of lead and copper, both of excellent quality. Crystals of iron pyrites are occasionally found in different places. From these few facts the geologist will perceive that this island consists partly of primitive clay-flate and mica-flate, resting probably upon granite; of grey wacke-flate, and of lime-flate which seems to belong to the rocks of transition of the Wernerian geologists; of sand-flate of the earliest formation, and of sand resting upon clay.

The agriculture of this island, though much improved of late years, still continues at a very low ebb. More than a third of the whole surface lies in an uncultivated state, and entirely appropriated to the feeding either of sheep or cattle. The value of land in this condition varies from five to ten shillings per acre; but arable land often rises above two pounds. The enclosures are formed generally of embankments of earth, unaccountably crooked and irregular, and containing from four to ten acres. Barley constitutes the chief grain raised by the farmers, as the soil and climate are thought to agree better with its growth than with that of any other corn. Potatoes and turnips are likewise cultivated in great abundance. Crops of flax are very common in every part of the island; almost every cottager growing a small quantity, both for home use and exportation. Hemp is grown in gardens, and on rich enclosures, but very rarely in the open fields. The plough in common use is of a light construction, and generally procured either from England or Scotland. Oxen to the small size of the horset, four are requisite to turn a farrow four inches deep. The Manks harrow and roller are generally of a good make, though light; but with respect to wheel-carriages, a total ignorance of their proper construction prevails. Cart-wheels are invariably very narrow and small. Drilling and hoeing machines are little used.

The native sheep of the island are small and hardy, bearing a resemblance to the South Down, which properly fed, their meat is of the most delicious kind. This is called the mountain breed, being reared entirely on the hills and uplands; but in the lowlands a larger species has been introduced.
MAN, ISLE OF.

introduced. Besides thee there is a third breed, called the Langton, which affords very fine wool of a dark buff colour, much used by the inhabitants in making stockings. Many hundred head of cattle are fattened annually for exportation; and fogs and poultry are reared in great abundance, as are also geese and ducks; but turkeys are rather scarce. The manner chiefs used by the farmers is farm-yard dung, or, if near the shore, seaweed. A regular rotation of crops is little understood or practised, and summer fallowing scarcely ever occurs. The indolent disposition of the men, (for the women are lively and active,) joined to the attractions of the herring fisheries, and the operation of the tithe system, are radical obstacles here to agricultural improvement, which even the Cumberland Society, lately extended to this island, will find it difficult to remove. Intimately connected with this subject is the state of the Roads and buildings, both of which have of late been greatly improved. Forty years ago, the former were dangerous for carriages even in summer; but at present they are very good during that period; though, owing to the clayey nature of their composition, they sometimes become impassable for several days in winter. Houses of the best sort, both in town and country, are constructed of hewn stone; and those of an inferior description of rough stone. Farm-houses and offices are usually small, irregular, and ill built: a few modern ones, however, are on a better plan. The meaner cottages consist principally of sods of earth, with a thatch of straw. The bridges are mostly in tolerable condition, being built and supported at the expense of the public, and requiring an act of Tynwald to authorize its erection.

Towns and Villages.—This island possesses a number of small towns and villages, situated principally on the coasts. The chief of these are Castleton, Douglas, Peel, and Ramsey. Castleton is considered as the capital, being the residence of the governor, and the seat of the superior courts; but Douglas is of more importance in a commercial point of view. In the centre of Castleton is Castle-Rushen, an irregular fortified building of stone, said to have been erected in the year 690, by the Danish prince Guthred, who was buried within its walls. The wide green which surrounds it, is supposed to have been the work of cardinal Wolsey. This fabric was the ancient mansion of the kings of Man, where they lived in all the warlike pomp of feudal magnificence. Douglas, only a century ago, was merely a group of huts; but it is now the most opulent and best built town on the island. The duke of Atholl's principal residence is situated in this vicinity. Ramsey is a neat town, where the demesne of the northern district resides, and holds its courts. Peel is likewise a pleasant village, and more distinguished, than any other spot in Man, for its remains of antiquity. Peel castle, placed on a small island, divided from the main by a narrow channel, deep during the flow of the tide, but easily fordable at its ebb, is a very noble remnant of ancient architecture. Near it are the ruins of two churches: one dedicated to St Patrick, of uncertain origin; and the other called St. German's, or the cathedral, which was constructed about the year 1245.

Commerce and Manufactures.—None of the mechanical arts having yet reached any degree of perfection in Man, its manufactures are few, and of little value. Indeed, the only one worthy of observation are those of Douglas, where weaving, towelling, fall-cloth, and buck-cloth are made. In commercial concerns, however, it is of more importance, great quantities of lead, cattle, sheep, fowls, butter, and eggs, being shipped from hence to England. Some strong linens and fall-cloth likewise form articles of export, but the chief source of opulence here, as in Shetland, is the herring fisheries: for the smuggling traffic, which proved so advantageous in former times, is now almost entirely cut up. About five hundred boats are regularly employed in the fisheries every season, beginning with July, and ending with September. A few years ago it was customary for the fishermen to offer up a prayer for success on leaving the harbour, but that practice has fallen into disuse. As yet, however, they make it a rule never to fail either on a Saturday or Sunday evening, lest the Sabbath should be violated. The ordinary size of the boats is about eight tons, and their value, including the nets, &c. somewhat more than 80l. Every night's produce is divided into nine shares, of which two belong to the proprietors of the vessels, one to the owners of the nets, and the residue to the fishermen. Of the white herrings, the greater proportion are sold in England, but most of those termed red herrings are exported to the different parts of the Mediterranean. Previous to the commencement of the late war, a falmon-fishery was established here upon an extensive scale, but since that period it has much declined. The imports to the island consist of manufactured goods of almost every description, together with coal, wine, brandy, and other puripous liquors: the balance of trade is greatly against the island. The fisheries, however, may probably be made up by remittances to the numerous strangers, who, in order to avoid the visits of a bailiff, or the extravagance of English living, resort hither either as a temporary or permanent retreat.

Antiquities.—The Isle of Man contains considerable vestiges of ancient times. The little Isle of St. Michael is joined to the Main, at Longnese's-point, by a high brealkwork, about one hundred yards in length, and on the Isle itself are the ruins of a circular fort, built by one of the earls of Derby. On the road from Castle-town to Douglas, at the distance of two miles from the former, stand the venerable remains of Rushen-abbey, founded in the year 1098 by Prince Macmarus. This establishment consisted of an abbot and twelve monks of the Clarenian order, who were so celebrated for their hospitality, as to acquire the title of almoners of the poor. The abbots, in later times, became a baron of the Isle, and was invested with the power of holding courts in his own name. Many of the kings of Man were interred in this monastery. Not far from Douglas appear the remains of another monastery for female votaries, said to owe its original foundation to St. Bridget, in the sixth century. The priores of this institution was likewise a baron of Man, and held courts in her own name. Immediately adjoining to Laxey, on an elevated site by the road-side, is a small circular range of stones, some of them standing erect, and others leaning towards the centre, which has apparently formed a tumulus, but is now mutilated. This monument bears the name of the Claversstones. The parish of Kirk-Andrews, north of Ramsey, is particularly distinguished by a variety of ancient remains. The entrenchment at Ballachury, situated on a small natural eminence, is in more complete preservation than, perhaps, any other erection of the same kind in the British dominions. It is of a square form, and has a very noble button at each angle; the whole surrounded by a wet fosse of ample dimensions. Many barrows are to be met with in this neighbourhood, some of which have been opened, and earthen urns discovered in them. In the parish church stands a square stone pillar, with a Runic inscription, thus translated by Mr. Beaufort: "The son of Ulf of the Swedes (or Swedes) erected this cros to the warrior Alfarin, the son of Gunnar." Many other Runic inscriptions and tumuli appear in various parts of the island; indeed, they are probably more numb
The Tyward is the only object that now remains to be mentioned. It is situated about three miles from Peel, near the side of the high-road leading to Douglas. The name of this artificial mount is compounded of the British words Tyng and Val, signifying the juridical hill. This monument of ancient days is in the form of an obtruncated cone, divided into three flages or circles, regularly advanced three feet above each other, but proportionally diminished, both in circuit and width, the nearer they approach the summit. The whole was formerly surrounded by a ditch and rampart of earth, including a space, on which stood a small chapel dedicated to St. John, lately pulled down.

Concerning the first erection of this mount nothing is known, either from history or tradition; but judging from its name and appropriation, it would seem to have been constructed by the aboriginal inhabitants of the island.

Population, and Means of Defence.—The number of inhabitants in this island has varied much at different periods. In the time of Bede, it is said by that author to have contained only 350 families. Hollinshed, who wrote about the year 1584, observes, "there were formerly in this island 1300 families, but now scarcely half that number." In 1726, the population was 14,511; in 1757, it had increased to 19,144; and, in 1792, to 27,613. At present it is thought to exceed 36,000 persons, an increase partly owing to the improved state of agriculture, and partly to the greater number of strangers who now take up their abode in this land of freedom from taxes and arrests. The military establishment of the island consists solely of a regiment of fencibles, who are enlisted voluntarily, and receive a bounty of three guineas. Their pay is the same as that of English regiments, and the service being easy, most of the individuals who compose them are engaged in some trade or business, for here military duty is not reckoned incompatible with the pursuits of civil life.

Language, Manners, and Customs.—From the number of strangers continually flocking to this island from Great Britain and Ireland, and the commercial intercourse that subsists between them, it may reasonably be supposed that the English language is usually spoken in the towns on the sea-coast. In the interior, however, the original Manks language still prevails. This last is merely a dialect of the Gaelic, or that used in the Highlands of Scotland, with a commixture of Welsh, Saxon, and Danish words. The radices, indeed, are chiefly Welsh. The New Testament, and several other publications, have been translated into the Manks tongue; and in the country parishes it is customary to preach in this language and in English every alternate Sunday.

With respect to the character of the people in this island, it is generally observed that the men are habitually of a lazy and indolent disposition. This is not improbably the consequence of the herring-fisheries, in which the greater part of them are engaged; for such pursuits, in certain conditions of society, are, beyond doubt, prejudicial to the more active concerns of agriculture and the arts. In fine, wherever fisheries are established upon a scale sufficiently extensive to afford employment to the men, the affairs of the field are left to the women in a great measure; and this is precisely the case in Man, the females being both the reapers and threshers of all the corn in the island. Hence it happens, that the women are as remarkable for their activity and frugality, as the men are for their idleness. Unfortunately, however, an extreme laxity of opinion prevails among them in respect to chastity. A servant girl, by becoming a mother, does not suffer any degradation of character. The event is, therefore, of no uncommon occurrence, and is probably the reason why women of the town are scarcely ever to be met with, even in Douglas. Like the Highlanders and Swifs, the Manks are much attached to their native vales and mountains, as well as to their ancient customs and laws. They conceive themselves to be independent of Great Britain, and were much affected by the fall of the island, because they feared it would blend the countries. A great fondness for litigation, and an uncommon love of hospitality, are striking, though somewhat contradictory, features, in the Manks character. So much, indeed, are they naturally disposed to charity, that poor's rates are wholly unknown, and there is no such institution as an hospital, or workhouse, in the whole island. Every parish, however, has a charity-school, and generally a small library, both of them supported by voluntary contributions, or funds arising from legacies or donations. Neither shoes nor stockings are worn by the lower orders, excepting on particular occasions. A blue cloak is the common body-dress of the women, and strangers are usually habited in a sailor's jacket, and trowsers of the same colour. This cloak is termed the Manks livery. The belief of fairies, and such imaginary spirits, still firmly maintains its influence over the inhabitants of this island; a circumstance ascribed by many to the natural gloom and solitude which pervades every portion of the country. These airy spirits are divided, by such as pretend to dwell in visionary lore, into two classes, the one comprehending the playful and benignant sprits, and the other the fullen and vandevic ones. The former, gay and beautiful, seek the margin of the brooks to sport among the bushes, or dance on the tops of the adjacent mountains; while the latter find a habitation in the hideous precipices of the sea-shore, and to their malignant influence the Manksman imputes every calamity which may affill him. A belief in the second fight, and in warnings and forswear, the knowledge of their own deaths, is no leas common than this fairy superstition. Many, in their lonely wanderings, have met with a visionary funeral, following them wherever they might turn, awfully portentous of the approaching dissolution of the devoted victim. These opinions are not confined to the lower orders alone, but are credited by individuals even of high repectability. In other respects, however, the superior classes differ considerably from their fellow islanders, and affinitate themselves as much as possible, both in dress, habits, and sentiments, to the fame orders in England. An Account of the People, and Customs of the Isle of Man, by George Woods, 8vo. 1811. A Tour through the Island of Man in 1797 and 1798, by John Fetham, 8vo. 1798. A Journal kept in the Island of Man by Richard Towney, eqv. 2 vols. 8vo. 1791.

Man is also an island in the Pacific ocean, in St. George's channel, between New Britain and New Ireland, about 50 miles in circumference; discovered by Captain Carteret in the year 1767. S. lat. 4° 15'. E. long. 151° 25'.—Alfo, a town of Hindoo van, in the Carnatic; 11 miles W. of Trichóre.

Man at Arms, in Ancient Military Language, derived the appellation from being completely armed de cap-a-pied, or from head to foot. The men at arms formed a part of the cavalry of our ancient English armies soon after the conquest, which consisted of knights, or men at arms and hobiers, or the infantry was composed of spears and bill men, crossbow men, and archers. However, in garisons the men at arms occasionally served on foot. These men at arms were chiefly composed of the tenants in capite, holding by military service, or their subbutes, sometimes called servientes. The defensive armour of a man at arms was a hauberk of double mail, composed of ringslets of iron linked together
MAN

MAN

together like a net, which covered the body, and to it were joined a hood, breeches, fockings, and fhabrons or hoes of the same construction: the hands and arms were also defended by gauntlets and sleeves of mail; the hauberck was the proper armour of a knight; an esquire might wear a shirt of mail over his gambeson, but might not use the hood, breeches, hofe, nor sleeves of mail. Sometimes, but not commonly, men at arms wore haborged on plate mail, formed of small round plates of iron, laid one over the other like scales of fish. Sometimes over the hauberck, but commonly under it, was worn a loose garment called the gambeson (which fea), defended to the knees, stuffed with wool or cotton, and designed for deadening the strokes of the sword or lance, which, though they might not divide the mail, would severly bruife the body without the interposition of the gambeson. Under or between the hauberck and gambeson, a breast-plate of forged iron, called a plaiiron, was occasionally put on; over which all men of family wore furcoats of fatin, velvet, or cloth of gold or silver, richly embroidered with their armorial bearings. By a trape hung over the neck, the men at arms carried a shield made of wood, covered with leather, bound or strengthened with iron or brass, having handles on the inside for brofing it, which was the term then in use for putting it over the left arm, Fr. bras. These shields were for at least a century after the conquest of a triangular form, pointed at the bottom, and a little convex in the direction of their breadth. The helmets worn by the men at arms were of different forms: some conical or pyramidal, with a small projection, called a "naflè," to defend the face from a transverse stroke; some cylindrical, covering the whole head down below the chin, with apertures for sight and breath; and others in which the face was totally uncovered. Helmets with beavers and visors do not feem to have been in use till the middle of the fourteenth century, about which time the hauberck was exchanged by many of our men at arms for plate-armour, so called from being formed of plates of iron. On the crests of their helmets' kings frequently wore their crests, earls and dukes their coronets, generals or other officers of rank either their armorial cognifances, or any other device at pleasure. This was done to give them a more terrific aspect to their enemies, and to render them conspicuous to their own officers and soldiers. To the above list of defensive armour we may add the war-faddle, whole arcon of bows of fleec covered the rider as high as the navel. The knights of the three or four reigns next following the conquest, commonly wore the prieu fpur, which had only a fingle point after which the roue, or wheel fpur, came in fashion; some of which rouelles were fix inches in diameter. Thus enveloped and loaded with incumbrances, we need not wonder, that in the heat of fummer, and dulf, and prudence an engagement, men at arms should be fuccumbed in their armour.

The offensive arms of a horfeman, or man at arms, were a fword or swords, a lance, and a small dagger, called a "Mifericorde" (which fce), and also iron maces fufpended at their faddle-bow. The horfes of the men at arms were no lefs encumbered than their riders; their faces, heads, and ears, were covered over with a fort of mafs, fo contrived that they could not fee right before them and be terrified. This mafs was called a "chafon," or fhafront. Befides other appendages, which it is needful to enumerate in detail, they were occasionally covered all over with mail, or linen stuffed and quilted like the gambeson, and adorned with rich embroidery. Horfes, thus covered, were called "harbard," and corruptly barbed horfes. These war-horfes, for preventing their being fatigued, were not mounted till the men at arms were certain of coming to action, and they had commonly hackneys for riding on a march. Barred horfes were in use in our armies at the time of king Edward VI. When plate-armour came into general use, about the middle of the fourteenth century, the accoutrements of the men at arms were a clofe helmet, with a vifor, or vifor and beaver revolving on the fame pivot, and capable of being lifted up at need. The neck and throat were defended by a gorget, or hallerelles, the cuirasses, the arms by brafsarts, the hands by gauntlets, the fhoes by poulfrons, the thighs by cuifarts, and the legs by iron boots, called greaves, and sometimes by boots of jacked leather. Under all thisfere was worn a jacket of thick fultan, or buff leather. About the time of queen Mary the appellation of men at arms, signifying the heavy-armed cavalry, seems to have been changed to that of spears and lances, and afterwards to cuiraffiers. The armour of a lancier was much the fame as that we have described: their offensive weapons were a lance (which fee), of fixteen or eighteen feet in length, a fword, and petrelens, which laft were something longer than the pistols then in use.

The horfiers (fee Höhlen) were a fpecies of light horfemen, chiefly calculated for the purpofes of reconnoitring, carrying intelligence, harassing troops on a march, intercepting convoys, and purfuing a routed army: their horfes were small and unable to refift the shock of a charge. Some derive the appellation from a Danish word, signifying a mare; but this is not likely, as the men at arms were chiefly mounted on flume-horfes, and in the days of chivalry it was considered a degradation for any knight or man at arms to be feen mounted on a mare. This name was more probably derived from the hobbles or fixle horfes which they rode. The etablifhment of horfiers has been commonly, but erroneously, referred to the reign of Edward III.; but they are mentioned as part of the British army that attended king Edward II. into Scotland, in the year 1322. The name seems to have been totally lost about the latter end of the reign of Henry VIII. or queen Mary; these troops being then diftinguifhed by the appellation of demy-lances and light horfes. The arms and appointments of a horfier, as directed by king Edward III., were a horf, a hagnefton or armour of plate, a bacinet, iron gauntlets, a fword, knife and a lance. Sometimes archers were mounted on light horfes, whence they were ftyled hobilier-archers. Grofe's Mil. Antiq. vol. 1.

MAN, in the Materia Medica of the Ancients, a name by which manna has been called by the oldest writers. There has been, however, some confusion in the history of manna, owing to the too general use of this word, the fame authors using it as the name of several other fubfances of very different kinds, which came to their hand in forms of small granules, or flakes like the manna. The fragments of frankincense, in particular, were called by this name, with the addition of the word thuri, and sometimes without man or men flanding fingly for that drug.

MAN, in Mythology, the name of a deity among the ancient Germans; whom they fuppofed to be the fon of Tufton, and celebrated with fongs, as the founder of their nation: and to him they conferated their groves and fofets.

MAN the Captian, on board a Ship. See CAPSTAN.

MAN the Side, or Ladder, is when an officer or any person of distinction is at the ship's fide ready to come aboard, the men are commanded to wait, and help him up the fide.

MAN the Top, or Tard, a word of command for the men to go up to the top, or yard, for some particular service.

MAN of War, the fame with a ship of war. See Ship and RATE.
Man of War Key, in Geography, a small island among the Bahama. N. lat. 26° 20'. W. long. 77° 15'.

Man of War Keys, small islands and rocks in the Spanish main, near the Mosquito shore. N. lat. 12° 55'. W. long. 88° 35'. Also, small islands at the entrance of Weli harbour on the S. coast of the island of Jamaica.

Manasa, a town of Peru, in the diocese of La Plata; 15 miles S. of Potosi.

Manasa, in the Jewish Cycles, a kind of offerings made in the temple, otherwise called Mincha. The word manasa is used in the Septuagint.

Manara, or Manara, in Geography, a small island, the name of which is derived from the Malabar words man, fend, and air, river, lying off the coast of Ceylon, about 60 miles S.W. of Jaffnapatam. Manara was formerly more flourishing than it is at present. The fort was small, but strong, square, and regular. The city now consists of only a few tiled houses, government offices, and some low huts, inhabited by boatmen and fisherma.

At Manara the island is separated from the coast of Ceylon by a small winding river; but when the tide flows, this river appears as an arm of the sea, and is about three miles over. It is called the "gulf of Manara." Manara lies in N. lat. 9°, and is about 25 German leagues in length, and one in breadth, including a salt water. The fort is situated near the channel or islet which divides Manara from Ceylon. There are besides seven villages in the island. At the extreme end, where boat is taken for the coast of Coromandel, there are four or five churches for the natives and Malabar Christians, besides that of Carcal used by the Dutch. The island is barren and sandy, with a few palmyras and cocoa-trees scattered here and there. The surrounding sea supplies abundance of fish. The passage from this island to Ramiferam, on the Coromandel coast, is not above 12 or 14 leagues, but the passage is interrupted by innumerable shallows and sand-banks, many of which are high and completely dry, except during the monsoons. Adam's bridge, or Ramas bridge, is formed by a line of sand-banks, which runs quite across from Manara to Ramiferam. (See ADAM'S BRIDGE.) It is an universal opinion among the natives, that Ceylon was either the Paradise, in which the ancestor of the human race refixed, or the spot on which he first touched on being expelled from the celestial paradise. Adam's bridge was, as they conceive, the way by which he passed over to the continent; and some of them imagine, that the gulf of Manara, like the Red sea in scripture history, closed after him to prevent his return. It is, however, universally believed, that Ceylon, at a distant period, formed a part of the continent, and was separated from it by some great convulsion of nature. In addition to other circumstances that favour this presumption, we may observe, that the appearance of the soil and the surface of the country are very similar on the W. coast of Ceylon and the opposite continent. The situation and appearance of the Maldives islands, on the other side of the peninsula of India, agree with those on the W. coast of Ceylon, to support the opinion that this continent must have been once much more extensive, till the ocean, from some unknown cause or other, exceeded its former boundaries.

The gulf of Manara, though 100 fathom to admit vessels of large size, is not altogether safe for the purposes of commerce. Sloops, donies, and various small vessels, convey goods by this passage from Madras and other places on the Coromandel coast directly to Colombo, instead of rounding the islands by Trincomalee and Point de Galle. Notwithstanding the obstructions that occur in this passage, the Dutch have found means to carry on a constant traffic in this way between the western coast of Ceylon and their factories of Trincomalee, Vipar, Manapara, Ponicall, and Kiloherre. Coarse cloths and calicoes were the chief articles thus imported by the Dutch, and in return they carried back areca and cocoa-nuts, betel leaf, fruits, arakk, and coya, or cordage made from the cocoa-tree. All these places are now in possession of the English, who may avail themselves by the traffic which they afford.

The short passage from Ramiferam to Manara forms a speedy communication of intelligence to people of business; and government has boats stationed here for the purpose of conveying the "tapal," or letter-bags, between Ceylon and the continent. The "Peons," a call of people employed for this purpose, travel at the rate of five miles an hour, and they are relieved at certain stages by fresh runners. They usually go from Cumbho to Manara, a distance of 150 miles, in three days. Here they take boat, and crofs over by Adam's bridge to Ramiferam, and then proceed along the Coromandel coast to Madras. An express will generally run from Cumbho to Madras in eight days. See RAmiferam.

The Dutch built a fort on the island of Manara, with a view to command the passage and the communication with the continent by Adam's bridge. It was principally intended to prevent the subjects of the king of Candy from smuggling over any of the produce of the island, particularly fishery; and also to cut off all intercourse between that prince and those of the continent, by which he might have formed alliances dangerous to their interests. The protection of the pearl-banks and pearl-fishery, which lie at no great distance from this island, was also another object for constructing a fort here. It also contributed considerably to the revenues of government, as a station where certain duties are levied on the vall quantities of calicoes, coarse muslins, cottons, and other articles, brought through this passage to Cumbho by the Moors, Malabars, and other inhabitants of the continent. These circumstances are sufficiently important in order to keep in this place a constant garrison, the existence of which is greatly overbalanced by its advantages. The garrison stationed here consists only of a company of Malays or Sepoys, under the command of an European officer; but during the pearl-fishery, an additional force is sent from Cumbho.

In proceeding along the coast of Ceylon from Manara, the country is found to be sandy, wild, and barren, equally destitute of accommodation and provisions. The woods are infested with wild animals, that it is very dangerous to travel along the roads here without a proper guard. The sea is skirted by a tract of low flat land: but farther inland there are rice and paddy fields, with some scattered huts. This appearance continues about 35 miles to the southward of Manara, where the wood and jungle again begin to approach to the shore, and to cover the whole surface of the country, till at Chilou the cinnamon woods face the commencement of the district of Nigumbo. At Mantote, near Manara, there are some remains of antiquity. A Gentoo city is said to have flourished there, and 50 have been built by that harmless people, who took refuge from the vellongs of the embankment of a tank, and a number of brick runs still remain. About 12 miles from Manara lies the village of Arippo, where the civil and military officers, who attend the pearl-fishery, reside during the season. This is the only place in their vicinity where good water can be procured. Here is a chapel for those of the Roman Catholic persuasion, who confit chiefly of the Parawas and Malabars, resorting hither during the season of the pearl-fishery. In the neighbourhood the woods are very full of deer and wild hogs.
hogs. At no great distance lies the bay of Condathy; which fee. Percival's Ceylon.

MANABACCA, a small island in the East Indian sea. S. lat. 3° 50'. E. long. 131° 45'.

MANABEA, in Botany, (from the Caribbean name of one of the species, Manaba,) Aubl. Guian. 61. t. 23-25. Jull. 107, Lamarck Illutr. t. 70, is referred to Schreber to Ephigila; fee that article. Wildenow in his Sys. P1. v. 1. 615, defines eight species of Ephigila, three of which are the more plants of Aublet; one is E. martiiacae of Jacquin and Linneaus; another the Nuxia of Combercon, Lamarck Illutr. t. 71; the three remaining ones being adopted from Swartz.

MANACA, a Brazilian baciferous shrub, with an umbilicated fruit, like that of the juniper, containing three elliptical seeds, of the size of lentis; the part used in medicine is the root, which is great, solid, and whitish; its medicinal properties, reduced to powder, has very considerable effects; but because it works very violently, both upwards and downwards, in the same manner as scarmony, or the fulfa, it is usually given only to very robust persons, and then with care. In a jilt dole; it has somewhat of a bitterness and acor. The root, macerated in water, makes a fomentation, or bath, for those who are afflicted with wandering pains in the joints, especially such as are contracted by cold; the plant is used as a vulnerary by the Brahtians.

MANACHA, in Geography, a considerable town of Arabia, in the province of Yemen, the seat of the dola of Harras, and famous for its fairs.

MANACHOE, a town of Hindooftan, in Bahar; 26 miles N.W. of Durbutah.

MANACIZO, a town of Naples, in the province of Otranto; 12 miles S.E. of Tarento.

MANACOR, a town of the island of Majorca, situated in a fertile plain, where persons of rank and of the most considerable property spend the summer season. Its population consists of about 7000 inhabitants. It contains a parish church, a monastery of Dominican Friars, and an hospital for invalids. The productions of the soil in its vicinity are corn of all sorts, vines, fruits, vegetables, and pastures for flocks and herds. Proceeding along the coast from Manacor towards the east, you pass San Screra, and on the north of the village discover "Arta," containing near 8000 persons. This town, built in a mountainous situation, is one of the richest in the island: it contains a parish church, a convent, a public oratory, and two chapels of cafe for the villagers. The land in the neighbourhood affords pasture for cattle of all kinds, and produces wine, olives, corn, and vegetables. The inhabitants cultivate the cotton tree very successfully, and make a large quantity of oil.

MANACUS, MANAKIN, in Ornithology. See Pipra.

MANADO, in Geography, a small island and town, near the north coast of the island of Celebes. N. lat. 1° 3'. E. long. 124° 32'.

MANAGE, or MANGE, an academy, or place for learning to ride the great horse; as well as for breaking horses to the proper motions and actions. The word is borrowed from the French mange, and that from the Italian maneggio, or some will have it, à man agendo, from acting with the hand. In every mange is a centre, or place defined for vaulting round a pillar; a course or career for running the ring; and, on the side, are pillars, between which are placed the horses intended for high airs.

MANAGE, or Manges, is also used for the exercise itself, either of the horse or the rider. See Horsemanship.

MANAGUERA, in Geography, a town situated on the west coast of Madagafcar.

MANAKIN, in Ornithology. See Pipra.

MANAM, in Geography, a town of Africa, in Sugiufellia; 16 miles E. of Sugulmefia.

MANAMAG, a small island in the sea of Mindoro. N. lat. 11° 27'. E. long. 120° 47'.

MANAMANGALUM, a town of Hindooftan, in Travancore, near the coast of Malabar; 40 miles S.S.E. of Cochin.

MANAMBE, a town on the east coast of Madagafcar. S. lat. 15° 20'. E. long. 50° 5'.

MANAMBOTCHE, a town on the coast of Madagafcar. S. lat. 15° 50'. E. long. 50° 5'.

MANAMBOUGE, a river of Madagafcar, which runs into the sea on the south coast. S. lat. 25° 20'.

MANAN, an island of the Atlantic ocean, near the coast of Main, in North America; 30 miles in circumference. N. lat. 44° 48'. W. long. 66° 45'.

MANANBATO, a town on the east coast of Madagafcar. S. lat. 24° 51'. E. long. 47° 30'.

MANANCIALS, a town of South America, in the government of Buenos Ayres; 190 miles N.N.W. of Buenos Ayres.

MANANGHERA, a river of Madagascar, which runs into the sea on the east side of the island. S. lat. 22° 45'. E. long. 52° 4'.

MANANGOHOU, a river of Madagascar, on the south coast, which runs into the sea, opposite to the island of St. Mary. S. lat. 17°.

MANANZ R1, a town on the east coast of Madagascar. S. lat. 21° 8'. E. long. 48° 20'.

MANAPAR, a town of Hindooftan, in the country of Tiuvaly, lying on the point of land projecting into the gulf of Manera; 33 miles S.E. of Palancotta. N. lat. 8° 18'. E. long. 78° 12'.

MANARA. See Manaar.

MANARAN, a small island in the sea of Mindoro. N. lat. 11° 20'. E. long. 120° 51'.

MANARDI, John, in Biography, a learned physician, was born at Ferrara in the year 1462. He pursued his studies in philosophy and medicine under that able teacher, Nicholas Lomincus, who was then professor of the sciences at Ferrara, and who took much interest in fostering his talents by private as well as public instruction. But Manardi has been accused of much ingratitude, in his subsequent conduct towards his master. In the year 1482 he was appointed medical professor in his native university, and occupied this post until 1505; when he quitted Ferrara, and resided for some years with Gian-Trancecco Pico, of Mirandola, to whom he was both physician and preceptor, and whom he assisted in publishing the work of the celebrated John Pico against judicial astrology. In 1512 he was invited to become physician to Ladulius, king of Hungary; he accepted the appointment, and remained in that country two years after the death of that prince, which occurred in 1516. On his return to Ferrara, he resumed his functions as a teacher in the beginning of 1519. At an advanced age he married a second wife, young, and of great beauty, by which he was supposed to have shortened his days. He died at Ferrara, on the 8th of March 1556, at the age of seventy-four; and a very honourable inscription to his memory was placed on his tomb by his widow. After his return from Hungary, he published the following works, which are all that he produced: I. "Medicinæ Epitola Recensorum Errata et Antiquorum Decretâ perifîmini reference." Ferrar. 1521. This work went through numerous editions, the latter of which were much augmented, to
the number of twenty books, with alterations in the title, 

"Epitola Medica Libri xx." Basle, 1540, 

folio; to which, and several subsequent editions, were added his "Annotationes et Commentaria in Joannis Mefiae Medicinae et Compotita," ultimate, "Curia Medica xx. Libris Epitola Medicae, et Consulationum adumbrata." Hanov. 1611, 

folio. These letters were written principally between the years 1590 and 1536. They contain a miscellaneous collection of remarks, of very various merit, upon the writings and practice of the ancients, with corrections and refutations. Haller terms Manardi a semi-Arabist and semi-Galenist; which implies a bold and obstinate mind, attached to the ancient doctrines only when they were not repugnant to cautious observation. His censors on the practice of the Egyptians are often expressed with great vivacity; but they are mingled with many unfelt and trivial discussions. He treats of the uses verna, as a new discharge imported from America, and recommends the cure by guaiacum in preference to mercury. 3. He also published "In praemium Artis parvæ: Galeni Librum Commentarii," Rome, 1525, 40. Gu. Biag. Elsey Diet. Hist. De la Med.

MANAS, in Geography, a river of Asia, which runs into the Caspian sea, 15 miles N. of Derbend. 

MANAS, Hotam, a town of Thibet; 125 miles N. W. of Tourfan. N. lat. 44° 58'. E. long. 86° 44'.

MANASQUAN, a river of America, in New Jersey, which runs into the Atlantic, N. lat. 40°. W. long. 74° 8'.

MANASSEH, Half Tribe of, that lay beyond Jordan, in Scripture Geography, was bounded by the tribe of Gad on the south, the Jordan and Semachonite lake on the west, the hills of Bashan and Hermon on the east, and part of the Lebanon on the north. This territory extended from 32° 30' to 33° 36' of latitude, and was more properly called, afterwards, Upper Galilee, or Galilee of the Gentiles. (See Galilee.) It had several large territories and considerable cities: those of the former form were known by the names of Gilead, Batanea, Gaulontis, Aurantis, Machonitis, Gethar, Auran or Amram, and Argob; all of them deriving their names from their capitals. The cities of this half tribe were Bozrah and Bozrah, Selicha, Maacah or Maacati, Gerphon, Aisharoth, Adriach or Hadradikhar, or the tents of Kedar, Suetar, Gamala, Efdrai, Gilead, Pella, Abel, Abel-Maacsah or Abel-Beth-Maacsah, Iabez-Gilead, Corazin or Coforad, Julias, Bethulia, near the desert of its name, Girafa or Girgafa, Hippo, Gader, and Ephron, besides a number of others of less note.

MANASSEH, Half tribe of, on this side of the Jordan, was situated south of the tribe of Zebulon. The territory of this Manasseh was hemmed in, N. and S., by Issachar and Ephraim, and, on the E. and W., by the Jordan and Mediterranean. It exhibited a variety of plains, mountains, vales, springs, and a good number of notable cities; among which were Beth-Shean or Seccothpolis, Salem, Aner, Bezech, Abel-Melahah, Caftum Alexandrinum, Tirihah or Terla, Acrabatha, Thebez, Thanae or Tanag, Gath-Rimon, Maccot, Ennon, Megiddo, Gilgal, Dor or Dora, Caearea Paleftina, and Antipatris.

MANASWARY, in Geography, a small island in the Pacific ocean, at the entrance into Dory harbour, near the N. coast of New Guinea. In 1775 captain Forrest found the true nut-meg tree on this island.

MANATANGNY CREEK, a river of America, in Pennsylvania, which runs into the Schuykill, N. lat. 40° 15'. W. long. 75° 40'.

MANATE, a river of Honduras, which runs into the bay, N. lat. 15° 45'. W. long. 88° 21'.

MANASTE, Lagoon, a bay on the coast of Yucatan. N. lat. 18° 22'. W. long. 89° 18'.

MANATEE, Bay, a bay on the S. coast of Jamaica. N. lat. 17° 51'. W. long. 76° 45'.

MANATENGHA, a river of Madagascar, which runs into the sea on the E. coast, S. lat. 23° 30'.

MANATI, a town on the island of Cuba, in a bay on the N. coast. N. lat. 24° 32'. W. long. 76° 20'.

MANATI, or Sea-cow, in Zoology. See Theriacus Manatus.

MANATI LAPIS, a name given to a bone, of which there are two found in the head of the manati, or sea-cow; they are roundish, and are usually of the size of a hand-ball. They are said to have great virtues against the f lone and gravel, when burnt to ashes, and given in white wine. The term need not, however, regret the scarcity of this remedy, for probably any animal bone, when burnt to ashes, is polluted of all its virtues.

MANATIRSKA, in Geography, a town of Russia, in the government of Irkutsk, on the Ichora; 84 miles N.E. of Kirensk. N. lat. 58° 43'. E. long. 109° 44'.

MANATOLIN, a chain of islands in Lake Huron, extending 92 miles in length, and about fix in breadth. The term, according to Carver, signifies in the Indian language the place of spirits, and the island is esteemed sacred by the Indians. N. lat. 45° 20' to 45° 49'. W. long. 81° 56' to 84'.

MANAZERUDAM, a district or province of Turkestan, N. of Fergana.

MANBAGE, a town on the S. coast of the island of Sibun. N. lat. 10° 16'. E. long. 123° 38'.

MANBALLA, in Zoology, the Ceylonese name of a species of serpent, called also the taisin, or dog-serpent, from its manner of flying at every thing that comes in its way, as our dogs do; it is a deep brown colour, beautifully variegated with white.

MANBED, in Geography, a town of Persia, in the province of Irak; 174 miles E.S.E. of Isphahan.

MANBONA, the capital of the kingdom of Sabia, in Africa, situated on the sea coast, at the entrance of the channel of Mozambique; 50 miles S. of Sofala. S. lat. 20° 45'.

MANBOOM, a town of Bengal; 54 miles N.W. of Midnapore. N. lat. 23° 6'. E. long. 85° 87'.

MANBOTE, in our Old Writers, a compensation or recompense for homicide, particularly due to the lord for killing his man or vassal.

MANG, in Geography, a town of Grand Churia; 50 miles W. of Badakhshan.

MANGA, a town of America, in West Florida, on the E. bank of the Millip Vienna, at the mouth of Hona-chitto river.

MANCAEBRILANGA, a town of the island of Borneo; 30 miles N. of Negara.

MANGANILLA, in Botany, a name given by Plumiier to a genus of plants, since characterized by Linnaeus in the name of hippocampe; which fee.

MANGENILLA, in Geography, a large bay on the N. side of the island of St. Domingo, about 4000 fathoms long from east to west, and 2800 broad from north to south. The S.E. part is very wide, and affords excellent anchorage even for vessels of the largest size. In other parts it is too shallow. The river Maffaree, which separated the French and Spanish colonies on the N. side of the island, runs a N. course towards its mouth N.W. and enters the eastern part of the bay. The river swarms with fish, particularly with those large mullets, which are highly prized at Cape Francois. Fishing in the bay is difficult on account of the drifted wood, but
but the negroes, being good divers, plunge to the bottom and difengage the feine, in doing which, the negroes, filh, and alligators are engaged in an amazing kind of contest. The negroes kill the alligators, knock out their teeth, and fell them for making corals, which serve to mark the luxury and pride of those who furnish them to the merchants of their children. The plenty of fish often attains ships of war to this bay. The mouth of Maffacre river lies in N. lat. 19° 44'. W. long. from Paris 74° 9'.

Mancha, L.s., an extensive province of Spain, north of New Castile, by which it is bounded on one side, on the W. by Extremadura, on the S. by Cordoba and Jaen, and on the E. by Marcia and Valencia. It is 43 leagues long and 33 broad; and divided into Upper and Lower. The capital of the former is Ciudad Real, and that of the latter Ocana. The soil is in general dry and dryly; and the country abounds in plains of considerable extent, but they are waste and almost wholly without trees. The rivers that water it are little more than rivulets. A great part of the province is surrounded by mountains, forming part of the chain beginning in Sierra d'Occa, called by the ancients "Montes Orofandani." The most considerable of these mountains is the Sierra d'Alcarce, extending from N. to S., towards the southern and easter parts of the kingdom of Jaen. In La Mancha also, near Alcarce, and at the side of the Sierra of that name, begins the famous Sierra Morena, or the "Montes Mariani" of the Romans. They continue to the kingdom of Cordova; a ridge spreads into Jaen, and they extend as far as Extremadura, and even to the banks of the Guadalquivir. The province of La Mancha contains 111 parishes, 78 monasteries and convents, two cities, and 121 towns, of which ten belong to the crown, and 75 to the military orders, 46 villages, one intendancy of a province, and one hospital. The principal towns are Ciudad Real, Ocana, Alcarfa, and Almagro.

Ciudad Real, which is reckoned the capital of La Mancha, is situated in a plain, which is rich, and productive of corn, wine, and fruits. This city has lost much of its ancient splendour; its woollen manufactories and trade have much declined, and its population is of couiple reduced to the number of eight or nine thousand persons. The town is regularly laid out; the streets are straight and well paved; and it has a square 150 paces long, and 75 broad, surrounded with two rows of boxes for the accommodation of the spectators at bull-fights and public fairs. This place is the residence of the intendent of La Mancha, and the grand vicar and ordinary of the archbishop of Toledo, and the principal place within the control of a corregidor. In the parish church of St. Mary is a spacious and lofty chancel; the chief altar of which is composed of four different orders of architecture, each of which is ornamented with pillars, upon the whole well executed. A great quantity of leather for shoes was formerly prepared in this city, and a considerable manufacture of them was established. The cardinal of Lorenzana, the archbishop of Toledo, erected at his own expense a hospital, which cost about 12,500D. erecting; and he also let on foot a manufacture of flannels and coarse woollen clothes; and he lately proposed to establish another of flax. For an account of the other towns, see the respective articles. The population is rather more than 200,000 inhabitants, or, according to the survey of 1787 and 1788, 206,160; and the clergy not numerous. The Mejia de Ocana is the richest and most fertile plain in the whole country.

La Mancha is a flat level country, and the soil is parched with heat. The productions of such a soil must necessarily be limited; it produces corn, and especially oats, in sufficient quantity to supply the neighbouring provinces. But the principal part of the country is fo deftitude of trees, that for several leagues in succession you scarcely see one. The most common trees are cheiftins of a dwarf species, which grow spontaneously; olive trees, however, are found in many parts, and also a number of vines, the bulk of which are those of Almansares, which bear. The other productions of La Mancha are saffron, honey, and fpar. No fruit is to be met with except in some particular districts, and in small quantiies. Almagro is famous for melons and potatoes. The meadows are not numerous, except for about four leagues between Ciudad Real, and Santa Cruz de Muela, where they are fine and extensive; immense herds are fed in these plains, and especially mules, which are of an excellent breed. The manufactories of La Mancha are now declined. They formerly fabricated ribbons, garters, workeflockings, tapeftry, and silks of different sorts, and a great quantity of leather-gloves, both at Ciudad Real and Ocana; at the former of those towns they made all sorts of woollen stuffs, but they have very much declined. A fabric of blond lace has been lately set on foot at Almagro, which employs 2500 people. The other branches of labour are reduced to four; one of hard fap at Ocana; another of flannels at the fame place and Campo de Cifuentes, at a third at Alazar de St. Juan, of gunpowder, and the fourth of falfpeter at Pedronera. Zebalque, and Alazar de St. Juan, the last of which furnishes annually 200,000 quintals of falfpeter to the crown, on whose account it is wrought. The wool spinning is a considerable fource of industry throughout this province, and employs from 12 to 16,000 people of all ages and sexes. Commerce is in a very low flate in this province: the only productions with which it furnishes the neighbouring provinces are a little fpar, oats, and wine, together with a small quantity of blond lace and shoe-leather. But these few articles do not counterbalance the imports from other provinces and countries, which supply La Mancha with flot, spices, falt provifions, hardware, licen, muffins, broad cloth, fine woollen fluffes, flks, and in a word all articles of luxury, and even many of neccifity with regard to clothing. The animal and vegetable kingdoms prevent nothing worthy of much attention in this province: but it has some mines and mineral waters that may deferve notice: fuch are mines of iron, ochre, rock-cryftal, hole, calamine, flag, &c. It has also mineral waters both for drinking and bathing. The multiplication of the arts and sciences, La Mancha does not excelt. The manor of this province differ little from that of Cafile. The people, fays La Borde, are more grave and folemn in their deportment, and more attached to ancient customs and ceremonies, and their constitutions more robust and fit for labour: their temper in general is mild and peaceable, and they are truly good-humoured. Perfons in the higher ranks pafs their lives in cafe and apathy; on the other hand, the common people are laborious and frugal; and both orders, fays La Borde, take no part in any fort of dilfipation, or even of diversion. Every thing is grave and formal. Other travellers, however, report, that this is the moft cheerful country in Spain; that the inhabitants are very fond of music and dancing. A player on the guitar, and a finger of fequilidas, are perfons in great requet in this part of the country. The girls, young men, and married women are faid to assemble at the firft found of the infrument; the best voices fing fequilidas, and the blind accompany them on their infruments. A local traveller fays, there is no labourer nor young female peafant who is not weel acquainted with Don Quijote and Sancho." The traveller, fays another writer, ean scarcely cu-
ter the province of La Mancha without having constantly in his thoughts the fabulous hero, whose name renders this country more celebrated than its spacious and parched-up plains could ever have made it. Cervantes, in his endeavours to ridicule the taste for romances, perhaps has left only a sober recollection of the spirit of chivalry, which his hero, notwithstanding his madness, always renders venerable. The names of Quintanar and Toboso are impressed on the memory of every one, and one looks round for the village of the famed and peerless Dulcinea, and the wood where the first meeting took place between her and the doughty Don Quixote. The colliers of all ranks of the people, in the principal towns of this district, is similar to that of New Castile. The peasant wears a close camisole of cloth, or leather, fastened with a leathern girdle, and on his head a square cap rising to a point. The fides, which are turned up, continually beat against each other: it is made of cloth, or leather, and is called a "montera." A stranger, who visited some of the assemblies of amusement in this province, would be astonished at seeing a labourer in the dress of Sancho, wearing a broad leathern girdle, become an agreeable dancer, and perform all his steps with grace, precision, and measure. The fongs and fequillas on these occasions are peculiar to this part of the kingdom, and it is to be remarked, that to singing and dancing the Manchegans add the merit of poetry. Most of the sequillas are volupitous, and turn on the subject of love or absence; though some are farical.

MANCHAC, a town or parish on both sides of the Millipii, in Louisiana, extending 12 miles on the river. See LOUISIANA.

MANCHE, LA, the Channel, one of the nine departments of the N. W. region of France, composed of Cotentin and Arrorachin, and opposite to Jersey and Guernsey, in 49 N lat. The five circles into which it is divided are Valognes, containing 143,777 inhabitants, St. Lo, including 90,329, Mortain 69,765, Arroraches, 94,711, and Coutances, 130,530. The soil, partly sandy and partly marshy, is better adapted to pasture than cultivation: it produces, however, some grain, flax, hemp, fruits, and roots. It has mines of copper, iron, and cinnabar, with mineral springs. Salt, in considerable quantities, is manufactured and exported. For a further account of this department, see CHANNEL.

MANCHESTER, a market town in the hundred of Stafford and county of Lancaster, England, is seated on the banks of the small rivers Irk, Medlock, and Irwell, at the distance of 183 miles from London and 33 from Liverpool. In point of commercial and political importance, though not a corporation, it is undoubtedly the second town in the kingdom. The whole population, according to the parliamentary census of 1800, amounted to 84,653 persons, of whom 44,500 were engaged in different branches of trade; 44,900 were females, and 39,110 were males. The amazing increase of population in this town is thrown by returns obtained in the years 1793 and 1811. In the former year there were 29,651 persons; and in the latter 98,733. The parish of Manchester comprehends several of the contiguous townships, the whole population of which is 136,870.

Manchester appears, from the testimony of Mr. Whitaker, to be a town of great antiquity. A site occupied by the ancient Britons is supposed to have been settled here 500 years before the Christian era. It did not, however, deserve the name of a town till after the invasion of this island by the Romans, when it became one of the fortified retreats of the brave but undisciplined natives. At this period it was called Mancenion, that is, the "place of tents;" but Agriculture, who conquered it A.D. 79, changed its name to Mancenium. It was afterwards called Manduesmedum, and Mancaster, from which latter term its present appellation is evidently derived. The Romans, upon achieving the conquest of this flatland, built an extensive castle upon the spot now denominated Castle-field, situated near the conflux of the Medlock with the Irwell; but every vestige of this is removed to make room for modern buildings. After having retained it in continued possession for somewhat more than 400 years, the declining fortunes of Rome compelled the legionary folders to abandon it to the original poftellors, who in their turn sold it to their new conquerors and tyrants the Saxons. During the dynasties of that ferocious people, Manchester was several times a place of military conflict, being seated on the immediate confines of the Northumbrian kingdom. Edward the Elder, king of the Mercians, is said to have fortified and rebuilt a considerable part of it, which time and violence had united to destroy. At the period of the grand Domedfay survey, two churches appear to have existed here, called St. Mary's and St. Michael's. Albert de Greley obtained from the Conqueror the lordship of the manor. In 1301 his grandfion, Thomas, granted a charter to his burgesses of Manchester, constituting their town a free borough. Lord de la Warr, the last male heir of this family, laid the foundation of the collegiate church, which tended, in no small degree, to promote its increase and improvement. This town in early times was a place of sanctuary, and one of the eight places to which that privilege was confirmed by Henry VIII. in 1540. The year following, however, it was removed to Chelfter, which the flattute declares "had a strong gaiul and a mayor, and had not the wealth, credit, great occupations and good order which Manchester had." In 1605, a petifion raged here, and carried off upwards of 1000 persons. Upon the breaking out of the civil war between Charles I. and the parliament, Manchester decidedely espoused the republican cause, and successively refited several fielges by the royal army, under the earl of Derby. Notwithstanding these circumftances, however, the inhabitants feem to have honoured the reforation of Charles II. with particular marks of joy.

From this short sketch it will readily be perceived that, in an historical point of view, Manchester is only entitled to a very small share of general attention: though regarded as a manufacturing town, it is dererely distinguished above every other in England. When it first began to be noted for its manufactures is uncertain; but in the time of Edward VI. Manchester cotton, Manchester rags, and Manchester friezes are frequently mentioned in various acts of parliament. In 1650, its trade is described as "not inferior to that of many cities in the kingdom, chiefly confilting in woollen friezes forlhnens, fack-cloths, mingled fluffes, caps, inkles, tapes, points, &c. whereby not only the better part of men are employed, but also the very children by their own labour can maintain themselves. There are, besides, all kinds of foreign merchandise brought and returned by the merchants of the town, amounting to the sum of many thousand pounds." About this time great quantities of linen yarn feem to have been imported here from Ireland, which being wrought into cloth, was refhipped for the Irish market. It was not, however, till after the middle of the last century, that Manchester rose to a pre-eminent rank among our manufacturing towns; a rank for which it is chiefly indebted to the ingenuity and invention of Mr. Hargreave and Sir Richard Arkwright. Previous to the year 1760, all the cotton yarn manufactured in the country was spun by hand, upon that well known domestic instrument called
called a one-thread wheel. Shortly after this period, Mr. Hargreave constructed a machine denominated a jenny, by which one person was enabled to spin from twenty to forty threads at a time. These machines soon came into general use, but were much limited in their employment till the year 1775, when Sir Richard brought the improvements of his predecessor to much greater perfection. This gentleman having established his extensive manufactories here, made Manchester the principal seat of the spinning trade, the rapid increase of which produced a corresponding increase in the buildings and population of the town. See the preceding articles of Arkwright, vol. ii. and Cotton, vol. x. for further particulars. In Brayley’s “ Beauties of England,” vol. iii., Derbyshire, is an interesting and ample memoir of Sir Richard Arkwright, with accounts of the present state and proceedings of the cotton manufactures.

As Manchester, notwithstanding its extent and political importance, is not a corporate town, the government is vested in a headborough, called the boroughreeve, and two constables. These are chosen annually from the most respectable of the inhabitants by a jury impannelled by the steward of the manor, at the courts leet, which are held by the lord of the manor twice every year at Easter and Michaelmas. The boroughreeve is usually one of the gentlemen who has served as constable for the preceding year, and is treated with more respect (the paraphernalia of a mace-bearer excepted), than any mayor in the kingdom. The chief duty of this officer is to preside at public meetings, and to distribute certain charities, denominated “boroughreeve charities,” all the judicial functions connected with the police being executed by the constables and their deputies. A court of requits is held every month for the recovery of small debts; and every Wednesday and Saturday several respectable magistrates sit in the court-room of the New-Bayley for the administration of justice in pleas of almost every description, whether civil or criminal. Quarter sessions also are held four times a-year; and, from pres of huntsmen, the court is sometimes obliged to continue its sittings for nearly a fortnight.

This town is divided into two portions by the river Irwell, which receives the Irk at a short distance from the collegiate church. The situation of Salford is very similar to that of Southwark, the communication between the two towns being kept up, as in London, by three bridges thrown across the river at different places. The most ancient of these is called the “Hanging bridge,” Old, or Salford bridge, and is supposed to have been originally founded in the time of the Romans. The present, built in the reign of Edward III., was formerly very dangerous for foot passengers, but in 1778 it underwent a thorough repair and extension. Blackfriars’ bridge, erected about fifty years ago, is constructed entirely of wood, and flagged for foot passengers only. But the finest bridge over the Irwell is the New bridge, commonly called the New Bayley bridge, which was founded in 1785, and is constructed wholly of stone. It consists of three large arches, and a fourth of smaller dimensions, left open in support of the duke of Bridgewater’s right to a tow-path to his quay, in Salford, agreeably to the tenor of the act, enabling His Grace to form his extensive canals. Six bridges are here thrown across the Irk, the chief of which are: Hutbank bridge, situated near the college, and Scotland bridge: nine are thrown over the Medlock, which runs in a serpentine course through the southern suburbs of the town. Oxford-street bridge forms a part of a street of that name. A variety of other bridges lie across the numerous canals which intersect the suburbs at different places, and at Knotmill, in the vicinity of Castle-field, is a very noble tunnel, through which the Rochdale canal passes, not far from its junction with that of the late duke of Bridgewater’s.

With respect to the plan and buildings of this town, it may be remarked, that the portion of it called the Old Town confiils of a very motley assemblage of old and new houses, closely huddled together, and exhibiting little elegance in their exterior appearance. Even the new streets, though much superior to the old, are uniformly narrow, except in a few instances where they have been improved by the acts of 1775 and 1791. In these latter, however, there are a number of very excellent modern buildings. Molyve-street and Portland place would do honour to the capital itself. Grovenor-square, when finished, will probably rival the finest in the kingdom. The suburbs of Ardwick-green and Salford crescent are peculiarly pleasant, and contain some handsome houses, which are mostly occupied by the wealthy manufacturers.

The churches and other public edifices of this town are numerous, but few of them are distinguished for architectural beauty. The College, or parish church, founded, as already mentioned, by lord de la Warr, bishop of Durham and rector of Manchester, is a venerable building in the rich ornamented style of the 15th century. In the interior its appearance is confused and heterogeneous. The windows still retain many rich remains of the painted glasses with which they were formerly ornamented. The roof is of elegant wood-work, interpersed with carved figures of angels playing upon different musical instruments. In front of the gallery, on each side of the clock, are suspended the colours of the 72nd regiment, raised in this town by subscription during the American war, whose noble conduct at the siege of Gibraltar is still remembered with exultation by every lover of his country, and particularly by the inhabitants of Manchester. Adjoining to this church are a number of small chapels well worthy of the attention both of the architect and the antiquary. A view of this church, with a particular account of its history and architectural peculiarities, written by J. H. Markland, F. S. A., is given in the third volume of “The Architectural Antiquities of Great Britain.”

St. Ann’s churh, situated at the end of the square to which it gives name, is distinguished for its handsome appearance. It was founded by lady Ann Bland in 1759, in compliment to whom it was dedicated to the saint whose name it bears. The church of St. Mary, situated between Deansgate and the river Irwell, is admired for its beauty and fine proportions of its spire, which measures 186 feet in height. The lantern which supports it is peculiarly striking, being composed of eight noble Ionic pillars, surmounted by a large globe, upon which is placed a golden crescent. St. John’s church is built in the style which is called modern Gothic. In the windows are several pictures, and a beautiful window of stained glasses. Two of the windows in the body of the church are also decorated with fine painted glasses. The other churches in this town are St. Paul’s in Turner-street, St. James’s in George-street, St. Michael’s in Angel-street, St. Clement’s in Léver-street, St. Stephen’s near Bolton-street, St. George’s in the neighbourhood of Newton-lane, and St. Peter’s, which terminates the prospect down Dawson-street and Molyve-street. The latter was designed and executed by James Wyatt, esq. In Salford is Trinity chapel, a neat stone edifice of the Doric order.

Besides these churches there are three others also belonging to the establishment, situated in the adjoining townships of Ardwick, Chorlton, and Pendleton, which, from their vicinity to Manchester, may not improperly be considered as belonging to it. Numerous chapels and meeting-houses, appropriated for the public worship of dissenters of almost every denomination
MANCHESTER.

denomination, are likewise differeed through various parts of the town. Catholics are numerous here, and the Methodists are found to comprise a very considerable proportion of the whole population.

The vast number of excellent charitable institutions with which Manchester abounds are highly creditable to the benevolence, liberality, and public spirit of its inhabitants. Indeed, in this respect, this town is not surpassed by any in the British empire, whether the suitability of the buildings for their respective purposes, or the liberal contributions by which they are supported, are taken into view. Among these establishments, Chatham's-Hospital, commonly called the College, is first referring to notice, by priority of foundation. It owes its existence and entire support to the munificent bequest of Humphrey Chatham, esq. of Clayton, whose will is dated the 16th of December 1651. At first, the number of boys clothed and educated here amounted only to forty; but from an increase in the value of the estates belonging to the foundation, the number was augmented more than thirty years ago to eighty. The building appropriated to this charity is situated on a lofty rock, near the confluence of the rivers Irk and Irwell, immediately adjoining to the collegiate church already mentioned, to which indeed it formerly belonged. Upon this spot Mr. Whittaker supposes the Romans had their praetorium, or summer camp; and certainly the situation was admirably adapted for that object.

In a large gallery, in this edifice, is a public library, likewise founded by Mr. Chatham, which now contains upwards of 15,000 volumes in various languages, and in almost every branch of science or literature, besides some very valuable manuscripts. The Infirmary, Difpenary, Lunatic Hospital, and Asylum, are all included in one spacious building, situated in the front of Lever's Row, which is considered as the highest ground in the town. The foundation of the first edifice was laid in 1753, for the reception of forty patients; but the number was soon afterwards doubled, and now there are 100 beds appropriated for the use of the sick. The Lunatic Hospital was opened in 1766, and the Difpenary in 1792. The annual subscriptions for the support of these institutions, amount to several thousand pounds. Here are two poor-houses, one of which was erected in 1792, on the side of the Irk, nearly opposite the College; and the other built the year following, at the upper end of Greengate in Salford. Both of them are handsome buildings, and admirably fitted up for the purpose to which they are appropriated. The Lying-in-Hospital was instituted in 1790, and not only provides professional aid for indoor patients, but likewise for the assistance of such poor married women as find it inconvenient to leave their own houses. The House of Recovery is intended chiefly for the reception of patients afflicted with contagious fevers. The other principal charities are the strangers-friend-society, instituted in 1751, and the boroughreeve's charity: the former designed for the relief of strangers, and the latter for the aid of the poor inhabitants in general. The Free-School is an excellent foundation, which owes its origin to Hugh Oldham, bishop of Exeter. In this school the greater part of the clergy of the town and neighbourhood have been educated, as well as many noblemen. There are, besides, several inferior charity and Sunday schools in various parts of Manchester.

Though in every respect a manufacturing town, Manchester has not wholly neglected the promotion of literature and science. Societies, having this object in view, are numerous. The chief of them are the Literary and Philosophical, instituted by Dr. Thomas Percival in 1781; and the Philological Society, which commenced its meetings in 1803. Here are also two very extensive public circulating libraries; the former founded in 1757, and the latter in 1792. The Manchester Agricultural Society was established in 1765, and has for its object the encouragement of the useful arts in general, by the distribution of premiums for scientific discoveries. A laudable practice is also adopted, of granting premiums to cottagers, who support their families without parochial aid; and in some instances likewise, honest and good servants are rewarded by honorary presents. The repository, designed to encourage and reward industrious females, has proved highly serviceable to many individuals, and is therefore justly entitled to liberal and careful support.

Besides these already noticed, many other public buildings and institutions, intended either for useful purposes or for amusement, may properly claim attention in this place. The Theatre, a commodious and extensive building, was erected in 1607. It is open during seven months of the year, and can in general boast of a very respectable company of performers. The gentlemen's Concert-room is elegant and capacious, and will accommodate upwards of 1200 persons. This is supported by a voluntary subscription; and strangers are admitted with a subscriber's ticket. There are likewise very excellent new and commodious assembly-rooms for balls, card-assemblys, &c. The New-Bayley, or Penitentiary house, is well deserving attention, both on account of the extent of the edifice and arrangement of its parts, and also for the economy observed in the interior. Immediately above the entrance is a large room, where the fejeons are held; and adjoining to it are several commodious rooms for the magistrates, jurors, &c. Beyond this, in the centre of a large area enclosed by lofty walls, stands the prison, an extensive building in the shape of a cross, three stories high. It is remarkable for the cleanliness with which it is kept, as well as for its regulations. Prisoners, not confined for capital crimes, are allowed the free exercise of their respective trades. A workhouse, on a large scale, has also been lately built.

A new structure, called the Manchester Commercial Building, or Exchange, was commenced in the year 1806, from designs by Mr. Harrison, architect. It was completed in January 1809, and is appropriated to the use of the merchants and manufacturers of the town, who subscribe certain shares of 50l. each, to defray the expenses of its erection. The building comprises an exchange-room, dining-room, drawing-room, ware-rooms, shops, and counting-houses, a library for the use of the subscribers, in addition to the public library, and a prize-office, with extensive cellars under the whole. It is built of stone, and presents a simple, but classical façade, with semi-columns of the Grecian Doric order. The exchange-room is very spacious, containing an area of 4000 superficial feet, in the centre of which is a glazed dome, 40 feet in height, supported by eight fluted columns of the Ionic order. Over a part of this room is a gallery, or semicircular suite of rooms, appropriated to an extensive library, belonging to Mr. Ford, a respectable bookfeller of this town, whose large catalogue contains a valuable assortment of scarce, curious, and interesting works.

The Trade of Manchester conficts chiefly, but not entirely, in the manufacture of cotton goods. Vellum papers, checks, a variety of small articles, such as filleting, tapes, laces, gauze, &c. are likewise made in great quantities. The silk manufacture has advanced rapidly here within the last ten years; and a manufactury for making and finishing hats is now carried on to a great extent. The profusion of goods made here is conveyed, by means of the Irwell and the numerous canals which intersect the town, to different ports both on the eastern and western coast. Liverpool, however, is the principal mart for the exportation of the cottons; and between
sween that town and Manchester there is a confluent and rapid communication both by land and water-carriage.

Manchester has two markets, called the old and the new, both of which are held twice a week on Tuesdays and Saturdays: the latter is the principal one for provisions; the former being mostly frequented for transacting the manufacturing business of the town with the country traders. Most of the streets are paved and lighted, and are guarded at night by about 200 watchmen. For the regulation of parochial affairs, Manchester is divided into fourteen districts. It gives title of duke to the noble family of Montague, some of whom have been distinguished characters. In the paths of literary fame, however, it can claim little distinction; but Byrom and Falsner may be properly ranked with what Fuller calls "the worthies of the place."

The environs of this town abound with old mansions, respectable villas, and a number of modern seats. Ancoats-hall, the manorial manson-house, is a venerable building, the parts of which are disposed in a most curious and grotesque manner. Hulme-hall, or Holme, is an edifice of a similar kind, exhibiting a remarkable specimen of ancient domestic architecture. It stands on the edge of a shelving bank of the Irwell, and exteriorly offers to the view a mock romantic and picturesque object. Heathen-howe, the feast of the earl of Wilton, lies about four miles to the north-east of the town. The house, a handsome modern structure of stone, stands on a commanding situation, in the midst of a very noble park, finely decorated with venerable trees and numerous thriving plantations. The other principal seats are Trafford-howe, Alkington, and Smidley-hall; near which fall is Boughton-hall, formerly the property of the Stanleys, earls of Derby. Every part of the surrounding country displays the highest state of agricultural improvement, and in times of prosperity presents one vast scene of enterprise and industry. Beauties of England and Wales, vol. ix. Aikin's History of Manchester, and its Environs, 4to. by J. Aiton. The Manchester Guide, 12mo. 1804. Whitaker's History of Manchester, 2 vols. 4to. 1771.

Manchester, a port and fishing town of America, on the sea-coast between Cape Anne and Beverly, in the county of Essex and state of Massachusetts. This township was incorporated in 1645 and contains 1082 inhabitants. — Alfo, a port-town of Vermont, in Bennington county, on Battenkill; 22 miles N.E. of Bennington and 59 N.E. of Albany in New York; the township containing 1397 inhabitants. — Alfo, a township in York county, Pennsylvania, including 1175 inhabitants. Well Manchester, in the same county, contains 794 inhabitants. — Alfo, a small port-town of Virginia, on the S. side of James river, opposite to Richmond, with which it is connected by a bridge. — Alfo, a town of Nova Scotia, 10 leagues N.W. of Cape Cano, which in 1783 contained 250 families.

Manchester House, a factory belonging to the Hudson Bay Company, 100 miles W. of Hudson's house and 75 S.E. of Buckingham house; situated on the S.W. side of Salkafawan river, in the N.W. part of North America. N. lat. 53° 14' 18". W. long. 129° 20'. — Alfo, a port-town in Antrim's county, on the N. bank of the Ohio, about 10 miles above Maffachusetts; incorporated in January 1802.

MANCHICOURT, Pierre, in Biography, a native of Be lune, in Artois, and director of the music in the cathedral of Dornick, who flourished in the middle of the sixteenth century, and whose name frequently appears among the composers of motets and songs, in four and five parts, Vol. XXII.

does not reward lovers of music of this period for the trouble of scoring his productions so much as many of his contemporaries; and, indeed, in three or four of them that we have examined, he seems not only a dry but a clumsy contrapuntist.

MACHINEAL HARBOUR, in Geography, a bay on the E. coast of Jamaica. N. lat. 18° 4'. W. long. 75° 58'.

MACHINEAL, in Botany. — See HIPPOMANE.

Dr. Peyfonyel, in his observations on the fruit of this tree, informs us that the savages use the juice of it to poison their arms, the wounds of which are thereby rendered mortal; that the rain which washes off the leaves, and falls on the human body, causes blisters to rise like boiling oil, and that even the shade of the tree is fatal to those who sit under it. However, timely application by purges and emetics have prevented their ill effects. Phil. Trans. vol. i. art. 105. p. 772.

MANCHULL, in Geography, a town of Hiddoollan, in the circar of Joodpour; 16 miles S. of Joodpour.

MANCIAT, a town of France, in the department of the Gers; 16 miles S.W. of Condom. N. lat. 43° 59'. E. long. 0° 7'.

MANNINELLA, in Botany. — See HIPPOMANE.

MANCINI, FRANCESCO, in Biography, composed an oratorio which acquired him great reputation, intitled "L'Amor divino triunfante nella morte di Cristo!" and hymns for the Florentine brotherhood of the Pietà, during Lent, which were published at Rome in 1700. Mancini was a Neapolitan, and, seemingly, the first opera composer of eminence in that country during the last century. Between the years 1700 and 1731, he produced several operas and intermezzi that were much esteemed by the first professors of his time, particularly Hassé and Geminiani, who always spoke of him as a very able master. The celebrated opera of Idaspe fade, or Hydaspes, brought on our stage in 1711 by Nicollini, was set by Farnaceo Mancini. In this oper it was, that Nicollini's battle with the lion gave birth to Addison's humorous papers on the subject, in the first volume of the Spectator.

Mancini, Thomas, fon of the chapel-mifer of Groningen, and one of the 53 examiners of the organ erected in that city in 1596, recorded by Werckmeister, in his "Org. Groning. Recit." See ORGAN, and WERCKMEISTER.

Mancini, Giambatista, maestro di canto della corte Imperiale, or singing-mifer to the Imperial court, and Accademico filarmonico, published in 1774, at Vienna, a treatise on singing in 4to. intitled "Penfieri e Rilieffioni pratiche," or practical thoughts and reflections on figurative song; a work of merit, superior to any treatise on the same subject that has appeared since the time of Tofo. The author was a scholar of the famous Bernacchi, the celebrated disciple of Piluccio, the founder of the Bologna school of singing, and master, not only of Mancini, but of Ama- dor, Guarducci and Rafo, the celebrated tenor, all renowned opera singers of the first class during the last century.

In the 11th article, or section of this book, the author gives a lift and character of all the most celebrated opera fingers, male and female, from the time of Piluccio down to Pacchiasatti and the Gabrielle. In the 11th section he describes the vocal organ, its several parts, physical defects, and qualities necessary to its perfection.

IV. Of the voce di petto, voice from the chest; voce di

3 C
M A N

...or fallet, and the art of uniting them; that is, the natural voice that comes from the chief, and the feigned voice that is merely formed in the throat, and the uniting them in such a manner, that the hearer cannot distinguish where nature ends and art begins.

V. Of intonation.
VI. Of the manner of opening the mouth, and emission of voice free from the teeth, nose, and throat.
VII. Of the portamento, and manner of forming, modulating, and conducting the voice.
VIII. Of the name of different registers of voice, of the accentuation and concealment of defects.
IX. Of the mezzo di voce, or swell, and description of the voice of Farinelli.

X. Of the shake and beat. The author calls the trill or shake the support, ornament, and life of song; "Oh trillo! sollegno, decoro, e vita del canto." Describes the shake alla capra, alla coccia, or that resembles the goat's cough, or the neighing of a horse.

XI. Of the cadence or close.
XII. Of agility of voice or rapid execution.
XIII. Of the knowledge and accomplishments necessary to appearing on the stage as a public singer.

XIV. Of recitative and action.
XV. Of the sobriety and regularity of conduct necessary to a student in singing.

The author in conversation mentioned to us at Vienna, what he has since inferred in his book, a curious operation performed at Naples by singer Francisco Piccillo, an eminent surgeon, on the organ of voice, by cutting the glands of the throat, when inflamed or prominent as to obstruct the free passage of the voice. It is certain, says singer Mancini, that the glands of the throat may be safely removed, but it is likewise certain that the defect still remains. The operation was performed at Naples on three several persons in a most dextrous manner, with two can-knives, without however molesting the voice.

The ingenious author of this useful tract, who had himself been a capital vocal performer on the opera stage, and drew his rules from long practice and experience, died at Vienna about 1779. A third edition of the "Pennerische Religione," and Mancini's "Treatise on Singing," appeared at Milan in 1778.

MANCIPUM, or MANCEPS, in the language of ancient jurisprudence, was a name used to distinguish those spoils that were taken with the hand; and whenever they were sold or emancipated, the purchaser required some assurance that they had been the property of an enemy; and not of a fellow-citizen.

MANCEPS, in Old Authors, denotes a carrier. There was an anciently an officer in the Temple called by this name, who is now called the steward; and both name and office are still retained in the colleges in both universities.

MANCO CAPAC, in Biography, legislator and first Inca among the Peruvians, was the twelfth in ascent from the Inca who reigned at the time of the Spanish invasion of Peru in 1532, which interval was computed by the natives at about 400 years. According to their tradition this personage, with his wife and sister Mama Oclo, otherwise called Caya Mama, both of majestick form and clothed in decent garments, appeared in an island of the lake Titicaca, and declared themselves to be children of the sun, sent to civilize and instruct the savage people who then inhabited that country. Manco accordingly instructed the men in agriculture and other usefull arts, while his wife taught the women to spin and weave. After this, Manco began to form them into a regular society, and to give them a fyllem of laws and policy. Manco Capac, toward the close of a long and prosperous reign, assembled his numerous family and principal subjects in the city of Cuzco, and after a suitable exhortation he expired in their sight. His memory was held in the utmost veneration by his own people, and as far as we can rely upon the tradition annexed to his name, he seems justly entitled to rank among the benefactors of mankind. In what is related to the intercourse rejected from this tradition, it will appear that some stranger from a civilized land arrived in Peru, and, by calling in the aid of religion, obtained an ascendency over the minds of the natives, which enabled him to form a regular government, and place himself at its head. Absolute power in the monarch was the necessary consequence of this sanctity of character, and the government took the form of a theocracy. Its civil institutions were directed to the preservation of order and tranquility; its religious rites were for the most part innocent and humane; and gentlemen and submissively distinguished the Peruvians among the nations of South America. Robertson's Hist. of America.

MANCORA, in Geography, a town of Peru, in the diocese of Truxillo, on the road from Guayaquil to Truxillo, on the Sea-coast, 70 miles N. of Payta.

MANCORN, a word used by the ancients to express what they call a sort of honey, which seems to have been evidently our modern sugar. They say that it was a sort of dry honey found concreted in caves or rocks, and was of the quality of salt, and that it was found in India and Arabia Felix, and that when taken into the mouth, it broke under the teeth like salt.

MANCUNIUM, in Antiquity, a town of Briton mentioned in the 18th iter or rout of Antoninus's Itinerary, and supposed to be the same with Mancehster; which see.

MANCUS, formed of manu causis, in Antiquity, an Anglo-Saxon gold coin, equal in value to 24 solidi, or thirty pence; and in weight to fifty-five Troy grains. The first account of this coin that occurs in the history of our country, is about the close of the eighth century, in an embassy of Cenwulf, king of Mercia, to Leo III., regaining the restoration of the jurisdiction of the see of Canterbury; this embassy was enforced by a protest of 120 marcuse. Ethelwold also sent yearly to Rome 300 marcuse; and these coins are said to have continued, in some form or other, till towards the conclusion of the Saxon government. The hoards of the nobility are chiefly estimated by this standard in Cnut's laws. It came originally from Italy, where it was called ducat, and is supposed to have been the same with the drachma or millesare, current in the Byzantine empire. Clarke on Coins, p. 380, &c. See Mark.

MANDA, in Geography, an island in the Fractis of Malacca, near the coast of Sumatra, about 35 miles in circumference. N. lat. 0° 28'. E. long. 103° 2'.

MANDACH, a village in the district of Wilden, in the Swaf canton of Aargau, on the left bank of the river Aar. The neighbourhood of this place is famous for the variety of petrifications with which it abounds. The fields in its vicinity furnish numerous fragments of immense cornua ammonis, most of them several feet in diameter, likewise large quantities of petrified coralloids, such as millepores, porpites, trachites, terebalinites. Not far from Mandach, at Holwyl, elephants' tusks have been found, together with various species of coadites, buccicites, turritites, oloracites, echinites, &c. Still more of these fossil remains occur at —— Deutsch-
Deutsch-Beuren, among which is a vast stratum of gryphite, the prototypes of which do no longer exist; and, in a bed of sand, a thin stratum of the shell called concha hypocreaphalides in its recent state, and hitherto not observed in any other place. Near Ellingen a stratum of small cockle is seen, perfectly un mixed with other substances. In the neighbourhood of Veltheim we find belemnites, ammonites, tellinites, &c. in great profusion; and at Cafeilen and Schenkenburg, oolithes, olaritites, chamites, &c.

All these petrifications in the district of Wildenstein are deposited in the sandstone formation, which overlays strata of lime-stone.

MANDADO, a small island in the East Indian sea, near the N. coast of Celebes. N. lat. 1° 18'. E. long. 124° 21'.

MANDAL, a sea-port town of Norway, in the province of Christiantand, at the mouth of a river of the same name; 10 miles W.S.W. of Christianland. N. lat. 58° 2'. E. long. 7° 43'.

Mandelig Islands, three or four small islands near the N. coast of Java. S. lat. 6° 27'. E. long. 110° 56'.

Mandamus, in Law, a writ issueing out of the court of king's bench, lent by the king, and directed to any proper corporation, or inferior court of judicature within the king's dominions; requiring them to do some particular thing therein specified, which pertains to their office and duty, and which the court of king's bench has previously determined, or, at least, supposes to be con nectant to right and justice. This is a high prerogative writ, of a most extensive remedial nature; and may be issued in some cases, where the injured party has also a more tedious method of redress, as in the case of admittance, or restitution to an office: but it issue in all cases where the party hath a right to have any thing done, and hath no other specific means of compelling its performance. A mandamus, therefore, lies to compel the admission or restitution of the party applying, to any office or franchise of a public nature, whether spiritual or temporal; to academical degrees; to the use of a meeting-house, &c. It lies for the production, inspection, or delivery of public books and papers; for the surrender of the regalia of a corporation; to oblige bodies corporate to affix their common seal; and to compel the holding of a court, &c. The writ of mandamus is made by statute (9 Ann. cap. 20.) a moat full and effectual remedy for the refusal of admission, where a person is entitled to an office or place in any corporation, and also for wrongful removal, when a person is legally possess ed. It may also be issued in purview of the statute, (11 Geo. I. cap. 4.) in cases within the regular time no election shall be made of the mayor or other chief officer of any city, borough, or town corporate, or (being made) it shall afterwards become void; to require the electors to proceed to election, and proper courts to be held, for admitting and swearing in the magistrates so respectively chosen. This writ issue to the judges of any inferior court, commanding them to do justice according to the powers of their office, whenever the same is delayed. For it is the peculiar business of the court of king's bench to superintend all other inferior tribunals, and therein to enforce the due exercise of those judicial or ministerial powers, with which the crown or legislature has invested them; and this, not only by restraining their excesses, but by quickening their negligence, and obviating their denial of justice. A mandamus may, therefore, be had to the courts of the city of London, to enter up judgment (Raym. 214.) to the spiritual courts to grant an administration; to swear a churchwarden and the like. This writ is founded on a suggestion, by the oath of the party injured, of his own right, and the denial of justice below: whereupon, in order more fully to satisfy the court that there is a probable ground for such interposition, a rule is made (except in some general cases, where the probable ground is manifest), directing the party complaining of to shew cause why a writ of mandamus should not issue; and if he shews no sufficient cause, the writ itself is issued, at first in the alternative, to do thus, or signify some reason to the contrary; to which a return or answer must be made, at a certain day. And if the inferior judge, or other person, to whom the writ is directed, returns or signifies an insufficient reason, then there issues in the second place a peremptory mandamus, to do the thing absolutely; to which no other return will be admitted, but a certificate of perfect obedience and due execution of the writ. If the inferior judge or other person makes no return, or fails in his respect and obedience, he is punishable for his contempt by attachment. But if he, at the first, returns a sufficient cause, although it should be false in fact, the court of king's bench will not try the truth of the fact upon affidavits; but will for the present believe him, and proceed no farther on the mandamus. But then the party injured may have an action against him for his false return, and (if found false by the jury) shall recover damages equivalent to the injury inflicted; together with a peremptory mandamus to the defendant to do his duty. Blackl. Com. book iii.

Mandamus was also a charge to the sheriff, to take into the king's hands all the lands and tenements of the king's widow, who, against her oath formerly given, married without the king's consent.

Mandans, the name of those Indians who inhabit the vicinity of the Misouri in Louisiana. These Indians are brave, humane, and hospitable; and are, upon the whole, the most friendly and well-disposed in this part of the country. About thirty years ago they lived in six villages, about forty miles below their present villages, on both sides of the Missouri. Repeated visitations of the small-pox, together with frequent attacks of the Sioux, have reduced them to their present number. They claim no particular tract of country. They live in fortified villages, hunt in their own neighbourhood, and cultivate corn, beans, squashes, and tobacco, which form articles of traffic with their neighbours, the Affiniboins: they also barter horses with them for arms, ammunition, axes, kettles, and other articles of European manufacture, which the Affiniboins obtain from the British settlements on the Assiniboine river. The articles which they thus obtain from the Affiniboins, and the British traders who visit them, they again exchange for horses and leather tents with the Crow Indians, Chyennes, Watapahatoes, Kiawes, Kanenavich, Stacfan, and Katakou, who visit them occasionally for the purpose of traffic. Their trade may be much increased. Their country is similar to that of the Ricaras: and their population is increasing. Jefferson.

Mandar, a town of the island of Celebes; 125 miles N. of Macaffar.

Mandara, a town of Egypt, on the E. branch of the Nile; 38 miles N. of Cairo.

Mandaree, a town of Bengal; 30 miles N.N.W. ofMidnapour.

Mandarin, a name given by the Portuguese to the nobility and magistracy of the eastern countries, especially to those of China.

The word mandarin is unknown in this sense among the Chinese, who, in lieu thereof, call their grandsires and magistrates.
mandarins, &c. The nobility, which includes the mandarins, is divided into three classes: The highest class contains the princes, the next the lords, and the third the commoners. The princes are the sons of the emperor, and are invested with the highest authority. The lords are the sons of the princes, and have considerable power. The commoners are the sons of the lords, and have less power. The nobility are the sons of the commoners, and have no power at all.

In China, there are three degrees of mandarins, each of which is subdivided into three classes. The highest degree is called the "minister," and includes the emperor and his immediate family. The second degree is called the "secretary," and includes the princes and the lords. The third degree is called the "mandarin," and includes the commoners and the nobility. The mandarins are the highest class of mandarins, and are the only ones who are entitled to the title of "mandarin." The mandarins are divided into three classes: the first is called the "chief mandarin," and includes the emperors, princes, and lords. The second is called the "second-class mandarin," and includes the commoners and the nobility. The third is called the "third-class mandarin," and includes the mandarins of the third degree.

The emperor is the highest authority in China, and is invested with all powers. He is assisted in his duties by a council of ministers, who are chosen from among the highest officials of the empire. The council of ministers is divided into three sections: the first section includes the ministers of state, the second section includes the treasurers, and the third section includes the secretaries. The ministers of state are chosen from among the highest officials of the empire, and are responsible for the administration of the empire. The treasurers are charged with the collection of taxes, and the secretaries are responsible for the collection of money and the preparation of documents. The emperor is assisted in his duties by the grand censors, who are chosen from among the highest officials of the empire. The grand censors are responsible for the supervision of the officials of the empire, and are charged with the task of investigating and punishing those who violate the laws of the empire.

The mandarins are the highest class of officials in China, and are the only ones who are entitled to the title of "mandarin." are accordingly continued in office or disgraced. The conduct of the viceroy himself is watched by inspectors, whose authority is formidable to him; and more especially to inferior mandarins, whom he has power to deprive of their employments for misbehaviour. In order to prevent partiality among the mandarins, relations in the fourth degree cannot have a seat at the same time in any of the provincial tribunals. Sick or supernumerary mandarins are liberally provided for by government. All mandarins, whether Tartars or Chinese, of arms or of letters, are obliged, every three years, to give in writing an exact account of the faults they have committed in discharging the duties of their office; and this kind of confession is examined at court, if the mandarin belong to any of the four first classes: but if it be made by any mandarins of the lower classes, it must be laid before the provincial tribunal of the governor. Informations, as the result of private inquiry, are addressed to the tribunal of mandarins, and there carefully examined: and distributive justice is exercised accordingly. Every mandarin who has discharged his duty with ability, zeal, and fidelity, is rewarded; but if he has been guilty of oppression and malpractices, he is not only dismissed, but impeached, and tried before the tribunal of crimes.

Since the time that the Tartars have rendered themselves masters of China, most of the tribunals, or courts of justice, &c. instead of one mandarin for a president, have two, the one a Tartar, and the other a Chinese.

The mandarinate is not hereditary. Duhalde. Grolier.

Mandarin is also a name which the Chinese give to the learned language of the country.

Besides the proper and peculiar language of each nation and province, they have one common to all the learned men in the empire. This they call the mandarin tongue, or the language of the court. Their public officers, as notaries, lawyers, judges, and chief magistrates, write and speak the mandarin.

MANDATA, in Geography, a town on the S.W. coast of Sumatra; 45 miles S.E. of Indrapour.

Mandatary, Mandaturius, he to whom a command or charge is given: and that comes to a benefice by a mandatum is called by this name.

Mandate, Mandatum, in the Canon Law, denotes a referent of the pope, by which he commands some ordinary,collator, or prefect, to put the person there nominated in possession of the first benefice vacant in his collation.

An apostolical mandate for the provision of benefices, is a monitory and comminatory letter from the pope to a bishop, by which he is enjoined to provide a sufficiency for those who have been ordained by him, or his predeceivers, from the tocature to sacred orders inclusively; and to allow them their sufficiency till they be provided with a benefice. This practice was occasioned by the bishops formerly laying hands on great numbers, and afterwards abandoning them to misery and want.

At first the popes only gave monitory mandates, which were no more than simple prayers and requisits, that did not bind the ordinary: afterwards they gave preceptory mandates, which did not annul the provisions of the ordinary; at last they set up executory mandates, by which the provision made by the ordinary, in prejudice of the mandate, were declared null; and the executor of the mandate, in default of the ordinary, conferred the benefice on the mandatory: but the pope's power in influing these mandates is now very much restrained, and almost totally annulled.

Mandates, Royal, to judges for interfering in private causes, constituted a branch of the royal prerogative, which was given up by our English Jutinian, Edward I.; and also by 2 Edw. III. c. 8, and 1 Ric. II. c. 10, it is enacted, that no commands or letters shall be sent under the great seal, or the little seal, the signet, or privy seal, in diffurance of the law; or to disturb or delay common right; and, though such commandments should come, the judges shall not enste to do right; which is also made a part of their oath by statute 18 Edw. III. f. 45 and by 1 W. & M. fl. 2. c. 2, it is declared, that the pretended power of suspending, or differing with laws, or the execution of laws, by regal authority, without consent of parliament, is illegal.

Mandatta, in Geography, a town of Hindoostan, in Candia; 30 miles S.S.E. of Indore.

Mandavee, a town of Hindoostan, in Guzerat; 25 miles E. of Surat.—Also, a town of Hindoostan, in Baglana; 12 miles N.N.E. of Bassen.

Mandawee, a town on the S. coast of the island of Borneo. S. lat. 3° 20'. E. long. 113° 30'.

Mandawee Islands, a cluster of small islands in the East Indian sea, near the S. coast of Borneo. S. lat. 3° 20'. E. long. 113° 30'.

Mandaya, a town on the W. coast of the island of Celebes. S. lat. 2° 53'. E. long. 119° 9'.

Mande, St., a small island in the English channel, near the coast of France. N. lat. 48° 51'. W. long. 2° 59'.

Mandegele, a town of the island of Ceylon, near the E. coast; 88 miles E.S.E. of Candy.

Mandelgur, a town of Hindoostan, in the circar of Meywar; 14 miles N. of Chectore.

Mandelli, a town of Abyflina; 150 miles E. of Gondar.

Mandelslo, John-Allbert, in Biography, a native of Meckleburg, was page to the duke of Holstein, and accompanied, as gentleman of the chamber, the embassadors whom that duke sent to Muscovy and Persea in 1617. From the court of Peria, he went to Ormus, and embarked for the Indies. On his return he drew up a "Journal of His Voyages," which is printed in the second volume of the Travels of Olearius, who was secretary to the embassy, and is held in much esteem. Morei.

Mandelstein, in Mineralogy. See Trap.

Manderia, in Geography, a town of Africa; 120 miles N.E. of Senaar. N. lat. 14° 45'. E. long. 35° 10'.

Manderscheid, a town of France, in the department of the Sarre, and chief place of a canton, in the district of Prum; 21 miles N.N.E. of Treves. The place contains 323, and the canton 2593 inhabitants, in 23 communes.

Mandery, a town of Hindoostan, in Dowlatabad; 10 miles W.N.W. of Ranaupur.

Mandeville, Sir John, in Biography, a celebrated early traveller, was born at St. Albans about the beginning of the fourteenth century. He was intended for the profession of physic, which he probably practised, but an ardent desire of visiting foreign countries induced him, in 1332, to set out upon a course of travels, in which he spent more than thirty years. During this period he extended his peregrinations through the greatest part of Asia, Egypt, and Lybia, making himself master of many languages, and collected a great mass of information, which he committed to writing in Latin, English, and French. He died at Liège in the year 1372. The only genuine edition of his travels is thus entitled, "The Voyage and Travaille of Sir John Mandeville, knight;" it was printed from the original MS. in the Cottonian library, 1727. The character of Sir John, for veracity, has been very differently regarded by different and competent judges; his narratives were highly esteemed in his own age, and they rendered him celebrated throughout Europe.
MAN

Europe. By some of his remarks it should seem that he had a general acquaintance with the science of the period in which he flourished.

MANDEWAR, in Geography, a town of Hindustan, 18 miles S.S.W. of Arrah.

MANDIBLE, the Jaw, in Anatomy. See MAXILLA and CROWN.

MANDIBULARES, or Manducatori Musculi. See M.Assessor and DEGLUTITION.

MANDIL, or Mandril, the name of a kind of cap or turban worn by the Persians.

The mandil is formed by first wrapping round the head a piece of fine white linen five or six ells long; over this they wrap, in the same manner, a piece of silk of the same length, and often times of great value. To make the mandil more fastened, care must be taken, that, in wrapping the silk, it be so managed as that the several colours found in the several folds make a kind of waves, somewhat like what we see on marbled paper.

The drap is extremely majestic, but at the same time very heavy: it serves either as a shelter to the head from cold, or as a screen from the excessive heat of the sun; it is said, that a blow of a cutlass will not penetrate it. In rainy weather they cover it with a kind of cloth or hood, made of red cloth.

The mode of the mandil has been in some time altered; during the time of Schah-Abbas II. it was round at top, in the time of Schah-Soliman, they brought one end of the silk out of the middle of the mandil over the head; and, lastly, in the reign of Schah-Hussein, the end of the silk, in lieu of its being gathered as before, was plaited in manner of a rope; and this the Persians account extremely graceful, and use it to this day.

MANDING, or Mandinga, in Geography, a country of Africa, situated on both sides of the river Jolba or Niger, towards its sources, and supplying those streams or rivers, called Baing and Kokoro, that form the Senegal. This country comprehends a considerable tract from between 11° and 13° N. lat. and between about 5° and 7° W. long. The inhabitants of this country, and those of other districts in the western part of Africa, who have probably migrated from hence, are called Mandingoes, and their language has a considerable extent. The government of this country is said to be republican; though that of the other African states is, in general, monarchical. In their complexions and persons, the Mandingoes are easily distinguished from those Africans who are born nearer to the equator; and yet they confine of very distinct tribes, some of which are remarkably tall and black; and there is one tribe among them (called taffo the Phulies) that seemed to Mr. Edwards to constitute the link between the Moors and Negroes, properly so called. They are of a less glossy black than the Gold Coast negroes; and their hair, though bushy and crispéd, is not woolly, but soft and silky to the touch. Neither have the Mandingoes, in common, the thick lips and flat noses of the more southern natives; and they are, in a great degree, exempt from that liability to beget children which exhales from the skin of most of the latter; but in general they are not well adapted for hard labour. After all, they differ less in their persons, than in the qualities of the mind, from the natives of the Gold Coast; who may be said to constitute the genuine and original unmixed negro, both in person and character. See KOROMANTYN NEGROES.

The Mandingoes, in general, are of a mild, sociable, and obliging disposition; the men are commonly above the middle size; and the women are sprightly, good-humoured, and agreeable. The dresses of both sexes consist of cotton cloth, of their own manufacture; that of the men is a loose frock, not unlike a surplice, with drawers which reach half-way down the leg, and they wear sandals on their feet, and white cotton caps on their heads. The women's dress consists of two pieces of cloth, each of which is about six feet long and three broad; one of which they wrap round the waist, which, hanging down to the ankles, serves for a petticoat, and the other is thrown negligently over the bosom and shoulders. In the construction of their houses, the Mandingoes, like the other Africans, in this part of the continent, content themselves with small hovels. A circular mud-wall, about four feet high, upon which is placed a conical roof composed of the bamboo cane, and thatched with grass, forms their common dwelling for people of all ranks. Their household furniture is no less simple; a hurdle of cane placed upon upright stakes, about two feet from the ground, upon which is spread a mat, or bulkhead's hide, anwers the purpose of a bed; a water jar, some earthen pots for draught their food, a few wooden bowls and calabashes, and one or two low stools, are the only necessary articles. As every man of free condition has a plurality of women, it becomes necessary, for the prevention of disputes, to accommodate each lady with a hut to herself; and all the huts belonging to the same family are surrounded by a fence constructed of bamboo canes, split and formed into a fort of wicker work. The whole enclosure is denominated a “firk,” or “fark.” A number of the females, separated by narrow passages, constitute what is called a town; in which the houses are placed without any order, except that the door is situated towards the south-west, in order to admit the fresh breeze. Their religion is, as we may conceive, blended with many superstitious opinions and practices. Although they admit the existence of a deity, as the maker and preserver of all things, they consider him as too remote and too exalted in his nature to regard the supplications of wretched mortals, or to alter for their fake any of his purposes and decrees. The prayers which are offered up at the appearance of the new moon are performed merely in conformity to a custom which has been transmitted to them from their ancestors. Subordinate spirits, as they imagine, are entrusted by the almighty with the functions of direction of all human concerns; and these spirits are much under the influence of certain magical ceremonies. The rite of circumcision prevails in this part of Africa even by those negroes, who have never received the religion of Mahomet. The Jallofs confine it to the males; but the Mandingoes, both Soninkeys and Buffreens, extend the ceremony to both sexes, as the ancient Egyptians did before them; and the operation is performed at the commencement of puberty. Mr. Park, in his “Travels,” informs us, that the negroes, in general, did not seem to consider this painful rite as an act of religious duty, and as such, essential to their future salvation; but rather as an operation of physical necessity; without which the marriage rate could not, in their opinion, be prolific. (See CIRCUMCISION.) We learn also from this observing and intelligent traveller, that the negroes of this part of Africa firmly believe in a life beyond the grave, and a state of retribution after death, in which the men will be rewarded, and had men punished. He conversed with the natives of all descriptions on this important subject, and pronounced, without the smallest hesitation, that a conviction of this great truth among the negroes is entire, hereditary, and universal.

Among the Mandingoes there are few or no influences of longevity; at 40, most of them become grey-haired and wrinkled; and few survive the age of 50 or 60, counting their years by the number of rainy seasons, one of which only occurs in the year. Their diseases, however, are few; the
the principal being the dyenmary, the yaws, the elephantiasis, and a leprosy of the worst kind. The Guinea worm is also in some places very common, especially at the commencement of the rainy season, and this they attribute to bad water; to which they likewise ascribe the goitres, or swellings of the neck, which are very common in some parts of Bambara.

The principal of their musical instruments are the kooingite, a sort of guitar with three strings; the koro, a large harp with eighteen strings; the mbingi, a small harp with seven strings; the balaton, composed of twenty pieces of hard wood of different lengths, with the shells of gourds hung underneath, for increasing the sound; the tanguang, a drum open at the lower end; and the tabala, a large drum used for causing an alarm through the country. Besides these, they make use of small flutes, bow-strings, elephants' teeth, and bells; and at all their dances and concerts, clapping of hands constitutes a necessary part of the chorus.

The beverage of the pagan Negroes is beer and mead, in the use of which they are apt to indulge to excess. The Mahometans drink nothing but water. The natives of all descriptions take tobacco, and smoke tobacco; and their pipes are made of wood, with an earthen bowl of curious workmanship. But in the interior districts, the greatest of all luxuries is felt. The arts of weaving, dyeing, sewing, &c. are universally practised; but the only artificers, acknowledged as such by the Negroes, are the manufacturers of leather and iron. They tan and dress leather very expeditiously, by first steeping the hides in a mixture of wood-ashes and water, until it parts with the hair; and afterwards using the pounded leaves of a tree called gogoo, as an astringent. Most of the African blacksmiths are acquainted with the method of smelting gold; in which process they use an alkaline salt, obtained from a ley of burnt corn-flakes, evaporated to dryness. They likewise draw gold into wire, and form it into a variety of ornaments, with great ingenuity and taste. Gold is found in every part of Mandingo, in small grains, nearly in a pure state, from the face of a pin's head to that of a pea.

The Mandingoes, most of whom are proselyted to Mahometanism, have frequent wars with each other, as well as with those nations regarded by them as enemies of their faith. The advantage possessed by a few of these people, of being able to read and write, is a circumstance on which the Mandingo Negroes in the West Indies pride themselves greatly among the rest of the states, over whom they consider themselves as possessing a decided superiority; and in truth, says Mr. B. Edwards, they display such gentleness of disposition and demeanour, as would seem to be the result of early education and discipline, were it not that, generally speaking, they are more prone to theft than any of the African tribes. It has been supposed that this propensity, among other vices, is natural to a state of slavery, which degrades and corrupts the human mind in a deplorable manner; but whether the Mandingo should have become more vicious in this respect than the rest of the natives of Africa, in the same condition of life, is a question not easily resolved. Edwards's 'Hist. of the West Indies, vol. ii.'

MANDOLY, an island in the East Indian sea, of a semicircular form, about 120 miles in circumference, separated from the west coast of Cilbo by the straits of Patientia, and belonging to the sultan of Bachian. The island is centrally traversed by the equator. E. long. 134.

MANDOE, a small island in the German ocean, near the coast of Slefwick; 10 miles W.S.W. of Ripen. N. lat. 55° 10'. E. long. 8 32'.

MANDOLA, a town of Italy, in the marquisate of Ancona; 30 miles N.E. of Spoleto.

MANDOLA, and Mandore, Ita.; Tefudo minor, Lat.; Mandole, and Mandolay, Fr.; a very small instrument, in form of a violin, with four strings, and a fretted neck, played with a quill in the right hand instead of a bow. About thirty years ago there was a Neapolitan here, of the name of Francee, who played admirably on this diminutive tinkling instrument, which had very little tone or variety of expression; yet, by his taste, fancy, and enthusiasm, Francee entertained lovers and nice judges of music during several hours, without tiring them with its monotonity, or rather total want of tone.

MANDORE, a small lute or guitar, with four strings, tuned fourths and fifths, sometimes thumbed with the finger, and sometimes played with a quill, like the mandoline.

MANDRA, in Geography, a town of Russia, in the government of Irkutsk; 75 miles N.E. of Kireik.

MANDRAGORA, in Botany. See ATROPA and DUDAIM.

MANDRAGONA, Chinse, is the plant Ginseng; which see.

MANDRAKE. See ATROPA and DUDAIM.

The roots of mandrake vary both in form and colour, being either divided or entire, and externally brown or black; hence they have been distinguished into male and female. The internal substance is white, and to the taste somewhat viscid, bitter, and nauseous.

MANDRAKE, in the 'Materia Medica,' has been recommended in cases of barrenness, but without foundation. All the eminent writers on mandrake regard the root to be an adonine and soporific; but in large doses it is said to excite maniacal fury. They employed it principally in continued watchings, and in those more painful and obilate affections which were found to reftit lefs powerful medicines. It was also used in melancholia, convulsions, rheumatic pains, seropulorous tumours, &c.; and for these purposes, either the expressed juice of the cortical part of the root, infipid, or a vinous decoction or infusion of the root, was directed. Pallas also mentions it as of frequent ufe for chronic difeases in some parts of Russia. (See ATROPA Mandragora.) The experiments, recited under that article, show that the mandrake acts as an opiate; which confirms the opinion entertained by the ancients; and hence it may be concluded, that if it be not admittted with great care, it may prove a deleterious and mental narcotic. This caution is the more necessary, as the berries of mandrake are said to have been eaten without producing any bad effect.

Woodville.

MANDRAKE-Wine, Manderagorica Vinius, a sort of medicinal impregnation of wine with the virtues of mandrake root. It is prepared by cutting into thin slices half a pound of the bark of mandrake roots, and straining them on a thread, and letting them down into a vessel containing nine gallons of white wine, so that they may hang loosely in it, and by that means fully impregnate it with their virtues. It was used in small doses as an adonine and soporific. It had the same effects as, if only inelled to, and was sometimes injected in clysters to the same purpose. They say that half a pint of this liquor, mixed with twelve times its quantity of wine, brings on a caras; and that even a smaller dose than this, if diluted, is mortal. See the preceding article, and ATROPA Mandragora.

MANDREL, a kind of wooden pulley, making a member of the turner's lathe.
MAN

Of these there are several kinds; as,
MANDRILLS, Flit, which have three or more little pegs or points near the verge, and are useful for turning flat boards on.

MANDRILLS, Pin, which have a long wooden shank to fit into a round hole made in the work to be turned.

MANDRILLS, Hollow, which are hollow of themselves, and used for turning hollow work.

MANDRILLS, Screws, for turning screws, &c.

MANDRILL, in Zoology, a species of baboon, or monkey. See Simia Maimon.

MANDSHURES, in Geography, people of Siberia who form two nations, the one called Mandhu or Mandshures, and the other Tungufes. Both these nations are related by descent, as we may conclude from their traditions, their language, and their bodily structure. The whole swarm together posse$$ extensive countries and deserts in eastern Siberia, and in the northern Mongolia. The Mandhu are still very powerful; one of their princely families being in hereditary possession of the throne of China. Before the Russians entered Siberia, the Mandshu people were in possession of all Daouria, or the eastern Siberia, from the Baikal quite to the Mongolian mountains, together with the regions adjacent to the Amoor, and its collateral rivers. They were at that time divided into several items, of which the Daourians inhabited the parts about the Selenga and the Upper Amoor; the Dutchshares dwelt between the Argoon and the Schilka; the Atchares about the middle Amoor; and the Ghiilak at the mouth of the Amoor, on the coasts of the Eastern ocean.

The Daourian Mandhu, not waiting for the arrival of the Russians in their territories, retreated to the Amoor, and into the empire of China. At the first Russian expedition, about the middle of the seventeenth century, the Daourians and Dutchshares were subjects of the Chinese emperor, who, as a native Mandhu, aided their flight, and afforded them protection. The Ghiilaks and Atchares submitted then in a state of independence, and accepted the Russian patronage without opposition. Their example was followed by considerable multitudes of the other two items; but most of them, by orders of the Chinese government, were transported from the Amoor, of which the Russians had made themselves masters, farther towards China. Afterwards, at a peace concluded at Nertchikuf, the whole of the Amoor, with all the Mandshures belonging to Russia, was ceded to China; and at present, the mountain-ridge Stannovoi Khiret, which stretches from Daouria northward between the rivers Lena and Amoor to the Eastern ocean, forms the boundary betwixt the two empires. In the frontier mountains themselves, however, are no Mandshures, but Tungufes, who are partly tributary to the Chinese, partly to Russia, or live in complete independence.

The Mandhu, particularly the Daourian, while they inhabited the modern Russia, were by no means an uncivilized people. According to their written accounts and traditions, they had a constitution composed of nomadic and civil parts, and adapted to their situation, their mode of life, &c. They lived peaceably among themselves and with their neighbours, attending sedulously to agriculture, grazing, and even to mining. Traces are still seen about the Bargudin, and other rivers, of their gardens, orchards, and fields, artfully laid out, and watered with artificial water-courses. The Daourian mine-works on the banks of the Argoon, still famous under the name of the Nertchikian mines, as well as all Daouria, afford numerous proofs of the mineral labours of the ancient Daourians. Tooke's Ruff. Emp. vol. i. See Tungusas.

The country of the Mandshures is divided by the Chinese into three great governments. 1. That of Chin-yang or Chen-yang; which lies. 2. The government of Kiren-Oula. (See Kirin.) 5. The government of Tsfichiar; which lies. See Manchow Tartars.

MANDSJADE, in Botany, is an Indian flagitious or pod-bearing tree, with a spiked pentapetalous flower, and long pods containing nodous scarlet-coloured beans; the tree is one of the tallest in the kingdom of Malabar, bears fruit the twentieth year after planting, and living near two hundred years.

The wood is of common use for various purposes, on account of its solidity; the leaves, reduced to powder, are used in the pagan religious rites; the seeds, which are not ungrateful to the table, are eaten by the common people, either boiled whole or ground to a meal; and are, besides, of great use to goldsmiths and jewellers, who, on account of their exact equality, employ them instead of grains in weighing their wares; for each melicita, as they call them, weighs four grains, such as are in use among the goldsmiths; who, also, of the bruised seeds, moistened with water and borax, prepare a glue for conglutinating the inner fott of vellies, when broken. Of the bruised leaves the phthalecins prepare a potion for mitigating pains in the loins.

MANDU, in Geography, a town of Hindooftan, in Mysore; 10 miles N.E. of Serinagapalum.

MANDUCATION, the action of chewing, otherwise called swallowed.

Manudcation is a term seldom used but in speaking of the eucharist. The Catholics maintain a real manudcation of the body of Christ; the reformed, on the contrary, take this manudcation to be only figurative, and by faith. St. Augustine calls it a spiritual manudcation. St. Pauud, in Geography, a town of Hindooftan, in Guzerat; 30 miles S.E. of Janegur.

MANDURIA, an ancient town of Naples, in Calabria, since.

After having sunk into decay, it was rebuilt at a little distance from its former site, and called "Cafale Nuovo," which name it retained till the year 1790, when, at the request of the inhabitants, the original name was restored. It contained about 4000 inhabitants. In 1793 it suffered very much by an earthquake.

MANE, a sea-port on the W. coast of Madagascar, at the mouth of the river Manafre. S. lat. 33° 55'.

MANE of a Horse, in the Manege. (See Horse.) The adjuntment of the mane of horses was an object of particular attention among the Armenians, and others who valued themselves on their breed of these animals. Some, as we learn from Vegetius, used to cut them clear off, a practice which he condemns, because it rendered the horse unseightly and deformed. Others clipped them, so as to make them resemble an arch or bow, called by us an "hog's mane." Others again separated the mane into notches, like the battlements of a tower; while some cut it close, but only on one side, leaving the hair long and flowing on the other, which was very graceful and becoming; the side on which the mane was turned and repofed being always to the right. To this Virgil alludes, when he directs the mane to be laid on the right shoulder.

"Denfa jubra, et dextro jaclata recurvatis in arnos." This method was practised by the Persians as well as the Armenians; and appears, by the above citation, to have been
been in use with the Romans, as well as that of shearing the manes of their "manni" or nags; whence Propertius says, his mistres Cynthia was carried in her litter by horned horses.

"Et mea detonis advecta est Cynthia mannis."

Varro likewise directs the mane to be turned to the right side: They also tied it in knots, or platted it, as the word "implicata" (lib. iv. c. 7.) aptly expresses. No particular reason is assigned for always turning the mane on the right side: it might be owing, perhaps, to the custom of mounting on the right, which was frequent, but not always, the practice; and in that cafe, the mane hanging on the side, from which the horfeman got up, offered itself to his hand to affift him in the action: while we, without any meaning, always mount on the left, and always turn the mane to the right. The Armenians, as well as the Parthians, had another method of trimming their horses, by which they made them as it were "double mane;" for the hair being cut away in the middle, the mane was divided, and falling down, clothed each side of the neck; a custom sometimes used at present, but generally among coast horfes. Berenger's Hill. &c. of Horfemanship, vol. i.

MANE-NEST is, a sort of covering for the upper part of a horfe's head, and all round his neck, which at one end has two holes for the ears to pass through, and then joins to the halter upon the fore-part of the head, and likewise to the surcingle, or long girth, upon the horfe's back.

MAN-EATER'S ISLAND, in Geography, a small island in the Indian sea, near the N. coast of the island of Java, between Batavia and Bantam.

MANEBELLO, a small island in the East Indian sea.

S. lat. 4°; E. long. 131° 58'.

MANEGE. A horfe is said to manege when he works upon volts and airs, which luppofes him broke and bred.

See Manage.

MANEGE for a Soldier's Horse, is a gallop of unequal swifhness, but fo that the horfe changes hands readily.

MANEGE, High, is the high or raised airs, which are proper for leaping horses. See Airs.

MANEGE. A horfe is said to be thoroughly manege, or a finished horfe, that is well broken, bred, and confirmed in a particular air or manage, fo as to bear wel upon the hand, know the heels, and fit well upon the hips.

MANELLI, Francesco, of Tivoli, in Biography, composer of the first Italian opera that was performed on a public stage in Venice, in 1635. The drama, intituled "Te- mitoche," was written by Ferrari, himself a composer; but the preference given to Manelli, either by the author of the words, or by the public, at such an era, is an indubitable proof of respect for his abilities; and a still more fulcious compliment to his talents, was his being retained by the same poet, and the same public, to compose a second opera, "Andromeda," in 1637. In subsequent years he composed four more operas, which had great successes. See Opera and Venice.

MANEQUIN, among Painters. See Layman.

MANERBIO, in Geography, a town of Italy, in the department of the Meda; 12 miles S. of Brefcia.

MANES, or MANI, in Biography. See Manicenes.

MANES, a poetical term, signifying the shades or souls of the deceased.

The heathens used a variety of ceremonies and sacrifices to appease the manes of those who were deprived of burial. See Lemures and Lemuria.

MANES, DI. were the same with inferi, or the infernal Vol. XXII.

MAN the gods, who tormented men; and to these the heathens offered sacrifices, to assuage their indignation.

The heathen theology is a little obscure with regard to these gods, manes. Some hold, that they were the souls of the dead; others that they were the genii of men; which last opinion suits but with the etymology of the word, and such is their origin according to Hesiod.

The heathens, it is pretty evident, used the word manes in several senses; so that it sometimes signified the ghosts of the departed, and sometimes the infernal or subterraneous deities, and in general all divinities that prefided over tombs, and the ghosts that were thought to wander about these tombs. Accordingly, their true origin may be referred to a prevailing opinion, that the world was full of genii, some of whom attended on the living, and others on the dead: that some were good and others bad, and that the former were called "familiar lares," and the latter lemures or larve. Thus, when Virgil says, "Quique fuos patimur manes;" it is, according to Servius, as if he had said, "we have each of us our genius." Apuleius, in his explication of the Lemures and Larve (see both these articles), says that the lares and larve are denominated "Dii Manes," and that the designation of gods is added to them by way of honour. Agreeably to this opinion it is no wonder that the ancients should confound the manes with the lares and the lemures.

The evocation of the manes of the dead seems to have been very frequent among the Thespians; but it was expressly prohibited by the Romans. See LARES.

MANESSON-MALLET, Alan, in Biography, a native of Paris, who flourished in the 17th century, and who was distinguished in the service of the king of Portugal as a military engineer. He is known, however, chiefly by his works, which continue till to be in request: they are "Martial Studies, or the Art of War," 1691, in three vols: "A Description of the Universe," &c. 1683, in five vols: "Practical Geometry," 1703, in four vols. His works are all illustrated with plans, maps, and other engravings.

MANETHOS, an ancient Egyptian historian, called the Schemite, from the place of his origin, was high-priest of Heliopolis in the reign of Ptolemy Philæsphus, about the year 524 B.C. He wrote in the Greek language a history of Egypt, the subject matter of which he affirms to have been extracted from certain pillars in the Sirdian land, on which inscriptions had been made in the sacred dialect of Thoth, the first Mercury, which after the flood were translated into the Greek tongue, but were written in the sacred character, and were laid up in books in the sacred recesses of Egypt by the second Mercury. But this account, which certainly related to the earlier portions of the history, is so incredible, by its reference to the Greek language, at a period when it could not be known in Egypt, that the writers of the Universal History refute these mistakes or corruption in the paffage of Eusebius containing it. The work of Manethos was divided into three tomes, the firll of which comprehended the history of the gods and demi-gods, who in his estimation were mortal men very eminent for virtue; the second that of the eight dynasties of kings, and the third of twelve. The history, which is, in a good measure, fabulous, is lost, but his dynasties have been preferred in the chronicle of Eusebius. Some fragments of the history are to be found in Josephus's work against Apion.

MANETTI, Gianozzo, was born at Florence in 1396: he was intended for trade, and received an education suitable to it, but being put into the house of a banker when he was only ten years of age, he became disgusted with the 3D employment,
employment, and was accordingly permitted to apply his mind to the various kinds of literature that were then cultivated. During nine years he devoted himself to these pursuits, after which he was appointed by the Florentines to give public lectures on the ethics of Aristotle, which were attended by a vast number of pupils. From the age of thirty-five, he was employed by the state in various lucubrations and studies and was several times deputed to preside over the public studies, which always flourished under his superintendence. He was sent on embassies to the republic of Genoa; to king Alphonso; to Francis Sforza; to the popes Eugenius IV. and Nicholas V.; to several of the Italian states, and to the emperor Frederick III., and on all these occasions he gave proof of great prudence and dexterity in the management of affairs, and of an eloquence which was the object of universal admiration. Notwithstanding the high rank to which he had attained, he found caufe for dissatisfaction at his own court, and retired to that of Nicholas V., who received him with great honour; but as he was cited to appear at Florence, on pain of banishment, the pope deputed him to go thither in the character of his embassador. His conduct in this new situation so ingratiated him with his countrymen, that from a culprit he became a principal magistrate. He afterwards returned to Rome, and was made secretary to Nicholas V., in which post he was continued by Calixtus III. Going to Naples on private busines, Alphonso kept him there with a pension for three years, during which he composed the greater part of his works. He died in 1459 with the character of one of the most learned and excellent men of his age. He was deeply skilled in the Hebrew language, and employed his great learning in this respect to confute the Jews from their own scriptures. He wrote a work against their tenets in ten books, which is said still to remain in MS. in the Laurentian library. Among his printed works are, "The History of Ptolema:;" "The Lives of Nicholas V., Dante, Petrarch, and Boccaccio;" "The Funeral Oration of Leonardo Bruni;" "De Dignitate et Excellentia Hominis," and some "Orations."
forts of grain, and of linen cloths, which are manufactured here in great quantities. The Turks have different mosques, as well as a garrison, in this place. Opposite to it is a Coptic convent, on the E. bank of the Nile, which is wholly inclosed with high walls, and into which the only mode of admission, in order to be secure against the rapacious Arabs, is that of being hoisted up in a basket, by means of a pulley; whence it has obtained the name of the "Convent of the Pulley." Two leagues below Manfellow, on the east bank of the Nile, is a chain of very high mountains, formed entirely of barren rock; the waters of the river have undermined them, so that their summit projects considerably beyond their base. This chain of rocks is called the mountain of "Aboufeda," from the name of a Mussulman saint who is buried there, and whom a small chapel has been erected. By the side of this monument of piety, or rather of the absurd superstition of the Mahometans, some men of the same religion, who are devout worhippers of saint Aboufeda, and, at the same time, determined robbers, live in retreats dug in the rock, and, formerly, as it is said, inhabited by Anchorites. But these excavations, as well as those in Scheick Abadé, and in the two chains of mountains between which the Nile runs, in the upper part of Egypt, are probably burial places and ancient tombs. However this be, the perfons who now occupy them are the most formidable pirates that obstruct the navigation of Egypt, and also the most difficult to be exterminated, as they take refuge in the inaccessible cavities of these mountains. Manfellow is 13 miles N.N.W. of Siout. N. lat. 27° 42'. E. long. 31° 36'. Sonnini's Travels in Egypt.

MANFORT, a town of Africa, on the Gold Coast, in the country of Fantin.

MANFRED, or MAINFROY, in Biography, king of Naples and Sicily, was natural son of the emperor Frederic II.; on the death of his father in 1250, he became poffefled of the principality of Tarento, and some adjacent counties. When his brother Conrad arrived from Germany, to take possession of the Sicilian kingdoms, he became jealous of Manfred's power and abilities, and took from him a part of his inheritance, but upon the death of Conrad, he became poffefsed of the regency in behalf of his nephew, the infant Conradin. The pope, however, claimed the kingdom as fief to the holy see, and excommunicated Manfred, who being unable to make opposition, received his holiness very submissive in Naples. Soon after he raised a body of troops, and defeated the papal army, and after other successes he recovered all the Neapolitan territory, and was received with great rejoicings into the city of Naples, where he behaved with much generosity and elecency. He afterwards passed over to Sicily, and a report being spread of the death of Conradin, he was unanimously elected king by the Sicilian and Apulian barons, was accordingly crowned at Palermo in 1258, and by a mild and very equitable administration, secured the affections of the people. His peace was in a short time disturbed by intelligence, that Conradin was not only alive, but claimed the crown as his birth right; to which Manfred replied, that he had conquered the kingdom from two popes, and what he had won by his valour he could not think of resigning, but would leave the kingdom to Conradin at his death. He founded a new city on the Adriatic, to which he gave the name of Manfredina, and peopled it with the inhabitants of Siponto, which he destroyed on account of its unhealthy situation. His troops gained a signal victory over the Guefts, in consequence of which the city of Florence acknowledged his sovereignty. In 1262, pope Urban IV. published a crusade against him, and in the following year conferred the kingdoms of Naples and Sicily upon Charles of Anjou, brother of the French king Lewis IX. Charles prepared to invade the country, and Manfred was as zealous in his dispositions to resist him; but he was at length betrayed by his barons, who secretly negociated with his rival; and in February 1266, Manfred, engaging with the French army near Benevento, after fighting with great valour, was defeated and slain. As an excommunicated perfon, his body was thrown into a ditch, and buried under a heap of stones. The pope afterwards ordered it to be taken up, and carried out of the territories of the church. Manfred, though blackened by his enemies, displayed the talents and virtues of a great sovereign; he was accomplished beyond any of his time, and if he were guilty of criminal ambition in gaining a crown, he wore it with honour. Mod. Univer. Hist.

MANFREDI, EUSTACHIO, an Italian mathematician and astronomer, son of a notary, was born in the year 1674. He enjoyed the benefits of an excellent education, and made so great progress in his studies, that at the age of eighteen, he obtained the degree of doctor of laws. He was, however, more attached to philosophy and the mathematics than to mere legal disquisitions, and applied himself most diligently to the sciences connected with or subfervient to the study of astronomy. In the midst of his learned labours he found time to write poetry, and the pieces which he produced at this period, were, after the author's death, collected and published in an 8vo. volume, which has been many times reprinted. In 1698, Manfredi was nominated professor of mathematics in the university of Bologna. All the time that he was not employed in the duties of his professorship, he devoted to the study of astronomy, and in company with Victor Stancari, he spent whole nights in contemplating the heavens, and observing the motions and passages of the stars and planets. An account was published of their observations made before the year 1703. In the same year Manfredi published a treatise "On the solar spots," and in the following season he was appointed by the senate of Bologna to the office of superintendent-general of the rivers and waters of the Bolognese. The duties of this office he conducted with a degree of skill and prudence, that proved highly beneficial to his country, and gave him a first rate reputation as a practical hydraulist. About the same time he was elected regent to the college of Monte-alto, founded by pope Sixtus V. at Bologna, for the education of young perfons of his province, who were intended for the church; in this situation, which was thought to be unworthy of his talents, he was enabled to do much for the establishment religion, by sending into its service many celebrated divines, and others who fulfilled a conspicuous rank in the republic of letters. In the midst of his various labours, Manfredi found leisure to continue his astronomical studies, and to attend to other mathematical subjefts; at the same time he corresponded with many of the most eminent persons of Europe, and began the composition of his famous "Ephemerides," which were afterwards published in several quarto volumes. In the year 1717, Manfredi was sent to Rome, on the subject of a dispute between the cities of Bologna and Ferrara, respecting the manner of conducting the inundations of the river Reno into the Po. On his return home, he refumed his astronomical labours, and in 1723 had the long wished-for opportunity of observing a transit of Mercury over the sun, of which he published an account in the following year, under the title of "Congregiss Mercurii de solis in Altronomia Specula Bononienis Scientiarum Inbitutum," Sec. In 1726 he was admitted an associate of...

MANGANADIA, a town of Hindoostan, in Cochin; 20 miles N.E. of Cochin.
MANGANESE, in Chemistry, an elementary oxydable body, and a metal. It may be obtained in a state of purity from any of its ores described in the next article. The native black oxyd, however, is the most convenient for affording this metallic substance. In order to obtain the oxyd free from the oxys of other metals, the black oxyd must be dissolved in muriatic acid. Sulphuric acid being gradually added, the lime and barytes, if it contain any, will be precipitated in the state of sulphates of those earths. The solution may contain oxys of iron and copper, besides that of manganese. Carbonat of potash being added will dissolve the manganese, but will precipitate the other oxys. The oxyd of manganese may be afterwards precipitated by pure potash.
The above solution of the different metals may also be treated as follows: The copper may be precipitated by a clean piece of iron, and the iron be afterwards separated by the succinat of potash. The oxyd of manganese may at the last be separated by pure potash. The oxyd of manganese, thus separated, is in a state of powder. Let this powder be made into a paste with oil, and put into a crucible lined with charcoal, and filled up with powdered charcoal, the whole being closely covered. The crucible is now to be exposed for an hour or two to the intense heat of a furnace, or a blast furnace, on the plan of Dr. Aikin's. At the bottom of the crucible will be found small metallic grains, which are the manganese in its metallic form. For this proceeds we are indebted to Ghana, who first succeeded in the reduction of this metal.
This metal, when pure, is of a greyish-white colour, of tolerable metallic luster. Its specific gravity is about 6.85. It is very brittle, and in hardness little inferior to iron. Hence it is not a malleable metal. It melts at 160° Wedgewood. It is not magnetic when perfectly free from iron.
It has no perceptible taste or smell; when exposed to the air it soon loses its metallic luster, and changes into the state of a brown powder, which ultimately becomes black. These changes are produced by its combination with oxygen, for which it possesses a stronger affinity at the common temperature than any of the metals, with the exception of the basis of the earth and alkalis. This property renders it of little or no use in the metallic state.
It combines with three doses of oxygen. The protoxyd, or first oxyd, is obtained by dissolving the black oxyd of manganese in nitric acid, adding, at the same time, some fusor or other inflammable matter, to take the excess of oxygen.
MANGANESE.

oxygen from the black oxyd. The solution, by this treatment, becomes a nitrat of manganese, with an oxyd at a minimum of oxydation. On pure potash being added, the protoxyd is precipitated of a white colour. It is composéd, according to Bergman, of 80 of manganese and 20 of oxygen in the 100.

This oxyd, exposéd to the air, soon changes to a brown, and ultimately becomes of a black colour, by combining with more oxygen.

The second, or deuteroxyd, is easily obtained by dissolv- ing black oxyd in fulbaric acid with heat. A portion of oxygen gas is separated, so as to constitute this oxyd. If to the solution pure potash be added, the oxyd is precipitated of a red colour. It is composted of 75 of manganese and 26 of oxygen, from the authority of Bergman. This oxyd, like the lait, attains more oxygen from the atmosphere, and becomes black.

The black, or peroxyd of manganese, may be obtained by exposéing the other oxyds to the air for some time. In a state of this purity it is found abundantly in nature, in which state it is used in bleaching linen and calico, to furnish oxygen to the muriatic acid.

When exposéed to a red heat it gives out one dofe of oxygen, and is converted into the second, or red oxyd. Hence its use in the chemical laboratory for furnishing oxygen gas.

It sometimes, however, contains carbonat of lime, in which case the gas obtained is liable to contain carbonic acid gas. This latter may be separated from the oxygen by passing the gas through lime water. The pure black oxyd is composted of 65 of manganese and 40 of oxygen.

The oxyds of manganese have not been examined by many chemists. We are indebted to Bergman for almost the whole of our knowledge of these compounds. If bodies combine in limited dozes, according to the hypothesis of Dalton, the relative proportions of oxygen will be found incorrect. Agreeably to the proportion of the red oxyd, which is 26 per cent. Dalton fixes the atom of manganese at 34, the oxygen being 7. Hence, for the protoxyd, we have 

$$\frac{40 + 7}{2} = \frac{100}{15}, \text{ or nearly } 15 \text{ per cent. of oxygen.}$$

For the second oxyd we have 

$$\frac{40 + 2}{2 \times 7} = \frac{26}{15}, \text{ or } 26 \text{ per cent. agreeably to the authority of Bergman.}$$

The black, or peroxyd, from the same data, will be 

$$\frac{40 + 3 \times 7}{3 \times 7} = \frac{100}{34}, \text{ or } 34\frac{1}{4} \text{ per cent.} \text{ Hence it would appear that the protoxyd and the peroxyd are a little over-rated.}$$

The black oxyd of manganese is used in the manufac- ture of flint glas, along with the oxyd of lead, to render the glas colours. The oxyd of manganese alone would give to the glas a purple colour, while the lead would render it of a yellow colour. In certain proportions, however, they produce no colour. May not this arise from the mixture of the three primitive colours constituting whiteneis, namely, the purple, or blue and red, of the manganese, with the yellow of the lead?

If this effect depended upon the oxygen of the manganese, to which it has by some been ascribed, the glas ought to be more coloured, from the oxyd of lead being more coloured in proportion to the oxygen it contains.

The black oxyd of manganese, when mixd with drying oil to form paint, cauæs spontaneous inflammation.

Manganese does not combine with hydrogen, nor, in all probability, with carbon.

The metal does not, according to Bergman, combine with sulphur. The same chemist, however, succeeded in combi- ning its oxyd with sulphur, forming a sulfuretted oxyd. It is of a green colour, and affords sulfuretted hydrogen by treating with acids. There is strong reason to believe that sulfurett of manganese may be formed, since a native sulfurett has been found.

Phosphorus combines with manganese, forming a crystalline, brittle, white substance, which is not decomposed at the common temperature. It is more fusible than manganese, but at this heat the phosphorus burns, and the manganese combines with the oxygen of the atmosphere.

Manganese combines with some of the malts, forming alloys.

Mr. Hatchett succeeded in alloying manganese with gold by the following process. The black oxyd was frequently heated with oil, till the oil inflamed. By this means the oxyd was partly reduced. This substance was introduced, with some gold, into a crucible lined with charcoal, and closely covered; a strong heat was applied. The gold by this means combined with some of the manganese, forming an alloy of a yellowish-grey colour. It was very hard, and susceptible of a good polish.

This alloy contained from 5th to 6th of manganese. The gold could be separated by cupellation.

Manganese does not combine with mercury; it combines with copper, forming an alloy of a red colour, which is malleable.

It combines with iron with great facility, and is often a component part of iron, made from iron ores containing manganese. It is said to be essential to the formation of flæ-el, and that no iron can be used for making feel but such as contains manganese. This, however, is very doubtful. The alloys of manganese with bismuth and antimony are difficult to form, and of no importance.

Salts of Manganese.—A though the oxyd of manganese combines with the acids like the rest of the metallic oxyds, the properties of most of these compounds have not been attended to by chemists.

 Sulphate of Manganese.—When dilute sulphuric acid is applied to this metal the water is decomposed, hydrogen gas is evolved, and the acid combines with oxyd, forming a sul- phate of manganese. The solution of this salt is colourless; it affords crystals by evaporation of a rhomboïdal form. It has a bitter disagreeable taste; when exposéd to strong heat the acid escapes.

This salt consists of the protoxyd united with the acid; and agreeably to the hypothesis of Dalton, the atom of acid being 34, and the oxyd 40 + 7; the composition of the salt ought to be 

$$\frac{40 + 7 + 34}{34} = \frac{100}{42}, \text{ which gives } 100;$$

42 of acid and 58 of white oxyd.

Oxy sulphate of Manganese.—This salt consists of the red oxyd of manganese combined with the acid.

It may be formed by distilling a mixture of sulphuric acid with the black oxyd. A quantity of oxygen gas comes over, and a liquid of a purple colour, which is water, containing the oxy sulphate. When evaporated it affords a gummy mafa, which gives some crystals with difficulty. When an alkali is added, the red oxyd is precipitated. This salt, from the above
above data, supposing it to be neutral, should be composed as follows, \( \frac{40 + 2 \times 7 + 34}{34} \), which gives 38.6 acid, and 34.

61.4 red oxyd. The way in which this salt is prepared, renders it probable that it is super-falt, a sub-falt being left in the retort.

The super-falt will be, therefore, \( \frac{40 + 2 \times 7 + 34}{34} \times 2 \) = \( \frac{100}{34} \), or 55.74 acid, and 44.26 of red oxyd. The sub-falt will be \( \frac{40 + 2 \times 7 + 34}{34} \times 2 \) = \( \frac{100}{24} \), or 44.7 acid, and 76 red oxyd. The fulphurous acid added to the black oxyd is converted into the sulphuric acid, and dissolves the remaining oxyd forming the fulphat.

Nitrate of Manganese.—When the metal is added to dilute nitric acid, fumes of nitrous gas, mixed with nitrogen, and, perhaps, the nitrous oxyd are diffusenged, arising from the decomposition of part of the acid, while the remaining acid dissolves the oxyd forming the falt in question. It may also be formed by adding the black oxyd to the acid, at the same time adding some sugar to take up the excess of oxygen, which the black oxyd contains above that of the white. Carbonic acid gas is, in consequence, evolved, and the white oxyd is dissolved.

The solution of this falt is colourless; it does not afford cryllals by evaporation. If the heat be continued to dryness the falt is decomposed, the acid being separated.

Its component parts, supposing it a super-falt, will be \( \frac{40 + 7 + 19 \times 2}{19 \times 2} \) = \( \frac{100}{44.7} \), or 44.7 acid, and 55.3 white oxyd.

Murate of Manganese.—The muriatic acid being added to the metal affords hydrogen from the decomposition of the water, while the oxyd is dissolved forming this falt. It consists of the acid combined with the white oxyd.

When the black oxyd is digested in muriatic acid, one part of the acid combines with the excess of oxygen in this oxyd, forming the oxynuratic acid, which escapes in the gaseous form: the remainder of the acid unites with the white oxyd. Of this falt there is little known; it is difficult of cryllallization, and is deliquescent.

When the muriatic acid is added to black oxyd in the cold, a red solution is formed, confining the red oxyd with the acid, and which is an oxynurat of manganese.

The muriat may, in all likelihood, confit of \( \frac{40 + 7 + 22}{22} \) = \( \frac{32}{32} \), or 32 and 67 base.

Phosphate of Manganese.—This falt may be formed by adding phosphate of soda to a soluble mangenathan falt. A white powder falls down, which is phosphate of manganese. It is, therefore, insoluble, or nearly so. Phlatas and borats of manganese may be formed by a similar process to the last; but these faltas have not been examined.

Carbonate of Manganese.—This falt is more soluble than most of the metallic carbonates. In precipitating metallic oxyds from their solutons where manganese is contained by the alkaline carbonates, the latter is held in solution by the carbonic acid. This affords a ready method of separating manganese from most other oxyds.

Oxalate of manganese combines with the oxyd of manganese, forming a falt in a state of insoluble white powder.

Tartarate of Manganese.—Tartaric acid added to the black oxyd of manganese, is partly decomposed by heat. The carbon of the acid combines with excess of oxygen in the oxyd. The remaining acid afterwards dissolves the reduced oxyd. On the citric acid it has a similar effect.

Scheele informs us, that the arfenic acid dissolves the white oxyd of manganese, forming a falt which affords crystals.

The succinic acid forms a soluble falt with the white oxyd. The succinat of potash, in consequence, has been employed to separate manganese from iron. The succinat of the falt being insoluble.

The reft of the falt of this metal are not known.

Manganese. The ores of this metal may be divided into the following species: 1. Grey manganese; 2. Black manganese; 3. Red manganese; 4. Sulphuret of manganese; and 5. Phosphat of manganese.

1. The grey manganese ore is subdivided into the radiated, saltated, compact, and crystal.

1. Radiated grey manganese; Strahliges graubraunblein-ertz. Wern.; Striated grey manganese ore, Kirw.; Manganë oxide métaïloide gris, Haüy.; Manganate métallique chalybien, Brongn.

Colour dark red-grey, palting into iron black; sometimes with variegated tarnish. It occurs massive, diffusenged, and cryllallized.

The primitive form of the cryllals is the four-sided rhomboidal prism, with edges of about 100° and 85°, according to Haüy; but of 115° and 655°, according to Hausmann's measurement. It is divisible in the direction of its six planes; and, according to Haüy, also in that of the short diagonal of the terminal planes; which latter is considered as erroneous by Hausmann; who, therefore, pronounces the form of the integral molecule to be the same as that of the primitive cryllal.

Its most remarkable seconde formes are:

A. The rectangular four-sided prism.

B. The oblique four-sided prizm (being the primitive form).

1. Summits truncated; plane of truncation straight.

2. Truncated obliquely at the summis; the plane of truncation either on one of the obtuse, or on one of the acute lateral edges of the prizm. The truncation is sometimes produced by two planes placed on two adjoining lateral planes.

3. Acuminate; the acuminating planes placed either on the obtuse lateral edges (edge of acumination 94° 7' 6''), or on the acute lateral edges (edge of acumination 118° 40' 36''). The planes of acumination sometimes again truncated.

4. D. Acuminated by four planes; the acuminating planes placed either on the lateral edges (with fummit sometimes truncated), or on the lateral planes. (Incline of the acuminating on the lateral planes = 118° 55' 6'.)

C. The fix-sided prizm. (Two opposite, primitive, lateral edges = 65°, the four others = 145° 30'.)

5. Summits truncated; plane of truncation straight or flat.

6. Acuminated by two planes placed on the seconde lateral planes; at the other solid angles more or less truncated.

D. The eight-sided prizm (with two lateral edges of 115°; two others of 124° 45' 46'; and four of 150° 7' 7'').

a. Summits truncated; plane of truncation straight or flat.

b. Obliquely
b. Obliquely truncated by two pentagonal planes.

c. Acuminated by four planes placed on the most obtuse lateral edges.

d. Acuminated by six planes, four of which are placed on the obtuse lateral edges, while the two others are placed either on the lateral edges of $124.45.46^\circ$, or on those of $115^\circ$.

e. Acuminated by eight planes placed on the lateral planes.

The crystals are generally aggregated and grown together in all directions; they sometimes form globular aggregations. Their size varies, but they are seldom found exceeding one inch in length, and the generality of them are very small. Upon the whole it may be said, that their thickness is at least four times exceeded by their length; while in the foliated manganese both dimensions generally approach more to equality. The greatest relative length we find in the six-sided prismatic crystals, which sometimes are of a lanceolate shape, the breadth of the two secondary planes often increasing to such a degree, that but little remains of the four primitive planes.

By the union of several prismatic crystals of equal length, a particular kind of prismatic aggregations is frequently produced, having fix, eight, or more lateral planes. They might be mistaken for simple crystals, from which, however, they are easily distinguishable: 1. By their lateral planes seldom forming sharp edges with one another, and being moreover always furnished with fringes, and even deep furrows; and 2. By their acuminate facets never exhibiting continued planes, but only transverse fissions intercepted by interstices left by the aggregated prisms, which are in close contact with each other.

The planes of the crystals are splendent, the primitive ones eminently so; the secondary planes are always longitudinally fringed. The surfaces of cleavage and fracture vary between shining and glinting; the lustre is metallic. Yields a dull iron black streak. It is opaque.

The texture of this ore is radiated, passing on one side into coarse fibrous, on the other into foliated. The amorphous, massive, and disseminated radiated grey manganese sometimes exhibits transverse fissures in the radius, in the direction of the terminal planes of the nucleus.

Fracture uneven, frequently displying small granular masses, approaching to wedge-shaped. Fragments wedge-shaped, and long (fringed); in the massive they are indeterminately angular and blunt-edged.

It is soft, brittle, and in large pieces pretty difficultly frangible. It foils strongly when rubbed.

Specific gravity 3.536-4.325, Muhlenbroeck; 4.143, Hagen; 4.2491-4.7564, Brillion; 4.181, Rinmann.

According to the analyses given of the radiated grey manganese ore, by Klaproth, 100 parts afford:

Klap. Beitr. ii.

This ore is found principally at Uhlfeld, on the Hartz; in Saxony, at Langeberg, Johengorgenladdt, Kamfördorf, Ilmenau, Salzfeld in Thuringia; in Sileia, at Konradwaldau, Kupferberg; &c.; in Bohemia, at Mies, Platten; in the Banat; in Carinthia, at Hüttengrenz; on mount St. Gothard; in Piemont and Istria, in the Vicentine territory; in various parts of Great Britain, in Cornwall, Devonshire, Somerfethire, Derbyshire; and also near Aberdeen, in Scotland. Jameson.

The radiated grey manganese ore of Uhlfeld occurs partially in veins, and partly as nodules, in clay-porphyry; it is accompanied with flesh-red barytes, usually crystallized in their hexagonal tables with flesh-red or white rhomboidal calcareous spar, compact and foliated black manganese, and with friable lithomarge of a rofe-red colour. Hauffmann in Mohr's Archiv. it b. p. 32.

2. Foliated grey manganese ores blattirige graubraunstein-ertz, Wern. (var. of Manganese oxide metafide oxii, Hauff.)

Its colour is the same as that of the preceding sub-species; it sometimes in a strong light appears iridescet.

It occurs massive, disseminated, and as covering of other ores. Also crystallized in four-sided, rectangular, and rhomboidal prisms, whose planes are nearly equal to each other; and in low four-sided prisms, with lateral planes either of the fame breadth, or with secondary planes encroaching on the primitive, and thus producing rectangular tables, sometimes bevilled at two opposite sides, sometimes rounded off; if rounded off in the whole of their circumference, the tabular passages into the lenticular form.

The crystals are generally globularly or botroidally aggregated, and often form the uppermost covering in druffy cavities formed of black iron-oxide, and lined by compact black, and amorphous foliated grey manganese ore.

The oblique four-sided prisms are sometimes so intimately united, as to display no more of their surface than a three-planed fold angle, formed by a terminating and two lateral planes. The crystals are always very small; the magnifying glass discovers their lateral planes to be striated; the terminating planes are smooth.

The lustre of the surface of the crystals and of the cleavage is metallic splendent; that of the crofs fracture lefs so.

The texture of this ore is imperfect, and mostly straight foliated, often delicately interlaced, and passing over into radiated.

Fracture uneven, sometimes exhibiting fine granular distinct concretions. Fragments indeterminately angular, blunt-edged.

It is soft, and brittle. It marks strongly when rubbed. Yields a black dull streak. Specific gravity 3.742, Hagen.

The grey radiated manganese ore is found in several places with the preceding sub-species, to which it is, indeed, very nearly related. It formerly occurred plentifully in the mine St. Joachim, at Zellerfeld, on the Hartz, as coating of the druffy cavities in black and brown iron-oxide, as also on quartz, &c. Hauffmann, loc. cit.

3. Compact grey manganese ores; Dichte graubraunstein-ertz, Wern.; Indurated grey ore of manganese, Kirw.

Its colour is blueish-black, passing into steel-grey; that of the streak iron-black; in a state of incipient decomposition it takes a dull-brown hue. In a strong light its surface is iridescet.

It is found massive, and in botroidal masses, formed by the union of many globular distinct concretions. They are sometimes confluent, when they form concentric, flat conchoidal distinct layers. The globules (at least in the variety from Hertzberg, described by Hauffmann) are divergently radiated towards the centre; but towards the circumference, the radiated passages through fibrous and granular into perfectly compact. The flat conchoidal layers approach to the columnar, and here and there to the facettarily diverging radiated structure, which again passes into compact.

Fracture even, very fine-grained, sometimes inclining to flat.
MANGANESE.

It is hard, brittle, easily frangible. It foils less than the preceding sub-species. Internally it is either matt, i.e. dull, or glintening with a metallic lustre; streak generally shining.

Specific gravity 4.125, Hauffmann.

According to an analysis of Mr. Hauffmann, it contains

Brownish black oxyd of manganese - - - 85
Silica - - - - 4
Oxygen - - - - 11

It is found in Saxony, at Johangeorgenflad, in the Palatinate, where it occurs with lithomarge; at the Wurzelberg, in the Hertzberg forest, on the Hartz, where it is used as flux for the reduction of a rich, but very refractory red hematite. Hauffmann, loc. cit.

In France it is found at Sauquet, near Thivoy, department of Dordogne, in the neighbourhood of Perigueux. This is known by the name of pierre de Perigues. Also at l'Avine, near Saint-Diez, department of the Vouges; at Macon; at St. Micaud, department of the Saone and Loire. Brongniart.

4. Earthy grey manganese ore; Erdezes grau-braunstein-erz, Wern; Ochre of manganese, Kirw.

It is found in Saxony, at Raffelau, Ilmenau, Ehrenloch, &c. in Bohemia, in Cornwall and Somersetshire. Brongniart refers to the earthy grey manganese of that of Saint Jean de Gandonenque in the Cevennes. It is very light and friable, and separates, like butali, into irregular prisms. It occurs in granite. Lenz, Wiedermann, and other authors, clafs with this sub-species, the black wood of Derbyshire and Devonshire, which is also known under the name of inflammable manganese, on account of the property it possesses of inflaming spontaneously, when mixed with one-fourth of its weight of linseed oil. It con_ilts, according to the analysis of Wielgewold, of 0.43 manganese, 0.13 iron, and 0.04 lead. Werner first made a distinct sub-species of it. According to other mineralogists, it is a variety of the black earthy manganese ore, (which see below.)

The frothy manganese (Braunstein-schaum of Wieden-
MANGANESE.

It is found massive, and in thin curved lamellar layers. It is dull; breaks shining or glimmering.

Fracture fine earthy; fragments indeterminately angular, blunt-edged. It is soft; foils strongly; feels meagre, and adheres to the tongue.

It has been found in St. Joachim mine, Zellerfeld (the massive), and at Illefeld, where it traverses clay-porphyrhy in all its directions. It is accompanied by foliated black manganese ore, which appears to pass into it by decomposition.

The friable variety is of a black and brownish-black colour.

It is found massive, in globular masses, in thin curved lamellar distinct concretions on black haematite, often also as thin coating on black haematite, and dendritic.

Internally it is dull; the surfaces of the lamellar distinct concretions sometimes glimmering; break shining.

Fracture fine earthy, fragments indeterminately angular, blunt-edged. It is perfectly friable; foils strongly, feels meagre, and adheres strongly to the tongue.

The variety from Huthal, or the Hartz, was analyzed by Klaproth with the following result:

<table>

It is found on the Hartz at the Iberg, at Zellerfeld, at the Galgenberg, near Chemnitz, and in the Huthal, on the Hartz, where, according, to Klaproth, it was found lying from the chinks of rocks as a foil, greyish substance, which, on being exposed to the air, was soon converted into a very fine black powder.

The friable earthy varieties, from the Hartz, are those of Grund, on a greyish-white marble-flake; and those of Leverkusen, on a green clay-flake.

Rents, who describes the friable black manganese ore, refers to it the end, mentioned above as a variety of the earthy grey manganese ore. It is, indeed, difficult to determine to which of the two the English black wed belongs, the different varieties of which require to be subjected to further examination.

Another substance nearly related to the wad is the friable manganese, a metallic, reddish-brown, filmy substance, incrusting black haematite, and referred by some mineralogists to iron froth, by others to the greyy manganese.

III. Red manganese ore; Rather braunstein, Werner; Mangané, filifère blanc et rouge, Häuy; Mangané, tilboide blanc et rouge, Brongni.

Its colour is rose red of various intensity; and sometimes a very light yellowish-brown.

It occurs massive and disseminated.

Internally it is dull.

Fracture even, passing into large and flat conchoidal, and also sometimes into fibrous fragments: indeterminately angular, pretty sharp-edged.

It is feebly translucent, hard enough to scratch glass; brittle, and easily fragilizable.

Specific gravity 3.233, Kirwan, that of the Siberian 3.676, Lampadius.

It is infusible before the blowpipe without addition, but assumes a brownish colour; if the flame be urged by oxygen gas, small particles will melt into a brownish-black bead, attractable by the magnet. The Siberian red manganese ore, analyzed by Lampadius, is stated by this chemist to be infusible by the heat of the blowpipe, when continued for a few minutes, into a shining black enamel; and much more easily with borax.

According to the analysis given by Ruprecht, that from Transylvania consists of

<table>

The analysis of red manganese from Kapnik by Lampadius, appears to be that of a red variety of pearl-spars; or perhaps of real carbons of manganese. The same chemist has, however, given an analysis of the red manganese of Siberia, which certainly belongs to the substance under consideration, although Mr. Lampadius himself appears to be of a different opinion. The results of his analysis are

The red manganese ore of Kapnik, which is placed by Mohs, near pearl-spars, under the name of Rothlif, is found there as part of a vein formation, together with black silver ore, (Schwartz-gilg-eertz,) brown and yellow blende, galena, quartz, and now and then with some pearl-spars. The veins containing this formation are mostly narrow, and often of a stratified structure, in such a manner that either massive quartz, or a mixture of quartz and red manganese, (Rothlif,) alternate with laths of black silver ore, and blende, or galena, from the sides towards the centre of the vein, where the lenses are generally incrusted with crystallized quartz, or also with pearl-spars. This, according to Mohs, is the general nature of those veins, which however, also contain other fossils before.

IV. Sulphur of manganese; Braunstein blende; Manganesite, Karth.; Schwartz, Klaur. Rents.

Its colour is between iron and pitch-black, here and there with a ruff-coloured covering, often with variegated tarnish. Colour of the powder dark brass-yellow passing into greenish.

It is found massive, or coarse-differed in red manganese ore, which it also traverses in foliated layers.

Texture in one direction imperfectly foliated; direction of the laths approaching to curved foliated. According to Häuy it is divisible into a rhomboidal pulp, which may be subdivided in the direction of the diagonals of its transversal section.

It is opaque; its lustre is semi-metallic shining; the ruff-coloured decomposing parts dull; streak shining.

Fracture fine-grained uneven; fragments indeterminately angular, not particularly sharp-edged.

It is soft, mild, and not difficultly fragilizable. Specific gravity 3.950. Klaur.

Infusible before the blowpipe. When pulverized it gives out sulphured hydrogen as the addition of nitrous acid.
According to Klaproth's analysis, it consists of

Oxid of manganese  -   -   -  82
Carbonic acid  -   -   -  5
Sulphur  -   -   -  11

98

Klap. Beitr. 3.

Vauquelin is of opinion, that the carbonic acid in the preceding analysis belongs to the matrix of this ore. According to this chemist the constituents are: manganese at the minimum of oxidation 85, and sulphur 15.

It is found in Transylvania, in red manganese ore accompanied with black tellurium, red and brown blende (fulphuaret of zinc), copper pyrites, &c.

According to Delrio it has also been lately found in Mexico.

V. Phosphat of manganese; Phosphor-mangan, Karlt.; Eifen-teeh irtes, Wern.; Manganæ phosphi (ferrifere), Haüy.

Its colour is reddish and blackish-brown, which passes into black; colour of the streak greyish, yellowish, or reddish-brown.

It occurs massive. According to Haüy it is divisible in the direction of planes, which appear to indicate a rectangular parallelopipedon for the nucleus. Internally it is shining and glossy, with a reflexious luster.

Fracture flat and imperfectly conchoidal, passing into fine-grained uneven; fragments indeterminately angular.

It is faintly translucent at the edges.

It is hard, passing into soft; brittle.

Specific gravity 3.05.

It is readily fusible before the blowpipe into a black enamel; and is entirely fusible in nitric acid without efference.

It is seldom found pure, generally containing iron, which, however, according to Darcey, appears to be accidental; the phosphoric acid being probably combined with the manganese alone.

The light coloured varieties contain but a small quantity of iron.

Vauquelin, who analyzed this ore, obtained the following result:

Oxid of manganese  -   -   -  42
Oxid of iron  -   -   -  31
Phosphoric acid  -   -   -  27

Journ. des Mines.

It has hitherto been found only near Limoges in France; it occurs in granite, in the same veins that contain the well known opaque beryl.

MANGANUM, Mzijzizito, among the Greeks, a general name for instruments to throw large stones with.

MANGATTI, in Geography, a town of Hindoostan, in Travancore; 18 miles N.E. of Anjengo.

MANGAVEIRAS, a town of Brazil, in the government of Para, 35 miles N.E. of Engenhoreal.

MANGABOONG, a town on the N.W. coast of Borneo. N. lat. 6° 3', E. long. 116° 9'.

MANGEART, Thoma, in Biography, a learned monk, who obtained a very high reputation by his knowledge, and was appointed antiquary, librarian, and counsellor to duke Charles of Lorraine. He died in 1763, and is known in the republic of letters for a work entitled

"Introduction à la Science des Medailles," fol. This work contains all the principles laid down in the elementary treatises on the numismatic science, and serves as a supplement to the "Antiquité expliquée" of Montfaucon.

MANGEE, in Geography, a town of Hindoostan, in Bahar; 13 miles W.N.W. of Chupra.

MANGEEA, or MANGYA, an island in the South Pacific ocean, discovered by captain Cook in the year 1777; but on which he could find neither a landing place nor anchorage. Such parts as fell under our navigator's observation were guarded by a reef of coral rock, on the outside of which the sea is of an unfathomable depth. It is full five leagues in circuit, and of a moderate and pretty equal height; though, in clear weather, it may be seen at the distance of ten leagues. In the middle it rises into little hills, from which there is a gentle descent to the shore, which, at the S.W. part, is steep, though not above 10 or 12 feet high, and has several excavations made by the beating of the waves against a brownish sand-flone of which it is composed. The descent is covered with trees of a deep green colour, very thick, but not high, seeming to be of the same sort, except near the shore, where are many of that species of dracaena found in the woods of New Zealand. On the N.W. part the shore terminates in a sandy beach, beyond which the land is broken down into small chafins or gullies, and has a broad border of trees resembling tall willows. Farther on the western the trees were of the same deep green above-mentioned; and were fupputed by some to be the rems, intermixed with low cocoa-palms, and a few of some other sorts. On the little hills were trees of a taller sort, thinly scattered; but the other parts were bare, and of a reddish colour, or covered with something like fern. Upon the whole Cook observes, that the island has a pretty aspect, and might be made a beautiful spot by cultivation. When this island was first discovered, several of the natives were observed to be armed with long spears and clubs, which they brandished in the air either with signs of threatening, or, as some thought, with invitations to land. Most of them appeared naked, except having a fort of girdle, which paling between the thighs covered that part of the body. Some of them, however, had pieces of cloth of different colours, which they wore as a garment, thrown over their shoulders; and almost all of them had a white wrapper about their heads, which was under a turban, or like a high conical cap. Their colour was tawny, and they were in general of a middling stature, but robust and inclining to corpulence. They were at first afraid of approaching the ship in their canoe; but being addressed by Omai in the Otaheitean language, their apprehensions subsided, and they came near enough to take some beads and nails, which were thrown into their canoe. They were at first afraid of touching these things, which probably arose from superstitition; for Omai understood, that when presents were offered them, they asked something for their "Eatoos," or god. When they were asked, if they ever ate human flesh; they answered in the negative, with a mixture of indignation and abhorrence. They wore a kind of sandals, made of a gruffy substance interwoven, probably to defend their feet against the rough coral rock on the shore. Their boards were long; and the inside of their arms, from the shoulder to the elbow, and some other parts, were punctured or tattooed, like the inhabitants of almost all the other islands in the South sea. The lobes of their ears were pierced, or slit, to such a length, that one of them stuck there a knife and some beads which had been given him; and the same person had two polished pearl-beads and a bunch of human hair, loosely twisted, hanging about his neck,
MANGELE WURZEL, in Agriculture, a plant of the tap-rooted kind, which has been lately introduced into field culture. It is a variety of the common beet. The author of a late work on husbandry remarks, that it grows to a large size, both in the root and top, the former being of a reddish call, and the leaves in the latter of an oblong form, extremely thick, fibrous, and succulent. Mr. Young, however, observes, that it is but little in cultivation at present; though in Norfolk, Sir Marden Martind finds the root advantageous for his cow food. The leaves are asserted to be "equal in quality to spinach, and from their frequently extending in length more than thirty inches, and in breadth above twenty, to greatly exceed that vegetable in point of produce."

Soil.—This, like all other tap-rooted plants that have been employed for the purposes of husbandry, thrives the best in soils of the deep, friable, sandy, or light loamy descriptions.

Preparation.—In preparing the ground for its reception, it is necessary to render it as deep and fine as possible in the mould. This may be best effected in the heavier sorts of land, by means of trench ploughing, in the manner of that for parnips; and in those of the lighter kind, by repeated common deep ploughings. In both cases, the frequent use of the harrows will be requisite. A proportion of good manure should also be turned in, so as to render the ground sufficiently rich for the perfect growth of the plants. After this, at the time of putting in the seed, the land should be thrown into two-bout ridges, which leaves the tops about two feet in breadth, and the furrows one. In this way a considerable increase in the depth of mould is provided for the roots of the plants. And in soils that are in some measure retentive of moisture, the lands are kept much drier, and in a flate more fit for the growth of the plants.

Seed and Method of sowing.—It is advised, that the seed should be carefully selected from such plants as are the most perfect of their kind, and that have been cultivated at a distance from other varieties. It should have arrived at a full state of ripeness, and be made use of while fresh. The most proper season for putting the seed into the ground in the common method of sowing, is in the early part of the spring as soon as the season will admit, as in the beginning or middle of April; but where the transplanting method is intended, it should be sown much earlier and very thinly, as the beginning of March, in order that the plants may be in a flate to be let out.

The most common method, where the surface of the land is flat, is to sow the seed thinly over the ground, in the manner that is practised for carrots, covering the seed in by means of very light harrowing. In this way, the plants are afterwards let out by the hoe to proper distances. But where the land is raised into ridges in the manner just described, another mode is practised: the seed is dropped singly by the hand into little holes made by a dibble, to the depth of about half an inch, all along the middle of them, at the distance of eight or nine inches from each other; the plants thus standing at the distance of three, feet, from row to row, and eight or nine inches apart in them. But as it is not necessary that they should stand nearer than 16 or 18 inches, every other plant may be removed, and used for filling up vacancies, where they occur, or if not wanted in that way, wholly removed by the hoe. In this mode the intervals can be kept perfectly clean by the plough or horse-hoe, and the rows by hand-hoeing.

In the practice of transplanting, the plants should be removed, when not more than three or four inches in length, and be planted out in rows upon ridges prepared as above at the distance of 18 inches each way. In performing the work, the holes should be made sufficiently deep to admit the roots without their being bent. The tops of the plants may be taken off before planting, but the roots should not be touched, nor should they be put in too deep. A rather moist soil should be chosen, if possible, for this business. But though the plants grow well in this method, the roots seldom become so large as when they have remained in their original situation.

All the culture that is afterwards necessary in this sort of crop, is to let out the plants to proper distances, where put in, in the first methods, and keep them clear from weeds by one or more hordinings, according to the manner of sowing that may have been practised, and other circumstances.

It has been stated that the application of this vegetable "has been chiefly in the feeding of neat cattle and hogs; in which both the tops and roots have been employed, but without that success which might have been expected from the manner in which it was brought to the notice of cultivators." It is probable, that upon the whole, the root has neither been found to be equal in quality as a cattle food, or to afford the quantity of produce that was supposed upon its first introduction, but from its being of a hardy nature, and not liable to be injured, either by insects or the effects of drought, as well as from its leaves being capable of being repeatedly cut over, it may be occasionally cultivated in situations where green food is much wanted in the latter end of the year, for milch cows or other sorts of live stock.

In some trials detailed in the Annals of Agriculture, the plants seem, however, to have afforded a large produce in leaves, when gathered every two or three days, from July till late in September; others have not found the whole produce, in leaves and roots, equal to that of the large cabbage, on the same kinds of soil, while the culture was considerably more troublesome and expensive, and the crop not so useful for the purpose of winter consumption.
In the trials of an ingenious cultivator, as related in the Bath Papers, the tops were found to be eaten with much greediness by cows, calves, and hogs, when cut green, during the latter part of the summer and in autumn, but the roots were almost wholly rejected at these periods, though in winter, after they had been taken up, they were eaten very willingly.

The great objections to this vegetable, as a field plant, are, according to a late writer, "the great expense of its culture, its being liable to degenerate, and the fibrous nature of the roots rendering their preparation as cattle food troublesome."

The roots frequently rise, it is said, to the weight of from five to eight or ten pounds, according to the goodness of the land; and they may be preserved in the winter, by being taken up and packed in the manner of carrots, or any other method.

MANGEN, in Geography, a town of the duchy of Courland; 16 miles S. W. of Pilkyn.

MANGER, in Ship building, a place parted off immediately within the hawse-holes. It prevents whatever water that comes in at the hawse-holes from running off, and is returned back again by the leakers in the mangre.

Manger, in Rural Economy, an internal part of the flable in which the corn or cut provender of the horse is put. It is a fort of box or crib, and the usual method is to have them the whole breadth of the stall; but this is unnecessary, as when eighteen or twenty inches in length, and fourteen or sixteen in breadth, they will be sufficient for every useful purpose. In the fixing of them they should be so contrived as to admit of being removed for the purpose of being cleaned. This can, however, never be done in the old method of fixing them; but, by a little contrivance, may be easily effected. It is, in many cafes, a convenient plan to have them in the corners or angles at the heads of the stalls. See STABLE and STALL.

MANGERA, in Geography, an island of Mexico, about four miles in circumference, in the gulf of Amapalla.

Mangerist, a channel of the East Indian sea, between the islands of Cumbaya and Flores, full of frail islands. Flores is also called Mangerey.

MANGEBARY, a town of Hindoostan, in Vifapour; 15 miles S. of Morrith.

MANGERON, a mountain of Ireland, in the county of Kerry, S. of the lake of Killarney, and forming a very interesting object in the scenery of that beautiful and romantic spot. It is one of the highest mountains in Ireland, being 2500 feet above the lake. From its summit, the two lakes, with the passage between them, and a large tract of country, may be seen to great advantage. To ascend Mangerton should therefore be a fixed object of every person who visits Killarney.

MANGET, John James, in Biography, a laborious medical writer, was born at Geneva in June, 1652. After going through his classical studies and the courses of philosophy, he commenced the study of theology, with the intention of entering the clerical profession, but after five years of labour, his inclination to medical pursuits prevailed, and by the aid of books alone, without any teacher, he made such a progress, that he was admitted to the degree of M.D. at Valence, in Dauphiny, in 1678. He then commenced the practice of physic, in which he obtained considerable reputation in his native city, which he refused to quit, though solicited by invitations from various quarters. In 1669, Frederick III. elector of Brandenburg, and afterwards the first King of Prussia, honoured him with the appointment of his first phyician. In his literary labours, Manget was indefatigable, even to the end of his long life. He maintained a correspondence with many of the learned men of his time, some of whom, especially Daniel le Clerc, the author of the History of Medicine, are said to have affidated him in his works. He died at Geneva in August, 1745, in the middle of his 71st year.

Among the numerous works of compilation, which Manget executed, originality is not to be expected; nor are they remarkable for judgment and accuracy. They are, however, still useful for reference. They are as follows: 1. "Medull Medico-spagyrica, &c." folio, Geneva, 1683; which contains a most abundant collection of pharmaceutical preparations, arranged in a very complex order. 2. In the same year he edited, "Paul Barbeite Opera omnia Medica & Chirurgica," with additional cafes and illustrations. 3. "Bibliotheca Anatomica," 1685; two vols. folio; a work which was executed in conjunction with Daniel le Clerc. He afterwards edited; 4. The "Compendium Medicinæ Practicæ," of J. And. Schmitz. 5. The "Pharmacopæa Schrodero-Hoffmanniana." 6. The "Tractatus de Febrisibus" of Franc. Pieu; and 7. "The Sepulchre of Democritus," in which he added several remarks and histories. 8. In 1697, he published his "Bibliotheca Medico-Practica," four vols. folio; 3 a vast collection of practical matter relative to all the diseases of the human body, arranged in alphabetical order. Other compilations of a similar kind he afterwards published relative to surgery, chemistry, and pharmacy: viz. 9. "Bibliotheca Chirurica, curiosa," two vols. folio, 1702; 10. "Bibliotheca Pharmaceutico-Medica," two vols. folio, 1703; and 11. "Bibliotheca Chirurgica," four vols. in two, folio, 1721. But in the mean time, he had printed his (12.) "Theatrum Anatomicum," cum Eucladii Tabulis Anatomicis," two vols. folio, 1716. This is a description of all the parts of the body, abridged from various authors; the oölology is that of Bidloo; the myology that of Brown; and the splanchnology that of Ray; and his flections are not to be praised. It has been justly objected to him, that he omitted to notice the differences of the anatomists of the sixteenth century. There is scarcely anything of his own in this work, except some morbid dillections. On the appearance of the plague at Marseille, he published a collection of facts and opinions on that diseafe, under the title of "Traité de la Peste recueilli des meilleurs Auteurs," two vols. 12mo. 1721; and, in the following year, 14. "Nouvelles Réflexions sur l'Origine, la Cause, la Propagation, les Préventions, et la Cure de la Peste," 12mo. 15. His "Observations sur la Maladie qui a commencé depuis quelques années à attaquer le gros Bestial," was a collection of the opinions of the Genevele physicians concerning the differential of horned cattle. The last work of Manget was his "Bibliotheca Scriptorum Medicorum veterum et recentiorum," at which he laboured when at least eighty years of age, and published it in two vols. folio, in 1737. It is the most important of his productions, being an afful collection of medical lives, and catalogues of writings. Esky Dict. Hist. Gen. Biog.

MANGEY, Thomas, a learned English divine, was educated at St. John's college, Cambridge, where, in due time, he took his degree of D.D. He was distinguished in the church as prebendary of Durham, and published an edition of "Philo Judæus," in 2 vols. folio: "An Answes to Toland's Nauuces;" and a volume of "Sermons on the Lord's Prayer." He died in the year 1755.

MANGIFERA, in Botany, is that celebrated fruit of the East Indies called Mango, whose different varieties are universally known and cultivated in that country, being as much esteemed, and nearly as various in quality, as the different

1. M. indica, Mango, Tree. Linn. Sp. Pl. 290. Jacq. Le Cap, v. 2. t. 357. Andr. Bot. Repot. t. 425. (Mangiféria indica; Rumph. Amb. v. 1. 63; t. 25).—Leaves divided, lanceolate-oblong. Four of the flaves abortive. Native of the East Indies. With us it is kept in the stove, where it blossoms in spring and autumn, though rarely. In India it forms a tall and spreading tree, not unlike an oak in its manner of growth, with thick and wide-extended branches, but the wood is far more brittle and leas hard and firm. Leaves scattered, flaked, simple, about a span long, and an inch or two wide, wavy, entire, tapering at each end, viscid, smooth and shining. Panicles terminal, compound, spreading, downy, of innumerable small white flowers, most of which are abortive. Fruit the size of a large plum, of an orange or tawny colour with a tinge of red; its pulp extremely juicy, with a rich sweet perfumed flavour, accompanied by a grateful acidity. Rumphius says it is the finest Indian fruit except the Mangobis (see Garcinia). In an unripe state it makes an excellent pickle, often brought to Europe.

3. M. axillaris, Axillary-flowered Mango. L. marck Dict. v. 3. 637. Willd. n. 3.—Leaves ovato-oblong, bluntish. Panicles axillary. Stamens ten. Found by Sonnerat in the East Indies. Lamarck, who received it from that intelligent traveller, describes this species as clearly distinguishable from the former by the above characters. The leaves are four or five inches long, and near two in breadth. Fruit the size of a small cherry, but that author saw it only in a dry, and possibly unripe state.

Another species is described in the Supplementum of Linnaeus, p. 156, by the name of M. pinaxa, but this is now referred by Willkomm to Spandalis, and, as it seems, justly. See Spandalis. Mangifera, in Gardening, comprehends a plant of the tree exotic kind for the low, of which the species cultivated is the Man, or tree (M indica).

There are several varieties, none of which are cultivated.

Method of Culture.—As the vegetative property of the feed or nuts of this species of tree does not seem to be long preferred, the readiest method to obtain plants, is to have a quantity of the nuts set in tubs of earth in the country where they grew naturally, and when the plants are grown a foot high, to have them shipped, placing a covering over them to defend them from the water and spray of the sea, being careful not to give them too much water in the paffage. When they arrive in a cold climate, they should be sheltered from cold. The plants should afterwards be set in pots filled with light kitchen-garden earth, and be placed in a dry stove, where, in warm weather, they should have fresh air daily, and in winter the air be kept up to temperate, as marked on the botanical thermometer; as they do not succeed well in the tan-bed of the stove.

And where the nuts are made use of, they should be set over in wax to preserve their vegetative property.

They are also capable of being increased from cuttings, in the manner of gardenia, in this climate.

Mangischlak, in Geography, a town on the E. coast of the Capfian fea, which is a place of considerable trade between the Tartars and Russians of Altranich; 150 miles S.E. of Altranich. N. lat. 44° 10'. E. long. 52° 14'.

Mangit, a town of European Turkey, in Dillerab; 22 miles N.N.E. of Tobak.

Mangrels, or Corn Island. —Mango, in the Spanish Main, about 15 miles long, five broad; near which is another small island called Little Mangareis. N. lat. 11° 44'. W. long. 82° 20'.

Mangle. See Laurina.

Mangles, or Mangket, in Bunting. See Rhizophora.

Mangillia, Juni 151. A Peruvian shrub, with the habit of a Chêne-palmier, but with small axillary pinnate-douws flowers, to which Dombey gave the name of Daba-mlia. It is called a Caballeria in the Flora Peruiana. See Myrcina, to which genus this plant is referred by Mr. R. Brown.

Mangcor, in Geography, a town of Norway, in the province of Aggerhus; 15 miles S. of Königswinger.

Mango, a town of Africa, in the kingdom of Agonia; which see. Also, a river of Sweden, which runs into the Wenner lake; 10 miles W. of Carinad, in the province of Waremidi.

Mango-Tree, in Botany. See Mangifera.

There are various sorts of this fruit, as there are of our apples and pears, which are very different, according to the countries where they grow: that species, which is without a stone, and is very grateful to the palate, seems to us only a variety or a degenerated fruit; the fruit is cut into slices, and eaten either without wine, or macerated in wine. It is also candied, in order to its preservation; sometimes they open it with a knife, and fill up the middle with fresh ginger, galick, mustard, and salt, with oil or vinegar, that they may eat it with rice, or after the manner of pickled olives.

As to its temperament, this fruit is cold and moist, though the Indian physicians affirm the contrary. We make use of pickled mangoes which are imported to us, as we do of pickled cucumbers. Thestones roasted are said to cure a lozenge, which Garcias found to be true. The wood of the tree, with cinders, is used for burning the carcasses of the Pagans, as being confectioned to this rite; whence it serves also for collars, in which they deposit their dead; it is, however, of a soft fulness, and of a short duration; it dafs supply the place of areas, or cayuga, in the chewing of betel; the same, calcined and reduced to powder, take away aches. Of the tender leaves, with the bark
of the avocado, that is, the ricinus, the seed of cummin and paraphegam, is made a decoction, which is said to be highly beneficial in the cough, asthma, and other affections of the throat. The bark of the tree pulverized, and taken in chicken broth, is an excellent diuretive of extravaatated and coagulated blood, occasioned by a fall, in any part of the body. The juice of the bark, with the white of an egg, and a very little opium, taken inwardly, is a pleasant remedy against the diarrhea, dysentery, and rheumatism. Of the gum of the tree, and the flowers of rice, with the addition of a small quantity of opium and pepper, are prepared pills, which also cure all sorts of fluxes of the belly. Of the flour of the dried kernels the natives have the art of preparing various kinds of food. James.

Mango, in Ornithology, a species of Troadillus; which see.

Mangon, in Military Language, formed from a Greek word of the same import, in the time of the elder empire, was used in general to denote all kinds of machines; and Mangonel was a diminution, applied to the smaller machines.

Mangonegro, in Geography, a market and port or town of Spain, in the kingdom of Seville, three leagues from Cordova.

Mangove, one of the smaller Friendly islands.

S. lat. 19° 52'. E. long. 185° 30'.

Mango puny, a town of Hindooftan, in Mynwar; 38 miles E. of Chettore.

Mangor, a town of Africa, in the ki gdom of Kayor.

Mangostana, in Farnoon. See Gardner.

Mangousté, in Zoology. See Vivera and Ichneumon.

Mangaba, in Geography, a town of Hindooftan; in Bahar; 55 miles N. of Haypour.

Mangrolla, a town of Hindooftan, in Guzerat; 55 miles N.E. of Surat.

Mangrove, in Botany. See Rhizophora.

Mangrove Grape. See Coccoloba.

Mangrove Island, in Geography, a small island among the Bahamas. N. lat. 26° 12'. W. long. 78° 45'.

Mangrove River, a river of New Zealand, so called by Lieutenant Cook in 1769, on account of the number of mangrove trees about it, which runs into Mercury bay. The fale and best way of failing into this river is to keep the south shore all the way on the bank. The country on the E. side of the river and bay is very barren, its produce being only fern, and a few other plants that will grow in a poor soil. The land on the N.W. side is covered with wood, and the soil, being much more fertile, with doubtless, produce all the necessaries of life with proper cultivation. The inhabitants have no plantations; their canoes are mean, and without ornament; they sleep in the open air, and say, that Taratnu, whose sovereignty they do not acknowledge, if he was to come among them, would kill them. Hence it was inferred, that they were outlaws; though they said that they had heppahs, or strong holds, to which they retired in time of danger. Hawke'sworth's Voy. vol. ii.

Mangeshape, a town of Silefnas, in the principality of Breeg; 8 miles N.E. of Breeg.

Mangul, a town of Hindooftan, in Coimbetore; 25 miles S.S.E. of Coimbetore.

Mangut, a town of Hindooftan, in Baramaul; 28 miles S.S.E. of Darsenpoor.

Mangutkoii, a town of Ruffia, in the government of Irkuttk, on the borders of China; 88 miles W. of Doro-

Mangheim, a city of Germany, now belonging to the electorate of Baden, is situated on a low plain, near the con-

opera executed at Mannheim in winter were represented in one of the largest and most splendid theatres in Europe, capable of containing 5000 persons. His electoral highness's suite at Schwetzingen, during summer, amounted to 1500 persons, who were all lodged in this little village at his expense. To a stranger walking through the streets of Schwetzingen at this time it must seem to be inhabited only by a colony of musicians, who are constantly exercising their profession; at one house, a fine player on the violin is heard; at another, a German flute; here an excellent hautbois; there a balzoon, a clarinet, a violoncello, or a concert of several instruments together. Music seems to be the chief and most constant of his electoral highness's amusements; and the operas and concerts, to which all his subjects have admission, form the judgment, and establish a taste for music, throughout the electorate.

MANHEIM, in Geography, a town of America, in Pennsylvania, in the county of Lancaster, containing 60 houses, and 1041 inhabitants, and a Dutch church; 11 miles N. by W. of Lancaster.—Also, a town in York county, Pennsylvania, having 1876 inhabitants.

MANI, in Geography. See MANICHEANS.

MANI, in Geography, a town of Africa, in Benguela, on the coast of the Atlantic; 16 miles S.S.E. of Old Benguela.

MANIA, in Medicine. See Mental Derangement.

MANIACI, in Geography, a town of Sicily, in the valley of Demona; 7 miles S.W. of Randazzo.

MANIANA, a country of Africa, situated S.E. of Barbary; the inhabitants of which are said to be cannibals. N. lat. between 13° and 14°. W. long. 1°.

MANIARY, a town of Hindoostan, in Bahar; 22 miles N.E. of Maiyef.

MANIAWICK, a town of Hindoostan, in the Carnatic; 30 miles S.E. of Tanjore.

MANIAYLY, a town of Hindoostan, in Oude; 40 miles S.E. of Goorapour. N. lat. 26° 17'. E. long. 84° 13'.

MANICA, a town of Africa, the capital of Chicanga, situated on the river Sofala, S. lat. 20° 20'. E. long. 28'. —Also, a river which rises in Chicanga, and runs into the Indian sea, S. lat. 25° 30'. E. long. 29° 30'; called also "Rio del Lagos," and "Rio del Spiritu Santo."

MANICA, properly a sleeve. See HIPPOCRATES's sleeve.

Hildanus calls by this name a particular sort of purpore, open at both ends, which he describes in his Treatise "De Gangraenae et Sphacelo," and gives a figure thereof. This he directs to be put about a limb, just before the place of amputation, before the operation is performed.

MANICARIA, in Botany, so named by Gartner, from manica, a sleeve, in allusion to the shape of the flower, which is like a pouch or bag; whence the older botanists called the plant in question Palma factice, and Sachtel Date. Gartner, v. 2. 468. t. 176. Willd., v. 4. 493. Lamarck Illust., t. 774.—Clas and order, Monocia Polysandra. Nat. Ord. Palme, Linn. Juff.

Gen. Ch. Cal. Common Sheath pouche-like, pointed at the base, interwoven with inumerable fibres, not burting, widely extensible, permanent. Stalk bearing male and female flowers, enclosed within the sheath, wand-like, with numerous, simple, straight, comprised, crowded, notched, toothed, downy, ruffly branches. —Male flowers very numerous, (above two thousand,) covering the branches of the flake. Cal. Perianth of one leaf, short, angular, torn, membranous. Cor. obovate, triangular, of three equal concave petals. Stam. Filaments twenty-four, capillary,分歧; authors oblong, furrowed. —Female flowers few, scarcely more than twenty, sese on the lower part of the branches of the flake. Cal. Perianth inferior, of one leaf, membranous, thin, obliquely parted, crenate and jagged. Cor. ovate, pointed, triangular, of three concave petals, four times as large as those of the male. Pit. German superior, turbinate, triangular, of three cells, yellow, short, thick, conical; stigma simple. Peric. Drupe globose, acutely tuberculated, dry, of three cells. Seed. Nuts solitary, very hard, roundish, smooth.

1. M. factice. Sachal Palm. (Palma factice ; Clf. Exot. 4. Bauh. Hift. v. i. 385. Ger. em. 1554.) —Native of South America. Clusius says it was found by some Dutch sailors on a desert island in the Atlantic ocean; Gartner, that it grows in Curacao and Dutch Guiana. Wildenow seems wrong in considering it a native of the East Indies. Of the tree itself, or its foliage, nothing is known. The fruit is occasionally seen in the museums of the curious, and resembles a sort of netted fibrous bag, from two to four feet long, containing numerous, globular, three-celled fruits, the size of a large cherry, or small walnut, whose outside is strongly macerated with sharp, prominent, unequal tubercles. Gartner had not seen the fruit in an advanced state, or he would not have supposed that it could be the same as his Cecroia lapidea. t. 6. f. 1. —We do not find the nuts to be very hard as Clusius describes them, and therefore conclude our specimen to be but about half ripe. The coat of the drupa is of a corky subflance, but densly fibrous, and is divided internally into three cells, each containing one nut, whose shell is smooth and brittle. One of the cells is occasionally abortive. Of the kernel we can determine nothing, it being but half formed.

MANICHEES, or MANICHAEANS, in Ecclesiastical History, a sect of ancient heretics, who afforded two principles; the one of their author Manes, Mani, or Manichaeus, a Persian by nation, and educated among the Magi, being himself one of that number before he embraced Christianity. See MAGI.

This herey had its first rise about the year 277, and spread itself principally in Arabia, Egypt, and Africa. Dr. Lardner, after having examined many authorities, with regard to the rise of Manicheism, both in Peria and the Roman empire, concludes with expressing his doubt whether it was known in the Roman empire before the very end of the third century, or the beginning of the fourth. St. Epiphanius, who treats of it at large, observes, that the true name of this herefarch was Cubricus; and that he changed it for Manes; which, in the Persian or Babylonish language, signifies wolf. A rich widow, whose servant he had been, dying without issue, left him flore of wealth; after which he assumed the title of the apostle or envoy of Jesus Christ.

We shall here subjoin some additional circumstances relating to this herefarch. Mani, always to be called by the Persians and Arabians, and usually denominated Manes, or Manichees, by the Greeks and Romans, was a Persian, or at least lived in the territories of the king of Persia. This is allowed by all those authors who speak of him. Cave and Tolius derive his name from the Greek noun μανίς, significaing madness, intimating that his name was the same as μανής, i.e. mad or furious; whereas the name is certainly Peric or Chaldæe. Cyril of Jerusalem says, that he changed his name from Cubricus to Manes, thinking by so doing to gain honour among the Persians, but
Manichees.

Mani (frequently spelt Manes, Manie, Mani, or Jovvn) was a common name of the princes of Seria and Arabia. The Greek writers continually represent Mani as a slave, purchased by a widow, and afterwards set at liberty. This widow, it is said, adopted him for her son, gave him a good education, and at length made him her heir. It has been doubted, however, whether Mani was ever a slave, as no notice is taken of this circumstance by the eastern writers; and even the Greek authors speak of him as rich, learned, educated among philosophers, and at the court of Persia in his early age. Manes, among the Greeks, was a common name for slaves; and hence it has been conjectured originated the common opinion of the Greek writers concerning Mani's servitude. The eastern authors, cited by Hyde and Herbelot, say that Mani was by profession a painter and engraver; that he had to fine a hand as to draw lines and make circles without rule or compass, and that he made a terrestrial globe with all its circles and divisions. It is also said that he was skilled in astronomy, and that he wrote a book of astrology.

It is probable, according to Beaufoire, that Mani believed our earth to have two hemispheres, an upper and a lower, both inhabited; and, consequently, that there are antipodes. He is represented as a learned man and a philosopher, and it is said that he wrote a system of philosophy, and invented a magical instrument, called by the Arabsians "Oud." That he was learned appears from various circumstances already recited.

Mani was not contented with the quality of apostle of Jesus Christ, but he also affirmed that of the Paraclete, whom Christ had promised to send; which Angustlin explains, by saying, that Mani endeavoured to persuade men, that the Holy Ghost did personally dwell in him with full authority. He left several discourses, and, among others, Addas, Thomas, and Hermes. These he lent, in his lifetime, into several provinces to preach his doctrine. Mani, having undertaken to cure the king of Persia's son, and not succeeding, was put in prison upon the young prince's death, whence he made his escape; but he was apprehended soon after, and flayed alive. Beaufoire gives no credit to the story of his attempt to cure the king of Persia's son.

The oriental writers, cited by D'Herbelot and Hyde, tell us, that Mani, having gained some esteem, began to gather together a number of people in the character of disciples, who opposed the worship and ceremonies of the religion of Zoroaster, professed at that time by the Persians. Sapor, on this account and the subsequent disturbances, would have had him punished, but Mani, perceiving his danger, fled into Turkellen, where he had full opportunity to propagate his opinions, and where he was regarded as a wonderful man, and even a god. Here it is said he lodged for a year in a cave, where he framed an imposture that multiplied the number of his followers, who all went from Turkellen into Persia upon the death of Sapor. Mani was protected in a singular manner by Hormizdus, who succeeded Sapor in the Persian throne, but he was unable to defend him, at length, against the united hatred of the Chalians, the Magi, the Jews, and the Parians: he was shut up in a strong castle, to serve him as a refuge against those who persecuted him on account of his doctrine. These writers add, that, after the death of Hormizdus, Varanes I. his successor, first protected Mani, but afterwards gave him up to the fury of the Magi, whose resentment against him was due to his having adopted the Sodocian principles, as some say; while others attribute it to his having mingled the tenets of the Magi with the doctrines of Christianity. Varanes having at first succoured him, afterwards brought him out of his castle under a pretence of disputing with the doctors of the Zoroastrian sect, flayed him alive, filled his skin with chaff, and had it hung up in a conspicuous place to terrify those of his sect; upon which most of his followers fled into India, and some even to China. All who remained in Persia lost their liberty, and were reduced to servitude. It is generally reported, both by the Eastern and Greek writers, that Mani was put to death by a king of Persia; but they seem to have no knowledge of the death of the king of Persia's son; and it is certain that the Manicheans celebrated the day of their master's death, which is generally supposed to have happened in the year 278.

It has been a subject of much controversy, whether Mani was an impostor who pretended to prophecy and inspiration. The learned Dr. Lardner has examined the arguments on both sides; and though he does not choose to deny that he was an impostor, he does not discover evident proofs of it. He acknowledges that he was an arrogant philosopher, and a great schelemt; but whether he was an impostor he cannot certainly say. He was much too fond of philosophical notions, which he endeavoured to bring into religion, for which he is to be blamed: nevertheless, he observes, that every bold dogmatizer is not an impostor. Lardner allows that Mani and his followers were Christians, and held many opinions in common with other Christians.

The doctrine of Mani, says Mofheim, was a motley mixture of the tenets of Christianity with the ancient philosophy of the Persians, in which he had been instructed during his youth. He combined these two systems, and applied and accommodated to Jesus Christ the characters and actions which the Persians attributed to the god Mithra.

He established two principles, viz. a good and an evil one: the first a most pure and subtle matter, which he called light, did nothing but good; and the second, a gross and corrupt substance, which he called darkness, nothing but evil. This philosophy is very ancient; and Plutarch treats of it at large in his Isis and Osiris.

Our fouls, according to Mani, were made by the good principle, and our bodies by the evil one; those two principles being, according to him, co-eternal, and independent of each other. In this notion, according to St. Augustin, his followers triumphed to a great degree, supposing that it afforded the best account of the origin of evil. Each of these principles is subject to the dominion of a superintending being, whose existence is from all eternity. The being who presides over the light is called God; he that rules the land of darkness bears the title of bale, or demon. The ruler of the light is supremely happy, and, in consequence, most wise, benevolent and good; the prince of darkness is unhappy in himself, and defers of rendering others partakers of his misery, and is evil and malignant. These two beings have produced an immense multitude of creatures, reforming themselves, and distributed them through their respective provinces. After a contest between the ruler of light and the prince of darkness, in which the latter was defeated, this prince of darkness produced the first parents of the human race. The beings, engendered from this original flock, consist of a body formed out of the corrupt matter of the kingdom of darkness, and of two fouls, one of which is sensitive and lustful, and owes its existence to the evil principle;
principle; the other rational and immortal, a particle of that
divine light, which had been carried away in the contest by
the army of darknefs, and immerfed into the mafs of ma-
lignant matter. The earth was created by God, out of this
corrupt mafs of matter, in order to be a dwelling for the
human race, that their captive souls might, by degrees, be
delivered from their corporeal prifons, and their celeftial
elements extracted from the gross subftance in which they
were involved. With this view God produced two beings
from his own subftance, viz. Chrift, and the Holy Ghoft:
for the Manicheans held a confubstantial Trinity. Chrift,
or the glorious intelligence, called by the Perfians Mithra,
subsisting in and by himself, and refiding in the fun, appeared
in due time among the Jews, clothed with the shadowy
form of a human body, to diſengage the rational soul from
the corrupt body, and to conquer the violence of malignant
matter, and he demonftrated his divine miffion by stupendous
miracles. The Jews, incited by the prince of darknefs, put
him to an ignominious death, which he suffered not in reality,
but only in appearance, and according to the opinion of
men. When the purpofes of Chrift were accomplished, he
returned to his throne in the fun, appointing apoftles to
propagate his religion, and leaving his followers the promife
of the Paraclave or Comforter, who is Mani, the Perfian.
Thoſe souls who believe Jesus Chrift to be the Son of God,
renounce the worship of the god of the Jews, who is the
prince of darknefs, and obey the laws delivered by Chrift,
and illuftrated by Mani, the comforter, are gradually pu-
rified from the contagion of matter; and their purificafion
being completed, after having paffed through two fates of
trial, by water and fire, first in the moon and then in the
fun, their bodies return to their original mafs; for the Ma-
nicheans derided the reffurrefion of bodies; and their souls
ascend to the regions of light. But the fouls of thoſe who
have neglected the falutary work of purifcation, pafs, after
death, into the bodies of other animals, or natures, where
they remain till they have accomplished their probation.
Some, however, more pereverfe and obfinate, are configned
to a feverer courfe of trial, being delivered over, for a time,
to the power of malignant aerial spirits, who torment them
in various ways. After this, a fire fhall break forth and
confume the frame of the world; and the prince and powers
of darknefs fhall return to their primitive feats of anguish
and misery, in which they fhall dwell for ever. These
mansions fhall be surrounded by an invincible guard, to pre-
vent their ever renewing a war in the regions of light.

Mani borrowed many things from the ancient Gnoſtics;
on which account, many authors conder the Manicheans as
a branch of the Gnoſtics.

In truth, the Manichean doétrine was a fystem of philo-
sophy rather than of religion. They made uce of amulets,
in imitation of the Basilidian; and are faid to have made profeffion of astronomy and alchemy. They denied that
Jesus Chrift, who was only God, assumed a true human
body, and maintained it was only imaginary: and, there-
fef, they denied his incarnation, death, &c. They pre-
tended that the law of Mofes did not come from God, or
the good principle, but from the evil one; and that for this
reason it was abrogated. They rejected almost all the
fared books, in which Christians look for the fublime
truths of their holy religion. They affirmed, that the Old
Testament was not the work of God, but of the prince of
darknefs, who was subfittuted by the Jews in the place of
the true God. They abominated entirely from eating the
flefh of animal; following only the doétrine of the ancient Pythagoreans; they also condemned marriage.
The refc of their errors may be fecn in St. Epiphanius and
Vol. XXII.

St. Augulfin; which laft, having been of their fect, may
be prefumed to have been thoroughly acquainted with
them.

Though the Manicheans profefled to receive the books of
the New Testament, yet, in effect, they only took too much
of them as suited with their own opinions. They firft
formed to themselves a certain idea or fcheme of Christiani-
y, and to this they adjusted the writings of the apoftles; pretend-
ing that whatever was inconftant with this, had been foifted
into the New Testament by later writers, who were half
Jews. On the other hand, they made fables and apocry-
phal books pafs for apoftolical writings; and even are ful-
pfred to have forged ferveral others, the better to maintain
their errors. St. Epiphanius gives a catalogue of ferveral
pieces publifhed by Mani, and adds extracts out of fome of
them. These are the Mysteries, Chapters, Gofpel, and
Trefury.

The rule of life and manners which Mani prefcribed to
his followers, was molt extravagantly rigorous and fervere.
However, he divided his disciples into two classes; one of
which comprehended the perfect Christians, under the name
of the elft; and the other, the imperfect and feeble, under
the title of auditors or bearers. The elft were obliged to a
rigorous and entire abstinence from fleep, eggs, milk, fift,
wine, all intoxicating drink, wedlock, and all amorous gra-
fifications; and to live in a State of the fervente penury,
nourifhing their emaciated bodies with bread, herbs, pulfe,
and melons, and depriving themselves of all the comforts
that arife from the moderate indulgence of natural paflions,
and alfo from a variety of innocent and agreeable pursuits.
The auditors were allowed to pollife houses, lands, and wealth,
to feed on fleep, to enter into the bonds of conjugal tender-
nefs; but this liberty was granting them with many limi-
tations, and under the stricteft conditions of moderation and
temperance. The general affemblie of the Manicheans was
headed by a prefident, who reprefented Jesus Chrift. There
was joined to him twelve rulers or mafters, who were de-
igned to reprefent the twelve apoftles, and these were fol-
elved by feventy-two bishops, the images of the feventy-
two diciples of our Lord. These bishops had prefbyters or
deacons under them, and all the members of these religious
orders were chosen out of the classes of the elft. Their
worship was fimple and plain; and confifted of prayers,
reading the fcriptures, and hearing public discourses, at
which both the auditors and elft were allowed to be pre-
fent. They also observed the Christian appointments of
baptifm of infants and the eucharift, communicating fre-
quently in both kinds. They kept the Lord's day, ob-
erving it as a falt; and they likewise kept Eafer and
Pentecoft.

Towards the fourth centurie, the Manicheans concealed
themselves under various names, which they fecceffively
adopted, and changed in proportion as they were discovered
by them. Thus they affumed the names of Encratites,
Apataatics, Saccophori, Hydroparasites, Solitaries, and
feveral others, under which they lay concealed for a certain
time, but could not, however, long escape the vigilance of
their enemies. About the clofe of the sixth centurie, this
fekt gained a very confiderable influence, particularly among
the Perfians.

Towards the middle of the twelfth centurie the fect of
Manichees took a new face, on occasion of one Confantine,
an American, and an adherer to it; who took upon him to
perfufe the reading of all other books besides the Evan-
gelifts, and the Epifles of St. Paul, which he explained in
fuch a manner as to make them contain a new fYSTEM of
Manicheism. He entirely discarded all the writings of his
predecessors;
predecessors; rejecting the chimeras of the Valentinians, and their thirty-ones; the fable of Manes, with regard to the origin of rain, and other dreams; but still retained the impieties of Busilises. In this manner he reformed Manicheism, infomuch that his followers made no scruple of amathematising Scythian, Buddas, called also Addas and Terebinth, the contemporaries and disciples, as some say, and according to others, the predecessors and masters of Manes, and even Manes himself, Confantine being now their great apostle. After he had seduced an infinite number of people, he was at last flown by order of the emperor.

This sect prevailed in Bofnia and the adjacent provinces, about the close of the fifteenth century; propagated their doctrines with confidence, and held their religious assembies with impurity. See on the subject of this article, Moliniani's Eccl. Hist. vol. i. p. 295, &c. 8vo. edit.; Lardner's Works, vol. iii., and Bayle, art. Manichæus.

MANICHORD, or Manichordon, a musical keyed-instrument, in the form of a small pianoforte. See Clavichord.

MANICKBURG, in Geography, a town of Hindoostan, in the province of Cattack; 5 miles S.E. of Chanda. N. lat. 19° 39'. E. long. 79° 59'.

MANICKPATAM, a town of Hindoostan, in the province of Cattack; 50 miles S. of Cattack.

MANICKPOUR, a circar of Oude, bounded N.E. by Oude proper, S.E. by Jompour, S. by Allahabad, S.W. by Currah and Corah, and N.W. by Lucknow; about 60 miles long, and 40 broad.—Also, the capital of the above circar; 30 miles N.W. of Allahabad. N. lat. 25° 59'. E. long. 81° 40'.

MANICKRAJE, a town of Bengal; 42 miles S.S.E. of Dacca.

MANICOU, in Zoology. See Opossum.

MANICOUGAN, or Black-river, in Geography, a river of Canada, which runs into the river St. Lawrence, near Manicooguan point, which is a cape on the north coast of the river. N. lat. 49° 12'. W. long. 67° 50'.

MANICOUGAN, a lake of Canada; 300 miles N.E. from Quebec. N. lat. 56° 20'. W. long. 60° 45'.

MANICUM STRYCHNUS, in Botany, a term used by the old Greek writers to express a kind of nightshade, which, when taken internally, caused madness. Pliny, describing this species, says that it has leaves like the ocyum or basil; and Theophrastus and Dioscorides say it had leaves like the eruca or rocket. Where Pliny had his information is not easily to guess, for he commonly copies from these authors; they are, however, much more to be depended on; and as the leaves of the ocyum or basil are not at all like those of the rocket, Pliny is certainly wrong in his account; and the most probable reason for his error is that he misook the Greek name of the plant, to which these authors compared the leaves of the manicum strychnum, and translated euzomomon, which is the name of the rocket, into ocyum, basil; a name somewhat like the Greek one in found, but wholly different in signification; the two plants basil and rocket not only having leaves very unlike one another, but being also of different genera. A yet greater error of Pliny, in regard to this plant, is his placing it among the crenulent garden herbs, and saying that it was in use as a food, immediately after he had told us of its causing madness in those who eat it. This is an evident confusion of the manicum solanum with the pomeum amoris or love apple, the fruit of which is eaten in foups at this time.

MANJEAH, in Geography, a town of Hindoostan, in Bahar, on the Soane; 18 miles S. of Rotafgar. N. lat. 24° 20'. E. long. 82° 57'.

MANIEN, a small island in the Pacific ocean, near the coast of Chili. S. lat. 45°.

MANIERA, Ital., Manner, a musical term to express a good or bad style of singing. In speaking of an individual performer, when it is said, "a una bella maniera," it implies that such performer, male or female, sings in good taste, in an elegant manner.

MANIFEST, in Commerce, a paper containing the particulars of a ship and cargo; which paper must be signed by the master of the vessel, before any of the goods can be landed.

MANIFESTO, an apology, or public declaration in writing, made by a prince, declaring his intentions in any enterprise, the motives that induced him to it, and the reasons on which his right and pretensions are founded.

MANIFOLD, Cape, in Geography, a point of land on the coast of New Holland, or New South Wales, so called by Cook in 1770, from the number of high hills which appeared over it; lying in S. lat. 22° 43', and distant about 17 leagues from cape Capricorn, in W. long. 168° 58'. Between these two capes lies a large bay, called "Keppel bay:" which see.

MANJHA, a town of Hindoostan, in Bundelcund; 60 miles S of Chatterpore.

MANIHOT, in Botany, an Indian name for the root of which Cassava bread is made. (See Jatrophia Manihot.) The Hibiscus Manihot seems to have been so named from the resemblance of its leaves to that plant, not from any similar use or quality.

MANILIA, in Geography, a town of South America, in the province of Tucuman; 30 miles E.S.E. of Rioja.

MANILUS, Marcus, in Biography, a Latin poet, known only by his work, from which it should be seen that he wrote in the reign of Augustus, after the defeat of Varus, and that he was, if not a native of Rome, at least a Roman subject. This poem is entitled "Astronomicon," treating, in two books, upon the fixed stars: A fifth book appears to have related to the planets, but this is entirely lost. It unite the ancient system of astronomy with the philosophy of the Stoics: there are passages in it which would not disgrace any poet of the Augustan age. The work has been elucidated by some very considerable critics. Joseph Scaliger published an edition of it at Paris in 1579, and one at Leyden in 1600. The edition of our countryman Bentley, in 1759, is in high esteem. Theof of Stobee, cum notis variis, and of Pignre, with a French translation, are much valued. Creech gave a translation of Manilus in English verse. The poem was discovered by the learned Poggius, in the sixteenth century.

MANILLA, in Geography, the capital city of Luzon, and also of the Spanish settlements in the Philippine islands. In compass it is about two miles; its length being about two-thirds of a mile; of an irregular form, narrow at both ends, and wide in the middle. It is well built; its streets are broad; its houses, though constructed of timber above the first floor, are handsome, and rendered beautiful by its galleries; and its churches are magnificent. It is a fortified city, and situated on the south-west coast, in a most advantageous position, on the banks of a considerable river, which washes its walls, and whose divided branches completely traverse the whole island. A third part of this city is occupied by convents; and the number of its Christian inhabitants is computed at 12,000. The suburbs extend to a considerable distance beyond the walls. Within a musket-shot of the gate of Pariam is the habitation of Chinese merchants, called
called Sangleys, whose shops in several streets are furnished for sale with silk, porcelain, and other commodities. The number of persons, who availing themselves of the indolence of the Spaniards and Indians, profitably employ themselves in this way, is very considerable. These Sangleys are under the government of an alcaide, to whom, as well as to other officers, they allow handsome salaries. Beyond the bridge adjoining to Parian are fifteen suburbs or hamlets, inhabited by Japanese, Tagalies, and people of other nations, under the government of an alcaide. Their houses, constructed of wood, are situated near the river, and erected on piles: the roofs are covered with palm-tree leaves, and the sides formed of canes; and they are ascended by ladders, as the ground is moist, or sometimes overflowed with water. The cattle flames at the west end of the city, having the sea on one side, and the river on the other.

We shall here subjoin some additional particulars relating to Manilla and its suburbs, extracted from the first volumes of the Travels of Pages, who resided some months in the island of Luçon or Luconia. The river, which flows under the city walls, is the harbour for merchant ships, and separates Manilla from the town of St. Croix. This latter town is in part equally well built with the capital, is populous in Indians and Spaniards, and is surrounded by three villages of the natives, which may be regarded as suburbs. At a short distance, on the opposite bank of the river, but on the same side with Manilla, are several considerable towns also belonging to the natives. Few merchants, and still fewer mechanics, reside within the walls of Manilla. The great feat of their manufactures, as well as the emperor of all kinds of merchandise, is the town named Parian, on the other side of the river, which is pretty regularly built, and inhabited chiefly by Chinese. From a small colony, the population of these people has increased so as now to amount to more than 20,000, who, after engrossing the whole of the manufactures, and the principal part of the trade of Manilla, began to turn their attention to agriculture. Possessed of a considerable degree of art and address, they are sober, industrious, affable, and lively.

Among the inhabitants of Manilla are Armenian merchants, Malays, natives of the Malabar coast, and of the kingdom of Siam, and also a few Japanese.

Articles of beautiful workmanship in gold, and a species of metal named tombac, which is esteemed one-third more precious, are manufactured by the artificers of Manilla; and the gold chains, made by their women, vie in beauty with the most elegant that are wrought in any part of the world.

In the year 1645, a great part of this city was destroyed by an earthquake, and 3200 persons perished in the ruins. The country surrounding this city is extremely fertile, and capable of any kind of cultivation; but the inhabitants have profited neither by the situation of the city, nor the fertility of its environs. The entrance of the river is obstructed by a bar, which is dangerous, with a rough sea; but no effectual labour has been undertaken for removing it. The soil is left uncultivated; and the law, by prohibiting exportation, discourages every attempt for increasing its produce. The consequence of this neglect has been occasional famine, when rains, or drought, or hurricanes, render the fecundity of the earth insufficient. The inhabitants, thus indolent in improving their natural means of wealth, direct their views and hopes towards the galleon, which fails every year for Acapulco. Formerly, a celebrated commerce was carried on between Manilla and this last-mentioned city, nearly in the same parallel on the west of Mexico, through a space of about 140°, or more than one-third of the circumference of the globe. The Manilla ships, called gallean (which fea), were then of large size; but at a later period, smaller vessels have been employed in this trade. The return of the galleon, or other vessels, was valued every year at Manilla at three millions of piastras, which were soon expended in merchandise, generally purchased of an English vessel under American colours. But this kind of traffic, as Someron states it, is a real loss to the inhabitants. On the one hand, they buy their merchandise at an exorbitant price; and on the other, they supply themselves with all the silver which enters their island. This writer adds, 'the force of habit, the convenience of trafficking with gold instead of merchandise, which is necessarily accompanied with some trouble, makes them prefer trading in money with the English vessels to the commerce with ships from the ifie of France, which would take in exchange the productions of their country, cardage, pitch, tar, cloth, sugar, oil, reeds, cane, indigo, cocoa, &c. which would be a commerce equally advantageous to both nations.'

The bay of Manilla, says M. de la Perouse, is open to ships of every size, but can be defended only by men of war; any expedition, therefore, against this colony, presupposes a decided superiority of naval force. The fortifications of the place, though regular and perfectly well kept up, could only retard for a few days the surrender of a city, which cannot expect succours either from Europe, or from any other quarter. The garrison is composed of only one regiment of mulattos. The corps of artillery, consisting of 200 men, as well as the 150 dragoons, are also Americans; and yet Perouse says, that he should not fear with 1500 men successfully to attack 3000 of them. 'Upon the whole,' he says, 'the conquest of Manilla appears to me easy, and certain, with a superiority of naval force, and 5000 troops, I might answer for its success.'

The city of Manilla was taken by the English in 1762; and the ransom of a million sterling remained unpaid. The Chinese, as we have already stated, were numerous in this city, till the beginning of the fourteenth century, when the Spaniards committed a dreadful massacre of these industrious people. In 1769, it is said that they were again expelled from all these islands by the sovereignty of the governor: since which time there has been a great decline in industry and produce. N. lat. 14° 36' 8'' E. long. 120° 51' 15''.

See Luçon and Philippines.

MANILLA, a town of Hindoostan, in Myfore; 14 miles W. of Tamderni.

MANILLE, or Menille, in Commerce, one of the principal commodities carried by the Europeans to the coasts of Africa, to traffic with the Negroes in exchange for slaves. It is a large brass ring in form of a bracelet, either flat or round, plain or engraved; with which the natives used to deck themselves, putting them on the finall of the leg, and the thick of the arm above the elbow.

The better sort among the Negroes wear silver and gold manilles; but these were of their own manufacture; most of the money they receive for their own merchandise being melted into manilles.

MANILLON, in Geography, a township of America, in Fayette county, Pennsylvania, containing 1207 inhabitants.

MANILVA, a town of Spain, not far from the route from Málaga to Gibraltar, situated across the mountains from Guayaro, and belonging to the house of Arcos. It is surrounded with vineyards, which produce an exquisite rich wine, known by the name of Manilva wine.

MANIMBOU, a town of Hindoostan, in the Carnatic; 15 miles S.W. of Pondicherry.
MAN

MANIMUNGALUM, a town of Hindoos, in the
Carmic; 16 miles S.W. of Madras.
MANINGEABO. See MENANGEBOW.
MANICTREE, or MANINTREE, a small irregular
town in the hundred of Tendring, and county of Essex, Eng-
land, is situated on the southern banks of the river Stour, nine
miles distant from Colchester, and 61 from London: though
only a chapelry to the parish of Mistley, it has the privilege of
a market. Whence it derived its present name is uncertain:
it ancient appellation was Scidinchnow, by which it is men-
tioned in Domesday book, as being then held by Adebriza,
countets of Albeamarle, and half fitter to the Conqueror.
It afterwards became the property of Maud de Clare, coun-
tets of Hereford and Gloucester, who beloowed the manor
on the nunnery of the order of St. Augustine, at Canon-
Lough, in Devonshire. After the dissolution, Manningtree
(called in the grant Many-tree, alias Scidinchnow) was given
by Henry VIII. to Sir John Rainworth. In the certificate
of chantry lands it is called “a great town, and also a
havent towne, having in yt to the number of 700 howeling
people.” In the year 1801, the population, as acertained
under the act of parliament, was 1016, occupying 129
houses. 953 of the inhabitants were returned as being em-
ployed in various trades and manufactures. The market is
kept on Thursdays and an annual fair on the Thursday in
Whitsun week. The river Stour was made navigable from
this town to Sudbury in Suffolk, by an act passed in the fifth
year of queen Anne. The principal imports are deals, corn,
coals, iron, and fish. Beauties of England and Wales,
vol. iv.
MANIPA, one of the smaller Molucca islands, about
2500 toises in extent from N. to S. Although this island is
very mountainous, it is populous, and contains about 1600 in-
habitants; and many canoes ply along its shore: five or six
leagues W. from Ceram. S. lat. 3° 21'. E. long. 127° 54'.
-Álfo, a river on the W. coast of Celebes, which runs into
the sea, S. lat. 3° 12'.
MANIPULATION, a term used in the mines, to sig-
ify the manner of digging the silver, &c. out of the
earth.
MANIPULUS, MANIPULUM, among the Romans, was
a little body of infantry, which, in the time of Romulus,
confined of a hundred men, and in the time of the consuls
and priticius, of two hundred.
The word properly signifies a handful; and, according
to some authors, was first given to the handful of hay which
they bore at the end of a pole, to dillingshiff themselves by,
before the custom was introduced of bearing an eage for
their ensign; and hence also the phrase, a handful of men.
But Vegetius, Modellius, and Varro, give other etymo-
lologies of the word: the last derives it from manus, a little
body of men following the fame standard. According to
the former, this corps was called manipulus, because they
fought hand in hand, or all together: “Contubernium autem
manipulus vocabatur ab eo, quod conjunctis manibus pariter
dimicabant.”

Each manipule had two centuries, or captains, called
manipulii, to command it; one whereof was lieutenant to the
other. Each cohort was divided into three manipules, and
each manipule into two centuries.

Aulus Gellius quotes an old author, one Cincius, who
lived in the time of Hannibal (whose prisoner he was), and
who, writing on the art of war, observes, that then each
legion consisted of sixty centuries, of thirty manipules, and
of ten cohorts. And again, Varro and Vegetius mention it
as the least division in the army, only confitting of the
tenth part of a century; and Spartan adds, that it con-
tained no more than ten men. This shows that the manipulus
was not always the same thing. See Legion.

MANIPULUS is also an ecclesiastical ornament, worn by
the priests, deacons, and sub-deacons, in the Romish church.
It consists of a little fillet in form of a role, three or four
inches broad, and made of the same stuff with the chasuble;
figurifying and representing an handkerchief, which the priests
in the primitive church wore on the arm, to wipe off the tears
they were continually shedding for the sins of the people.
There still remains a mark of this usage in a prayer rehearsed
by thuse who wear it; “Merear, Domine, purate mani-
fulum petus & doloris.”

The Greeks and Maronites wear two manipules, one
on each arm.

MANIPULUS, in Pliny, denotes a measure, or fixed quan-
tity, of herbs, or leaves, eis. a handful; or fo much as the
whole hand can grasp: it is generally marked in prescrip-
tion, with an M.

MANIQUE, in the Materia Medica, the name given by
authors to an American root, commended greatly for curing
tertian and quartan agues, and as an infallible remedy against
venomous bites. Redi procured some of this famous root,
and gave it many very fair trials, but could never discover any
of these virtues in it.

MANIS, in Natural History, a genus of quadrupeds
the class Mammalia, and order Bruta, of which there are,
according to Gmelin, two species, but Dr. Shaw mentions
three. The generic character is, that it has no teeth; the
tongue is round, and extensible; the mouth is narrowed
into a fount; the body is covered above with movable bony
scales.

This genus presents an appearance as extraordinary as
that of the Dallypis, being covered on every part, except
the belly, with strong and large scales, constituting a com-
plete suit of armour, capable of defending the animals, when
rolled up, from the assaults of the most ferocious enemies.
This covering, together with the length of the body and
tail, gives an aspect so much resembling that of a lizard,
that the creatures of the genus are commonly known by the
name of the lizards, though they are in no other respect
alied to the lizard tribe than in their covering. They are,
however, admitted to form a sort of link of approximation
between the proper viviparous quadrupeds and the lizards.
In their nature they are harmless, and feed in the same
manner as the ant-eaters, by thurling out their very long
tongue into the noes of ants and other insects, and swallowing
their prey, by suddenly drawing it back. They are found
chiefly in India and the India islands.

Species.

PENTADACTyla, five-toed or short-tailed manis. The
tail in this species is not so long as the body, it is very thick
at the bafe, and from thence gradually tapering, but ending
obtusely. The head is small, and the ears are like wise small
and rounded. The feet are furnished with five toes each,
of which those on the fore-feet are extremely strong, except
the exterior one, which is much smaller than the rest. The
whole animal is covered with thick, strong, and large scales,
which, when full grown, are perfectly smooth, but in those
of which they are smaller, they are fricated about half way from
the bafe. They are channelled at the bafe, but at the edges
they are sharp, rounded, and imbricate. It inhabits Guinea,
China, and India. The colour of the animal is of a pale
yellow-brown, and the surface is glossy. It measures,
including the tail, from six to eight feet in length. In Ben-
gal, it has obtained the name of the “Thunderbolt Reptile,”
from the hardnefs of its scales, which are said to be capable
of striking fire like a flint. It lives in woods and marshy places, and feeds on ants, by laying its long tongue across their paths. It walks slowly, and when pursued, rolls itself up, and is then so securely armed, that even a leopard attacks it in vain. It is said to be capable of destroying the elephant, by twisting itself round the trunk, and thus compreffing that tender and sensitive organ with its hard feet.

Tetradactyla, four-toed or long-tailed manis. This animal is lefs than that already described; it is found in India; the scales are much channelled, each is armed with three points; the under parts are covered with hair, and the tail is three times as long as the body. The legs are very short, and scaled like the body, and on each of the feet are four claws, of which those on the fore-feet are stronger than those on the hind. The colour is an uniform deep brown, with a yellowish cast, and with a glossy or polished surface. From the tip of the nose to the extremity of the tail, its whole length is about five feet.

Latisimma, or broad-tailed manis, is denominated, in the sixtieth volume of the Philosophical Transactions, in which there is a figure of the animal, the "New Manis." The creature here described was killed in the house of a merchant at Tranquebar, having been discovered in the cavity of a wall. When attacked it rolled itself up in such a manner as to leave only the back and tail visible, so that it was destroyed with much difficulty. It had five toes on the fore-feet, and four on the hind; the scales were of the shape of a needle; the belly quite smooth; the exterior scales ended in a sharp point, somewhat incurved; the tail was very broad, decreasing to a point. It is doubtful, after all, whether this animal belongs to a distinct species, or whether it be a variety of one of those already noticed. "In reality," says Dr. Shaw, "the differences do not seem sufficient to constitute a specific distinction, and are, probably, owing to the differences of age and sex. In the British Museum there are specimens of different sizes, which shew these gradations. In one, the scales, all over the animal, are so regularly and completely truncated at the extremity, as to exhibit the appearance of so many hexagons. In another they are remarkably broad and rounded; and in a third, which is a very large specimen, they are less obtuse at the tips, and somewhat irregularly terminated, as if notched, or worn through age. The proportional breadth of the tail also varies somewhat in these specimens, and seems greatest in those in which the heel advanced in age;"

MANISSA, in Geography, a river of Africa, forming the southern boundary of Inhambane, and running into the Indian sea. S. lat. 25° 50'.

MANISTIE, a river of Canada, which runs into lake Michigan, N. lat. 43° 30'. W. long. 85° 40'.

Gen. Ch. Perfctt Flowers imbricated, alternate, at the opposite sides of a zigzag jointed spike, one to each joint, which is hollowed out to receive the base of the flower. Cal. Glume of two valves, single-flowered; the outermost valve largest, coriaceous, rounded, rugged in the middle, either notched or entire at the top and sides; innermost smaller, broadly lanceolate, membranous, closely preflid to the former. Cor. Glume of two valves, membranous, thin and transparent, smaller than the calyx and concealed therein; the outer valve embracing with its edges the inner, which is smaller. Neotary a membranous scale. Stam. Filaments three, capillary, prominent; anthers oblong, incumbent. Petal. German ovate, superior; styles two, short, thread-shaped; ligulas oblong, bearded, spreading beyond the glumes at each side. Peric. none, the calyx including the seed. Seed solitary, one.

Male Flowers marginal, alternate, at the back of the spike, projecting at each side, one to each joint. Cal. Glume of two valves, single-flowered, nearly cylinrical; the valves equal, parallel, ovato-lanceolate, obtuse, fribated, coriaceous, bordered with a membrane. Cor. Glume of two valves, membranous, thin, nearly as large as the calyx; the outer valve ovate, obtuse, convoluted; inner lanceolate, placed, scarcely longer than the outer. Neotary a membranous scale. Stam. Filaments three, very short, sometimes wanting; anthers as in the perfect flowers.

Eff. Ch. Perfect Flowers. Calyx a glume of two unequal, opposite valves, single-flowered; the outer valve rounded and rugged. Corolla smaller than the calyx. Stamens three. Styles two.

Male Flowers. Calyx of two equal, parallel, oblong valves.

Obj. This genus is one of the few that may properly be allowed to remain in the chlas Polygammia, as having a very different structure in the two different kinds of flowers. Such is the case with the British genus Aristplex, but with few others admitted into this chlas by Linneus. These however, in our opinion, excuse, if not justify, the prefer- vention of it in the Linnaean system.

1. M. maurus. Munro-tail Scaly-grafs. Linn. Mant. 500. Linn. fil. Nov. Gram. Gen. t. 1. f. 1–3. Roxb. Corom. v. 2. 19. t. 117.—Outer glume of the perfect flowers elliptical, depressed, notched at the top and sides. Sheaths of the leaves smooth.—Found by Koenig in dry elevated barren ground on the coast of Coromandel, not unfrequent. Dr. Roxburgh gathered it in the same country, and informs us that it is called by the Telingas Nalla Papacoco. The root appears to be perennial, consisting of long, tough, downy fibres. Stems several, branched, jointed, lefby, fimeo, compressed, folid, from 9 to 18 inches tall; decumbent and throwing out roots at their lower part. Leaves alternate, channelled, short, narrow, acute, fimeo, with long inflated sheaths. Spikes about two inches long, linear, forialy at the ends of the principal, as well as the fhort filateral, branches, composed of numerous, closely imbricated, flowers. The outer glume of such as are furnished with both faments and pilils is shaped like a fiddle, its dilk marked with two transversal elevations, and somewhat hairy, its membranous margin purplish. Dr. Roxburgh found two male flocules in the oblong-leaved calyx, and his description of the structure and position of the calyx-glumes differs from that which we have adopted, as well as from what we can discern in the dried specimem, in which those valves are certainly parallel, not opposite to each other, a very remarkable and distinguishing character between the male flowers and the perfect ones. The common italk, or rocks, is zig-zag, consisting of short, turbinate, angular, slightly downy joints, each of which bears near its base, on one fide, a single perfect flower, and at its fummit, on the opposite fide, a male flower.

...in dry calcareous situations, in the south part of Jamaica; Roxburgh in bully places, on the coast of Coromandel. The latter observes that both this and the foregoing are coarse grasses, not eaten by cattle. The root of the present is said by Swartz to be annual. It consists of numerous, nearly smooth, fibres. Stem a foot or two in height, branched from the bottom, leafy, round, smooth, slender. Leaves broad, taper-pointed, more or less hairy, with tumid, ribbed, very hairy, and minutely tuberculated, theae. Spikes terminal, the fmalts of small, lateral, axillary, leafy branches. Each spike is about an inch long, composed of numerous imbricated flowers, on a zigzag stalk, the united ones conspicuous on one side, the males on the other. The outer calyx-gland of the former is orbicular, pale or purplish, the fife of a small pin’s head, strongly reticulated with elevated ribs, and intermediate depressions. Swartz says there are two inner glumes, which are ovate, nearly equal, pointed, white and pubescent. Roxburgh’s figure does not accord with this. The former writer describes the corolla as of two minute, ovate, whitish glumes, half the size of the outer valve of the calyx, and the nectary of two extremely diminutive, fleshy, whitish scales, forming a cup at the base of the germen and stamens. The male flowers are rather larger, each containing two parallel, equal, ovate calyx-glumes, which are flariated and hispid, with a small, white, bivalve corolla, and a familiar nectary to the other.

**MANITOU, or MANITOUALIN Islands, in Geography,** a cluster of islands towards the N. shore of lake Haron, stretching from the vicinity of Cabots head, north-westtherly across the lake to lake George, below the falls of St. Mary. These islands are held feared by the Indians.

**MANITOU Kimen, a poll of Chinfe Tartary, in the country of the Kalkas. N. lat. 43° 22’. E. long. 106° 49’.

**MANITOU Ouou, a town of Chinfe Tartary, in the country of the Monguls. N. lat. 42°. E. long. 113° 14’.

**MANITZKAIA, a town of Ruffia, in the country of the Coflacks; 46 miles E.N.E. of Azof.

**MANIVAL, a town on the E. coast of Madagafcar. S. lat. 17° 10’. E. long. 50°.

**MANKAKO, a town of the ifland of Celebes, in Buggefs bay, in which is a good market for gold and fago. S. lat. 1° 47’.

**MANKALIA, a fea-port town of Bulgaria, on the Black fea; 68 miles E.S.E. of Slifiitria. N. lat. 44°. E. long. 28° 30’.

**MANKANET, or St. Joseph, a town of Africa, in Galam, in which is a French factory.

**MANKAP, a small ifland in the East Indian fea, near the S. coast of Borneo. S. lat. 3° 2’. E. long. 169° 58’.

**MANKETS. See Mogavans.

**MANKOWA, a town of Ruffia, in the government of Irkutt; on the Angara; 44 miles S.E. of Balgansko.

**MANKOUH, a town of Peria, in the province of Khoraflan; 66 miles N. of Mefehid.

**MANKOW, See Ivy Coast.

**MANKUTOSKA, a town of Ruffia, in the government of Irkut; 28 miles N. of Stretensk.

**MANLIUS, Marcus, furnamed Capitolinus, in Biography, a distinguifhed Roman, was brought up to arms, and is said to have already served the office of conful, when he was one of the garrifon of the Capitol at its fiege by the Gauls in the year 390. On the attempt of the enemy to surprize it by night, Manlius was the first perfon awakened by the noise of the galleys kept in the fortrefs. He ran to the ramparts, threw down two Gauls who had mounted to the top; and the alarm being caught by the centinels, the enterprise was defeated, and the Capitol saved. For this heroic act, Manlius received a house in the Capitol, with the title of Capitolinus. The high reputation which he now enjoyed, induced his ambition to become the firft man in Rome. Camillus, the favour of his country, was at the head of the patrician party, and Manlius, jealous of his power, threw himself into the opposite party, and began to court the Plebeians, by raising at the rich, and patronizing their insolvent and enflaved debtors, of whom there was always a great number in Rome. He liberated several of these at his own expence, and flood forth as the public advocate of the people in the division of the conquered lands. On account of some false charges which he exhibited against the nobles, he was thrown into prison; still, however, he was regarded as the hero of the party, and when he was liberated, he kept no measure in his hostility to the nobles, but he exposed the abolition of confulates and ditfae of the monarchical and a perfect equality of rights. He offered himself as a leader to enforce these changes, and is said to have formed a plot to seize the Capitol, and usurp the sovereign power. The senate now paffed a decree, enjoining the military tribunes “to take care that the republic should suffer no detriment,” which was the form of inveiling them with absolute power. Manlius was charg’d with the crime of aiming at regal power; he appeared before his judges with mourning, unsupported by his nearest relations, who were of the opposite party. To excite the favour and compaffion of the people, he produced four hundred perfon’s whose debts he had paid; he displayed thirty fuits of armour won from as many foes slain by him in single combat; a mural crown, and eight civic crowns; and he enumerated thirty-seven rewards received from his generals for acts of extraordinary valour. Latly, he pointed to the Capitol itself, which he had faved, and which was full in view from the Campus Martius, the place of trial, and invoked its gods to his affittance. So long as this object was in their sight, the people professed to fubmit to the authority of confulates, but when the place of the assembly had been altered to a grove from which the Capitol could not be fen, sentence was obtained againft him, and he was condemned to be thrown down from that very rock which he had defended from the attack of the Gauls. This execution took place in the year 384 B.C., and a decree was at the fame time paffed, that no patrician fould from that time dwell in the Capitol. Plutarch. Livy.

**MANLIUS, Titus, furnamed Torquatus, a celebrated commander of the fame famy with the preceding, the fon of Titus Manlius: Imperius, who after he had lerved the office of dictator in 363, was cited before the people to answer for various acts of cruelty, and one of the charges against him was for keeping his fon Titus, in the country, at work among his faves, for no other rea’n than that he was of low parts, and had an impediment in his speech. The young man being informed of this accusation, went to Rome by night, and proceeded directly to the house of the tribune Pompeius, his father’s accuser, demanded a private interview; then drew a dagger and threatened him with inflant death unless he took an oath to drop the prosecution against his father, with which he very readily complied. The people were fo well pleased with this inflance of filial piety, though in favour of a man whom they detefted, that they raised the young Titus to the poft of legionary tribune. Some time afterwards, when the Gauls, invading the Roman territory, had advanced within three miles of the
the city, and both armies lay on opposite banks of the Anio, one of the enemy, of gigantic stature, came to the bridge and challenged the bravest man among the Romans; Manlius begged to be allowed to accept the challenge, and armed with a short sword and buckler advanced to the encounter. Victory decided in his favour, and the Gallic, considering the death of their champion as an omen of ill success, abandoned their camp in the night, and made a precipitate retreat. Manlius obtained the name of "Torquatus" from having torn a golden collar from the neck of his antagonist, and putting it on his own. In the year 355, he was nominated to the dictatorship, though he had not yet been consul, on account of his great merit. He was a second time dictator, and then succeeded to the consulship. In the year 340, he marched with Decius Mus, to suppress a dangerous war with the Latins, and it was resolved, that no soldier nor commander should quit his ranks, or even fight, without express permission, on pain of death. Soon after Manlius, the son of Torquatus, who commanded a detachment of horse, meeting with a squadron of the enemy, was challenged to single combat by its leader; he in the height of his ardour accepted the offer, and flew against him. Having stripped him of his armour, he went triumphantly to his father's tent, and relating the deed, laid the spoils at his feet. The consul immediately, and in the name of the Roman army, pronounced against him sentence of death for disobedience of orders. In the ensuing battle, Decius was slain, and the event remained in doubt, till Manlius, by a skilful movement, decided the day and gained a complete victory. On his return to Rome, he was received with honour by the senators, but the younger part of the citizens abhorring his rigour towards his son, refused to go out to meet him. He was afterwards offered the consulship by general consent, but he declined it, telling the people, that as they could not bear his severity, so neither could he put up with their licentiousness. Livy. Univer. Hist.

Manlius, in Geography, a poll-town in Onondago county, New York, incorporated in 1794, and the seat of the county courts. It is well watered by several creeks, which unite at the N. E. corner of the town; and the stream assuming the name Chittenengo, runs N. to Onanda lake, lying 10 miles N. of the centre of the town. It comprehends that part of the Onondago reservation, bounded by the Genesee road, and W. by Onondago creek and the Salt lake. It contains 960 inhabitants.

Manna, a district, and also a river, on the south-west coast of the island of Sumatra. In this district a progresse in the art of cultivation is discovered, superior to what appears in almost any other part of the island; that occupied by the Batais excepted. Here the traveller may see fields of land, in size from five to fifteen acres, regularly ploughed and harrowed. Mr. Mariden accounts for this difference by observing that Manna is by much the most populous district to the southward, with the smallest extent of sea-coast. Necessity obliges them to cultivate the earth; or otherwise they would be obliged to abandon their native soil. In order to understand the rate of produce, we must first explain the terms used in describing it. "Paddie" is rice, whilst it is in the husk; and paddie in Sumatra and the Malay islands is distinguished into two sorts, viz. "laddang," or upland paddie, and "fawoo," or low-land; and these are always kept separate, and will not grow reciprocall. From grounds tilled as they are, in the district of Manna, the produce is reckoned at 30 for one; from the laddangs in common it is about 60 or 80. The favors are generally supposed to yield an increase of 100 for one, but in some of the northern parts 120. The excess of this proportion of produce above that of our fields in Europe, which seldom exceeds 15, and is often under 10, is ascribed to various circumstances; viz. the difference of grain, rice being extremely prolific; the more genial influence of a warmer climate; and the earth gradually loosing, by an excelle cultivation, its fertility; but principally, as Mr. Mariden conceives, to the different style of cultivation. The Sumatrans, who do not grind time or labour, make holes in the ground, and drop into each a few grains; or, by a process still more tedious, raise the seed in beds, and afterwards plant it out. The district of Manna, as well as other parts of Sumatra, is subject to very destructive earthquakes. By a severe calamity of this kind that occurred in 1770, a village was destroyed by the houses falling down and taking fire, and several lives were lost. The ground in one place was rent for a quarter of a mile to the width of two fathoms and depth of four or five. A bituminous matter is described to have flowed over the sides of the cavity, and the earth, for a long time after the shock, was observed to contract and dilate alternately. Many parts of the hills far inland, could be distinguished to have given way, and as a consequence of this, Manna river was so much impregnated with particles of clay that the natives could not bathe in it. At this time was formed, near to the mouth of Padang-goochie, a neighbouring river, called the Pong, a large plain, seven miles long, and half a mile broad, where had before been a barren narrow beach. A small but beautiful cascade descends perpendicularly from the steep cliff, which, like an immen rampart, lines the sea-shore near Manna. No country in the world is better watered than this. Springs are found wherever they are sought for. The rivers on the western coast are innumerable, but too small and rapid for the purposes of navigation. The vicinity of the mountains to that side of the island occasions this profusion of rivulets, whilst it prevents their accumulating to any size. At Manna the "Soopatan," that is, the flowering apparatus, on which an oath is administered, is a gun-barrel. When used for this purpose, it is carried to the spot in flate, under an umbrella, and wapt in silk. This parade has an advantageous effect, by influencing the mind of the party with an high idea of the importance and solemnity of an oath. In England it is to be regretted, that the familiarity of the object, and the summary method of administering oaths, are well known to diminish their influence, and to render them too often nugatory. The Sumatrans sometimes swear by the earth, lying their hands upon it, and wifying that it may never produce ought for their nourishment if they speak falsely. Mariden's Sumatra. The town of Manna is distant 300 miles S.W. from Indrapoor. S. lat. 4 25'. E. long. 102° 40'.

Manna, a town of Africa, in Salloukadoo, near the Senegal. N. lat. 12° 29'. W. long. 8° 50'.

Manna, in Pharmacy, a medicinal drug, of great use in the modern practice, as a gentle purgative, and cleanser of the first passages.

Manna is a white sweet juice oozing from the trunk, branches, and leaves of a kind of sli-tree, being the Fraxinus Oros (which fee), chiefily in Calabria, during the heats of summer.

Manna has been erroneously held to be a kind of mel aurum, or honey-dew, which, falling in the night, gathers on certain trees, and even on rocks, and on the earth itself; where it hardens with the sun. But what refutes this opinion is, that such dews melt in the sun; whereas manna whitens and hardens in it. Add, that such dews are only found on the tops and extremities of the leaves, whereas manna is chiefly found to lodge on the trunks of the branches: and that the honey-
dew falls only on trees open to the air; whereas manna is found on trees which are under cover; as was experienced by Dr. Cornelius, who gathered manna from branches covered on purpose with cloth; and Lobel affirms us, that manna had been gathered from branches of the asph, which had been thrown the day before into a cellar. It is much more rational to rank manna amongst the number of gums, which, exuding from the juice of the tree, is condensed into those flakes in which we see it.

Manna is far from being peculiar to the asph-tree of Calabria, on which it is usually found. The Ornius is not the only species of Asph or Fraxinus which produces it. It is afforded, though in less abundance, particularly in Sicily, by the Fraxinus rotundifolia and excelsior: these three species are cultivated in Sicily, and planted on the declivity of a hill, with an easterly aspect for the purpose of procuring manna. After 10 years' growth, the trees begin to yield the manna, but they do not afford it in very considerible quantity till they are much older; and as manna is no other than the matter of the sensible tranpiration of trees and plants in general, it is found on many different kinds, in different quantities.

At Briancon, in France, they collect manna from all forts of trees that grow there; and the inhabitants observe, that such summers as produce them the greatest quantities of manna, are very fatal to their trees. Their walnut-trees produce annually a considerible quantity; but if there happen a year in which they produce more than ordinary, they usually find many of them perish in the following winter.

It seems very plain from the whole, that manna is only the extravasated juice of the tree, which cannot furvive to great a lot of it; and what not a little confirms this, is, that the very hot summers are always those which are the most abundantly productive of manna. The ancients were sensible of this spontaneous production of manna, of several species of trees, so very different from one another, and from thence fell into the error of supposing it something wholly foreign to the tree; an error very natural to those who did not know that the nutritive juices of very many trees are nearly, if not wholly the same. It was from this opinion of its origin, that they called it aerial honey.

Dr. Cullen very properly supposes manna to be a part of the fugar so universally prevalent in vegetables, and which exudes on the surface of a great number of them; and he thinks that the qualities of these exudations are very little, if at all different. The principal trees known to produce these mannas in different climates and seaons are, the larch, the fir, the orange, the walnut, the willow, the mulberry, oaks, the hagi, Maunorum, or Hedytherum albi, of Linneas. Of this latter Dr. Fothergill prefixed a specimen to the Royal Society, which he confidered as the "Terenabinis" of the Arabians. (Phil. Trans. vol. xiii. p. 87.) The Citrus ladaniferus in some parts of Spain produces a manna, which, in its recent flake, has no purgative quality, and is eaten by the shepherds, so that some fermentation seems to be necess-
ary, in order to give it a cathartic power.

The Italians gather three kinds of manna:—Manna di corpo, which oozes spontaneously from the branches of the tree in the month of July. Manna forata, or forratella, which is not gathered till August, after an incision of the tree, when the flux of the firit has ceased. Manna di fconda, which iffues of itself, in little drops, like a kind of sweat, from the nervous part of the leaves of the asph, and gathers into grains about the bigness of thofe of wheat, which are hardened by the fun in August. The leaves are frequently found so laden with these grains, that they feem covered with snow.

Although the manna exudes spontaneously upon the asph-
trees, yet for obtaining it more copiously, incisions are made through the bark by means of a sharp crooked instrument
and the seaon thought to be the most favourable for infi-
tituting this process is a little before the dog-days commence, when the weather is dry and ferene. The incisions are first made in the lower part of the trunk, and repeated at the distance of an inch from the former wound, full extending the incisions upwards as far as the branches, and confining them to one fide of the tree; the other fide being reserved till the year following, when it undergoes the same treatment. On making these incisions, which are of a longitudinal direction, about a fan in length, and nearly two inches wide, a thick whitifh juice immediately begins to flow, which gradually hardens on the bark, and in the course of eight days acquires the confidence and appearance in which the manna is imported into Britain, when it is collected in baskets, and afterwards packed in large chells. Sometimes the manna flows in such abundance from the incisions, that it runs upon the ground, by which it is mixed with various impurities, unless prevented, as is usually the cafe, by interposing large concave leaves, chips, chips of wood, &c. The buncels of collecting manna usually terminates at the end of September, when the rainy seaon sets in. Dr. Cirillo's account of the manner of collecting manna in the kingdom of Naples was communicated to the Royal Society, and was published in Phil. Trans. vol. ix. This ingenious writer begins with correcting a mistake, founded on an erroneous opinion of the ancients, which relates the belt and parcel manna to be that which is obtained from the leaves of the tree. He never saw such a kind, and all those who are employed in the gathering of the manna, know of none that comes from the leaves. The manna is generally of two kinds, not differing in their intrinsic quality, but in the manner by which they are procurcd. In order to have the manna, says our author, those who have the management of the woods of the Orni in the months of July and August, when the weather is very dry and warm, make an oblong incision, and take off from the bark of the tree about three inches in length and two in breadth; they leave the wound open, and by degrees the manna runs out, and is almost suddently thickened to the proper confidence, and is found adhering to the bark of the tree. This manna, which is collected in baskets, and goes under the name of "manna groffa," is put in a dry place, because moist and wet places will soon dillow it again. This firt kind is often in large irregular pieces of a brownish colour, and is frequently full of dust and other impurities. But when the people want to have a very fine manna, they apply to the incision of the bark thus drawn, or small bits of thrums, so that the manna, in coming out, runs upon thofe bodies, and is collected in a sort of regular tubes, which gives it the name of "manna in cannoli," that is, manna in tubes; the second kind is more esteemed, and always preferred to the other, because it is free and clear. There is indeed a third kind of manna, which is not commonly met with, and which our author says he has seen since he left Calabria; it is very white, like fugar; but as it is rather for curiosgty than for use, he says no more of it. The two forts of manna already mentioned undergo no kind of preparation whatsoever, before they are exported; sometimes they are finer, particularly the "manna groffa," and sometimes very dirty and full of impurities; but the Neapolitans have no intcrest in adulterating the manna, because they have always a great deal more than what they generally export; and if manna is kept in the magazines, it receives often very great hurt by the southern winds, so common in our part of the world. The changes of the weather produces a sudden alteration in the time that the manna is to be gathered; and

for
for this reason, when the summer is rainy, the manna is always very scarce and very bad.

Manna is generally distinguished into different kinds, viz. the manna in tears, the canulated and flaky manna, and the common brown or fat manna; differences which depend upon their respective purity, and the manner in which they are procured from the tree, and not upon the nature of the drug itself. When the juice transludes very slowly, the manna is more dry, transparent, and pure, and consequently of higher estimation; but when it flows more copiously, it concretes into a coarse brown unctuous mass; and hence we perceive that by applying straw, &c. to receive the flowing juice, the manna becomes much improved. Houlé, who tasted the manna when flowing from the tree, found it much more bitter than in its concrete state; and this bitternes he attributes to the aqueous part, which is then abundant: whence it appears that the manna is Millerated by all the circumstances which promote evaporation. Manna is a substance in many things very nearly related to sugar and to honey; it is insinuable in the same manner, and it melts in water as easily as sugar, and liquifies even in a moist air, and by the affluence of heat, in rectified spirit also; the impurities only being left by both menstrua. On infusing the watery solution, the manna is recovered of a much darker colour than at first. From the saturated spirituous solution great part of it separates as the liquor cools, concreting into a flaky mass, of a snowy whiteness, and a very grateful sweetness. When exposed on hot coals, it swells, takes fire, and leaves a light bulky coal. When boiled with lime, clarified with white of egg, and concentrated by evaporation, it affords crystals of sugar. By distillation manna affords water, acidi, oil, and ammonia; and its coal affords alkali.

M. Lemery, in his analysis, drew from manna a vinous liquor, of the same kind with that obtained from honey. Mead also may be made of manna, in the same way that it is made from honey; but it is neither so strong, nor so agreeable to the taste of honey. Fried as much meal as was made from two pounds of manna, M. Lemery separated by distillation eight ounces of a sort of brandy, and on rectifying this, procured an ounce and a half of a pure burning spirit, like in all respects to rectified spirit of wine. This spirit of manna is accounted by some a fusiform, and is given from half a dram to a dram and a half. M. Lemery having left the remaining liquor, after the distillation of the spirituous part of the manna meal, in a warm place for two years, found that it deposited to the bottoms of the bottles seven drams of an essential salt of manna, which was white, hard, brittle, and formed into fine needles, and was of an acid taste, with an admixture of sweet. This salt is purgative, and its dose is a dram. All the remaining acid liquor being distilled, there remained at the bottom of the retort a quantity of matter of the consistence of honey, which weighed twenty ounces; so that out of two pounds of manna, there had been twelve ounces consumed, to make the spirit, and to give the acidity to the remaining liquor. This honey-like solution, being finally distilled with alsting fire, there arose a reddish liquor of an acid taste, and with a strong empyreumatic smell, and with this a few drops of blackish oil; after this operation, the remainder in the retort was four ounces of a very light black coal. The coal, it is to be observed, is here only one-eighth of the weight of the manna, which is somewhat singular, since in the purest honey, treated in the same manner, it always weighs one-fourth of the original whole quantity. It is plain from hence, that manna is a much purer substance than honey: it is also remarkable, that in farther treatment of this coal, there is a small quantity of iron always discovered in it.
**MANNA.**

On the contrary, the Hebrews and Orientals believe, that the fall of the manna was wholly miraculous. Whatever was the nature of this substance, which is not easy, or perhaps possible, for us to ascertain, it was by the dispensation of Providence a nutritive food, and served the children of Israel during their migration in the deserts of Arabia for forty years. From their eighth encampment in the wilderness of Sin, Manna began to fall on Friday morning, the sixteenth day of the second month, which from thence was called Iyar; and, according to Usher, this was Friday the seventh of June (Exod. xvi. 14, 15). It continued to fall daily in the morning, except on the sabbath, till after the pasch over Jordan, and to the pascher of the eighteenth year from the Exod., i.e., from Friday the seventh of June, A. M. 2553, to the second day of the paschower, Wednesday the fifth of May, A. M. 2553, B. C. 1451. This manna, whatever it was, fell in such quantities, during forty years, as to be sufficient for the sustenance of about a million of persons. Every Friday it fell in a double portion (Exod. xvi. 2, 3); and though on other days it putrefied, if it were kept from one day to another, yet on the sabbath it suffered no such alteration. Thus, the Israelites were instructed in their constant and necessary dependence on the providence of God.

Manna Albigniana, a word used by some authors to express that kind of manna called by others manna majlickina, from its drops resembling mastic in small tears. It is called albigniana from the plant which produces it, being collected from the albagi manusorum, in the same manner as the common manna from the Calabrian sp.

Manna Libanotis, in the Materia Medica, a name given by the old Greek writers to the small flakes and fragments of the frankincense, which fell off the larger pieces in the gathering and putting them up. See Leontos Likanitis.

Manna Majlickina, a name given by some authors to a kind of manna which they describe as resembling mastic in its colour, and the size of the lumps it is collected in. This is what we usually know at this time under the name of manna Perfichia, or Persian manna, which is even now in use in medicine, in the East, as a common purge.

Manna Perfichia, Persian Manna. It does not appear in the writings of the ancient Greek physicians, that they were acquainted with any species of manna, though medicine be now so common in the shops. They had the word indeed, but they applied it to a very different sense; what they called manna being what some authors still called the manna of frankincense, that is such pieces of the common olibanum as broke off in the carriage from the larger pieces.

Phil. Trans. N° 478. p. 86. in vol. xil.

The Arabians are by some supposed to have first brought what we call manna into use in medicine; but if they were not the absolute inventors of this use of it, it is certain they were the first who made it general and common as a purge. Their country afforded several distinct species of manna, all which seem to have been so common among them, that they thought descriptions of them needless; and for that reason have not left us sufficient accounts of them, from which to determine what were their characters and differences. They distinguzhed three kinds of this purging medicine, under three absolute different names, which were manna, terenjabin, and firoof; but it is not easily proved whether these are all now known, or by what appellations they are at this time distinguished.

Rawolf, in his Itinerary published by Mr. Ray, and Tournefort in his voyage to the Levant, have given the cleared accounts, in regard to this subject, of any of the known writers; and if to these we add Celsius, we have among the three all that is to be expected of any certainty upon the subject; yet the descriptions of these, though eye-witnesses of all they write, have not prevented so eminent and late a writer as Geoffroy, from falling into an error concerning the manna of the Arabians. It is very evident, however, that we have still one species of the manna Arabum, that is, the terenjabin, produced in some parts of the world, there having been specimens of it sent over into England from Peterborough, near which place it is collected from a plant known among botanical writers under the name of albagi manusorum.

This is usually called manna Perfgnia; it appears at first sight a mixed mass of dirty reddish-brown colour, but, upon a nearer view, it is seen to consist of several forts of particles. First, a great number of globular, crystalline, and almost transparent bodies of different sizes, and of a yellowish-white colour; the biggest of these do not much exceed a larger coriander-see in size, and they have somewhat the appearance of small lumps of mastic, but are of a somewhat reddish cast. Secondly, there is among these a large quantity of small prickles, and other little woody bodies, which seem to have been the pedicles of leaves. Thirdly, there are a few small leaves which are of firm texture, and terminate in narrow points. Fourthly, there are a large number of small long reddish coloured pods, of a sweetish gelatinous tinge, containing from one to six or seven hard, irregular, and kidney-shaped seeds, which to the taste are very foul. And fifthly, there is usually some sand and earth among it. Four ounces of this manna diffused in water usually leave about one ounce of these substances in the water.

The globules firft described are something hard, they break between the teeth like sugar-candy, and are of a pleasant sweet taste, but have much less of the manna flavour than the Calabrian, but enough of it to discover to what family the substance belongs: the seeds, flicks, leaves, and pods, seem to be all of them parts of the plant which produces the manna; and the seeds having been found with us, have raised plants of the albagi. About the year 1537, when Rawwolf wrote his Itinerary, it appears that large quantities of this kind of manna were brought from Perina to Aleppo, where it was then known by the name of tranfchibil, or tranfchibbin, a corruption doubtless of the word terenjabin, or, as it ought to be written, according to Desfingin, terrejabin.

Rawwolf also expressly informs us, that this species of manna was gathered from a plant called albagi. This plant is minutely described by Tournefort, who confirms the account of the manna being gathered from it, which Rawwolf had given so long before.

Tournefort says, that it is chiefly gathered about Tauris, a city of Persia, under the name of tranjabin, or terenjabin, mentioned by Avicenna and Scarpion; he adds, that those authors thought it fell upon certain prickly shrubs; whereas it is really the nutritious juice of the plant, and that, during the great heats in that part of the world, there are perceived small round drops, as it were, of honey standing upon the leaves of this plant; and that these harden into globules about the size of coriander-seeds, and are then gathered by the inhabitants, together with leaves, flicks, dirt, and the like foreign matter, which greatly take off from their virtue. M. Tournefort observes, that this manna is greatly inferior to the Calabrian in virtue; and that twenty or thirty drams of it are given for a dose. Philos. Trans. N° 475. p. 90. ubi supra.

Celsius tells us, that the terenjabin of the Arabians is gathered from a prickly shrub, such as the albagi is described
M A N

to be; and Arienna declares, that it was found upon a
thorny plant; though his translators have been misled
from a word resembling two Arabic words, to make it flonc,
not a plant, that it was gathered from.

It appears very plainly from the whole, that this substance,
now known in Russia, and some other parts of the
world, under the name of manna perfescum, is truly the
terefinste of the Arabians and of Clutius, Rawveu, and
Toumfort; only that the word is spelt differently by the
latter authors, and it is probably also that name called by
Baxhine, and some other writers, manna maidifhina orientalis,
from the round globules it is composed of resembling the
drops of malluch.

M A N N A Thrucis, the marnia of frankincense, a term used by
the ancient physicians to express such small pieces of frank-
incense, or olbaum, as broke off from the larger in
the carriage. See Leptos Libanu.

M A N N A COTIE, in Geography, a town of Kemaon;

of Congo.

M A N N E R, in P a i n t i n g , is not only employed in its
natural fenee, as deignatory of that peculiariry in each
painter's mode of composition, drawing, and execution,
which, like diversity in hand-writings, characterizes the
productions of different individuals; but it has also a tec-
nical meaning, in it which is commonly employed by artifts
and connofieurs, viz. to mark certain kinds of deviation
from nature in the works of artifts, into which, either
through conceit or weakneis, they have fallen, by endeav-
uouring to obtain that high portion of acknowledged excel-
lence, known by the name of style; of which manner may be
considered as the bathos.

The proper application of this word in the art is evident.
No two painters have ever executed their works in a manner
exactly similar, how nearly foever they may have imitated
each other. In every cafe variety still appears, extending
through every portion and principle of their compositions,
as well as in their execution of them: just as men think and
write differently upon the fame subjects, and convey their
ideas by different characters, though tracing the fame let-
ters.

It is by this divcrsity that connofieurs are enabled to
tell the authors of pictures, whose names as fouh
would otherwise have been lost; by this the different schools
of art are pointed out, and the works of the artifts edu-
cated in them; although some of superior excellence have
varied their manner, in the course of their practice, more
than once. Thus, Titian is said to have had his firt, fe-
cond, and third manner; Raphael, his Perugino manner,
his own, and that framed in imitation of Michael Angelo.
By this, also, the gradual advance of the art may be traced,
from its earher periods, to its arrival at the highest perfec-
tion which it attained in the Italian and Flemifh schools.

This is the natural and obvious fenee of the word; the
other is more eaily felt, thn defined. Every artift and
amateur, converfant with the necfities and beauties of art,
knows and feels that nature is not to be copied at all times,
and under every situation. Her works must be flected and
imitated only in her happiest moments, in her very best pro-
ductions. When an artift underfaids, and can exhibit in
his works thofe peculiaries which exaltify the purity of
this fect clafs of natural objects, in all their differing char-
acters, and can avoid the trifling matters which are uue-
cessary in grand representations, adhiring only to that which
is truly charaderiftic, and giving to it all possible truth and
force, he has obtained that dignified power which is de-
not have been employed by them but to overcome some local disadvantage; in that case, style becomes their proper name. But the want of this consideration has often led students to the admiration of these very defects, and a blind imitation of them, which necessarily generates manner. Thus, Rubens's style of colour is in itself so violent, that, if not fully maintained in all its harmony, it deferves no better title than manner, and becomes completely so in the hands of most of his imitators.

Titian's colour justly merits the most distinguished ap- plication. It is true to nature, but it is in her simple garb, robbed of her minuter reflections and refinements, yet care- fully followed in her general principles, and enriched and heightened by a favourable selection and arrangement of objects, their being placed in agreeable lights, and viewed in a chosen direction. The Venetians carried it to manner; even Tintoretto and P. Veronese, the best and grandest amongst them after Titian and Giorgione. Having im- biped a taste for the rich and luxurious colouring of their predecessors, they could not be content without endea- vouring to extend its boundaries; and in doing, lost sight of nature, and adopted their own fancies as improvements upon her fylem, and thus lurk in some measure to manner- ists.

It is when the practice of art has become matured by skilful men, that others build styllms for their conduct upon the works of their predecessors; and though it is very proper that a style be acted upon, as it greatly facilitates and improves the practice, yet too ready and strict a reliance upon it is almost the certain guide to manner: to avoid which, a constant reference to nature is absolutely necessary. Hence, after the period when M. Angelo, Raphael, Titian, and Corregio, lived and exerted their powerful talents in the perfection of the art of painting, succeeding artists, not ended with their vigour of perception, endeavoured to dis- cover in their works some means of keeping up with them; to establish some stylym, on which they had or might have proceeded in their extraordinary and beautiful productions: it thence became as much an object to imitate the works of some favourite artist as those of nature; and the true inten- tion of the art, being thus but an accessory rather than a principal, was too often sacrificed. Almost the whole num- ber of the ingenious men who learned in the school of the Caracci, and followed the principles inculcated there, may be properly termed mannerists.

The manner, or the ease which a style gives, of effecting something attractive to the eye, and dazzling to the understand- ing, is too seductive to be frequently refuted by the inexperienced and vain. Those who have been early taught by stylym to impose upon themselves, and led to imagine they exhibit great ingenuity in managing a pencil with dext- erty, will most likely never believe that it is more difficult, and far more praiseworthy, to think justly, and to imitate attentively the precefe terms of an expression, though it be wrought with a heavier hand, and more laborious study. Manner, considered thus, is a kind of receipt for making a picture, a ready mode of combining the necessary ingre- dients; in which, however, though the hand of the artist may sometimes by accident add a larger or smaller proportion of any one of them, the result is inevitably of nearly the same quality, and is in constant danger of being misapplied: for it is equally as ridiculous to suppose that one kind of execution or mode of composition will suit the representation of all kinds of subjects, as to believe that one composition of medical drugs is adequate to the cure of all kinds of diseases.

Manners, in Poetry, denote the inclinations, genius, and humour, which the poet gives to his persons, and whereby he distinguishes his characters.

Aristotle defines manners to be that which discovers the inclination of him who speaks, and shews what he will re- solve upon, or what reject, before he was actually deter- mined: whence he concludes, that manners have not place always, and in all kinds of discourse.

One instance will make this definition clear. In the first book of Virgil, Aeneas is represented extremely pious, de- termined to execute the will of the gods, at all adventures. In the fourth book he has a difficult choice proposed; being engaged, on the one hand, out of a principle of love, gratitude, and honour, not to quit Dido; and having, on the other hand, an express order from the gods to depart for Italy. Now, before it appears on which side he has determined, what he has before said should shew his will and inclinations, and which part he will take. And those pre- ceeding discourse, which discover his future resolution, make what we call the poetical manners.

Those make it plain doubt he will abandon Dido to obey the gods; this he does in effect; and the manners, there- fore, are good, and well conducted. Had he disobeyed the orders of Jupiter, to stay with Dido, the manners had been ill; because they would have foretold a resolution con- trary to what he was really to take. But had there been nothing to make us foresee any resolution of Aeneas at all, neither that which he actually took, nor the contrary, in that case there had been no manners at all. It is the man- ners, as before observed, that distinguish the characters; and, unless the manners be well expressed, we shall never be acquainted with the persons at all; nor, consequently, shall we be either terrified with foreseeing their dangers, or melted into pity, by feeling their sufferings.

The manners should have four qualities; they should be good, like, suitable, and equal.

The manners are good, when they are well marked or ex- pressed; that is, when the discourse of the persons makes us clearly and distinctly feel their inclinations, and what good or evil resolutions they will take. Likewise of manners only relates to known and public persons, whose characters are in history, with which the poetic characters must agree; that is, the poet must not give a person any quality con- trary to any of those which history has already given him. And here it may be observed, that the evil qualities given to princes, and great men, ought to be omitted by poets, if they be contrary to the character of a prince, &c. but the virtues opposite to those known vices ought not to be im- posed; as by making him generous and liberal in the poem, who was avaricious in the history.

The manners must likewise be suitable; that is, they must be agreeable to the age, sex, rank, climate, and condi- tion of the person that has them. Horace observes, " In- terit multum Davusine loquatur, an heros." Again, the manners must be equal; that is, they must be constant, or confident, through the whole character; or the variety or inequality of the manners, as in nature, so in the drama, must be equal. The fearful must never be brave, nor the brave timorous; the avassious must never be liberal, nor vice versa. In this part Shakfpear's manners are ad- mirable.

Besides these four qualities above mentioned, there is a fifth essential to their beauty; which is, that they be ne- cessary; that is, that no vicious quality, or inclination, be given to any poetic person, unless it appear to be ab- solutely necessary, or requisite, to the carrying on of the action.

MANNERIST, in Painting, one who adopts a man- ner,
in his works, or a peculiar and affected mode of producing effect in them unauthorized by nature.

MANNERSDORFF, in Geography, a town of Austria, on the Leitha, celebrated for its medicinal waters; 17 miles S.S.E. of Vienna.

MANNI, GENARO, in Biography, composer of the archiepiscopal church, and a great and much respected master at Naples, in 1756. His style of church music much resembles that of Leo, with equal invention and learning. At the death of Jonelli, he formed a plan for a public funeral for that truly great musician, and had interest sufficient to have it executed with uncommon solemnity and splendour. See Jonelli; also GENARO.

MANUfFRA ARMOR, in the Materia Medica, the name by which the round-leaved aeth, on which the manna is found, is often called.

MANNIN Bay, in Geography, a small harbour on the W. coast of the county of Galway, Ireland, adjoining that of Ardbeer, in which latter there is better anchorage and shelter.

MANNING a Hawk, in Falconry, making her tractable and tame.

MANNFING the Fleet, is the providing of it with a sufficient number of men for any expedition. One of the methods commonly recurred to for this purpose is that of impressing men, by warrants from the Lord high admiral to the captains, which are by them affixed to their lieutenants; and to such as the more effectual effect, called tenders, are hired into the service, to proceed from place to place, with those officers and press-gangs, not only to receive volunteers, but to impress any feamen whom they find. The power of impressing men for the sea-service by the king's commissiou, says judge Blackstone, has been a matter of some dispute, and submitted to with great reluctance; though he hath very clearly and learnedly been shown by Sir Michael Tertull, that the practice of impressing, and granting power, to the admiralty for that purpose, is of very ancient date and hath been uniformly continued by a regular series of precedents to the present time: whence he concludes it to be a part of the common law. The difficulty arises from hence, that no statute has expressly declared this power to be in the crown, though many of them very strongly impel it. The Stat. 2 Ric. II. c. 4 speaks of mariners being arrested and retained for the king's service, as of a thing well known and practiced without dispute; and provides a remedy against their running away. By Stat. 2 & 3 Ph. & M. c. 16, if any waterman, who uses the river Thames, shall hide himself during the execution of any commission of impressing for the king's service, he is liable to heavy penalties. By 5 Eliz. c. 5, no fisherman shall be taken by the queen's commission to serve as a mariner; but the commission shall be first brought to two justices of the peace, inhabiting near the sea-coast, where the mariners are to be taken, to the intent that the justices may choose out and return such a number of able-bodied men, as in the commission are contained, to serve his majesty; and by 7 & 8 W. III. c. 21, 2 Ann. c. 6 & 4 & 5 Ann. c. 19, 13 Geo. II. c. 17; &c. special protections are allowed to seamen in particular circumstances, to prevent them from being impressed. And ferrymen are also said to be privileged from being impressed, at common law; all which do most evidently imply a power of impressing to retide somewhere; and, if any where, it must, from the spirit of our constitution, as well as from the frequent mention of the king's commissiou, reside in the crown alone.

But, beside this method of impressing, which is only defensible from public necessity, to which all private con-

-erations must give way, there are other means tending to the increafe of feamen, and for manning the royal navy. Parishes may bind out poor boys apprentices to masters of merchantmen, who shall be protected from being impressed for the first three years; and if they are impressed afterwards, the masters shall be allowed their wages. (2 Ann. c. 6.) Great advantages in point of wages are given to volunteer seamen, in order to induce them to enter into his majesty's service. (1 Geo. II. flat. 2. c. 14.) It is also usual to promise, by proclamation, a bounty to all seamen and able-bodied landmen, who come into the service by a certain time; and every foreign seaman who, during a war, shall serve two years in any man of war, merchantman, or privateer, is naturalized ipso facto. 13 Geo. II. c. 3.

About the middle of king William's reign, a scheme was set on foot (7 & 8 W. III. c. 21.) for a register of seamen, to the number of 30,000, for a constant and regular supply of the king's fleet, with great privileges to the registered seamen, and, on the other hand, heavy penalties in case of their non-appearance when called for; but this registry, being judged to be rather a badge of slavery, was abolished by 9 Ann. c. 21. Blackf. Com. vol. i. p. 419, &c.

MANNINGTON, a town of America, in Salem county, New Jersey.

MANNNOZZI, GIOVANNI, in Biography. See GIOVANNI DA SAN GIOVANNI.

MANNUS, MAN, in Mythology, the son of the German god Tufton: of whom, according to Tacitus De Moribus Germanorum, these people were described.

MANO ABONICA, Ital.; Main Harmonique, Fr.; Harmonic Hand. See Hand, Harmonic.

MANOD, in Geography, one of the smaller Philippine islands. N. lv. 128. E. long. 122 24.'

MANOEUVRES, To, in Military Language, is to manage any body or armed force, as to derive full and unexpected advantages before the enemy from superior skill in military movements. It consists in distributing equal motion to every part of a body of troops, that the whole may be enabled to form, or change its position, in the most expeditious and best method, to as to answer the purposes required of a battalion, brigade, or line of cavalry, infantry, or artillery.

MANOEUVRES consist chiefly in those various movements or evolutions, in which soldiers are exercised, in order to fit them for defensive or offensive operations. See BATTALION, Manual and Platoon Exercizes, and Review. The platoon exercize has been altered as well as the manual. (See Platoon and Battalion.) The exercise is performed a little lower, three seconds being allowed between each motion. It is no longer done by signal, from beat of drum, but all by word of command.

The infantry manoeuvres, which were formerly so numerous, are now reduced to 18; which are ordered to be practiced and performed in every regiment. The following are the movements, explanations of which, and directions for performing them, are given in the books of exercize. See Battalion.

1. Forming the battalion into close columns in the rear of the right company. 2. Clofe column in the front of the left company. 3. Clofe column in a central company, facing to the rear. 4. Changing position in open column. 5. Throwing back the wings. 6. Changing position by a countermarch. 7. Counter-march by files in the centre of the battalion. 8. Marching in open column. 9. Echelon change of position. 10. Taking up a new line by the echelon movement. 11. Changing position to right or left. 12. Retreating in line. 13. Marching to a flank in echelon.

6-
therefore the bubble as of will grew and mull fmall 16. where it is jiving, arifing will the heat's part was compofed both. In kind rimental manometer the part of the tube below this quicksilver. A scale is placed on the fide of the tube, which marks the degrees of dilatation arifing from the increase of heat in this flate of the weight of the air, and has the fame graduation as that of Fahrenheit's thermometer, the point of freezing being marked 32. In this flate, therefore, it will fow the degrees of heat in the fame manner as a thermometer. But if the air becomes lighter, the bubble infed in the ball, being lefs comproprefed, will dilate itself, and take up a space as much larger as the comprefling force is lefs; therefore the changes arifing from the increase of heat will be proportionally larger; and the instrument will fhow the differences in the density of the air, arifing from the changes in its weight and heat. Mr. Ramfden found, that a heat equal to that of boiling water, increafed the magnitude of the air from what it was at the freezing point \( \frac{223}{273} \) of the whole. Hence it follows, that the ball and the part of the tube below the beginning of the scale is of a magnitude equal to almost \( \frac{414}{273} \) degrees of the scale. If the height of both the manometer and thermometer be given, the height of the barometer may be thence deduced by this rule; as the height of the manometer increafed by \( \frac{414}{273} \) is to the height of the thermometer increafed by \( \frac{414}{273} \) is to 29.7 to the height of the barometer.

In the 67th volume of the Philosophical Transacions for 1777, page 689, Col. William Roy has given a defcription of the manometers to be ufed to afercertain the expansion and contraction of dry and moif air by change of temperature. They were of various lengths, from four to upwards of eight feet; they confifted of ftraight tubes, whole bores were commonly from \( \frac{1}{4} \)th to \( \frac{3}{4} \)th of an inch in diameter. The capacity of the tube was carefully measured, by making a column of quicksilver, about three or four inches in length, move along it from one end to the other. Thfe spaces were severally marked with a fine edged file on the tubes, and transferred from them to long flips of falteboard, for the fubfequent construction of the fcales respectively belonging to each. The bulb attached to one end of the manometer at the glass-house, was of the form of a pear, whole point being occasionally opened, dry or moif air could be readily admitted, and the bulb sealed again, without any sensible alteration in its capacity.

The air was confined by means of a column of quickfiver, long or fhort, and with the bulb downward or upwards, according to the nature of the preffed experiment. Here it muft be obferved, that from the adhufion of the quickfiver to the tube, the instrument will not act truly, except it be in a vertical position; and even then it is neceffary to give it a fmall degree of motion, to bring the quickfiver into its true place, where it will remain in equilibrium, between the exterioe preffure of the atmosphere on one fide, and the interior elfatic force of the confined air on the other.

Pounded ice and water were ufed to fix a freezing point on the tube; and by means of falt and ice, the air was farther condenfed, generally four, and sometimes five or fix degrees below zero. The thermometer and manometer were then placed in the tin veffel, among water, which was brought into violent ebullition; where having remained a fufficient time, and motion being given to the manometer, a boiling point was marked thereon. After this the fire was removed, and the gradual defects of the piece of quickfiver, correfponding to every 20 degrees of temperature in the thermometer, were fuccedively marked on a deal rod applied to the manometer. It is to be obferved that both instruments, while in the water, were in circumstances perfectly similar; that is to fay, the ball and bulb were at the bottom of the veffel.

In order to be certain that no air had efcape by the fide of the quickfiver during the operation, the manometer was frequently placed a fecond time in melting ice. If the barometer had not altered between the beginning and end of the experiment, the quickfiver always became fixesary at or near the fird mark. If any sudden change had taken place in the weight of the atmosphere during that interval, the fame was noted, and allowance made for it in afterwards proportioning the fpaces.

Long tubes, with bores truly cylindrical, or of any uniform figure, are fearely ever met with. Such, however, as were ufed in these experiments, generally tapered in a pretty regular manner from one end to the other. When the bulb was downwards, and the tube narrowed that way, the column of quickfiver confined the air lengthened in the lower half of the scale, and augmented the preffure above the mean. In the upper half, the column being shortened, the preffure was diminished below the mean. In this cafe the obferved fpaces, both ways from the centre, were diminiheid in the inverse ratio of the heights of the barometers at each fpace, compared with its mean height. If the bore widened towards the bulb when downwards, the obferved fpaces each way from the centre were augmented in the fame inverse ratio; but in the experiments on air lefs denfe than the atmosphere, the bulb being upwards, the fame equation was applied with contrary figns; and if any extraordinary irregularity took place in the tube, the correffponding fpaces were proportioned both ways from that point, whether high or low, that afwerved to the mean.

The obferved and equated manometrical fpaces being thus laid down on the palfiboard containing the meafures of the tube; the \( \frac{214}{273} \) of the thermometer, in exact proportion to the fectons of the bore, were confructed along fide of them; hence the coincidences with each other were eafily fon; and the number of thermometrical degrees anfwerling to each manometrical space readily transferred into a table prepared for the purpose." For the important reults obained by these instruments, see BAROMETER, Measurement of Altitude.
It may not be amiss to observe that Colonel Roy's results on the expansion of dry air have been generally confirmed by the subsequent experiments of Dalton and Gay Lussac; but those on moist air have been found less satisfactory, unless in such cases when water in a liquid state is present. Mr. Dalton has given a theorem, derived from his experience, to ascertain the expansion of moist air (that is, when water is present in the liquid state) for any temperature. Supposing the space occupied by the dry air at the given temperature to be 1, the atmospheric pressure $p$, and $f$ = the force of steam at the temperature; then the space of the moist air will be $\frac{p}{p - f}$.

The striking peculiarity of manometers of the above construction, and that on which their chief excellence depends, is that a mercureial column of about $\frac{1}{4}$th or $\frac{1}{10}$th of an inch in diameter, slides freely up and down a glass tube, without suffering any air to pass either way. This character it, however, obtained only by preferring the tube and mercury very clear and dry. If any dust, moisture, or oxide be found in the tube, the mercury becomes less free in its motion, and the air is apt to break the mercureial column, and gradually escape. A bore of less diameter would occasion too much friction, and one of greater would suffer the mercury to fall down.

When the expansion or dilatation of the air in any experiment amounts to one-half of the original volume, or any other quantity exceeding that, a manometer of a still more simple construction may be used, namely, a straight tube, or one without bulb, of the same bore or capacity as Col. Roy's. It must be divided into equal spaces, by means of a sliding mercureial column, on account of the irregularity of the bore incident to such tubes; a small drop of mercury may then be let down by a clean iron wire to any part of the tube, so as to constitute a sliding column of about half an inch in length.

Another species of manometer may be used when the object is to measure the force of steam or vapour, generated over certain liquids by heat. In this case a tube similar to the preceding may be bent into a fisheon with parallel legs, the shorter leg of which must be closed, or hermetically sealed, and the longer open. A few drops of the liquid must be conveyed to the extremity of the closed leg; after which the greater part of the tube may be filled with mercury, so as to leave no space with air between the mercury and the liquid; the manometer must then be put into water, &c. of a known temperature, and held in a perpendicular posture, with the bending low, and so that the extremity of the tube containing the liquid may be wholly immersed in the warm water, whilst the other extremity is without. The heat will expand part of the liquid into steam, which will depree the mercury in the same leg, and elevate it in the opposite, till an equilibrium of pressure is established. The elastic force of the steam will evidently be equal to the pressure of the two mercureial columns, or the difference of the heights of the two mercureial columns in the fisheon, according as the column in the open or closed leg exceeds that of the other. If the difference of the heights is expected to be upwards of thirty inches, some inconvenience arises from the great length of tube requisite: in this case an ingenious contrivance has been invented to obviate it; the open end of the manometer must be hermetically closed, so as to inclose a column of atmospheric air of due volume; when the steam formed in the liquid, and the mercury deprefsed, it condenes the air in the other leg, and the space occupied by the condensed air, as is well known, is inversely as the force; then the quantity of this force thus ascertained + the difference of the two mercureial columns, will give the whole elastic force of the steam. Great care must be taken that the air-column of the fisheon is clear of the liquid that generates the steam. By this fort of instrument Mr. Dalton finds the force of steam from sulphuric ether at 212 Fahr. = 236 inches of mercury. See Manchesfer Mem. vol. v. p. 507.

The straight tube manometer is the most elegant and simple instrument to prove the important property of elastic fluids above alluded to, namely, that the space occupied by any permanent elastic fluid is inversely as the pressure. For this purpose a small given portion of air is confined in the bottom of a long tube, of forty inches or more. A column of twenty-five inches, more or less, of mercury is admitted into the tube to cause the air to be pressed; when the tube is held horizontally, the confined air is pressed by the atmosphere only: when the tube is held perpendicular, the air has the pressure of the atmosphere + that of the mercureial column; and when it is held downwards, the air has the pressure of the atmosphere — that of the mercureial column. By marking the spaces occupied by the air in these circumstances, they are found to be inversely as the pressures.

Saunier, in his Essays on Hygrometry, describes his manometer: it was nothing but an ordinary barometer: a simple straight tube was filled with boiled mercury, and its open end was immerged in a cup of the same liquid; the whole was then inclosed in a large glass balloon, except a few inches of the upper extremity of the tube, to which a scale of degrees or equal parts was attached, to shew the variation of the altitude of the mercury. The tube passed through a circular hole in a tin plate which covered the opening of the balloon, and which was very carefully luted, as was the passage of the tube, so as to be perfectly air-tight. In this case it was evident the instrument was no longer a barometer, as it was cut off from the action of the air out of the balloon, but the mercury was supported by the density or elasticity of the air within the balloon, and must be subject to such fluctuations as took place in it, independently of any change of weight in the atmosphere. By means of this apparatus, Saunier found that atmospheric air, in passing from extreme dryness to extreme moisture, in the temperature of 65 Fahr., increased about $\frac{1}{4}$th in elasticity; and vice versa, in passing from extreme moisture to extreme dryness, it diminished $\frac{1}{4}$th in its elastic force, the temperature being all the time uniform.

MANONOETOC, in Natural History, a name given by the people of the Philippine islands to a species of horned owl, common in those parts.

MANOOR, in Geography, a town of Hindooftan, in the province of Dindigul; 27 miles N.W. of Dindigul.

MANOORGUDY, a town of Hindooftan, in the circur of Maloor; 20 miles N. of Neermull.

MANOR, or MAXNOR, an ancient lordship, or royalty; consisting of demesnes and services, and of a count-baron, as incident thereto.

The word is formed from the French masir, a manor- house; and that from the Latin mensis, to remain or dwell; as being the lord's usual place of residence.

Manor is the name with what was formerly called barrenis, bareny; as it is still called lordship; and lord or baron was empowered to hold a domestic court, called the "court-baron," for redressing misdeemors and nuisances within the manor, and for settling disputes of property among the tenants. This court is an insepable ingredient of every manor; and if the number of suitors should遂 fail as not to leave
leave sufficient to make a jury or homage, that is, two tenants at the leaf, the manor itself is lost.

A manor is a kind of noble fee, granted out partly to tenants, for certain services to be performed, and partly referred to the use of the lord's family; with jurisdiction over his tenant, for the lands, or eftates, held of him. As to the original of manors, we are told there was ancedently a certain complaint drawn out of lands, the same belonging by the form man of worth, for him and his heirs to dwell upon, and to exercise some jurisdiction, more or less, within that circuit, such as he thought good to grant; but performing such services, and paying such yearly rent, as by this grant was required. Now the lord afterwards parcelled the same to other meany men, received rent and services from them, and by that means, as he became tenant to the king, the inferiors became tenants to him. The superior lord, under whom the smaller manors continue to be held, is called, in such cases, the lord paramount over all these manors; and his feignor is frequently termed an honor, not a manor, especially if it hath belonged to an ancient feudal baron, or hath been at any time in the hands of the crown. In proceeds of time the inferior lords parcelled out and granted to others more minute eftates, to be held of themselves, and do downwards without limit; till at length their superior lords observed, that by this method of subinfeudation they lost all their feudal profits, of warships, marriages, and echates, which fell into the hands of these meaner or middle lords, who were the immediate superior of the "terre-tenant," or occupier of the land; and also that the meaner lords themselves were impoverished thereby, that they were disabled from performing their services to their own superiors. This occasioned, fill, that provision in the 32d chapter of Magna Charta, 9 H. III. (which is not to be found in the first charter granted by that prince, nor in the great charter of King John,) that no man should either give or sell his land, without referring sufficient to answer the demands of his lord; and afterwards the statute of Welfm. 3, or "quia emptores," 18 Edw. I. c. 1, which directs, that, upon all sales or feoffments of land, the seffor shall hold the same, not of his immediate seffor, but of the chief lord of the fee, of whom such seffor himself held it. But these provisions, not extending to the king's own tenants in capite, the like law concerning them is declared by the statutes of "prorogative Regis," 17 Edw. II. c. 6, and of 34 Edw. III. c. 15, by which it is laid all subinfeudations, previous to the reign of Edward I., were confirmed, but all subsequent to that period were left open to the king's prorogative. And from hence it is clear, that all manors existing at this day, must have exil'd as early as king Edward I.; for it is essential to a manor, that there be tenants who hold of the lord; and by the operation of these statutes, no tenant in capite since the acquisition of that prince, and no tenant of a common lord since the statute of "quia emptores," could create any new tenants to hold of himself.

At this time a manor rather signifies a jurisdiction, and royalty incorporeal, than the land and fuit: for a man may now have a manor in grofs, i.e. the right and interest of a court baron, with the perquisites, and another enjoy every foot of land belonging to it.

A manor may be compounded of divers things: as of an house, arable land, pasture, meadows, wood, rent, advowson, court-baron, &c. And this ought to be, by long continuance of time, beyond man's memory. It is held by some, that a manor cannot now be made, since a court-baron cannot be made; and without a court-baron, and at least two fuitors, there can be no manor. A manor may contain one or more villages or hamlets, or only a great part of a village; and there are capital manors or honors, which have other manors under them, the lords whereof perform customs and services to the superior lords. There may be also customary manors, granted by copy of court roll, and held of other manors. But it cannot be a manor in law, without freehold tenants; nor a customary manor, without copyhold tenants. The custom remains, when tenements are divided from the roll of the manor, the tenants paying their services; and he who hath the freehold of them may keep a court of survey, &c. See VILLEIN, COPYHOLD, and TENURE.

MANOR Courts are such as are held within the manor, for the purpose of adjudging the various rights, claims, &c. It is observed that the business of holding these, depends on whether they are held of right, or merely by custom. It is added, that "if the copyhold tenure is so far worn out, in any manor, that there are not two ancient or feudal tenants remaining within it, the court has lost its legal power. It cannot by right take cognizance of crimes, nor enforce amercements." It is, however, allowed that manorial courts have their ues, in regulating farm-roads, drift-ways, and water-courts, and in preventing nuisances of different kinds within a manor, and it is generally right to prefer the customs of holding them for these purposes. Where copyhold tenure remains in force, and where legal forms are to be observed, they are held by a law reward.

MANOR, in Geography, a township of America, in Lancaster county, Pennsylvania, containing 1804 inhabitants.

MANORCOTT, a town of Hindoostan, in Madura; 15 miles N. of Coilpetta.

MANORE, a town of Hindoostan, in Baglana; 38 miles S. of Damum.

MANOR-HAMILTON, a small poit-town of the county of Leitrim, Ireland, on the road to Sligo; being near 11 miles south of that town, and 94 miles N.W. from Dublin.

MANORIAL CLAIMS, the claims which the lords of manors have upon their tenants, and which are different in different cases, according to the nature of the manor. In respect to the appropriation of comnusand lands, these claims should, according to a late writer, be regulated by the particular advantages which the lord of a given manor may enjoy, and which he may continue to enjoy, while they remain open and uninclosed, whether they may arise from mines, quarries, water, alien tenants, fuel, clavor, meadow, game, &c. The claims of lords, as guardians of the soil, which is productive of pasturage only, is, in most instances, merely honorary; and it is for the legislation to apportion the share of lands, to which they are entitled, as an equivalent for such. But their claims, in the right of the soil on which thriving timber is standing, are more substantial; as out of these, they have in effect a real yearly income, equal to the annual increasing value of the timber; a sort of advantage which they of course will continue to enjoy, if the commons remain open and uninclosed, as long as the timber continues to increase in value. Their claims in this respect, consequently depend on the quantity of timber, and its state of growth, conjointly taken. It is supposed that, "young thriving timber, not only affords an annual increale of value at present, but will continue its benefits for many years to come, if it be suffered to remain undisturbed, or the fell which supports it, during the estimated period of its future increase; whereas dotards and blighted trees, which afford no increase of value, do not entitle their owners to any share of the foil they stand upon; the trees themselves, or their intrinsic value, appear to be all that the lord has a right to claim."
MAN

It is conceived that the claims of the crown, or of hereditary 
rangers on forest lands, should be satisfied on the same 
principle.

MANORPOUR, in Geography, a town of Hindootlan, in 
Mewat ; 25 miles S.W. of Cottihal.

MANOS, a town of the island of Cuba ; 20 miles E.N.E. 
of Havana.—Also, a cluster of small islands in the Spanish 
Main, near the coast of Darien. N. lat. 0° 17'. E. long. 
75° 45'.

MANOSQUE, a town of France, in the department of 
the Lower Alos, and chief place of a canton, in the district of 
Forcalquier, which, before the revolution, was the resi-
dence of a governor, and contained seven churches and a 
commandery of Malta ; near it is a medicinal spring ; seven 
miles S. of Forcalquier. The place contains 5360, and 
the canton 11,527 inhabitants. N. lat. 44° 50'. E. long. 5° 
51'.

MANOT, a town of Hindootlan, in Aurungabad ; 60 
miles E.S.E. of Aurungabad.

MANOU, a kingdom of Africa, E. of Qoja.

MANOUARAN, a small island in the North Pacific 
sea, near the coast of Waygou. N. lat. 0° 6'. E. long. 
131° 10'.

MANPOUR, a town of Hindootlan, in Benares ; 12 
miles N.W. of Bilzigue.—Also, a town of Hindoo lan, in 
Babul; 35 miles S.W. of Babar.—Also, a town of Hindoo 
lan, in Oude; 40 miles S.E. of Gorrackpore.

MANQUES SECAS, a cluster of small islands in the At-
lantic, near the coast of Brazil. S. lat. 2° 25'. W. long. 
44° 50'.

MANQUE Verdes, a cluster of small islands in the At-
lantic, near the coast of Brazil. S. lat. 2° 25'. W. long. 
44° 46'.

MANRESA, Minors, or Manoses, a town of Spain, in 
Catalonia, which gives name to a vicultur, i. e. governed 
by a vicultor (vaquerus) or jurisdiction, situated on a river, 
which soon after runs into the L. Obregat ; it is defended 
by a castle, and contains several convents ; 25 miles N.N.W. 
of Barcelona. N. lat. 41° 44'. E. long. 1° 44'.

MANNIQUE, D. Jorge, in Biography, a Spanish poet 
of the old school, who has retained, to the present period 
of time, a large share of popularity, and who flourished in the 
fifteenth century. He is chiefly celebrated for the forty-
two stanzas upon the death of his father, which are in 
verse, and which, being upon a subject that interests 
everyone, are read with pleasure by all persons from the 
throat of the friar's cell; they have been frequently reprinted with 
paraphrases and commentaries. The other pieces of this 
poet are to be found in the "Cancionero." It was affirmed 
by Joam II. of Portugal, that it was as necessary for a man 
to know these stanzas by heart, as to know the psalms of 
David.

MANS, i.e., in Geography, a city of France, and cap-
ital of the department of the Sarthe, and chief place of a 
district, situated at the confluence of the Huine and Sarthe. 
Before the revolution it was the capital of Lower Maine, 
The seat of a bishop, the seat of a governor, an electorate, 
bailliwick, &c. and contained a cathedral, two collegiate, 
13 parish churches, and 12 religious houses. It is divided 
into two parts, one containing 9366, and the other 7855 
inhabitants. The canton of the former contains 13,906, 
and that of the latter 11,534 inhabitants; on a territory 
of 140 kilometres, in 16 communes. N. lat. 48°. E. long. 
1° 17'.

MANSALA, a town of Sweden, in the province of 
Nyland; 51 miles N. of Borgo. Vol. XXII.

MANSAPE, a town of Lower Siam, near the coast. 
N. lat. 13° 15'. E. long. 102° 20'.

MANSARA, a town of Hindootlan, in Bahar; 13 miles 
S. of Durbugah.

MANSAROAR, a lake of Tibet, about 115 miles 
in circumference, whence springs the southern branch of the 
Ganges.

MANSART, Francis, in Biography, an eminent French 
architect, born at Paris in 1598, was son of the king's car-
penter, and received those instructions which led him to 
embrace, as an architect, from the celebrated Gautier; but 
for the high rank to which he attained in his profession, he 
was indebted to the force of his own genius. His taste and 
judgment, united with a fertile imagination and sublime 
ideas, enabled him to equal the greatest masters in his plans; he 
was, however, too apt to alter his designs, and even, in aiming 
in perfection, to demolish what was already not only well 
done, but fearlessly to be surmounted. This character was 
the means of preventing him the honour of finishing the fine 
neftry of Val-de-Grace, founded by Anne of Austria, which 
he had commenced in 1645, and which, when raised to the 
first story, the queen put into other hands, to prevent its 
defraction by him who had reared it. He was employed 
by the president Longueau to build his great chateau de ma-
isons, near St. Germain's; and when a considerable part of 
it was erected, he pulled it down again without acquainting 
the builder with his intentions. After this, it is to his credit, 
that he finished it in a very noble style, and it is reckoned 
one of the finest architectural monuments of that age. A 
better idea cannot be given of his character than this; Col-
bert applied to him for a design of the principal front of the 
Louvre, and Mansart produced many sketches of great 
beauty, but when told he must fix upon one to be invariably 
followed, if approved, he declined the business. His last 
great work was the portal of the Mmns in the Place 
Royale; he died in 1666, at the age of fifty-nine. He is 
known as the inventor of a particular kind of roof called 
the mansarde. He had a nephew Jules-Hardouin, who was 
also eminent in his profession as an architect, and was 
educated by his uncle. He became a favourite of Lewis XIV. 
and was enabled, under his patronage, to realize a large 
fortune. Some of his principal works were the chateau de 
Clagny; the palace of Verailles; the house of St. Cyr; the 
gallery of the Palais Royal; the palaces of Louis-le-
Grand, and des Victoires, and the dome and finishing of the 
"Invalides." He died suddenly at Marly in the year 1708.

MANSBY, in Geography, a town of Sweden, in Weil 
Bothnia, on the Calx; 23 miles W.N.W. of Turca.

MANSCEO, a bailiwick in Georgia, S. of the Mufcle 
thalaws, in the Teneffee river, remarkable for the manmoth 
bones found here.

MANSDOF, a town of Prufia, in Pomerelia; seven 
miles N. of Marienburg.

MANS, Mans, Mansus, or Mens, formed a man-
us, abiding, as being the place of dwelling, or residence, 
in ancient Law-Books, denotes a house or habitation; either 
with or without land.

Mans, Capital, mensus capitalis, denotes the manor-house 
or lord's court.

Mans, or Mansus præfature, is a parsonage or vicarage-
house, for the incumbent to reside in.

This was originally, and still remains, an essential part of 
the endowment of a parish-church, together with the glebe 
and tithes. It is sometimes called præfaturium.

MANSSEL, in Geography, an island in the N.E. part of 
3 H. Hudson's
MAN

Hudson’s bay, between Southampton island and the coast of Labrador. N. lat. 62° 38'.

MANSERET, a town of Spain, in the Alturia of Oviedo.

MANSFIELD, Peter Ernest, Count de, in Biography, a German statesman and commander: in 1552 he was made prisoner at Ivoy, which place he governed. He afterwards became governor of Luxemburg, where he maintained tranquillity, while the rest of the Low Countries was in a state of civil war. He had afterwards the entire command of Brabant. He died at the advanced age of 87, in the year 1604.

Mансфельд, Ернст, граф de, в Биографии.

MANSFIELD, ERNEST, Count of, a celebrated general, born in 1585, was the natural son of the foregoing Peter Ernell, count of Mansfield. He was brought up at the court of the archduke Ernell, governor of the Low Countries, who sent him at an early age into Hungary, to learn the art of war under his brother Charles. He served the emperor and the king of Spain in Hungary and the Low Countries, and was legitimated by the former, on account of his bravery. He received some presents from the Spanish government, which caused him to quit its service in disgust, and he entered into that of the duke of Savoy. He had been brought up in the Catholic religion, but did not scruple to enter into the league of the Protestant princes against the head of the empire, and henceforth he became one of the most formidable enemies of the house of Austria. He was sent by Frederic, elector palatine, in 1618, into Bohemia, to support the revolters from the authority of the emperor. The Bohemians appointed him grand-master of artillery and general of infantry; he took Pilfen, and gained other advantages. After Frederic, who had been elected king, had lost the battle of Prague in 1620, Mansfeld kept on the war till he was compelled by the superior forces of Tilly to retire into the palatinate. His heroism was now everywhere celebrated, and though lying under the ban of the empire, without clait or property of any kind, he had rendered his name so famous by his spirit of enterprise, and his singular faculty of recruiting after losses, and keeping the field though often defeated, that he found himself courted at the same time by the king of France, the French Protetants, the kings of Spain and England, and the republics of Holland and Venice. He determined, however, to join the duke of Bouillon, and the reformed party in France, and performed many feats of surprising valor. When he had disbanded his troops he visited France and England, and from the latter country he obtained troops, with which he assisted the prince of Orange to raise the siege of Breda. In 1625 he returned to Germany, and after ravaging the archbishopric of Cologne, joined the king of Denmark in Lower Saxony; a train of ill success now pursuad him, and he was anxious to try his fortune at Venice; with this view he set out, accompanied by twelve officers, although at that time labouring under a flux fever. He, however, passed through Servia and Bosnia, and arrived in Dalmatia, but with such an increas of his disorder, that he was obliged to stop at a village near Zara. There, finding his end approaching, he exhorted his companions to remain true to the liberty of their country, and tranquilly expired in November 1626, at the age of forty-one. He had every quality of a great captain, and he always acted with fidelity and inestimable zeal in the service of the party whose cause he espoused. The want of regular authority, and resources, obliged him to contrive at the disorders committed by his soldiers; and his marches were sometimes so destructive, that the house of Austria named him the “Attila of Chrislendom.” Moreri. Mod. Univer. Hist.

MANSFIELD, in Geography, a town of Westphalia, in the county of Mansfeld, having a castle on a high rock, which was formerly a fortres, and the residence of the counts of Mansfeld, now in a considerably dilapidated state; 36 miles N.N.E. of Erfurt. N. lat. 51° 38'. E. long. 11° 41'.

Mansfeld, County of, a principality of Westphalia, bounded by the electorate of Saxony and Querfurt, the duchy of Merseburg and the duchy of Magdeburg, the principalities of Anhalt and Alberlidad, and the county of Stolberg. Its greatest length is 28, and greatest breadth 16 miles. Although it is generally mountainous, it affords good corn land and paturage, with a considerable extent of woods, vineyards, chases, and fisheries; besides a salt-work and mine, and a slate from which copper is extracted. This slate bears impressions of all kinds of animals, especially of fishes. In this county are also two lakes, almost continuous and communicating with each other; and yet the water of the one is salt, and that of the other fresh and sweet. These lakes abound with fish, which furnish employment and subsistence for the adjoining inhabitants. They supply also a great number of wild-ducks, geese, snipes, and other water-fowl. The county contains seven towns. The prevalent religion is Lutheranism, introduced into the country by the activity and zeal of Albert VII., count of Mansfeld. This county is partly a part of Saxony and Magdeburg. At the peace of Tilsit, the Prussian part of this county was annexed to Westphalia.

MANSFIELD, a town of Prussia, in Natzegon; 10 miles S.S.W. of Konigberg.

MANSFIELD, EARL OF, in Biography. See Murray.

Mansfield, in Geography, a market town and parish in the wapentake of Broxtow, Nottinghamshire, England, is situated in the forest of Sherwood, at the distance of 14 miles from Nottingham, and 138 from London. It appears to have been a place of high antiquity; coins of several Roman emperors have been found in and near the town; and the recent discovery of ancient relics near Mansfield Woodhouse is an indubitable proof that the Romans had a station or settlement in this vicinity. In the Domesday survey “Mansfield,” as it was anciently called, is mentioned as a royal manor; and successive monarchs have granted several privileges to it. A market was established by a charter of Henry III.; and a fair by a grant from Richard II. When Sherwood forest was a royal chase, here was a royal villa which the sovereigns kept as a hunting seat; and, to use the words of an old inquisition, “Henry Fitzcomberge held the manor of Cuckney, in the county of Nottingham, by the service of shearing the king’s palfrey when the king came to Mansfield.” Le- land’s account of this place is not very favourable; he calls it “a little pore frett, a thoroughfare at the end of the wood;” but at present it is a large and opulent town; the houses, which are in general well built, were flated in the population return of the year 1851, to be, in number, 12,455, and occupied by 59,058 persons. The market, which is held on Thursdays, is generally well flocked with corn and cattle; and here are now three annual fairs, chiefly for cattle and cheese. Several considerable manufactories are established here; a great trade in fine-lone is carried on with Nottingham; and the malting business is very extensive. The church is a commodious structure; and here is a respectable free-school, with two scholarships at Jesus college, Cambridge, founded by queen Elizabeth in the third year of her reign.

At the distance of a mile and half from the town, is the township and chapelry of Mansfield Woodhouse, which contains
tains 211 houses, and 1112 inhabitants. In the year 1786, Hayman Rooke, esq. of this place discovered, within about a mile from the village, two Roman ville, which he called Urbana and Rufica; the former containing nine rooms, the latter thirteen; with hypocauts, baths, and other appendages: the walls of most of the rooms appeared to have been flucced, and painted in tipes of various colours; and in the centre-room of the Urbana was a tessellated pavement. Mr. Rooke also found the remains of two Roman sepulchres, with urns, bones, &c. : and various fragments of paterae and pots of Roman ware, with other relics of antiquity, were discovered in the rooms of the villas.

Within a few miles from Mansfield are several magnificent mansions, viz. Workhop, the seat of the duke of Norfolk; Clumber, the duke of Newcastle's; Throsby, lord New-"wark's; and Welbeck, belonging to the duke of Portland. In popular language this part of the country is called the dukery, from the number of feats belonging to dukes. History of Nottinghamshire, by Thoroton and Throsby, three vols. 4to. 1767.

MANSFIELD, a township of America, in Suffolk county, New Jersey, situated on Mussoneunek river, about seven miles S.E. of Oxford, and containing, in 1790, 1482 inhabitants. —Also, a township in Bristol county, Massachusetts, 29 miles southerly of Bolton, incorporated in 1776, and containing 1515 inhabitants. —Also, a township in Chittenden county, Vermont, between La Moiré and Osion rivers, about seven miles from each, and 153 miles N. by E. from Bennington. Mansfield mountain rises in this town. Its inhabitants are 12. —Also, a township in Burlington county, New Jersey, on the S. side of Black's creek, containing 10,000 acres of excellent soil, noted for its fine pastures and large dairies; eight miles W. by N. from Burlington. The inhabitants are for the most part friends. —Also, a township in Windham county, Connecticut, about 30 miles N. of New London; containing 2560 inhabitants.

MANSIATRE, a river on the W. coast of Madagascar, which runs into the Strait of Mozambique. S. lat. 10° 45'.

MANSIELLA, a town of Spain, in the province of Leon; 10 miles S.E. of Leon.

MANSION, MANSO, a manor, a dwelling-house, or habitation, especially in the country.

Among the ancient Romans, manso was a place appointed for the lodging of the princes, or holders, in their journey; and in this sense we read primam maninam, &c. It is with us most commonly used for the lord's chief dwelling-house within his fee; otherwise called the capital manur or manor place: and manor-house is taken in law for any house or dwelling of another; in case of committing burglary, &c.

Mano, or Manso, was sometimes also used in the same sense with mando; that is, for such land as one plough could till in a year.

MANSLAUGHTER, in Law, is a species of felonious homicide, and denotes the unlawful killing of a man, without any malice, either express or implied; which may be either voluntarily, upon a sudden heat; or involuntarily, but in the commission of some unlawful act. (1 Hal. P. C. 466.) As when two persons, who before meant no harm to one another, falling out on some sudden occasion, the one kills the other; this is voluntarily manslaughter. But in this and every other case of homicide upon provocation, if there be a sufficient time for passion to subside, and reason to interpose, and the person provoked afterwards kills the other, this is deliberate revenge, and amounts to murder. (Folt. 256.) Thus, if a man takes another in the act of adultery with his wife, and kills him directly upon the spot; though this was allowed by the laws of Solon, as likewise by the Roman civil law, (if the adulterer was found in the husband's own house,) and also among the ancient Goths: yet in England it is not absolutely ranked in the class of punishable homicide, as in the case of a forcible rape; but it is the lowest degree of manslaughter; and therefore in such a case the court directed the burning in the hand to be gently inflicted, because there could not be a greater provocation. (1 Hal. P. C. 486.) Sir T. Raym. 212.) Manflaughter, therefore, on a sudden provocation differs from excusable homicide, in being in the nature of a mere homicide: further, if two persons play at sword and buckler, unless by the king's command, and one of them kills the other, this is involuntary manslaughter, because the original act was unlawful. (3 Inst. 56.) So where a person does an act, lawful in itself, but in an unlawful manner, and without due caution and circumspection; as when a workman flogs down a stone or piece of timber into a street, and kills a man; this may be either misadventure, manslaughter, or murder, according to the circumstances attending it: if it were in a country village, and he calls out to all people to have a care, it is misadventure only; but if it were in London, or other populous towns, where people are continually passing by, it is manslaughter, though he gives loud warning. (Kel. 450.)

And murder, if he knows of their passing, and gives no warning at all; for then it is manslaughter against all mankind. (3 Inst. 57.) The crime of manslaughter amounts to felony, but within the benefit of clergy; and the offender shall be burnt in the hand, and forfeit all his goods and chattels. By a law of king Canute, if a man is killed openly and premeditatedly, the murderer shall be committed to the relations of the deceased; but if on his trial the fact be proved, and not to have been wilful, the bishop is to judge him. There is a manslaughter punishable as murder, by statute; by 1 Jac. I. cap. 8, if any person shall slay another, not having then a weapon drawn, nor being flenck at first, so that he dies within six months, although it were not of malice aforethought, it is felony without benefit of clergy; but this doth not extend to persons slaying others je defendendo, or by misfortune, &c. with no intent to commit manslaughter; and the statute relates to the party only that actually gave the stroke, or flabb'd the other, and not to those that were aiding or abetting. Blackst. Com.

MANSLE, in Geography, a town of France, in the department of the Charente, and chief place of a canton, in the district of Ruffec; 12 miles N. of Angouleme. The place contains 1230, and the canton 14,536 inhabitants, on a territory of 2600 kilometres, in 25 communes.

MANSO GIAMBATTISTA, in Biography, marquis of Villa, an eminent patron of polite literature, was born at Naples in 1561. He was brought up to the profession of arms, and, in the early part of life, served in the armies of the duke of Savoy, and in those of the king of Spain. After his return to Naples he devoted his time to literature, of which he was a cultivator and patron. He founded at Naples the academy Degli Oziofit, which held its first assemblies in his house. He was the friend of Tasso, who has inherited his dialogue on friendship with the name of Manso: he patronized the poet Marino, and honoured the memories of each of them with a biographical eulogy. The great Milton was known to him, and treated by him with much kindness. He praised him very highly in a Latin dialogue, though at that time only a young man, and in the infancy of his fame. Milton repaid his civilities by addressing to him a Latin eclogue.
MY DAK

cologue entitled "Manus," which is thought to be one of his best performances in that language. The works of Mano are chiefly of the light and amatory kind. He was the principal promoter of the college of Nobles in Naples, to which, at his death, he left all his property.

MORENI.

MANSORA, in Geography, a town of Arabia, in the province of Yemen, and government of Hadramut; 12 miles E.S.E. of Taiz.

MANSURA, or Mandsora, a town of Egypt, on the right bank of the eastern branch of the Nile, built as a bulwark against the Christians. The Christians of Syria, settled here, are the chief traders; and the principal articles are the fine rice growing round the lake, and fel ammoniac. Here are also large chicken ovens. A canal is made from the Nile to the lake Manzaleh. Dr. Pocock supposes that Manfora was the ancient Tanis or Zon of scripture; 24 miles S.S.W. of Damietta. N. lat. 31°. E. long. 31° 36'.

MANSORA, a town of Africa, in the kingdom of Fez, near the sea-coast on the river Guir; 60 miles W. of Meknes.

MANSORAH, or Mansourah, the name with Bokor or Bokter; which see.

MANSORIUS MUSULUM, in Anatomy, a name given by some writers to that muscle of the face more generally known under the name of the molester.

MANSOURAH, in Geography, a ruined town of Algiers, without walls and inhabitants; 12 miles E. of Boujebah. — Allo, a river called Silus, which runs into the sea; 18 miles E. of Boujebah.

MAN-STEALING, in Law. See Kidnapping.

MANSTEIN, Christopher Herman De, in Biography, a military commander and writer of memoirs, was born at Peterburg in 1711. He obtained the rank of captain of grenadiers in the Russian service, and, soon after the death of Anne, was commissioned to arrest the regent Biren and his family. For this service he was rewarded with the rank of colonel, and with an estate in Ingria. Of both these he was deprived on the accusation of Elizabeth to the throne of Russia, and he then, without hesitation, entered into the Prussian army as a volunteer, obtained considerable promotion, and was killed by a musket-shot in the year 1756. He is known as a writer by "Memoirs of Russia, historical, political, and military, from the Year 1727 to 1744," written in the French language. These were sent by the earl marshal Keith to David Hume, translated into English, and published in 1779. They were afterwards published in French at Lyons in two vols. 8vo. They are reckoned valuable as a fair and authentic narrative of the important events which happened during that period, and they are esteemed as remarkably accurate in their accounts of military transactions.

MANSUM, in Geography, a river of Africa, on the Gold Coast, which runs into the Atlantic; five miles W. of Frederickburg.

MANSURA, a town of the Arabian Trak, seated on the Euchrates; 110 miles W.N.W. of Baffa.

MANSUKUTINA, a town of Hindustan, in the circle of Chisac; eight miles S.S.W. of Ganjam.

MANSURKAT, an islet in the river Nile; 25 miles N. of Syrene. — It is a town of Arabia, in the province of Yemen; eight miles N. of Basal Fakh.

MANSWORTH, a town of Aulflria; nine miles S.E. of Vienna.

MANTA, La, a town of Austria; in the department of the Stura, situated between the Maritime and Cottian Alps; with a cattle placed on an eminence near the town. The gardens are filled with trees of citrons, oranges, and myrtles, and tender plants not capable of enduring the other parts of Piedmont; two miles S. of Saluzzo.

MANTAY, a bay of the Pacific ocean, on the coast of Para, about 20 miles S. of the equator, famous formerly for a pearl fishery, which has been discontinued, and deriving its name from a multitude of large fishes called manjas, in the capture of which the adjacent inhabitants are employed.

MANTALINGA, a town of the island of Sibu, one of the Philippines, inhabited by natives, exempted from tribute, because they first acknowledged the sovereignty of the Spaniards.

MANTANNARE, a small island in the East Indian sea, near the N.W. coast of the island of Borneo. N. lat. 6° 38'. E. long. 116° 27'.

MANTARO, a river of Java, so called from the province it pervades, joins the Maranon at 12° 6', and serves to propel the chief river towards the N.E.; the course having formerly been towards the N.W. See MANSON.

MANTAGA.

MANTA, a port of preparation of butter used by the Turks when they travel with their caravans. This is first boiled over the fire, and then falted and kept in vessels made of tough leather, worked round a wooden frame, of the same shape with the vessels in which they bring their balams from Morocco.

MANTEGAR, or Mantiger, as it is sometimes written, in Zoology, is the tufted ape, with a nose and head fourteen inches long; the nose of a deep red, face blue, and both naked; black eye-brows; ears like the human; on the top of the head is a long upright tuft of hair; and on the chin another; two long tusks in the upper jaw; fore-feet like hands, and the nails on the fingers flat; the hind-feet have the thumbs less perfect, and the nails imbricated; the fore-part of the body and the inside of the legs and arms naked; the outside covered with mottled brown and olive hair; that on the back dully; the buttocks red and bare; and the length from the nose to the rump thirty feet two inches. This animal is very fierce and balaconious; will sit in its ramp, and support itself by a flick; and in this attitude hold a cup in its hand, and drink out of it; its food is fruit. Pers. See Sivina Moron.

MANTEGNA, Andrea, in Biography, born at Padua, or in its district, of low parents, in 1431, became the pupil of Squarione, who was so deeply struck with his talents that he adopted him for his son. He repented of it when Andrea married a daughter of Jacopo Bellini, his competitor. But the cenure, which now took place of the praise he had before lavished on his pupil, only added to his improvement. Certain balsam-relieves of the ancient Greek Ryle, possest by the academy in which Andrea studied, captivated his taste by the correctness of their outline, the simplicity of the forms, the parallelism of the attitudes, and directness of the drapery; the dry fertility with which he copied these, suffered him not to perceive that he had lost the great prerogative of the originals, the soul that animates them. The sarcins of Squarione on his picture of St. Jacopo, made him sensible of the necessity of expression and character; he gave more life to the figures in the story of St. Chriphophoro; and in the face of St. Marco, in the church of St. Giuliana, united the attention of a philosopher with the enthusiasm of a prophet.

The
The criticisms of Squarcione improved Mantegna in expression, the friendly advice of the Bellini directed his method and fixed his principles of colour. During his short stay at Venice he made himself master of every advantage of that school, and in some of his pictures there are tones and tints in flesh and landscape of a richness and zest equal to the best Venetians of his day. Whether he taught the Bellini perspective is uncertain: Lomazzo affirms, that "Mantegna was the first who opened the eyes of artists in that branch."

The chief abode and the school of Mantegna were at Mantua, where, under the auspices of Marchese Lodovico Gonzaga, he established himself, with his family; but he continued to work in other places, and particularly at Rome, where the chapel which he had painted for Innocent VIII. in the Vatican exiled, though injured by age, at the accession of Pius VI. The style of those frescoes proved that he continued steady in his attachment to the antique; but that from a copyist he was become an imitator.

Of his works in oil, Mantua possesses several; but the principal one, the master-pieces of the artift, and the embellishment of his powers, the picture called La Virgine della Vittoria, painted for J. F. de Gonzaga, Marchese di Mantua, in honour of a victory he gained over the French upon the banks of the Taro, and afterwards placed in the Oratorio de Padri di S. Felippo, is now among the spoils of the Louvre. The Madonna is seated on her throne with the infant standing on her lap, and giving benediction to the kneeling marquis in arms before her. At one side of the throne itands the archangel Michael, holding the mantle of the Madonna; at the other St. George, St. Maurice, John the Baptist, and St. Elizabeth on her knees. The side of the throne is ornamented with figures relative to the fall of Adam: the scene is a leafy bowery peopled by birds, and here and there open to a kind sky.

No known work of Mantegna equals, in design, the style of this picture: they generally threw him dry and emaciated: where he appears in all the beauty of select forms: the two infants and St. Elizabeth are figures of dignity, fo is the archangel, who seems to have been, by the concet of his attitude, and the care bestowed upon him, the painter's favourite object. The head has the beauty and the bloom of youth: the round flabby neck and the breadth, to where it confines with the armure, are treated with great art; the expression is, to a high degree, spirited and characteristic. The countenance of the Madonna is mild and benign; that of Chrit, humane. The future prophet is announced in the uplifted arm of John. The guardian angel kindly contemplates the supplicant, who prays with devout simplicity. The whole has an air of life. All the draperies, especially those of St. Elizabeth, are elegantly and correctly folded: with more mufs and less interection of surfaces they would be perfect.

The extreme skill of execution, as it has not here that dryness which distinguishes most other works of this master, does not impair the brilliancy of colour. The heads of the Madonnas, of the infant, of St. Michael, have a general bloom of tones. The lights are everywhere true, the shades alone are sometimes too grey, or too intense. The general fcale of the light has more fercuity than splendour, more the air of nature than of art, but the reflexes are too often cut off too glaringly from the opaque parts. The whole of the picture has preserved its tone to this day, is little damaged, and in no place retouched.

Of the remainder of Mantegna's works, besides some frescoes of considerable merit, but much injured, in a saloon of the castle of Mantua, and the well-known Triumph of Cæfar, in various compartments at Hampton Court, little now remains. His name is more frequent in galleries and collections than his hand: tanknifs of form, rectilinear folds, yellow landscape, and minute polished pebbles, are the genuine signs of originals, than correctness of design and delicacy of pencil. It is not probable that a man so occupied by large works, and so much engraving, should have had time to finish many cabinet pictures: the series of his plates consists of upwards of fifty pieces, executed by his own hand, and though he was not the inventor of the art, he was certainly the first engraver of his time.

Andrea had great influence in the style of his age, nor was the imitation of his style confined to his own school: Francesco, and another of his sons, finished some of the frescoes which he had begun in the castle, and added the beautiful ceiling, which shows that the science of foreshortening what the Italians call "del tutto in fuo," though Melozzo be its reputed author, was carried much farther by Mantegna and his followers. He died in 1505, aged 74. Futel's Pilkington.

MANTEIGAS, in Geography, a town of Portugal, in the province of Beira; 27 miles S.E. of Vilafranca.

MANTELET, in Military Language, a kind of movable parapets, made of planks about three inches thick, nailed one above another to the height of about six feet, generally cased with tin, set upon little wheels, and guided by a long pole: so that in a siege they may be driven before the pioneers, and serve as blinds, to shelter them from the enemy's small shot.

There are also other sorts of mantlets, covered on the top, of which the miners make use to approach the walls of a town or castle. See Plate VI. Fortification, fig. 0.

The double mantlets form an angle, and stand square, making two fronts, which cover both the front and flank of the fappers, &c. when at work; these have double planks, with earth rammed in between them; they are five feet high, and three in breadth, sometimes covered with plates of iron.

It appears from Vegetius, that mantlets were in use among the ancients under the name of vicerie: but they were built lighter and much larger than our's, being eight or nine feet high, as many broad, and sixteen long; they were defended by a double covering, the one of boards, the other of lattices, with the ribs of oars; and were covered without with flints, deeped in water, to prevent fire.

MANTERA, in Geography, a small island in the Atlantic, near the coast of Africa N. lat. 10° 44'.

MANTES, a town of France, and principal place of a district, in the department of the Seine and Oise, seated on the Seine, over which is a bridge of thirty-six arches. The place contains 4300, and the canton 13,865 inhabitants, on a territory of 1324 kilometres, in 23 communes. N. lat. 48° 59'. E. long. 1° 48'.

MANTICA, in Zoology. the name by which Pisto and some other writers have expressed the pouche or bag of skiu under the belly of the opossum, into which the young are received in time of danger.

MANTICUS, in Mythology, a name given to Hercules under which title he had a temple without the walls of Mithymna in Asia. This temple was built by Mantius the chief of a colony of Mithymnians, about 604 years before Christs: or, as others say, the leader of a colony which settled in the ille of Zacynthus, now Zante. Pauly. in Mfillen.

MANTICORA, in Natural History, a genus of insects of the order Coleoptera, of which there is but a single species. The generic character is, Antenae filiform, the joints
joints cylindrical; four feelers whicla are filiform, the thorax is rounded before, and emarginate behind; the head is projecting, and the mandibles are exerted; the shells are united; it has no wings.

Species.

**Maxillosa.** Body large and black; head subglobular, imprefled on each side; mandible toothed at the inner base; thorax imprefled in the middle, and elevated behind; the margin rounded and notched at the tip; shells above, flat, rough, deflected at the edge, with a very sharp lateral ferrate line; legs simple and black. It is described by M. Olivier, in his "Histoire Naturelle des Infétés," as inhabiting the Cape of Good Hope.

**MANTINEA,** in *Ancient Geography,* a town of Arcadia, E. of the river Ophis, and N. of Pallantium. This town, in the time of Homer, appears to have been considerable. Antiope, the daughter of Cepheus, is said to have transported the inhabitants of the old city to a more convenient situation than that which it originally occupied to the banks of the river Ophis; and it is fabulously reported that Antiope was led to the selection of the spot on which the New Mantinea was erected under the guidance of a serpent, whilst others say that the river derived its name from its winding or serpentine course. After the peace of Antalcidas, fo called because he was the ambassador employed by the Greeks in negotiating it with the king of Periia, in the year 387 B.C., the Lacedemonians, under the conduct of their king Agesipolis I., laid siege to Mantinea, as a punishment of its inhabitants for having taken part with the Athenians in the preceding war. Having defended themselves with invincible courage during the former, the Lacedemonians availed themselves of the approach of winter by daming up the current of the river, which was thus made to overflow its banks and overwhelm the houses of Mantinea, upon which the inhabitants were constrained to abandon the noble city which they had long occupied, and to retire to their old villages. After the battle of Leuctra, in the year 370 B.C. the Mantineans returned to their city and rebuilt it, deriving assistance in this undertaking from the Thebans: but they afterwards took part with the Lacedemonians against their coadjutors. A battle was fought near Mantinea by the combining powers, in which, though the Thebans were victorious, they lost their famous general, Epaminondas. Some time after the formation of the Achaean league, Aretas made himself master of Mantinea: but the Achaean were defeated in a subsequent battle by the Lacedemonians, under the command of Cleomenes, who took several of their cities, and they were reduced to the necessity of seeking the succour of Antigonus, king of Macedon. Thus aided and encouraged, the Achaean obliged Cleomenes to retire with great precipitation to Mantinea. But he was soon constrained to abandon it to the force brought against him by Antigonus, who took possession of it without any great requisition. The Mantineans, in compliment to Antigonus, suppressed the original name of their city, and called it "Antigonia," by which appellation it was distinguished till the time of Adrian, who called it to refuse its ancient name of Mantinea. Pauly and Fihimhas has particularly described this famous city and its magnificent temples. The first was a large edifice, separated into two parts by a high wall; on one side of which was the statue of Aesculapius by Alcamenes, and on the other that of Latona with her children, by the celebrated Praxiteles. Elevated upon a column was a statue of the historian Polybius, who rendered signal service to the Achaean in their wars with the Roman republic. Another temple was that of Ceres and Proserpine, in which was a sacred fire which was kept continually burning. The temple of Juno was situated near the theatre, and the goddess was seated on a throne of ivory, having on both sides of her Minerva and Hebe, all which were the works of Praxiteles. Near the altar was the tomb of Arcas, son of Calibio and grandson of Lycoius. Another temple which disgraced the city was dedicated to the infamous Antinous, who contributed to the licentious debauchery of Adrian. From the centre of the town five roads passed in different directions to the principal places of Arcadia.

**MANTINERA,** in *Geography,* a small island in the Mediterranean, near the coast of Naples. N. lat. 39° 55'.

**MANTIS,** in *Natural History,* a genus of insects of the order Hemiptera, of which there are sixty-four species distributed over the globe, but none of them are found in this country; two or three of them arc worshipped by the Hottentots, as the Isis and ichneumon were of old by the Egyptians.

The generic character is, Head unfeated; mouth armed with jaws; feelers filiform; antennae fagaceous; thorax linear; wings four, which are membranaceous and convolute, the under ones plaited. The fore-legs are compressed, ferrated beneath, and armed with a single claw, and lateral jointed prows; the hind-legs are smooth, and formed for walking. This is thought to be one of the most singular genera in the whole class of insects, and the imagination can hardly conceive shapes more strange than those exhibited by some particular species.

**Species.**

**Filiformis.** Body, as its name imports, is filiform, apicous, and brown; the legs are longer than the body, unarmed. The antennae are black, and it inhabits South America.

**Feural.** Body is filiform, apicous, and green; the legs are longer than the body; the hind thighs are spiny at the tip. It inhabits Guadaloupe; it is large, long, and filiform. The antennae are of a moderate size, green tip with brown; body smooth glabrous, without wing-cafes; thighs angular; the four hind ones spiny.

**Calamus.** Body filiform, apicous, greenish; thighs fagiate. Antenna yellowish; head smooth yellowish; body cylindrical; legs yellowish; the thighs are fagiate, with raised lines. It inhabits Santa Cruz in America.

**Rosa.** Body filiform, apicous, green; thighs toothed; the legs are short and brown, the thighs are toothed beneath. It is found in many parts of Italy.

**Angulata.** This species is apicous: the head and thorax spiny; wing-cafes rounded, very short; thighs angular beneath. This is sometimes designated the "Mantis gigas," and it is an inhabitant of Guadaloupe. The body is of a cheetful brown; the head has two spines and numerous raised dots; thorax with two sharp spines on the anterior lobe, and numerous raised dots; the fides ferrate; wing-cafes short, rounded, reticulate; thighs very angular, the four hind ones spiny beneath.

**Gigas.** Thorax rough and roundish; wing-cafes very short; legs spiny; with respect to colour, the thorax is speckled with green; the wing-cafes are reticulate, the base and tip green, pale in the middle; wings pale with transverse brown bars. It inhabits Ambon.

**Cylindrica.** Thorax cylindrical; fore-legs united to the fore-part of the thorax; wing-cafes very grey, the base and beneath rusful; the wings are brown dotted with white.
MANTIS.

Its habitation is not clearly ascertained, but it is not found in Europe.

PHTHISICA. Thorax roundish, muricate; the wing-cases are very short; the legs are unarmed. It inhabits South America and India.

NECYDALOIDES. In this species the thorax is rough; wing-cases oval, angular, very short; the wings are oblong. It is found in many parts of Afia. The wing-cases have a raised flexuous line down the middle; the wings are brown, and as long as the abdomen.

ATRIOPHICA. Thorax four-spined; wing-cases very short, mucronate at the base. It inhabits Java. The head is unarmed; the wing-cases are ovate, truncate at the tip.

SINOSA. Head and thorax spiny; wing-cases very short and acute. It is found in India. The antennae are as long as the body; the thorax is brown, rough, with a double spine each side on the fore-part; wing-cases brown; wings brown, convolute, as long as the abdomen; fore-thighs unarmed, the red spiny.

BISPINOSA. Thorax is rather round, with two spines on the fore-part; wing-cases very short; wings rofe colour. It inhabits America. The colours of this species are very fine; the antennae are yellowish; the head is green, with a short spine each side on the crown; thorax green, yellowish on the back; wing-cases green, fricate with black; wings large, rosy, the outer margin green; abdomen linear, yellowish, green at the tip; the legs are spiny.

JAMAICENSIS. This, agreeably to its specific name, is found in the island of Jamaica; and it differs from the last only in having no spines on the thorax.

LATERNARIS. Linear and black; the wing-cases are very short; gibbous, and yellowish at the sides; the antennae longer than the body, black; thorax yellowish at the sides; wing-cases with a raised tooth in the middle; wings large, black, edged with yellow; the legs are black. It inhabits Brasil.

ACRITA. The head and thorax are spiny; and the wing-cases have a sub-compressed tubercle in the middle. It is found in the East Indies. The antennae are as long as the body, varied with black and white; head brown, with numerous sharp spines; thorax brown and spiny; wing-cases concave and very short; the wings are large and dusky, with a broad pale rufous border on the outer edge, spotted with black, and marked with a broad white band.

LINEARIS. Linear, brown; wing-cases very short, sub-spinous at the base; antennae as long as the body; wings long and brown; fore-thighs membraneous. It inhabits the East Indies.

ROSIA. This species is linear and green; front fulvous; wing-cases very short; and the wings are rosy, with a green rib; antennae longer than the body, brown, with three or four white rings; thorax smooth, linear, greenish; wing-cases vaulted with a black thick spine in the middle; the wings are fricate, and the legs yellow.

FLAVELLICORNIS. Thorax dilated and membraneaceous at the tip; fore-thighs terminating in a spine, the rect in a lobe; antennae peduncate; these are large, very much feathered and falcate at the tip; the front is projecting, narrower in the middle, notched at the tip; wing-cases and wings longer than the body, dusky, sub-pellucid and dilated at the anterior margin. It inhabits Tranquebar.

GONGYLOIDES. This is one of the most remarkable of the Mantis genus; from the thinness of its limbs, and the grotesque form of its body, especially in its dried state, it seems to resemble the conjunction of several fragments of withered flaks; which is the case also of the larve of many of the genera, before the wings are formed. The thorax is uncommonly long and narrow; the head is small and flat, with two filiform antennae; behind thefe, two large polished eyes are placed; the rostrum has the shape of an awl, but it is often split towards the extremity into two points; the elytra, which cover two-thirds of the body of the insect, are reticulated, and croffed over another; the wings which they cover are veined and diaphanous; the four hind-legs have the appearance of being winged, on account of those large membranous lobes which emerge from their joints; the anterior pair are armed with spines at their first articulation, and towards their extremities they are ferrated on one side. It inhabits various parts of Africa and Asia.

PAUPTERTA. Thorax is linear and spiny; fore-thigh terminating in a spine, the others are lobate. It is found in Coromandel, and also in some parts of Portugal.

MENDICA. Thorax margined, toothed; wing-cases varied with white and green; the margin is dotted with white. It inhabits Alexandria. The head is yellowish; front horned; legs yellowish.

TRUNCATA. Thorax dilated each side at the tip, yellowish; the wings are black at the base, and tip with white. This is a small insect, and inhabits Cayenne. The thorax is linear, rough, membraneaceous, and thinly crenate at the tip; abdomen short, flat; dilated; wing-cases as long as the abdomen, and yellowish, with a brown callosus dot in the middle.

STRUMARIA. This is a green insect. The thorax is much dilated in its whole length; wing-cases and wings are longer than the abdomen; the body is short; and the abdomen yellowish. It is found in South America.

TRICOLOR. The sides of the thorax are expanded, lobate; head horned; fore-legs very broad. It inhabits India. The eyes of this species are very remarkable, terminating in sharp ear-like horns; wing-cases pale, spotted with white; wings red at the base, brown in the middle, and tip with white.

CANCELLATA. Thorax dilated at the sides, membraneous, and flat; the body is of a dull brown colour; the thorax is flat.

SICCIPOLIA. The thorax is denticulate; the thighs are oval and membraneaceous. It inhabits India. The insects of this species are usually denominated walking leaves, from their exact resemblance in colour and shape to a dried leaf. They have no wings, or, at most, mere rudiments; the first two pair of thighs are ferrate, the others simple; the body is very much dilated and rounded.

PSEUDOCORNIS. Thorax smooth; crown subulate; antenna pediculate. It inhabits Jamaica.

OCULATA. Thorax triangular, filiform; eyes oblong, projecting, spiny; the head is of a pale colour; the eyes are large, pointed, and conic; the thorax smooth terecaceous, the angles more dusky; wing-cases shorter than the wings, white diaphanous, fricate, and obtuse; legs long, dusky, and unarmed.

SUPERSTITIOSA. Thorax linear, triangular, slightly ferrate on the fore-part; wing-cases greenish; the rib of the wings is transversely fricate. It is a large insect, and is found in Africa. The thorax is rough on the fore-part, smooth behind; the wings are whitish, having a rib with transverse raised brown line.

UNDATA. Thorax carinate, grey; wings white, with black waves. It inhabits Tranquebar. The antennae are filiform and pale; the thorax is filiform, triangular, and rough; wings shorter than the abdomen; thighs lobate at the tip, thanks at the base; the abdomen is long and filiform.

TIRORATA. Thorax is smooth subcarinate; wing-cases green,
green, with scattered ferruginous dots; the wing-cases are shorter than the wings. It is found in America.

Striata. Thorax carinate, and slightly ferrate at the sides; wing-cases oblanceolate, hyaline, frilled with brown, and shorter than the wings; the head is grey; the antennae are simple; and the body is brown.

Oratoria, or Camel-cricket, is the chief of the European Mantis genus. It is found in most of the warmer parts of Europe, and is entirely of a beautiful green colour. It is nearly three inches in length, and in its sitting posture is observed to hold up the two fore-legs, slightly bent, as if in the attitude of prayer: hence the common people have conferred upon it the reputation of a sacred animal; and a popular notion has often prevailed, that a child or traveller, having lost his way, would be safely directed by observing the quarter to which the animal pointed, when taken into the hand. It is, however, in its real nature, a very rapacious animal, devouring all smaller insects that fall in its way, for which it lies in wait with anxious audacity. It is also of a very quarrelsome nature; and when kept with others of its own species, in a flate of captivity, will attack its neighbour with the utmost violence, till one or the other is destroyed in the contest. Among the Chinese, this quarrelsome property in the genus Mantis is turned into a fimilar entertainment with that afforded by fighting cockers and quails to Europeans. To insects of this kind Mr. Barrow is supposed to allude in his "Travels in China." He says, "They (the Chinese) have even extended their inquiries, after fighting animals, into the insect tribe, and have discovered a species of Gryllus that will attack each other with such ferocity, as seldom to quit their hold without bringing away, at the same time, a limb of their antagonist. These little creatures are fed and kept apart in bamboo cages; and the custom of making them devour each other is so common, that, during the summer months, scarcely a boy is to be seen without his cage of grasshoppers." The M. religiosa, with the thorax subcarinate, is a rare variety of this species.

Precaria. Thorax ciliate with small spines; wing-cases green, with a divided white and brown spot. An inhabitant of Africa. The head and thorax are of a yellowish-green; eyes ferruginous; fore-legs with a ferruginous spot; wing-cases longer than the body; wings hyaline, spotted with green. This is the supposed idol of the Hottentots, which those superstitious people are reported to hold in the highest veneration; the perfon on whom the adored insect happens to light, being considered as favoured by the distinction of a celestial visitant, and regarded ever after in the light of a saint.

Sancta. Thorax slightly ferrate, yellowish-green; wing-cases green, immaculate; wings hyaline. It is found chiefly in the south of France. The wings are greenish at the tip; fore-flanks with two black spots beneath.

Siphaglyras. Thorax ciliate, wing-cases green, with a white spot in the middle. It very much resembles the M. precaria, but the thorax is shorter, thicker, and more ciliate. It inhabits America.

Monacha. Thorax smooth, telpacens; wing-cases and wings green hyaline; the fore-flanks have two telpacens dots on the fore-side. It is found at the Cape of Good Hope.

Obscura. Thorax slightly ferrate, dull grey; wing-cases with a black spot at the base; the wings also have one at the tip. It inhabits Africa. The head is grey, with a black frontal spot; thorax dull, with a black dorsal line; fore-legs slightly ferrate; the other parts simple.

Hyalina. Thorax ciliate; wing-cases hyaline, edged with green; front is two-toothed. It is found in America. With respect to colour, the head is brown; antennae ferrate; wings hyaline, frilled with brown at the tip.

Fenestra. Thorax smooth, wing-cases hyaline; exterior margin of the wing-cases brown. It inhabits Africa. The thorax is linear; exterior margin of the wings is brown at the tip; legs pale; fore-flanks with a few black spots within.

Bidens. Thorax is rough; wing-cases green, with black bar; wings brown-black on the disk. It inhabits America. The head is brown; front with two sharp approximate teeth; thorax linear, grey, with a few black raised dots; wing-cases with two oblique brown bands; legs brown; tighis pale at the base, and tupp with black; flanks of the second pair lobate.

Griesa. Thorax smooth; wing-cases and wings grey, hyaline, spotted with brown. A specimen in the British Museum is middle-sized. Thighs of the fore-legs a little dilated at the upper margin; tipes on the lower; the other legs varied with grey and brown.

Minisialis. Thorax rough, crenate, as long as the head, ferruginous on the fore-part; wing-cases green; the head is yellowish; antennae brown; thorax carinate; outer margin of the wing-cases subferruginous; fore-thighs fulvous; abdomen brown, pale at the tip. Found in New Holland.

Urbana. Thorax entire; wing-cases green, with a ferruginous dot and band. It inhabits India.

Rustica. Thorax smooth, brown; wing-cases shorter than the wings, brown hyaline; antennae hairy. It inhabits the shores of Patagonia; the head is grey-brown, with globular flemmata; the legs are yellowish.

Nasuta. Thorax spiny and ciliate; front projecting, spiny, emarginate. It inhabits the Cape of Good Hope. Head flat; front two toothed on each side, and widely emarginate at the tip; thorax black with a raised tubercle before and behind; wings and wing-cases grey hyaline, with numerous brown dots at the nerves; the legs are black and annulate.

Lorata. Thorax three-lobed; front with a bisid horn; eyes conic, pointed. This also is found at the Cape, and is particularly described by Thunberg; the mouth is varied with green and brown; the front is greenish, with a projecting bisid horn between the antennae; wing-cases green, with a white base and spot in the middle; wings black, tupp with white; body varied with green and white; margin of the abdomen elevated and lobate.

Pulchra. Thorax green throughout; the wings are brown hyaline, ferruginous at the base. It inhabits Transkebar. The antennae are brown; head and thorax green, a little yellowish at the edge; wing-cases green, the margin yellow at the base; abdomen above brown, beneath green; legs yellow.

Nasuta. Linear, ash-coloured, spotted with black. This is an inhabitant of the Cape, and has been described by Thunberg; it is the tutelar deity of the Hottentots.

Perspicua. Duky; wings and wing-cases hyaline; but the wings have a brown marginal spot and tip. It is a small insect, and is found at Cayenne; the wing-cases have a small black dot towards the base.

Pacana. Wings reticulate, white with a lateral ferruginous spot; ends of the legs echinate. It inhabits France and Germany. The thorax is cylindrical, and entirely brown.

Minuta. In this the thorax is cylindrical and yellowish; wing-cases hyaline, with a greenish rib. It inhabits South America. The wing-cases have a small white dot in the middle;
middle; the abdomen is greenish, and yellowish on the back; the legs of a greenish colour.

**Pusilla.** Thorax cylindrical, yellowish; wing-cases and wings hyaline, immaculate. It inhabits Africa.

**Carolina.** Thorax subcylindrical, carinate; wing-cases whitish, waved with brown. It inhabits Carolina; wings and their cilia shorter than the body.

**Labiata.** This is an inhabitant of India; it is linear, greenish, unarm'd; sides of the head green.

**Maculata.** Cinnamonous; thorax winged, subpinous; legs spotted within with black. This is found in the islands of Japan.

**Genesis.** This also is cinnamonous; the thorax is unarm'd; the head is conic entirely. It inhabits Africa and India.

**Paua.** Livid and smooth; wing-cases and wings hyaline; segments of the abdomen edged with black. It inhabits America.

**Cingulata.** Thorax brownish; wing-cases green, reticulate with black, and marked with four blackish spots; wings blackish, with black lines, the edge yellowish-brown. It inhabits Jamaica. Abdomen annulate with black; it is two-spined at the tip.

**Gigantea.** Brownish; neck, thorax, and thighs ferrate. It inhabits Italy.

**Angusta.** This is of a greenish colour; the tail is forked; the antennae are filiform, and as long as the body. It inhabits Antiqua.

**Sibiriaca.** This is supposed to be a variety of the M. pausilla, and is an inhabitant of Siberia; the body is varied with yellow and brown; wings hyaline with reddish nerves.

**Harperea.** Cinnamonous; thorax toothed; wings half as long as the body. It is found also in the deferts of Siberia.

**Pennicornis.** The crown of this insect has a conic spine; the antennae are feathered and linear; the hind thighs terminate in a lobe. It is found in the deferts bordering on the Caspian sea, and very much resembles in shape and colour the M. gongylodes.

**Mantle, or Mantletree, in Architecture, is the lower part of the breast or front of a chimney.** It was formerly a piece of timber that lay across the jambs, and supported the breast-work; but by a late act of parliament, chimney-breasts are not to be supported by a wooden mantle-tree, or turning-piece, but by an iron bar, or by a brick or stone arch. See Chimney.

**Mantle, Mantlings, or Lambrequin, in Heraldry, that appearance of folding of cloth, flourishing, or drapery, that is in any achievement drawn about the coat of arms. This, properly speaking, is an ornament that was anciently fixed to the helmet, like that now worn round the caps of our light dragoons. It is suppos'd originally to have been the representation of a mantle, or military habit, worn by ancient cavaliers over their armour, to preserve it from rust; or, as others hold, a short covering only worn over the helmet to defend the head from the weather, which, in after-times, was lengthened, and made to hang from the helmet below the whole shield. Sometimes it hung in a loofe, flowing, ragged manner; sometimes it is represented as cut or entire, and hanging back over the neck of a warrior, in which case it is called a "Cappeline." The forms of these ancient mantlings, and the manner in which they usually waved from the helmet of a warrior, are well represented on ancient seals. In length of time, the use and locality of these mantlings seem to have been forgotten; for we find the heralds, through an unaccountable inadvertency, forming them like cloaks to receive or cover the whole achievement, instead of pursuing their ancient mode of representing them, as being coverings for the head, or ornaments flowing from the helmet of the warrior, and of the colour of his arms. According to such modernized manner of bearing mantlings, those of the sovereigns are supposed to be of gold doubled with ermine; those of the peers, crimfon velvet, folded, and ermine inside; and those for knights and gentlemen, crimfon velvet doubled with white satin. The prevalence of this mode becoming so general, that all sorts of person, painted mantles of crimfon and ermine on their carriages, at Edmondston, in the year 1765, proposed to several of the peers to paint (on their carriages) their arms, placed in mantles of crimfon, with their edges thrown back so as to show their doublets, or linings, which should be of ermine, and containing a number of rows of ermine spots, equal to those of the guards on their coronation robes, expressing their respective degrees, viz. a baron two rows, a viscount two and a half, an earl three, a marquis three and a half, a duke four, &c. This proposal having met with general approbation, was carried into execution, and had the desired effect of throwing the distinction between the several ranks and degrees of our nobility. After which Edmondston formed mantles for the knights companions of the several orders, taken from the mantle and robes which they wear at their installation.

The mantle is always laid in blazon to be doubled, that is, lined throughout with one of the furs, as ermine, pean, vairy, &c. See Coat.

**Mantle of the Knights of the Garter. See Garter.**

**Mantle is likewise a term used in Falconry.** They say the hawk mantles, that is, spreads her wings after her legs.

**Mantle, Lady's, in Botany. See Alchémilla.**

**Manto, or Olancho el Viejo, a town of Mexico, in the province of Honduras. N. lat. 14° 4'. W. long. 86°.**

**MANTON, Thomas, in Biography, a learned English divine, was born in the year 1620.** He was educated in grammar-schooling at Tiverton-school, and when he was about fifteen years of age was entered at Wadham-college, Oxford. Here he took his degrees, and was ordained deacon by the bishop of Exeter at the age of twenty. He was first settled at Cottenham in Devonshire, and afterwards at Stoke Newington, in the vicinity of London, where he was highly esteemed as a preacher and exponent of the holy scriptures. From Newington he went to St. Paul's Covent Garden, having been precented to that living by his grace the duke of Bedford. In 1653, he was appointed one of the chaplains of the protector Oliver Cromwell: but in 1666 he took an active part with the Presbyterian ministers in general, in bringing about the reformation of King Charles II., for which service he was nominated one of the chaplains to his majesty, and, in consequence of the king's mandamus, created doctor of divinity. He refused to submit to the act of Uniformity, and under the operation of that act he was, in 1662, ejected from his living, after which he held a private meeting in his own house, but was perfecuted and imprisoned for exercising the ministerial functions. He was highly esteemed by persons of great consequence in the state, and was confulted by them with respect to all the treaties for the comprenhension with the established church. He had great weight among his own brethren, on account of his zeal and activity in their affairs. He died in the year 1677. He was esteemed a man of great learning as a theologian, and was deeply read in ancient and modern history. He is characterized by doctor Bates as a divin of rich fancy, a strong memory, and happy elocution, improved by diligent study.
MANTUA, in Geography, was, previously to the arrangements subseuent to the French revolution, a duchy of Italy, bounded on the N. by the Breffian and Veronese, on the E. by the Ferrarice, on the S. by the duchy of Modena, and on the W. by the Cremonese. In length it is about 50 miles, and in breadth 45. It is watered by the Po, which runs through the middle of it, and also by the Oglio, Mincio, Secchia, &c. which discharge themselves into the Po. This territory abounds with corn, fruits, and legumes, and it affords some wines, great quantities of flax, and many good horses. The small duchy of Mantua was taken possession of by Lewis of Gonzaga in the year 1528, and was held by the house of Gonzaga from this period; till at length the last of the family was put under the ban of the empire. In 1703, the emperor transferred to the duke of Savoy that part of the duchy of Montferrat, which had been possessed by the dukes of Mantua as a fief. In 1707, the Infernalists over-run the whole duchy, and duke Charles IV. died in the following year under the ban of the empire. From this time the house of Austria continued in possession of the duchy, annexed to the government of the Mihnes, till by the peace of Luneville it was ceded to the Cispalian republic, now the kingdom of Italy; and it forms the department of the Mincio, which falls under Mantua.

MANTUA, the capital of the late duchy and of the present department of the Mincio, situated on a lake formed by the inundations of the river Mincio; about 20 miles in circumference, and two broad. The two chief bridges leading to this city over the lake are Ponte di Molini, defended by two citadels, and Ponte di St. Giorgio, with fortifications at both ends. The water divides the city into two parts nearly equal, which communicate with each other by six bridges. In summer, when the water flagillates, the inaccessibility of the air confines the higher classes of inhabitants to leave the city. The streets are, in general, long, broad, and straight, with handsome stone houses, fine squares, and stately churches. On the other side of the lake are three suburbs. Mantua comprehends four collegiate churches, 21 parochial, 14 other churches and ainas-houses, 11 oratories, 40 convents; and without the city are three parish churches, two other churches, and seven convents. The Jews, of whom there are about 4,000, live in a distinct quarter. The population, exclusive of the garrison, was formerly estimated at 50,000; but it has since been reduced, so that at present it does not amount to more, as some say, than 16,000, or, according to others, 12,000. The position and fortifications render it a place of great strength. In the cathedral, which is a work of Julius Romano, are preserved of the most celebrated masters. The church of Antonio is more famous for relics than any other in the city. The Franciscan church has an elegant inlaid and a good library. The edifice formerly occupied as the ducal palace is spacious and roomy; but the ducal gallery and museum were pillaged in 1630 by the Imperialists, so that it is now empty and in ruins. The palace church, however, has fine valuable relics and other rich furniture, besides two pictures of inestimable value, viz. one of the Baptist of Constantinople the Great, and the other of the Martyrdom of St. Anthony. The university was founded in 1625. The silk and other manufactures are now inconsiderable. This city, after enduring a long siege, was taken by the French in February, 1797; 70 miles S.S.W. of Venice. N. lat. 45° 8'. E. long. 10° 34'.

MANTUA, in Geography, an ancient town of Sweden, in the province of Tavalland; 37 miles E.S.E. of Tavallhus.

MANTUA, in Ancient Geography, a town of Italy, S.E. of Brixia, and S. of the lake Borens on the Mincio. Although this town is celebrated for its antiquity, its origin being traced to the Tufi, 600 years B. C., it is still more distinguished as the place near which Virgil was born. The town was encompassed by a lake, which was formed by the waters of the river.
MANTUANO, in Biography. See Venusti Marcello.

MANTUANUS, the poetical name of Battista Spagnuolo, was born at Mantua in 1448; he entered into the order of the Carmelites, and pursued his studies in various cities, and under different masters. He was particularly attached to Latin poetry, but without neglecting his graver studies. He bore several important offices, undertook many journeys, and was finally made general of his order in 1573. He died in 1516, and a marble statue, crowned with laurel, was erected to his memory. The name of Mantuanus once found so high that some writers placed him in parallel with Virgil; others carried the matter still farther, and thought the Pagan ought not to be mentioned in comparison with the Christian poet. He is said to have written 35,000 verses. Erasmus thought highly of his talents, but Scaliger ranked him with mere versifiers. His "Poetical Works" were published at Bologna, in folio, in 1562; and at Antwerp they were re-published in 1575, in 4 vols. Svo.

MANUAH, in Geography, a town of Hindostan, in Guzerat, in the gulf of Cambay; 10 miles S. of Goge.

Manual. Manualis, signifies what is employed, or used by the hand, and whereof a present profit may be made.

Thus, such a thing is said to be in the manual occupation of one, where it is actually used or employed by him.

Manual is the name of a service-book used in the church of Rome, containing the rites, directions to the priests, and prayers used in the administration of baptism and other sacraments, the form of blessing holy water, and the whole service used in processions.

Manual Excercit, in Military Language, is the exercise of the musket, independently of powder and ball. About the year 1757, a new manual exercise was introduced into the British army, very much resembling the modern improved system of Frederick, the father of the great king of Prussia; who was the first that caused the manual exercise to be contracted; and the motions performed close to the body. This exercise has of late been simplified and reduced to a smaller number of motions. The following are the seven movements of the present manual exercise: 1. Order arms; three motions. 2. Fix bayonets; one motion. 3. Shoulder arms; one motion. 4. Prentit arms; three motions. 5. Shoulder arms; two motions. 6. Charge bayonets; two motions. 7. Shoulder arms; two motions.

See Battalion.

About the same time the evolutions, manoeuvres, or field movements, which were various in different corps, and very numerous in some, were reduced to one standard, and confined in number to 18. The purposes of these changes were fixed in the "Regulations" to be, the reorganization of celerity with order; to prevent hurry; to induce precision and correctness; to inculcate and enforce the necessity of military dependence, and of mutual support in action; to adopt such motions only as are necessary for combined exertions in corps, rejecting only what is curious on parade; and to make utility, not show, the principal object. See Battalion, Formation and Order of the Battalion.

MANUBALISTA, the ancient name of the croft-bow; which see.

MANUBIÆ, among the Romans, the spoils of the enemy, or rather the money made of the booty when sold by the quaestor.

MANUCAPTON, in Law, a writ which lies for a man, who being taken on suspicion of felony, and offering sufficient bail for his appearance, is refused to be admitted thereto by the sheriff, or other having power to let to main-prize.

MANUCNADNCUR, in Natural History, a name given by the people of the Philippine islands to a very beautiful species of parrot, which is found very frequently wild in the woods there. It is of the same bigness with the common parrot, and is variegated with a great many different colours.

MANUCODE, in Ornithology. See Paradisa Regia.

MANUCODIATA. See Paradisa Apoda, Merops Flavicans, and Mucicapa Paradisi.

MANUCODITOTA. See Tudus Paradisus.

MANUDBCTOR, a name given to an ancient officer of the church; who from the middle of the choir, where he was placed, gave the signal for the choiristers to sing, and marked the measure, beat time, and regulated the music. The Greeks called him metacores, because seated in the middle of the choir; but, in the Latin church, he was called manuador; from manus, and duct, lead; because he led and guided the choir by the motions and gesture of the hand.

MANUEL, Comnenus, in Biography, emperor of Constantinople, was appointed successor to his father, John Comnenus, at his death in 1139, to the prejudice of an elder brother. The soldiery approved of the nomination on account of his military talents and heroism. He is said to have equalled the most renowned champions of chivalry with regard to warlike prowess, but at the same time no one surpassed him in luxury and diffolute indulgence during the intervals of peace. Soon after his accession he marched into Asia with a powerful army, and having recovered several towns in Phrygia, which had been taken by the Turks, he laid siege to their capital Iconium. He was unable to reduce this important place; and after securing the frontiers by garrisons he returned to Constantinople. During his stay in the capital, he married German, or Irene, sister-in-law to the German emperor Conrad, but this connection did not prevent him from engaging in a criminal commerce with his own niece Theodora. In the crusade of 1146, led by Conrad, Manuel, jealous of the passage of a number of ferocious bands through his territories, is charged with having used means for their destruction, and it has been affirmed by the Latin historians, that he privately acquainted the Turkish sultan with the designs of the crusaders. Roger, king of Sicily, having made himself master of the isle of Corfu, which was considered as part of the Constantinopolitan empire, and having also plundered Corinth, Thebes, and other towns of Greece, insulted Constantinople itself. Manuel, therefore, assembled a great fleet, with which he recovered Corfu, after which he carried war into the dominions of his enemy, and reduced the greatest part of the provinces of Apulia and Calabria, by means of his lieutenant Michael Palaeologus. His successes were so great and important, that he even entertained hopes of acquiring Italy and the western empire; with this view he attached to his cause several nobles in Rome itself, and married his niece to one of the family of Frangipani. His expectations were, however, defeated through the jealousy which subsisted between the Roman and Greek churches, and he was obliged to make a treaty and renounce his conquests, retaining only the shadow of a nominal sovereignty.
regency. Manuel had been engaged, in person, against the Servians, whom he repulsed with great loss, and several of whose towns he took and destroyed. In a progres after wards through his Asiatic dominions, he was promptly entertained by the princes of the West; but an infult which he received from the Turks on his return, induced him to transport a powerful army into Asia, with which he struck such terror into the sultan, that he sued for peace, which was immediately concluded. When Manuel had overcome his foreign and political enemies, he engaged in religious contests, and disturbed the church by endeavours to introduce heterodox opinions. Finding his life drawing to a conclusion he put on the monastic habit, determining to retire from the world. He died in 1177, after a very busy reign of thirty-eight years. He left a son, Alexis, who succeeded him. Unver. Hilt. Gibbon.

MANUEL PAREDÓGUS, emperor of Constaninople, born in 1349, was second son of John Paredóagus. His father was not only reduced to a servile dependence on the Turkish sultan, but meanly submitted, at his orders, to deprive his eldest son Andronicus of his sight; he, therefore, associated Manuel to his scepître, which now ruled over little more than the metropolis and its immediate district. On the death of John in 1391, Manuel was serving by compulsion in the army of Bajazet, but upon receiving intelligence he escaped, and arriving at Constaninople, mounted the throne. Bajazet immediately invested the city, and compelled the new sovereign to purchase a peace on very ignominious conditions, and after carrying on the contest a short time, he resigned the royal power to his nephew, and embarked for Venice. From Venice he made a progress through the principal courts of the West, to engage the sovereigns to contribute their aid for the defence of the bulwark of Christendom against the Mahometan armis. He visited Italy, France, England, and Germany, and was every where received with a respect and commiseration due to his great misfortunes, but he was unable to rouze the princes to any effectual efforts. After an absence of two whole years he returned, in 1402, to the Morea, where he heard of the defeat and capture of Bajazet by Tamerlane, and of the temporary relief of Constaninople. He was now restored to his throne, and his competitor banished to Lesbos. He soon after recovered several of his provinces, which he enjoyed till his death in 1425; at the age of seventy-six. Unver. Hilt. Gibbon.

MANUEL, DON JUAN, grandson of king St. Fernando of Castile, is frequently referred to in Spanish history during the reigns of Ferdinand IV. and Alonzo XI., with whom he was sometimes at open war; but having at length effected the marriage of his daughter Colanza with the infante D. Pedro, then heir of Portugal, peace was established between them. He was present at the great battle of Salado, in October 1340, after which, the victory being so complete and tremendous, Spain was never more endangered by the African Moors. He died in 1347. Don Juan Manuel holds a still higher rank in the literary than in the political history of his country; his writings are among the earliest specimens of Castilian prose; they are twelve in number, of which the titles are given in the General Biography, but only one of them, viz. "El Conde Lucanor," has yet been published. This was first printed by Argote de Molina, in 1575, and it was re-printed in 1642. It is a dialogue between the Conde Lucanor and his friend Patronio, in which the latter offers his friend some good advice, and allulates all his precepts by examples. Gen. Bikg.

MANUFACTORY, from manufactus, made with hands, a place where several artificis and workmen are employed in the same kind of work, or make a commodity of the same kind.

MANUFACTURE is popularly used to signify the work itself; and by extension, the like work carried on independently in different parts of the country.

In the French we say, the cotton manufacture, woollen manufacture, silk manufacture, worst manufacture, tapestry manufacture, muslin manufacture, &c. manufacture of hats, flcketings, &c.

By 23 Geo. II. c. 13, if any perfon exports any tools or utensils used in the flilk, linen, cotton, or woollen manufactures, he forfeits the same, and 200l. and the captain of the ship, having knowledge thereof, 100l. And if any captain of a king's ship, or officer of the customs, knowingly suffers such exportation, he forfeits 100l. and his employment, and is for ever made incapable of bearing any public office. And every perfon collecting such tools for exportation, shall on conviction forfeit them, and 200l. (See also 14 Geo. III. c. 71.) By 21 Geo. III. c. 37, the above penalties on the captain of the ship and officer of the customs are augmented to 200l.; and a perfon having in his custody, or procuring to be made any such tool, shall forfeit the same, and 500l., and any officer of a ship, convining at it, shall forfeit 500l., and if it be a king's ship, forfeit also his office, and be incapacitated.

Much was done under the auspices of the magnanimous prince Edward III., for establishing our domestic manufactures, by prohibiting the exportation of English wool, and the importation or wear of foreign cloths or furs, and by encouraging cloth-workers from other countries to settle here.

Manufacture, Cotton, one of the leading and most important branches of our national industry and commerce.

The history of its altonishing progress in the last century, the succeasive improvements in the machinery, which have been made by various inventors, and the extent of the trade, with other curious important facts, are detailed under the article Cotton: it is needless, therefore, to recapitulate these circumstances, and we shall proceed at once to describe this extensive manufacture, as conducted on the most improved system in some of our largest cotton-mills. Many of our readers may have viewed a cotton-mill with wonder, but not with intelligence, nor with leisure to trace the steps by which the wool from the bag ultimately attains the form of a very thin thread. Bewildered by such a complication of machinery all in motion, very few, we imagine, are able to recollect, with diffincns and intelligence, the essential part of the processes by which the form of the cotton is so wonderfully changed. Such readers will not think a page or two misemployed, in giving a brief account of the different operations the cotton passes through, from the raw cotton or cotton wool, as imported, to the finished thread; and we shall afterwards enlarge upon each subject, and describe the machinery by which these operations are effected in the most expeditious and perfect manner. For the explanation of these, we have appropriated 13 of our plates, which are entitled Cotton Manufacture.

Cotton, it is well known, is the produce of a shrub in the warmer climates of the East and West Indies, and even in the more temperate countries which border on the Levant. It comes to us packed in bags, without any further preparation.
preparation than being pretty carefully picked out of the pod in which it grows; but full much dirt, dust, and other impurities remain in it. The cotton wool is imported either in bags or in bales: the bags weigh from 12 cwt. to 5 cwt., and the bales usually weigh 3½ or 3½ cwt. On arriving at the cotton-mill these are unpacked, and the contents examined at the same time it is turned over and beaten with a flack, and the gross impurities picked out with the fingers. This is called forting, and the object of the beating is to soften and open the fibre of the cotton, so as to expose every part. The forting is performed immediately when the bags of cotton are opened, but it has still to undergo a second examination, called picking: the principal object of the first examination, or forting, being intended to ascertain the quality of the cotton, and to find what kind of goods it is best adapted for manufacturing, and in this examination the coarsest impurities and yellow damaged parts are picked out.

After forting the cotton, it is carried to the carding machine, and the coarser sorts of cotton to the opening machine, which is known to the workmen by the name of devil. In the carding machine, the cotton is spread upon a platform of ropes strained very tight, and a number of rods strike very smartly upon it, by which they open the fibres and loosen the knots of cotton preparative to the succeeding operations: at the same time the violence of the carding loosens and shakes out all dirt, dust, and cotton seeds, of which the cotton in its raw state contains a great number, and which would be very prejudicial to the operations of the more delicate machines. The cotton, when first packed up in the bags, is compressed very closely, for the convenience of stowage, and this condenses it into a hard matted mass; but the carding machine, striking it violently with small sticks, causes the fibres, by their natural elasticity, and the motion occasioned among them, to gradually loosen and disengage themselves, and the cotton, by repeated strokes, recovers all its original volume.

The opening machine has the same objects, and produces the same effects, though in a very different manner, as it consists of a rapidly revolving cylinder, on which a great number of iron teeth, or spikes are fixed, which tear and open the cotton against other similar teeth, which are fixed in a stationary half cylinder or hood, enclosing the other. The opening machine is used for the finer kind of cotton, and the opening machine, which acts in a more rapid and less effective manner, is employed upon the coarser sorts. After carding or opening, the cotton is again picked, to remove those finer particles of dirt which were before enveloped in the cotton, but are exposed by the operation of the machine. It is performed by women, who remove all extraneous matter, and every particle of yellow or damaged cotton. The perfection of the article to be produced, depends in a great degree on the care with which the picking is performed, and this is almost the only process, in the cotton spinning, which cannot be performed by machinery, because it necessarily requires a discretionary power.

The cotton wool being picked clean, is next mixed, that is, the contents of different bags are mixed together with a view of obtaining a sameliness in the quality of the cotton which is to be spun. In this operation the greatest art of cotton-spinning consists, and it is that department in which experience alone guides the manufacturer. By a judicious mixture of different sorts of cotton, some spinners will produce a very fine and capital yarn, from such cotton as would, if spun alone, or improperly mixed, only produce coarse and low priced goods. The mixture is effected by making a pile or heap, consisting of successive layers, of the different kinds of cotton which are to be mixed; then by raking away a small quantity at a time from the edges of the heap, striking the rake from the top to the bottom, through all the different layers, the cotton will be very equally mixed. Sometimes the cotton wool is dyed, and different colours are mixed together. It is now spread out, very evenly and regularly, upon a long cloth, which is rolled up and carried to the carding machine. This consists of a number of cylinders, covered with wire teeth or cards, and revolving with considerable velocity in opposite directions, nearly in contact with each other, and covered by a dome also lined with cards. The cotton, being introduced among these, is continually combed, or carded, by the teeth, until almost every individual fibre is separated and drawn straight, and every little knotty and entangled part disengaged. By passing gradually through the machine from one cylinder to another, the cotton is dispered lightly and evenly among the teeth over the whole surface of the roll, or finishing cylinder, from which it is detached by the mechanism in a continued fleece. This is drawn off, and lapped upon a cylinder turned slowly round by the machine, until the fleece has made a great number of turns upon the cylinder: it is then broken off, by dividing it at the part, so that it forms a fleece called a lap, which is the length of the circumference of the cylinder, and consisting of fifteen or twenty thicknesses, by which admirable circumstance very great regularity is obtained in the thickness of the lap, because if any one part of the fleece produced by the machine is thinner or thicker than it ought to be, in consequence of any irregularity in the spreading of the cotton-wool upon the cloth, previous to carding, such irregularity will have no sensible effect upon the ultimate thickness of the lap, because it is composed of thirty or forty flèts, and there is no probability that the inequalities of these several flèts will fall beneath each other, but every chance that they will be equally dispersed through the whole, and thus correct each other. The lap, when taken off, is laid flat on a cloth, which, with it, is rolled up and conveyed to a second carding-machine, called the finishing card, while the flèt is called the breaker. In this second card it undergoes a similar process to the first, but instead of the flèt being received on a cylinder, it is contracted by passing through a funnel in which the flèt, being hemmed in on both sides, is gradually contracted to a thick roll, which may be continued to any length as long as the machine is supplied with cotton. This roll or band of cotton is drawn off between two rollers, which compres it into a pretty firm, flat ribband, about two inches broad. The rollers deliver it into a tin can, placed to receive it, and in this it is removed to the drawing frame.

Drawing frame. — This machine consists of several pairs of rollers, between which the cotton is passed, and every successive pair is drawn through moves, by means of the wheel-work, with a greater velocity than those preceding it, so as to stretch out the band or sliver of cotton, in the same manner as it would be drawn out, if one part of the sliver were held between the finger and thumb of one hand, and another part, at an inch or two distant, being held in the other hand. Then by drawing the two hands a little to the extent of four inches, it is evident two inches in length of the cotton sliver would be extended or drawn out to four inches. In like manner, the first pair of rollers through which the sliver passes, are pressed together with a sufficient weight to hold the cotton firmly between them. The second pair of rollers are situated at one or two inches distant, and are made by the wheel-work to revolve more swiftly than the first. The difference of velocity, however, is but small, though the consequence is, that the sliver will be lengthened in the same proportion;
proportion; for the second rollers take up the cotton much faster than the first pair will deliver it out: it must, therefore, be either forcibly pulled through between the first rollers, or it must be stretched a little, by the fibres flipping among each other, or by a small break. When the extension is small, the only effect of it is merely to begin to draw the fibres (which are at present lying in every possible direction) into a straight and parallel position, which is most favourable for the subsequent extensions. The drawing frame contains a third, and some of them a fourth pair of rollers, by which the sliver undergoes a second or third draught; but the combined effect of all these drawings is generally to extend the sliver to four times the length it was when first put to the machine. But as this would reduce the sliver to one-fourth of the fize, which is not intended in this stage of the process, four ends or slivers are introduced between the rollers together, and being drawn into one, which is four times the length, it will of course be of the same fize as any one of the four which is put in. This drawing process is repeated three or four times, and the alteration it makes in the sliver is to equalize the fize of the sliver, on the same principle as before the detachement of the breaking card, viz. by repeatedly combining four together, and drawing them into one; it also improves the fibres longitudinally and in the most perfect state of parallelism. The operation of carding effects this in a certain degree; yet the fibres, though parallel, are not straight, but many of them doubled, as may easily be supposed, from the teeth of the cards catching the fibres sometimes in the middle, which become hooked or fastened upon them.

Though the general arrangement of the fibres of a sliver from the mufliing card is longitudinal, yet they are doubled, bent, and interlaced in such a way, as to render the operation we are now speaking of absolutely necessary.

When the cardings have been passed four or five times through the drawing frame, every fibres is stretched out at full length, and disposed in the most even and regular direction, so that each fibre will, when twisted into a thread, take its proper bearing, in consequence of every one being straightened and having the same tension.

The sliver in this state presents a most beautiful appearance, being fo extremely regular in its fize, and all the fibres drawn fo straight, that it bears a fine glossy or silky appearance. It is upon this sliver or riband of cotton woof that the operation of spinning begins. The general effect of the spinning process is, to draw out this massive sliver, and to twist it as it is drawn out: but this is not to be done by the fingers, pulling out as many fibres of the cotton at once as are necessary for composing a thread of the intended fize, and continuing this manipulation regularly across the whole end of the riband, and thus, as it were, nibbling the whole of it away. The fingers must be directed for this purpose by an attentive eye; but in performing this by machinery, the whole riband must be drawn out together and twisted as it is drawn. This requires great art and very delicate management: it cannot be done at once, that is, the cotton roll cannot be first stretched, or drawn out to the length that is ultimately produced, from the tenth of an inch of the sliver, and then twisted. There is not cohesion enough for this purpose, it would only break off a bit of the sliver, and could make no further use of it; for the fibres of cotton are very little implicated among each other in the sliver, because the operation of carding and drawing has laid them all parallel in the sliver; and though compressed a little, by its contraction in the card from a fleece of twenty inches to a riband of two, and afterwards com-

MANUFACTURE OF COTTON.

pressed between the rollers of the drawing frame, yet they cohere so slightly, that a few fibres may be drawn out, without bringing many others along with them. For these reasons, the whole thickens and breadth of two or three inches are stretched to a very minute quantity, and then a very flight degree of twist is given it, viz. about two or three turns in the inch, so that it shall now compose an extremely soft and springy cylinder, which cannot be called a thread or cord, because it has scarcely any firmness, and is merely rounder or flenderer than before, being stretched to about four times the former length. This is called roving, and the operation is performed in the

Roving Frame.—This machine is constructed in a great variety of forms, but all of them have the same object in view, viz. to draw out the sliver, so as to reduce it from a large band to a coarse and loose thread: but as this extension would render it so extremely tender, that it would scarcely hang together in passing through the succeeding machines, the roving frame, immediately after having drawn and extended it to the intended fize by rollers, operating in the same manner as the rollers of the drawing frame, gives it a very light twist, as before mentioned, and this loose thread, which is called the roving, is the first rudiment of a thread. Although it is extremely tender, and will not carry a weight of two ounces, it is much more cohesive than before, because the twist given to it makes all the longitudinal fibres bind each other together, and compacts those which lie athwart; therefore it will require twice the force to pull out a fibre from among the rest, but still not near enough to break it. In drawing a single fibre others are drawn out along with it, and if we take hold of the whole assemblage in two places, about an inch or two a funder, we shall find that we may draw it to near twice its length, without any risk of its separating in any intermediate part, or becoming much smaller in one part than another. It seems to yield equally over all parts.

Our readers will now perceive, that these processes will ensure all that is wanted, and prepare a roving that is uniform, soft, and still very extensible: in short, it is the last treatment of spinning, by which it is made a fine and firm yarn.

It is evident that the roving produced by these operations must be exceedingly uniform. The uniformity really produced exceeds all expectation; for even although there be some small inequalities in the carded fleece, yet these are not noticed, which the card could not equalize, but only confit of a little more thickness of cotton in some places than in others, this inequality will first be diminished by the lifting of the fibre in the breaking card; and when such a part of the sliver comes to the first roller of the drawing frame, it will be rather more fretched by the second than a third part would be. That this may be done with greater certainty, the weights of the third rollers are made very small, so that the middle part of the sliver can be drawn through, while the outer parts remain fast held.

Such is the state of the roving as prepared by the roving frame. All the preceding processes are to be considered as the preparations: and the operation of spinning is not yet begun. These preparations are the most tedious, and require more attention and hand-labour than any subsequent part of the process. For the slivers from which the rovings are made are so light and bulky, that a few yards only can be piled up in the cans to receive them from the carding and drawing: a person must therefore attend and watch each roller of the drawing and roving frames, to join fresh slivers as they are expended. It is also the most important department
MANUFACTURE OF COTTON.

ment in the manufacture; for as every inch will meet with precisely the same drawing and same twisting in the subsequent parts of the process, therefore every inequality and fault of the fibre, instead of as it quits the finishing card, will continue through the whole manufacture, in a greater or lesser degree, being only diminished, not corrected, by the drawing, doubling, &c. The spinning of cotton-yarn now divides itself into two branches. The first performed by what were called jennies, when worked by the hand, but since they are moved by the power of a mill, they are called mules; the manner of action resembles the ancient spinning with dillflap and flannel. The second method, called spinning of rovings, or water-spinning, because it was the first spinning performed by a water-wheel, is in imitation of the spinning with the fly-wheel, or jack and flyer. The two methods differ in the same manner, as the old wool or cotton-wheel differs from the spinning with the flax-wheel. Mr. Arkwright's chief invention, the substitution of the machinery for the immediate work of the human finger, was at first only applied to the manufacture of twist, or water-spinning. We shall, therefore, first direct our attention to this.

The water-spinning proceeds little more than a repetition of that gone through in making the first flwers or rovings, which are formed on bobbins, either by the roving frame, or are afterwards wound on bobbins by the hand. These bobbins are set on the back part of the

Spinning-frame, in which the roving is drawn and extended to any required degree of firmness; and the proper twist being given to it, forms it to the required thread. The spinning-frame is provided with cylinders of rollers, in the manner of the drawing-frame, through which the roving passes, and is drawn out according to the size of the thread which is required to be spun, which varies from four to seventeen times; and it is then twilled more or less, as the thread is required to be hard or soft; therefore, the spinning proceeds scarcely differs from the roving, except in the twist that is given it, after the half stretching, in its length. This is much greater than the roving, being intended to give the yarn hardness, and firmness, so that it will afterwards break rather than stretch any more. The perfection of the ultimate thread or yarn depends, in a great measure, on the extreme softness of the roving; for it is this only which makes it susceptible of an equable stretching, all the fibres yielding and separating alike; and this property will be greatly influenced by the quality of wool given by the roving-frame. For these points no very distinct rule can be given: it varies in different mills, and with different species of cotton wool, as may be easily imagined. The immediate mechanism, or manipulation, must be skillfully accommodated to the nature of that fibre, which the fibres of cotton exert on each other, enabling one of them to pull others along with it. This is greatly aided by the contorted curled form of a cotton fibre, and a considerabie degree of elasticity which it possesses. In this respect, it greatly resembles woolen fibres, and differs exceedingly from those of flax; and it is for this reason that it is so extremely difficult to spin flax in this way: its fibres become lank, and take any shape by the slightest compaction, especially when damp in the slightest degree. But beside this, the surface of a cotton fibre has a hairiness or roughness, which greatly augments their mutual friction. This probably is the reason why it is so unfit for tents, and other dressings for wounds, and is refused by the fopages even in the meanest hospital. But its hairiness and elasticity fit it admirably for the manufacture of yarn. Even the shortness of the fibre is favourable; and the manufacture would be very difficult, if the fibre were thrice as long as it generally is. If it be just so long that, in the finished thread, a fibre will rather break than come out from among the refl, it is plain that no additional length can make the yarn any stronger, with the same degree of compaction by twisting. A long fibre would indeed give the same firmness of adherence, with a smaller compaction by twisting. This would be an advantage in any other yarn; but in cotton, the compulsion is already as great as can be allowed; were it less, it would become woolly and rough by the smallest usage; and it is already too much impregnated to tease out. Now, suppose the fibres much longer, some of them may chance to be stretched along the fibre through their whole length. If the fibre is pulled in opposite directions, by pinching it at each end of such long fibre, it is plain that it will not stretch till this fibre be broken up, or drawn out; and that while it is in its extended state, it is acting on the other fibres in a very unequal manner, according to their positions, and renders the whole apt to separate and draw more irregularly. This is one great obstacle to the spinning of flax by similar machinery.

Mule-spinning.—A great proportion of the cotton is spun in the mule instead of the water-frame. The preparation it undergoes for either method is the same; at least the processes are similar, except that the quantities of draft, and some other particulars, may be varied in the preparation of the cotton which is to be thus spun in this machine, which is called a mule, either because it is a kind of machine which might easily be turned by a mule, or more probably because it is a sort of mongrel, partaking of the nature of both drawing and spinning, or uniting the action of both the roller and spidle. It consists of three sets of fluted brass rollers, the flutes of which turn into each other. The first set goes faster than the second, and the second faster than the third; which, when the fibre of carded cotton enters, it is a little lengthened out between the first and second, and farther ill between the second and third; after passing which, it is slightly twisted by the rapid circular motion of the spidile. This has the same effect as the spinning-frame; but the quantity of draft between the rollers, or extension of the fibre, is not, like the water-frame, to the full extent which the thread is intended to be. The remainder of the stretching is performed in this manner: the spidile of the mule, which give the twist to the thread, are fitted in a frame, so that they can be moved backward and forward in a straight line, and from the rollers; a certain length of the roving being therefore given out by the rollers, the spidiles are removed backward to take it up as fast as it comes, and in this motion they twist it lightly: at the same time, but after a certain quantity of the roving, a yard for infiance, has been given out by the rollers, their motion ceases; but the spidile continues to recede from them, another half yard for infiance, continuing to twist the thread all the while. By these means, it is evident that the thread will be stretched from a yard to a yard and half in length; by this contrivance, the cotton will bear a greater degree of extension than any other, because it is constantly twisted at the same time that it is extended in length. The invention of mules forms quite an epoch in the history of the cotton trade. A vast improvement was made, about 35 years ago, by the introduction of the spinning jennies. By this invention, from twenty to forty spidiles were turned at a time. The spidiles were the same as the mule, and had the same motion; but this machine was not provided with rollers to draw out the cotton, previous to twisting, merely depending upon the stretching, to give it the proper extension requisite to form the roving into a thread. But the combination of the jenny with Mr. Richard Arkwright's invention of drawing, by rollers, forms a method superior to both, at least
MANUFACTURE OF COTTON.

leaf for fine goods. The method of stretching gives the means, as we have before mentioned, of very great extension; but if this be carried so far as to draw out the coarse loose roving to a fine thread, there will be great danger of its drawing irregularly, that is, more in one place than another. In the original method by the Jenny, the rovings were prepared by the hand-wheel: they were loose, coarse, untwisted threads, partaking somewhat of the nature of cardings, though approaching in some degree to spun twist. They were obliged to be prepared by the hand-wheel, because the cardings, which were prepared by hand-cards, were in detached pieces of a certain length, and regularly tapering towards each end: the joining of these together, in such a manner as to produce an equal and regular roving, required a care and attention which could not be effected by machinery.

The combination of Sir R. Arkwright's system of preparation with the Jenny produced the mule, which, without the defects of its original, is now in the most expeditious and perfect manner. The advantage of this mode of preparing the threads over that of the Jenny is, that the fibres of the cotton are all laid longitudinally, and nearly in as small number as is wanted, before they are begun to be much twisted; by which means, threads of any required fineness are made much stronger than they were from rovings, made upon the spindle of the hand-wheel in the Jenny, which twisted them too much in the first instance; and in the subsequent extension or stretching, by the removal of the spindle, for rendering them finer, many of the fibres were necessarily broken. On one of these mules 240 threads are often spun at once; and two of them may be managed by one woman, with a child to tie the threads which may occasionally break.

It is needless, as the Jenny has become an obsolete machine in the cotton manufacture, to enter into any further details, particularly as the mechanism so nearly resembles the Jenny still used in the Woollen manufacture. See that article.

The reader moderately acquainted with mechanics, cannot but perceive that by each of the operations now described, the cotton-wool is prepared, and drawn into a fine strong thread, by repeatedly drawing the sliver till its fibres become straight, then reducing it in the roving frame to a coarse thread, and by a flight twisting giving it sufficient strength to bear such an extension as will reduce it to the size intended, and then it is immediately twisted into a hard thread. All these processes are only a substitute for a single pull of the finger and thumb of the spinner, which the mechanist accommodates precisely to the peculiar condition of the lock of wool which he touches at the moment; he can follow this through all its irregularities, and, perhaps, no two succeeding plucks are alike. But when we cannot give this momentary attention to every minute portion, we must be careful to introduce the roving in a state of perfect uniformity, and then every inch being treated in the same manner, the final result will be equable, and the yarn will be uniform.

The thread being now finished, either by the water-frame or mule, it is carried to the Reel, by which it is taken off the bobbins of the spinning frame, or the cops of the mule, and formed into hanks. The hank is a measure in cotton trade, composed of seven legs, each of 120 yards in length. The reel or frame round which the thread is wound is one yard and a half in circumference, and at every 80 turns (or bouts) which it makes, the 80 turns of the thread are tied together to keep them separate, and this measures out 120 yards, which is called a ley: but the thread is not cut at the ley, it is continued to be wound on the reel, till seven such leys, or 840 yards, are reeled: it is then cut and called a hank, which is tied up.

The different sizes of cotton yarn, or thread, are denominated according to the number of these hanks which will weigh a pound. The hank of 840 yards in length is the measure used in all English cotton-mills, and thus affords a very accurate and convenient standard for the size of the cotton. The number is ascertained by weighing each individual hank in a little weighing instrument, which flies by an index what number of such hanks will weigh a pound. Each hank being twilled up is suspended on the hook of this instrument, and the number being ascertained, the hank is put on a proper shelf till they are all forded. Then by a table on purpose it is seen how many hanks of any number will weigh reals, and this number being counted out from any one shelf, is packed up in the bundling prefs, and tied in papers, marked, and sent away for market. Sometimes, the cotton intended for weaving is warped in the warping-mill before it is sent away from the mill; this saves the weaver an immense deal of trouble.

Some of the twill is wound on quills for the shuttle; and others, again, are formed into hanks, some of which are tightly bound round at certain intervals previous to their being dyed, in order to prevent the parts if tied from taking the colour. This is done that the threads may be disposed to warp in the weaving loom, so as to produce the clouds which are seen in various species of the cotton goods, especially gingham.

Some of the cotton thread is dyed in the hank, and other cotton which is intended for weaving, knitting, \\
&c. or to weave fine goods, is bleached; and because in this process, or in dyeing, some shrinking takes place, it is wound from the hanks upon bobbins again by the winding machine, and from these bobbins it is again reeled into hanks, in which it is packed up and sent to market: other cotton thread for weaving, mending, and domestic use, is wound into balls of a figure resembling a cake, and the many interjections of the thread are so managed as to produce a very beautiful appearance.

The denominations of the quality of the different kinds of cotton threads are chiefly divided into yarn and twist, and this is called mule twist, or water twist, as it is spun either in the mule or water-frame. That thread which is denominated water-twist, is used for weaving calicoes, &c. It is spun hard, that is, with a great deal of twist, so that it forms a strong hard thread. It is manufactured of all numbers, from 10 to 60 hanks per pound. The mule-twist is used for weaving mufflins and the finest cotton goods. The essential differences between this and the water-twist are, that the mule produces much finer articles than are attempted on the water-frame, at the same time it makes a softer thread. As it requires much less power to work it than the water-frame, the manufacturer spins every thing in the mule which will admit of it; but it will only produce the soft kinds of thread. The mule will spin all numbers, from the lowest to 150 or 170 hanks per lb. The trade of Manchester is chiefly mule spinning, whilst the water-twist is mostly spun in the country by water-mills, because the great power it requires is too expensive for steam-engines, at least the water-mills have the advantage, being usually in situations where they have their power at a less expense than those turned by steam-engines.

Stocking yarn is spun softer than twist, and two threads are afterwards doubled together in the doubling machine, and then slightly twisted round each other in the twisting machine.
MANUFACTURE OF COTTON.

china. Sometimes one of the threads is dyed black, or blue, before the twisting, and then it produces a speckled thread, which is called one-thread white. This yarn is chiefly used in theocking-frame; it is spun in all numbers, from 10 hanks in the pound up to 60. The threads of flocking yarn are but slightly twisted, so that its composition of two threads is always distinctly visible.

Sewing cotton is made either from twist or cotton yarn doubled, and twisted very hard together by passing it a second time through the spinning-frame, so as to form a strong thread, which may be compared to a small rope, as the two threads make one very compact and defined thread.

Mending cotton is the same as sewing, but of less twist: indeed the distinction is trifling.

Knitting cotton is twisted with two or three threads, but not so hard twisted as sewing cotton, though it is harder than mending. This cotton is frequently bleached after it is twisted.

Candlewick cotton is a very loose coarse thread, made from the cheapest and most inferior kind of cotton: being only intended for the wick of candles, no great care is used in the manufacturing. A great deal of candlewick is made from tow which is bleached, and makes an article something like the cotton in appearance, but by no means equal to it in quality. This is known by the cant term of bump, and many large mills are employed in spinning it. The cotton candlewick is known by the name of Turkey, which is made from Smyrna or other cheap inferior kinds of cotton. It is spun generally about 10½ to 11 hanks per lb., and sent off to market wound up in large balls. Oxford candlewick is made from inferior cotton, about seven hanks to the pound. Wiltshire candlewick is made from wale cotton, about No. 7. These articles are spun without the care requisite for yarn or twist: they are usually spun by mules, and in some mills for coarse goods they do not take the trouble to form them into rovings at all, but spin the candlewick at once from the fivers, as prepared by the drawing-frame.

To pursue the progress of the cotton after being spun into twist, we must remove from the cotton-mill to the cottage of the weaver. Here, the warp being fixed in the loom, or, in the language of the weaver, warped, it is divided to give passage to the weft in the shuttle, either by two, three, or more treads; or if the pattern or course of changes in the order of raising and depressing the threads of the warp be various, so that the weaver could not manage the requisite number of treads, it is done by a great number of strings which pass over pulleys above the loom, and are drawn one after another by a little boy, above whose head they are disposed in two rows by the sides and between two looms. These looms are, therefore, called draw-boys. These boys will shortly be set aside for machinery, which is rapidly introducing a substitute. For the formation of sprigs, &c. of various colours, there are often as many flutes as there are of little fivelooms, such as they use for the weaving of tapes, introduced occasionally, as many as there are sprigs in the breadth of a piece. Quiltings appear to be two distinct cloths, tied as it were together by ditches, which go through both cloths, and in some cases, as in bed-quilts, there is a flannel which throws in a quantity of coarsely spun cotton, to serve as a kind of wadding. The counterpanes are woven with two flutters, one containing a much coarser weft than the other; the coarser of the threads is picked up at intervals with an iron pin, rather hooked at the point, so as to form knots disposed in a fort of pattern.

When the goods are come from the loom, most forts of them, previously to being bleached, are fired or dressed, by being drawn, and that not very quickly, over red-hot cylinders of iron, by which the superfluous nap is burnt off. To see such an operation performed upon so combustible a substance, naturally fills a stranger with the utmost concern and astonishment. They are then washed in a wheel with soap and water, and having been well scourced with an alkaline liquor, are dipped in the oxygenated muriatic acid, diluted to its proper strength. These preparations are repeated alternately, till the goods have attained the requisite whiteness; and between each dipping they are laid out upon the ground, and exposed to the action of the sun and air. When completely bleached, they are either smoothed upon long tables with smoothing irons, or calendered; that is, stretched and pressed between a course of rollers, by which they acquire a fine gloss. Callicoes are printed exactly in the same way as the kerseymeres in Yorkshire, but the works are usually upon a much larger scale. See PRINTING.

Thicklets, cordarous, velveteens, &c. are cut upon long tables, with a knife of a construction somewhat like the fling of a wafp, terminating in a very sharp point, defended on each side by a sort of sheath. This point is introduced under the upper course of threads which are intended to be cut, and with great ease carried forward the whole length of the table.

The rapid increase of the cotton trade appears to have been owing, in a great measure, to the more liberal introduction of machinery into every part of it, than into any other of our staple manufactures. The utility and policy of employing machines to shorten labour, have been a subject which has exercised the pens of many ingenious writers, while their introduction into almost every branch of manufacture has been attended in the outlet with much riot and disorder. They are undoubtedly wonderful productions of human genius, the progressive exertions of which neither can nor ought to be stopped; they enable a manufacturer to produce a better article than can be made by the hand, in consequence of the uniformity and certainty of their operations, and at a much lower price, in consequence of the vast quantities of goods they are capable of performing. They thus support the credit of our manufactures abroad, and enable us under the vast load of taxes, and consequent increase in the price of every necessary of life, to meet our foreign competitors with advantage at market. They can even allow the goods to furnish in their passage a considerable revenue to government. And although they do, undoubtedly, on their first introduction, throw some persons out of employ, by changing the nature and course of business, they almost immediately make up for the inconvenience by astonishingly multiplying the absolute quantity of employment. If they have taken away work from carders and spinners, they have returned it them back tenfold, as winders, warpers, weavers, dressers, dyers, bleachers, printers, &c.

It is this machinery which we have now to explain. An extensive cotton mill contains most interesting specimens of human ingenuity and resource, and flows in a flashing manner what may be done, when the talents of a great number of individuals are directed to one common object, and where the most trifling part is of such importance (from the frequent repetition of it which is necessary) as to become worthy the consideration of the manufacturer to devise machinery for accomplishing it in a better or cheaper manner. There is, in the cotton trade, such a spirit of improvement, that they have, as a body, a prejudice in favour of old established customs than perhaps any other class of men: this is doubtless a reason of the great perfection of their art.
as they have made trials of new ideas, without those years of reflection which men in other trades require before they will venture to embark in any new improvement, though ever so promising and favourable in appearance.

Our readers, who are unacquainted with the subject, will now by this sketch have obtained such a general idea of the cotton manufacture, as will enable them to comprehend the technical terms which are necessary to be used in the subsequent explanation of the machinery, and those references which must sometimes be made from one process to another. A large cotton mill is generally a building of five or six stories high: the two lowest are usually for the spinning frames, if they are for water twist, because of the great weight and vibration caused by these machines. The third and fourth floors contain the carding, drawing, and roving machines. The fifth story is appropriated to the reeling, doubling, twilling, and other operations performed on the finished thread. The sixth, which is usually in the roof, is for the batting machine, or opening machine, and for the cotton pickers, who for a large mill are very numerous. This loft is not always so occupied; many manufacturers thinking it better to have out-buildings for these parts of the process, and only to have such parts in the mill as require the aid of the large water-wheel, or steam-engine, which turns the whole mill. If the mill is used for spinning instead of the water frame, then the cards are usually put below, because they are then the heaviest and most powerful machinery.

The first machine we shall describe is the Batting machine. Plate II. Cotton Manufacture, fig. 1, is an elevation sideways, and fig. 2, an elevation endways, the frame being in both described by dotted lines, that it may not obscure the mechanism: figs. 3, 4, and 5, are detached parts of the machine. The moving power is communicated by the mill to an horizontal axis, on which the fly-wheel, C, is fixed, to regulate the motion. On this axis four cranks are formed, as shown at i, ii, iii, iv, making equal or right angles with each other; and connecting rods, b, being extended from these cranks to the lower ends of the levers, g, g, which are moveable on the centres, f, cause them to vibrate alternately when the cranks are turned. There are four of these levers situated on each side of the machine, all the four on each side having one common centre at f. Each crank on the main spindle has two connecting rods upon it, to actuate two different levers; but which are situated on opposite sides of the machine, of course receive their motion alternately: at the upper ends, e, e, of the levers which, as the figure shows, are much longer than the lower ends, that is, the centre of motion, f, is placed considerably beneath the middle of the levers. At the upper ends, e, e, of the levers joints are formed, by which they are connected with rods, x: these perform the batting, by flinging in the manner we shall describe upon the platform A, where the cotton is spread. This platform is formed of a long cord, which is repeatedly passed over two rollers, one of which is shown at m, and the other is at the opposite end of the machine: the cord passing round from one of these to the other twenty or thirty times, and having all the turns made parallel to each other, at about an inch asunder, it forms an horizontal platform for the support of the cotton; but to fill up the interstices between these ropes another stationary fet is placed. These are strung between two fixed beams of the frame, as shown in fig. 4, which is a plan (and a section is situated immediately beneath it: The roller m, fig. 1, is kept in continual rotation by a train of toothed wheels, marked k k k k l, which communicate the motion by a pinion on the main axis from one to another, and lastly to the roller by means of a contrate wheel h, in which a pinion acts. By these means the endless rope, which extends from one roller to the other, and forms one-half of the platform for the cotton, is in constant motion, and the cotton which is laid upon it at one end travels slowly to the other, receiving in its passage the blows of the rods x, which strike upon it alternately. Their action is produced in this manner; the levers g, g, are forked at the upper ends, as shown in fig. 5, so as to afford a sufficient length of bearing for a short axis 3, 4, on which the rod x moves. The small dotted circle 3, in this figure, represents the place where the rod unites with the axis, or rather where a small iron tube proceeds from the axis; and in the end of this the wooden rod, x, is inserted, and held fast by means of a screw clamp, or hoop, surrounding the end of the tube, and comprising it upon the rod, one side of the tube being split down to admit of this compression. Upon the same axis as the rod x are fixed two small pulleys 1, 2, to each of which a strap is attached, and, after making a turn round their respective pulleys, these are conducted away to a fixed part of the framing, in the manner shown in fig. 1. These straps are of such a length, as to hang loose during a greater part of the time; but when, by the motion of the top of the levers g, g, fig. 3, they come to their tension, they operate upon the pulleys 1 or 2, fig. 5, and turn them half round with their axis, at the same time turning over the rods x, x. This motion is more clearly explained by fig. 3, which will, at the first view, be seen to be only a detached sketch of the parts already described in fig. 1. A represents one of the vertical levers (g, g, fig. 1.), and B its centre of motion, upon which it travels from the position A, to that represented by the dotted lines B, by the action of the crank rod joined to the lower end of it, as before described; therefore the two positions, A, B, are to be considered as the extremes of its motion. E represents the pulleys which are fixed on the axis of the batting rod b, the two appearing as one in this view. One of the straps of these pulleys is fastened by one end at m to a fixed part of the frame, and the other end is made fast to the pulley at o. The other strap has one of its ends fastened to the pulley at k, while the opposite end is attached at i to a lever i m, whose centre, G, is stationary. The lower end, m, of the lever has a strap attached to it, which proceeds to the lever A, and is made fast thereto at l. The operation of this connection may be thus explained: in the position B, the strap, if, (answering to ik in the other position) hangs dead, as in the figure, while the other strap, ir, has come to its tension, and has turned over the batting rod to the position g. Now, suppose by the action of the crank rod the lever is moved towards the position A, it proceeds for some distance with the rod g, remaining horizontal, and merely drawing along endways; but when it is advanced rather more than half way, the straps, l m and ir, come to their tension: the former pulls the lower end, m, of the lever, m i, after it, and, of course, the upper end, i, at the same time moving in an opposite direction, draws the strap, il, with it, turning the pulley E, and the batting rod attached to it, over into the position b, and flinging on the cotton spread on the platform. This motion is performed almost instantaneously, because, the strap i k being drawn in one direction, whilst the centre of the pulley it is fastened to moves in an opposite direction, these motions cause the pulley E, and the batting rod which is attached to it, to turn over with a double velocity, to what it would have had if simply actuated by the motion of the lever A; so that this rapid motion causes the batting rod to fling with an exceedingly smart stroke upon the cotton laid upon the platform. In
returning back again to the position B, which the crank causes it to do very shortly after having made the stroke, it proceeds, as before mentioned, to the beyond half way, with the irars hanging slack and having no action; but when it has pased rather more than half way, the irar, n, becomes tight, and turns the pulley over, bringing the batting rod to the position g, ready to make another stroke; but in turning it over to this position, the rod does not move with such velocity as to strike a blow upon the cushion d, fig. 1, which is placed to receive it, because the irar, f, is fixed to a stationary point n, instead of having a motion in the opposite direction to the lever, as the other irar l, which caufed the stroke upon the cotton. In fig. 1. the frame is marked B, and o, o, represent the levers i, C, m, fig. 3. The lever g, fig. 1, which is nearly in a vertical position, appears to have two of the rods x proceeding from it in opposite directions. This appearance is occasioned by there being two levers in that position exactly behind each other; though they are moving in opposite directions, therefore one of the rods, x, remains upon the cotton at A: the other, which belongs to the lever concealed behind, is represented as just rising from the cushion d. Fig. 2. is an edge view of the machine, where A represents the irar which communicates motion to the machine by means of two pullies, called the live and dead pulley, from the circumstance of one pulley being fitted loose, so as to flip round freely upon the axis, whilst the other pulley is fixed fast upon the axis: therefore when the endlefs irar is shifted upon the loose or dead pulley, it flips round without communicating any motion to the machine; but when it is shifted on the other pulley, the machine immediately commences its motion. E represents the fly-wheel on the opposite end of the axis, and B, B, B, B, are the four cranks which actuate the levers C, C, C, C: f is one of the rollers on which the endlefs cord or platform, D, is wound, and it extends from this to a similar roller on which a wheel, g, is fixed; then returning again to the rollers, f, and after having made in this manner more than twenty turns round the two rollers, the ends are strained tight and fixed together, so that it appears like fig. 4. forming a platform on which the cotton lies, and is regular in its motion from f to g by the motion given to the roller f through the cog-wheel e, and the other train of wheel-work which communicates with the main axis, as before described. At the sides of the platform two boards are fixed which form a trough, and prevent the cotton getting off sideways. The batting rods strike down through openings or notches d, d, d, d, cut in these boards. The dotted lines represent other notches to admit the batting rods on the opposite side of the machine, which, as in this figure shews, are not precisely opposite, but the rods on one side strike in the interval between those of the others. The cotton, after passing along with the moving cords through the machine, is thrown off, and falls upon a table i, fig. 5, which is covered with an endlefs canvas cloth, and is strained over two rollers b, k, which are kept in constant motion by an endlefs band passing round the wheels b and g. By this motion of the cloth the cotton is conveyed away as fast as the batting machine finishes it, and is taken off this table by women, who discharge it into baskets, in which it is conveyed to the picking room. The opening Machine, or Doxil.—This machine comes next to be described, being used for similar purpofes as the batting-machine, though it is not to be confidered as one of the fame feries, being used for the coarser fort of cotton in the fame stage as the batting engine is used for the finer forts. Plate 111. contains drawings of one of these machines, in which fig. 5. is a plan, and fig. 6. a section. In either of these A A represents a cylinder, put in rapid motion by an endlefs band passing round the pulley K. This cylinder has a great number of teeth fixed into its periphery, and the hood or arch, E E E, contains a set of similar teeth or spikes fixed withinide it. This cating consists of a number of parallel bars or lags, one of which is shewn in perspective in fig. 5: these are supported by an iron semicircle B B, fig. 3, also erected on each side of the frame. Each of these circles has a number of pins, P P, projecting from it, and every lag has a notch, or cleft, cut at each end, by which they are hung on these pins, forming a very fimple manner of fixing the lags; but they can be easily removed when required, to clear the machine from the flue and impurities which it gets out of the cotton. In front of the cylinder a pair of feeding rollers, d, d, are fixed, through which the cotton passes to the machine: these rollers are fluted and placed immediately above each other, as shewn in fig. 3; then a heavy weight L, being suspended from the pivots of the upper roller, causes them to press together with a fufficient force to draw cotton in between them, and the flutes or indentations of the two rollers mutually locking into each other, they take the cotton more certainly. The lower roller is turned round by means of a bevelled wheel l, fig. 1, fixed on the spindle, which receives its motion from a similar bevelled wheel k, fixed on the extreme end of a spindle I, fixed perpendicularly to the axis of the main cylinder, and receiving its motion therefrom by a wheel b, which is turned by an endlefs screw g, cut upon the extremity of the spindle of the great cylinder.

The cotton is spread upon an endlefs revolving cloth, which is strained between two rollers, a, b, and is in conflant motion, in the direction of the arrow in fig. 2. This motion is communicated to the roller, a, by means of equal cog-wheels d, d, which are connected by an intermediate toothed wheel, as shewn in fig. 2; M S is a grating, or frame of brafs wire (shewn separate in fig. 4.) which is extended beneath the cylinder, and against this the cotton is urged by the action of the teeth of the cylinder, and the dirt, dust, and flue, escape through it. It should be understood, that the frame for the machine is closely boarded up on all sides, to keep in the dust and flue which is separated from the cotton. Fig. 5. shews the manner in which the teeth are disposed in it, so that the teeth in the several rows oppose the spaces between the teeth of the others: at i is a small flip of sheet iron, which stands up perpendicular to the face of the lag like the spikes, and is supported by a kind of wedge, or prop of wood, as seen in the section of the machine, fig. 2. These flips of iron run across the whole length: the teeth on the cylinder are disposed in a similar manner, and are provided with a similar iron plate. Their use is to retain the cotton which is worked in the machine from passing through too quickly, and escaping without being sufficiently worked by the teeth. The cotton is spread evenly upon the cloth b d, which being in conflant motion towards the cylinder, carries the cotton along upon it, and delivers it between the two rollers d, d: these give it regularly to the cylinder, which is rapidly revolving in the direction of the arrow near A: its teeth take the cotton, and carry it round between the cylinder and the hood, working it between them, to open and unravel every knot or tuft of cotton, part of which gets formed by the action of the cylinder into a small roll at every one of the iron plates i, and this roll, by the motion of the cylinder, keeps revolving slowly round, so that every part of its circumference is successively subjected to the action of the teeth of the cylinder.
MANUFACTURE OF COTTON.

as they pass by them. The plates upon the cylinder act in a similar manner, and when the cotton is thrown out imbibed at M, upon the floor immediately beneath the feet cloth, it has been opened in every part, so as to completely disentangle it, and the dust, cotton feeds, or any other extraneous matter, drops out through the wire grating, S M, upon the floor.

The opening machines used in some of the most improved mills, are provided with two cylinders revolving against each other, so that they resemble two of those machines put together, by which means the cotton is more completely worked in pulling through them. The cylinders have then none of the plates fixed upon them, because they are unnecessary, and the spikes or teeth are arranged in a spiral line round the circumference of each cylinder, so that they do not in their motion fall behind each other, and therefore work and open the cotton more effectually. Another great improvement in this double cylinder machine, is the addition of a flue or trunk, which proceeds horizontally from the opening or mouth M, where the cotton is delivered, for a considerable distance, and in the bottom of this is a revolving flue, which receives the cotton as it is thrown out, and conveys it away to the end of the room containing the machine. Here it falls out into a basket, in which it is conveyed away to the picking room. The flue or trunk at this point rises up, and leads into a chamber of considerable size, and from this returns by a small trunk to the back of the machine. The operation of this trunk is, that the wind raised by the rapid motion of the cylinders proceeds along this narrow trunk with a considerable velocity, and blowing along over the surface of the cotton, which is traversing slowly along with the endless cloth in the bottom of the trunk, it carries away the flue or small cotton with the stream into the large chamber above-mentioned. Here, in consequence of the large area which the air has to pass through, the current is very slow, and the flue subdues quietly on the floor of R, from which it may be taken up in considerable quantities every week, and is a valuable article for making candlewick, or to mix with inferior cottons for that purpose; whereas, if suffered to fly about in the rooms, as in the machine delineated, it does great injury to the work people, for this flue is taken into the lungs by the respiration, causing asthma, and pulmonary complaints; but in the improved machine, this flue is preferred for useful purposes.

The next machine, in the order of the cotton manufacture, is the Carding machine. This is shown in Plate IV., where fig. 1. is a plan, fig. 2. a section, fig. 3. an elevation, and fig. 4. various parts to explain the action of this machine. It will not be amiss first to give a short idea of the nature of the operation to be performed by the machine. The card may be compared to a brush made with wires instead of hairs, fluff through a fleec of leather; the wires not being perpendicular to the plane, but all inclined one way in a certain angle. See fig. 4. of this plate, D, C, are these fleeces of leather for a pair of cards, and A, A, or B, B, represent the teeth or card-wires respectively belonging to each. Beneath is a view of one wire, inflated, showing the two teeth, with their bend in the flank, or what is called knee-bend, by which they are inclined to the leather in the manner before mentioned. Now we may conceive that, cotton being flue upon the teeth of one of these cards, another may be applied to it, and combed or scraped in such a direction as to strike the cotton inwards upon the teeth, rather than tend to draw it out. The consequence of a repetition of the strokes of the empty card, in this direction upon the full one, is a more equal distribution of the cotton upon the surface of the card-teeth; and in doing this, the fibres are combed and laid straight. Then if one card be drawn in an opposite direction over the other, it will, by consequence of the inclination of its wires, take the whole of the cotton out of the card, whose inclination is the contrary way. In this mode, the operation was formerly conducted by fleeces of cards nailed upon boards, which were worked together by hand. To explain how the carding machine imitates this process, we must return to the figures, in which A A is a large cylinder, turned rapidly round by an endless strap on the pulley R. The surface of the cylinder is covered with cards, the fleeces of leather for which are glued or nailed on in stripes or fleeces parallel with its axis, and disposed in such a direction, that when it revolves in the direction of the arrow, the teeth upon it go with their points forward, so that if a lock of cotton was held against them, it would be drawn inwards upon the teeth. The cylinder revolves under an arch C C, lined with the same kinds of cards as shown in fig. 2.; the teeth disposed to meet those of the cylinder. This arch of cards is supported on two iron arches, fixed on each side of the cylinder. These iron arches or bridges have spikes on them, on which the several pieces, lags, or flats which compose the arch are fastened; exactly the same as described in Plate III. of the opening machine.

One of the iron arches is shown at E E, in fig. 2., but is not drawn off its full breadth, because it would have concealed the surface of the cylinder from the sight; but in fig. 1. they are seen at C C, and in fig. 3. at f f. The card-teeth on the cylinder, and those beneath the arch, do not touch each other, but work as close together that a half crown can be put in the space between them without touching, and they are made very accurately circular, that they may always accurately preserve the same distance between.

B is a second cylinder of cards, the teeth meeting the first, as the figure shews. This cylinder revolves much slower than the first, its motion being taken from a small pinion, \( Z \), on the end of the axis of the great cylinder. This works a wheel, situated on a flue or pin \( z \), which has also a pinion fixed to it, working a wheel \( t \), fixed on another flue, and this carries a small pulley \( v \), which communicates by an endless strap with a pulley, \( E \), fixed on the end of the pinple of the small cylinder. As the whole of this train of wheel-work consists of small wheels turning large ones, it is plain the motion of the cylinder, B, must be very slow. On the opposite end of its axis is a bevelled wheel W, working another upon the end of an axis \( h \), which has, at its opposite extremity, a pinion, turning a face or contrate wheel \( i \), which is on the axis of the fluted feeding rollers between which the cotton passes, and is delivered to the cylinder. The cotton is, as was before described of the opening machine, spread out upon a feeding cloth D, which travelles constantly round two rollers \( k \) and \( l \), one of which is turned by a pinion from the feeding rollers by means of an intermediate wheel at \( k \). A small heavy roller, or cylindrical weight, is put upon the cloth beneath, as shewn at \( f \), fig. 2.; and, by its weight, always keeps the cloth to its proper tension, preferring a flat surface above, for the cotton to be spread out upon, and then advancing with the cloth, it is thrown in between the fluted feeding rollers, which deliver it gradually and equally to the cylinder, which carries it round, and works it against the cards fixed within the arch. In this process it becomes very equally distributed over the teeth in the cylinder, and gets carded in so doing. The cotton continues in this manner hanging sometimes in the teeth of the cylinders, and sometimes in those of the arch, but advancing slowly from one tooth to the next, till it has passed clear through the arch, and then it comes to the small cylinder \( B \), which, as before-mentioned, is revolving slowly, in such a direction that its surface
MANUFACTURE OF COTTON.

The surface moves the same way as the cylinder, but much slower, and its teeth meet the teeth of the cylinder. Now, as before stated, it is the property of two cards meeting each other to distribute the cotton between them; therefore, the teeth of the cylinder B, having no cotton upon them, receive a full half of what is upon the teeth of the cylinder A, and as it constantly turns round, and bringing up fresh empty teeth, which in their turn take away the cotton from the great cylinder in a constant stream, and would soon empty it, but that it is fastened again with raw cotton from the feeding roller. The cotton taken up by the cylinder B soon proceeds with it beneath, till it comes to the opposite side, and then it is removed by the 

"taker off." This is a red or iron bar fitted parallel to the axis of the cylinder, and cut on the lower edge with fine teeth like a comb. It rides and falls parallel to itself, being united to two rods, K, which are guided by sliding through small holes made in two standards shown in fig. 2, and the lower ends of these rods are jointed to two cranks e, f, fig. 3; formed on a spindle, which is turned by a pulley p, with an endless flap from a pulley, S, fixed on the main axis, close behind the great pulley R. Now by the motion of these cranks, the rod g rides and falls, and at the same time moves a little to and from the surface of the cylinder B; indeed it defibrates a kind of ellipse, and being fo contrived by the direction of the motion of the cranks (caused by efloring the flap which works them), that it is defibrating at the time when its edge is nearest to the cylinder, and scrapes downwards again, or rather between the teeth thereof, and in consequence removes the cotton from them the whole length of the cylinder at once; and the motion of the crank is so quick, that by the time this piece of cotton, so detached from the teeth of the great cylinder, has moved round with the cylinder, B, as much as its own breadth, the crank makes another stroke, and, in consequence, the second piece detached from the teeth adheres to the first; the third adheres to the second, and so on. The cotton is thus stripped or skinned off the cylinder, B, in a continued and connected fleece. The dispersal of this fleece constitutes the only difference between the breaking and finishing card. In the former it is received upon a plain cylinder, about half the size of the great cylinder A, A, which is turned round with a proper velocity by an endless cord from a pulley on the axis of the cylinder B, a small roller resting lightly upon the top of this cylinder with its own weight; and by this pressure causes the fleece to lap regularly upon the cylinder, which continues to turn until it has made 15 or 20 revolutions. The fleece, being then broken off, forms a small fleece, consisting of 15 or 20 thicknesses, called the lap, which is carried to the finishing card, and treated exactly as the raw cotton was at first. The advantage of this method of treating the cotton has been explained, in a preceding part of this article, to consist in the great equality thus produced in the thickness of the lap, which being fed to the finishing card will produce an equal and regular fliver therefrom, and on this circumstance the perfection of the ultimate thread very intimately depends.

The finishing card is that which is represented in Plate IV. The fleece or lap produced by the breaking card is spread out upon the feeding cloth D, and thus introduced to the machine, which cards it in exactly the same manner as we have described, and the take off operates in the same way. But the fleece F, fig. 1, instead of going to the lapping cylinder, as we have described, is gathered up into a tin funnel marked m in fig. 1, and in fig. 2: it then passes between a pair of rollers m n, which compress and flatten the fleece in its contracted state into a pretty firm and connected fliver or band, and deliver it into a can n. These rollers are situated upon a spindle extending across the frame, and turned round by a pulley upon the end of it, which is connected by an endless band with the pulley E, upon the spindle of the cylinder B. By these means the cotton is reduced from the wool to a fine regular and even fliver, which is conveyed away in the tin can to the drawing frame, which we shall soon describe.

The carding engines in many mills are provided with small cylinders, known among the workmen by the technical term cards. These are covered with cards, and revolve, so that their teeth act with the teeth of the great cylinder, through proper openings left between the top lugs of the arch. These small cylinders are turned round slowly by proper bands and pulleys from the main axis. These cards are situated in pairs, one of which operates to take the cotton off the great cylinder, in the same manner as described of the cylinder B, but instead of being provided with a take off, to strip the cotton from its surface, it runs close to the other arch, of similar dimensions to itself, but turning with a different velocity, and the teeth meeting, so as to take it off the first arch. This second arch, having thus become charged with cotton, delivers it again to the great cylinder. The object of this contrivance is to obtain a more perfectly equal distribution of the cotton upon the surface of the cylinder, at the same time the arches tend, by giving the cotton to the cylinder in a new direction, to work it more, as they prevent the cotton passing so quickly through the machine.

The employment of arches does not seem to afford any very great advantages, and it is not a very general system. When a card is applied to the lower part of the cylinder, immediately beneath the feeding roller, it is called a "tummer:" in this case it takes the cotton from the feeding roller, and gives it to the great cylinder as it revolves. The great cylinder of a carding engine, as well as any other part which the flue can escape, should be carefully inclosed by a tin plate, or thin boarding, to prevent its escape into the room, where it does great injury to the work people, producing an irritating and incessant cough, which is exceedingly hurtful, as well as the pernicious effects of such extraneous matter being received into the lungs. Carding engines have been used with two great cylinders, surrounded by a multitude of small arches, in the same manner as those used for wool. (See Woollen Manufacture.) These, having two cylinders, card the cotton sufficiently at one operation, without using a breaking card. The method is not near so perfect, because the equality and regularity of the fliver, produced by doubling the lap of the breaker 15 or 20 times, cannot be so completely attained by any other means, but leaves this equalization to be performed in the drawing frame. The double card, however, answers very well for coarse goods, and saves a great deal of attendance in conveying the lap of the breaking card to the feeding cloth of the finisher. Since the time that the drawing for Plate IV. was made, the cotton manufacturers have almost universally adopted what were at that time only partially employed, viz. cast iron frames for the carding machines, and iron circles for the cylinders, which are covered with lags of the best seasoned mahogany, or other wood least liable to warp. These circumstances, though they do not alter the parts of the machine, are great improvements of it, as the deadness of such framing, and the liability of their figures, enables the cylinders to run much closer together, without the danger of the teeth of the cylinder coming in contact at times, as they will sometimes do in wooden frames, and thus destroy the card teeth very soon, as well as produce less perfect work. The same remark applies to all the other cotton machines, and, in point of expense, cast iron is far cheaper than wood when
MANUFACTURE OF COTTON.

when a number of the same part are to be made, so that they can all be call from the same pattern: in point of stability and duration no comparison can be made; and when the mill is built fire proof, the safety from fire is not a trifling advantage, as it favors the manufacturer the heavy expense of insurance, or, what of course is nearly equal, the risk of losing his property by fire.

The drawing frame comes next to be described. Plate V. fig. 1 is an elevation of the machine, and fig. 2 is a plan of what is called a drawing frame of four heads, which is, in fact, a system composed of four distinct machines of exactly the same construction, but arranged on one frame, in the most convenient position to be used successively. Fig. 3 is a front view of one of the heads or separate machines drawn detached; and fig. 4 is a section answering to it. In fig. 1 A represents a clatter, consisting of four of the cans brought from the carding machine: the four rollers from these are passed through the rollers of the machine, and united into one liver, which is received in the can C, the machine having drawn it out, and extended it to four times the length of the others; it is therefore the same size as any one of them. The construction of the rollers is explained by fig. 3, and also the figure at the left hand end of fig. 2, in which a b represents a live and dead pulley, upon the spindle of the principal, or front roller, by which it receives its motion from an endless drap. This roller is shewn, in fig. 2 and 3, to be double, that is, it has two lengths or acting rollers upon it, each of which receives two distinct rollers from the cans H, H, fig. 2. In fig. 4 these two lengths of rollers appear like one, being behind each other, and exhibiting the circle marked a, the other circle descried within this being the neck between the two lengths. This roller has another, marked b, placed directly over it, the pivots of which are retained in a vertical notch in the frame, and immediately above the pivots for the lower roller, as is shewn in fig. 17; so that the whole weight of the upper roller rests upon the surface of the lower one, the bearings or notches in which its pivots are received being only to guide, not support it. Another pair of similar rollers, e, d, are situated at a small distance from the former, and receive their motion by pinions c, d, fig. 2 and 3, which are fixed on the pivots of each respectively, and are connected by an intermediate wheel, e, fitted closely on a fluid, in the manner very plainly shewn in fig. 11, which also expresses the grooves or notches in the standards; in these the pivots of the rollers are retained sideways upon one another, but, as before mentioned, the upper one rests upon the lower one. A small cross bar, i, fig. 4, extends from the pivot, or neck, of one of the upper rollers, d, to that of the other one, e; and from the centre of this bar an iron rod, with a heavy weight, f, at the lower end of it, is suspended by a hook formed at the upper end; so that this weight, as well as the weight of the upper rollers themselves, is the upper rollers, b, d, upon the lower ones, a, c, and thus the fiber of cotton, g, which passes between them, is held very firmly down on the fibers in the surface of the lower roller, and cannot slip between them. The wheel e, fig. 2 and 3, which is fixed upon the pivot of the first roller, is much smaller in diameter than the wheel, d, upon the pivot of the back roller, to which it gives motion by the intermediate wheel e; therefore it follows, that the motion of the front rollers, a, b, fig. 4, will be as much quicker than the back roller c, d, in proportion as the wheel, d, is larger than the wheel, e, which give it motion; that is, the number of revolutions they will respectively make in any given space of time (as a minute for instance) will bear that proportion: but the back roller, c, (as shewn in fig. 4,) is much smaller than the other. The velocity of its circumference will, therefore, be flower than a, in a still greater proportion than the proportion of the two wheels; and the proportion is such, that the roller, a, b, will, or ought to, draw four times the length of cotton through them which the back pair, c, d, will permit to pass in the same time. The four rollers, therefore, being introduced from the cans l, l, l, l, fig. 2, between the back rollers c, d, fig. 4, and prefixed with such force upon the flutes of the lower roller c, that they cannot slip through them, and the other pair of rollers, a, b, holding the fibers in the same manner at another part, the consequence of their different velocities is, that as the front rollers, a, b, fig. 4, move to much quicker, they draw the fiber forwards faster than the back rollers will suffer it to come; it must be drawn out, or extended in length, between the two pair of rollers, in proportion to their relative velocities, which, as before-mentioned, is the same as the proportion between the wheels c, d, fig. 2 and 3, communicating the motion from one to the other, multiplied by the proportion between the diameter of the two rollers, a and c, fig. 4.

The four rollers, after passing through these in two distinct pairs, are all drawn together through a tin funnel f, fig. 2, by means of a pair of rollers, the upper one, i, of which merely presses upon the fiber lightly by its own weight, and delivers it into the can k; the lowest of this pair of rollers receives its motion from the pinion, c, on the end of the spindle of the main, or front rollers, by means of an intermediate wheel, z, fitted upon a flud or pin in the frame, and turning a pinion, b, fixed on the extremity of the spindle of the lower of the two rollers. These pair of rollers do not draw or extend the cotton, their velocities being accurately adapted to take up the four fibers as fast as they come through the others in two distinct pairs, and by drawing them through the funnel, j, to unite the four into one, and the flutes of the roller completes their passage and connected fiber, which, though compounded of four, is only the same size as any one of the four put in, because it is drawn out to four times the length, and the effect of the machine has only been to straighten and lay the fibers parallel to each other; for the motion the drawing produces among them, always tends to extend each individual fiber to its full length: and it is necessary to unite several fibers together, or the drawing would reduce the fiber to such a small size, that it would not bear sufficient extension without separating and breaking across. The plan, fig. 2, shews the disposition of four distinct heads, or sets of rollers, A, B, C, D, all fixed upon one iron frame, E, the upright of which is shewn in fig. 1. D is the first head, or that through which the fibers from the carding engine in the cans, m, m, m, m, are first drawn and united into one, which is delivered into the can n. In this head fix cans, or ends, are shewn entering at once, in two sets of three each, and are all united into one, which will, therefore, if the rollers only draw four times be rather thicker than those put in, but the number of ends put in, as well as the draught of the rollers, is optional: and as the command of the cotton-spinner, who alters them for different kinds of cotton, or different kinds of yarn to be spun as he finds best, having the means of changing the pinions for others of different sizes. It is plain that the can, n, will be filled with the fiber in one-fourth or one-fifth of the time that the four or fix cans, m, m, will be exhausted; and, therefore, it will furnish four cans, or ends, to the second head, c, which are placed at a, and drawn into one at p. Four of these, when filled, go to q, and are drawn into one by the head B, and delivered into r, which is taken to s, and by the head A, delivered into the can d, in which it is carried to the roving frame. The several heads, as the figure shews, are revered,
referred, with respect to each other, on the frame, to avoid the necelity of carrying the cans round to the opposite side of the frame in passing from one head to the next. Being thus referred, that is, the flyer of one moving in a contrary direction to that next it, it requires the belts, which turn the several live and dead pulleys, and which all come from one common axis, on which as many drums are fixed, to be alternately crossed, and put on in the common manner.

The drawing frame in Plate V. has now (1812) been drawn some years by a gentleman at Manchester, since which, the cotton manufacturers have very generally adopted a method of using three, and sometimes four pairs of rollers, instead of only two pair in each head: by this means, they draw the cotton at two or three times, and, by extending it only a small quantity at each, it is found to draw much more equally than by taking the whole draught at once. The construction of one of these heads will be readily understood, by examining a figure in the drawing (Plate IX.) of the spinning-frame we shall shortly describe, which drawing the writer of this article made from one of the spinning-frames in one of the most complete cotton-mills in the kingdom. The rollers used in this spinning and the drawing-frame are so nearly alike, that one may be very well understood from a description of the other.

The Roving-frame.—The preceding machines having prepared a diver, of which the fibres are laid parallel, it is necessary to reduce this fibre to a convenient size for spinning into a small thread; but to make a sufficient extension to effect this reduction, it is necessary to give the fibre a slight twist as it is drawn, so that it may have sufficient cohesion to undergo the spinning.

The preparation of such rovings as shall be perfectly regular in size, and have an equal quantity of twist in every part, and which shall be exceedingly soft, is a most essential point in cotton-spinning. As it is impossible to correct the imperfections in the spinning, they will be given to the thread. A great number of different constructions of roving-frame have been in use, at different periods, among cotton-spinners; but it is only lately that by a machine, called the double-speeder, it has been brought to perfection. The old roving-can frame, first introduced by Sir R. Arkwright, is represented in Plate VI., which was drawn which that machine was much more extensively used than it is now. The figure immediately beneath the title of this plate is a plan of the roving-can frame, and the figure below is a front elevation: in this, A is a horizontal beam supported by standards at each end, and carrying the several heads of rollers, and is therefore called the roller-beam. The machine contains four heads or frames of rollers, each of which receives four ends or slivers from the cans, D, D. See also the section in the corner. They enter two together between the back roller e, and are drawn out between them and the front rollers, b, d, to the proper degree of fineness, but which varies with the quality of the yarn which is to be spun. The fibre, after passing through the rollers, is received into a tin can C, through a small funnel, N, at the mouth thereof. The can is supported on a pivot at bottom, and is kept in rapid motion by a band, working on a pulley fixed at the bottom of the can. The neck of the can, N, is guided by a collar, to keep the can steadily upright, as it revolves. The rollers of the machine are the same as those of the drawing-frame: they are turned by endless straps upon the pulleys, p, of the front rollers, coming up from similar pulleys on an horizontal spindle extended beneath the machine, through its whole length, and receiving motion by a live and dead pulley, E F, from the mill. The same spindle has pulleys upon it, which, by means of bands, actuate the pulleys on the bottom of the can. These bands are of course conducted over pulleys, to change their directions, from the vertical pulleys on the spindle of E F to the horizontal pulleys on the bottom of the can; but these are not shown in the drawings. Each of the bands drives two cans, passing round the pulleys of both. The cans are made with a door, to open on one side, for taking out the cotton-rovings, which falls into them from the rollers; and this door is kept closed by a ring, which fits upon the outside of the can, and keeps the door shut, when pulled down to the largest part of the cone; but when lifted up to the top, as shown near N, the door can be opened, and the contained cotton taken out. L is what is called the clearer: it is a piece of wood placed over the top-rollers, and pressing gently upon them; its use is to prevent any part of the cotton tempting, that is, adhering to the roller, and being carried round with it, so as to wind it up, instead of drawing it through. The manner of action, in this machine, is easily gathered from the description: the slivers pass two together through the rollers, and are reduced or drawn out therein to the proper degree of fineness; then falling into the funnels, N, of the revolving cans, they are, by the rapid motion thereof, twisted round; because the centrifugal force differs the cotton to lie round the inside of the can in a regular coil, forming as it were a lining of cotton to the whole of the interior surface; and by this means the thread of the roving becomes in a wad attached to the can, and is twisted round by its motion, so as to form a coarse loofe thread, with a very slight twist, and a very soft and open substance. The cans, when they have been in motion such a length of time as the attendant knows, by experience, they will be full of cotton, the ring is raised up, and the door opened to take out the roving, which is put into a box, and carried to a simple machine, called the winding-block: see the figure at the right hand corner of the plate. In this figure, m is an elevation, the box, containing two piles or coils of the roving, is plainly seen: just above it is a cylinder of considerable size, mounted upon a proper spindle, which is turned round by means of a wrench: k, k, are two small bobbins, mounted on a wire, and receiving the end of the roving; they rest with their weight upon the surface of the great cylinder, and are by the motion thereof turned rapidly round, so as to wind up the roving very quickly on them. The rovings are conducted through the winding holes in a slrip or ruler of wood, which is moved slowly backwards and forwards, to lay the cotton equally on all parts of the length of the bobbin, and make a cylindrical figure to the surface of the cotton wound upon it. It is the necessity for this winding of the cotton upon bobbins by a separate process, which is the great object to the roving-can frame, because the tender roving is damaged by every operation it undergoes, viz. removing it from the cans, and winding it upon the bobbins, which must be done preparatory to the spinning. Another objection to the roving-can frame is the uncertainty in the manner of twisting; because, when the cotton applies itself to the interior surface of the can, by the centrifugal force, it occasions a stretching or draught on the roving, tending to lengthen it out before it is sufficiently twisted to make any reliance to the slightest draught.

This would occasion no inconvenience, if the degree of draught or extension thus occasioned was constant, and uniformly the same; but this is not the case: for it constantly happens that the roving, by gradually gathering from the circumference toward the centre of the can, in the manner of a spiral, and when it arrives in the centre it coincides with the axis of the can, and of course, as no centrifugal force operates to draw it out in length, it merely twits it round.
MANUFACTURE OF COTTON.

round. In consequence of these irregularities in the action, which are constantly happening, the rovings thus produced are always full of thick and thin places; for when the cotton lies close at the inside of the can, it is considerably stretched by the centrifugal force, and becomes thinner and longer, and with less twist in any given length; but when it happens to fall in the centre of the can, it is of a larger fize, and of a more rapid twist; but the quantity of these irregularities is very uncertain, because, even when the end of the roving, where it rests upon the coil of it, which is settled in the bottom of the can, is in the centre of the can, it is to be presumed that no draught will take place; but this is not certain, because the roving may swing out into a belly, and by its vibration will occasion some draught, though not so great as in the fall influence. For these reasons, the roving-cans are not found to produce such perfect rovings as many other methods, and they are generally laid aside. Sir R. Arkwright saw these defects at first, and in his earliest machine devolved a pair of rollers to be placed in the mouth of the funnel of the can, which were, by very ingenious mechanism, kept in constant motion, with such a velocity as to gather the cotton fliver regularly into the can, as fast as it was delivered by the drawing-rollers. By these means the fliver was held between the rollers, and, from their revolution with the can, received a determinate quantity of twist for every given portion of length. The advantages of this were very great, to caufe the rollers, in the mouth of the can, to take the fliver with the exact velocity required, as fast as the upper rollers delivered it; and even when this was accomplished, the objections we have pointed out would in such a machine take place within the can; and after all the operation of winding the rovings upon the bobbins, preparatory for the spinning-frame, by the winding-block, is certain to do them injury, stretching and extending them improperly. The next improvement in roving was the use of skeleton-cans; these are light frames of iron, revolving on vertical pivots, in the manner of the cans themselves, in Plate VI. Within each of these skeletons or frames a common tin can is placed, and revolves with them, receiving the rovings as we have above described. These cans, when full, are removed to a machine called the stretching-frame, which gives them rather more twist, and extends them still farther in length, at the same time winding them on bobbins, which are called cops or cuppins, being bobbins of the only one end, the other end being a point, so that the cop in figure resembles a fireball, or pine-apple. The construction of the stretching-frame is the same, except in its proportions, as the mule: we must, therefore, defer the description of this method of roving till we have explained the mule, when we come to speak of the spinning process. Many mills, where cotton is spun on the most improved and economic flyflem, have adopted a method of roving altogether upon the stretching-frame, producing rovings at once from the slivers of the drawing-frame; and this method is found to succeed very well, and be a great improvement upon the method of employing the roving-can frame. We shall next describe a roving machine, called by the workmen in cotton-mills, the Double-speeder.—This is a roving-frame, which is extremely perfect in its operation, making better work than any other method: it is an improvement upon some machines made by Sir Richard Arkwright, at a very early period of the cotton manufacture; but the improvements are so effential and ingenious, that the maker or makers of them deserve the whole credit. Who is entitled to the invention of these improvements, we have not been informed; but we have seen machines, made by Samuel Smith of Rambottom, near Bury in Lancashire, which were extremely good. The drawings, entitled Plate VII., or roving-frame, Plate I. and Plate VIII., Cotton Manufacture, of which we have given an account, have, like those preceding it, been made before the improvements were brought to the perfection they have since attained; and though the machine has the same parts, the proportions are such, that a machine, made exactly after them, would not operate so completely as those made by Mr. Smith, to whom we refer cotton manufacturers, who wish to adopt such machines, rather than attempting to make them from the drawings in our plates. They will serve, however, to illustrate the principles and mode of their construction. Plate I. is a horizontal plan of the machine; and Plate VIII. is an elevation, taken in front of the machine. In this figure, A represents the live and dead pulley, which communicates motion to the whole: it is fixed on a short axis, on the extreme end of which is a pulley, B, which communicates, by an endless strap, with another pulley, D, on an horizontal axis g: and this has at the end a bevelled wheel, which turns another on a vertical axis 4, at the lower end of which a conical drum or barrel, H, is fixed; and beneath this it is formed cylindrical, to receive a strap, which passes round the pulleys, b, b, on the lower ends of the several spindles, I, I, i; and then returning to the drum again, the ends are united, and form an endless belt, which runs round the whole, turning them all at once with the same velocity; 4, 4, are small rollers, situated at intervals between two pair of the spindles, I, 1, and being bent the strap out of the straight line, and thus cause it to press against the pulleys, b, b, of the spindles, and apply to a sufficient portion of their surface, to turn them round. This is very plainly shewn in Plate I.; each of the spindles, I, I, I, has at its upper end a forked piece of iron, q q, fixed on, which is called the flyer; and one of the forks is made tubular, to receive the roving as fast as it is twilled by the motion of the flyer, and convey it to the bobbin, which is fitted quite loosely on the spindle. The cans from the drawing-frame are, as shewn in Plate I., set behind the machine; and the slivers are drawn through a double pair of drawing-rollers, turned by means of a train of wheel-work from the main spindle, bearing the live and dead pulley, A, Plate VIII. The slivers pass singly through the rollers, and are drawn out or extended finely; they then pass forwards, and two are drawn together through another double pair of drawing-rollers, the attempt to make them from the drawing-frame. Plate VIII.; a, b, are the pair of wheels which turn them from the main spindle; f f, the weights; and e, the clearer. These rollers deliver the sliver to the flyers, at the top of the spindles, I, I, where it first passes through a collar, or eye-hole, r, formed on each of the flyers, exactly in the centre of the spindle, and thence it passes through the tube, g, before mentioned, to the bobbin p: the two back pair of rollers extend or draw out the sliver twice; then the two front pair, which are shewn in Plate VIII., draw it again, and the slinders twist it once for every inch and a half. The tube of the flyer, running swiftly round the bobbin, lays the roving upon it as fast as the rollers deliver it out. The bobbins, p, p, are constructed so as to rise and fall upon the spindles, I, 1, that they may lay the roving, coming from the end of the tube, g, regularly upon the length of the bobbin. This is done by an horizontal bar, or rail of wood, N, which has holes through it, to admit the several spindles, I, 1, 1, and the weight of the bobbin p, p, rests upon it; so that when it rises and falls parallel to itself, it takes the bobbins with it, elevating them as at p, in fig. 2. In this position, the bobbin receives the roving, and winds it on the lower part of them; but as the machine continues to wind, the rail with the bobbins gradually sinks down; so that every turn of the roving falls close to, but not upon, the former turn, thus dispofing it equally through
through all the length of the bobbins; and when they have been fixed to the lowest point, and the bobbins have been filled up to the top, it rises gradually up again. This ascending and descending motion of the rail and bobbins is thus produced: the vertical axis of the conical drum, \( H \), has a bevelled wheel upon it beneath, (not seen in the figure) which turns another, \( \alpha \), fixed on a horizontal spindle; at the other end of which is a pinion, \( \beta \), turning a toothed wheel upon the end of an horizontal axis \( \omega \), which carries a bevelled wheel, \( \psi \), fixed a horizontal axis \( \nu \), which has an endless screw at the upper end, turning a wheel, \( \alpha \), upon a long horizontal axis, which has two pulleys or wheels, \( \beta \), on it: each of these receive a chain, which chains, at the lower end, support the rail \( N \); and when the chains wind up, they elevate the rail with the bobbins; but when they let down the chains, the rail, \( N \), descends. The revolution of the motion which is necessary to effect this, is done by the wheel, \( \omega \), having another bevelled wheel, exactly similar to it, fixed on the same spindle, \( \omega \), and very near to the horizontal wheel worked by it: therefore this wheel, on the spindle, \( \omega \), being made to work either in one of these wheels or the other, will, in consequence, turn round one way or the other, elevating or depressing the rail \( N \), and the bobbins accordingly; the lower pivot of the vertical axis, \( \psi \), is supported in a horizontal lever, which is, by the motion of the rail \( N \), when it arrives at the highest point of its movement, moved to bring the wheel to work in the opposite bevelled wheel, on the pinion \( \psi \); and then it turns \( M \) in a contrary direction, bringing the rail \( N \), down again; and when it arrives at the lowest point, the bevelled wheel is again thrown in gear with the wheel \( \omega \), and being thus turned in a contrary direction, it raises the bobbins up again. The connecting parts by which the bevelled wheel is shifted every time it is necessary to reverse the motion, are not shown in the drawing, but they may easily be imagined; \( x, x \), represent the weights which are suspended from the upper front rollers, the same as those used in the drawing frame.

What we have hitherto explained of this machine is the original roving-frame, tried by Sir Richard Arkwright in finding the defects of the roving-can frame. The objections to this machine in its original state were, that the bobbins, when they became filled with roving, required so much more force to turn them round, in consequence of their superior weight, than when they were empty and unladen; that they acted, to stretch or draw out the rovings, in the same manner as the can before mentioned; for the revolution of the flyer \( q \), round the bobbin \( p \), gives the twist to the roving at the noil or socket, \( s \), of the spindle; and if the bobbin was stationary, it is evident the roving would be lapped round it once for every turn of the spindle; but this would require the roving to be delivered out by the drawing-rollers much faster than they are intended to do. The consequence of the bobbin being fixed would be, that the roving must be stretched out to a sufficient length to supply as much length as the motion of the end of the tube of the flyer, \( q \), requires. Now suppose, instead of the bobbin being fixed stationary, it is only retained by the friction of rolling its lower end upon the rail \( N \), the roving will then only be stretched with as much force as will drag the bobbin round after the flyer, with as much velocity as the difference between the quantity of motion of the end of the flyer, and of the roving, as delivered out by the drawing-roller: this difference will enable the bobbin to take up all the roving as it is made.

Now it is plain, that to drag a heavy bobbin thus about, must require more strain on the roving than for a light bobbin, and in consequence, it is always drawn out smaller towards the time when the bobbin becomes filled. This is particularly hurtful, because the roving, which will afterwards spin to the greatest advantage, is so extremely delicate as not to be able to bear the slightest strain; and if the machine requires it to undergo any strain, it must be twined harder, and this will render it less fit to undergo the spinning. The manner in which these objections are obviated in the double spooler, is by introducing machinery which will give motion to the bobbin, and turn it round with such a velocity, that it will take up the roving just as fast as it is produced; but it is necessary, in effecting this, that the velocity shall be altered every time the bobbin has a new layer or roving beginning to be lapped upon it, because every time this happens the bobbin increases in its diameter, and must therefore move in such a manner as will cause its acting circumference to keep the same velocity at all times. To describe this see fig. 1, where for every bobbin, \( p \), a small pulley is shown resting upon the rail \( N \), the spindle passing through its centre. The bobbin, which rides upon it, has a hole made in the under side of it, and the wheel having a pin entering this hole, so that the wheel, being turned round, compels the bobbin to turn with it. An endless strap, \( m \), passes round all these wheels, having binders \( s \), or pulleys, which bend the strap, and cause it to act upon a sufficient part of the circumference of the wheels, to take such hold as will carry them round. This endless strap also passes round a cylindrical barrel \( L \), fixed upon the upper end of the conical barrel \( K \), which is of the same dimensions as the barrel \( H \), but inverted, that is, the large end of the barrel, \( H \), is opposed to the small end of the barrel \( K \). This being the case, as endless strap, \( m \), which is passed round both, will communicate the motion of one to the other, and if the axes of the two cones are parallel, the strap will propel the web, whatever quantity of the strap will be loosened, by acting on a small part of one cone, it will act at the same time to be tightened, or taken up as much, by being upon the larger part of the opposite cone; but it is plain that this alteration of the acting point of the strap will produce a correspondent alteration in the velocity of the motion of the cone \( K \), which is turned round by the strap. Thus, the motion of the cone, \( K \), is equable and uniform in velocity, being actuated by wheel-work from the principal spindle of the machine. Now suppose the strap, \( m \), at the top of the cone \( K \), then it acts with a small diameter upon the large diameter of the top of the cone \( K \), which therefore moves much slower than \( H \). Now by shifting the strap lower down upon the cones, the acting diameter of \( K \) is increased, while \( K \) diminishes till they come to a point, where they will be of equal diameter, and of course have equal velocities; but beneath this point, the diameter of \( K \) will be the smallest, and of course its velocity will be greater than \( H \), which actuates it. When the machine is first put to work, and the bobbins are all empty, they must move slowly, because they are required to follow the flyer round, so that they will only take up as much as the rollers produce; for if they were stationary, they would gather up, as before-mentioned, as much as the motion of the end of the flyer, therefore, within certain limits, the flower the bobbin moves, the more it will take up; and if it moved as quick as the end of the flyer, it would take up none at all. For this reason, at first starting the machine, when the bobbins are all empty, the strap, \( m \), must be at such a height up the cones, that the bobbins will have their proper velocities to wind up the rovings as fast as they are required, and the bobbins rise or fall, as is requisite, to lap the roving equally upon them; but having thus covered each bobbin with one layer of roving, and beginning to wind another layer upon it, the acting diameter of the bobbin is

Vol. XXII.
increased, and it must therefore turn so much quicker, (that is, it must make so many more turns in any given space of time,) as will cause the increased acting circumference to wind up no faster than it did when it was smaller. This seems, at first hearing, to be a paradox, that it should be requisite to turn round quicker to wind up no faller upon the increased radius; but it is to be considered that, by the bobbins being moved quicker, it follows and keeps nearer the end of the flyer tube, and therefore winds up left, because the quantity which the bobbin will take up depends on the difference between two motions, that is, the difference between the flyer and that of the bobbin which follows it. This increased velocity of the bobbin is occasioned by the lever. m being, at the time when the bobbin is filled with roving up to the top, or down to the bottom, depressed or shifted down on the cones a small quantity, which occasions, as before-described, a small increase in the velocity of the motion of the cone K, and of the bobbins. The depression of the lever is performed by a lever, which takes hold of the lever with a fork, and when urged, leads it up or down upon the conical barrel. This lever is actuated by a snail, upon the axis of which is fixed a ratchet-wheel, turned round by proper clinks, levers, and other connecting mechanism, one tooth every time the bobbins and rail, N, begin to ascend and descend, or, in other words, arrive at the extreme limits of their motion. Then the snail acting on the lever depresses the lever a sufficient quantity, to produce the alteration of velocity required.

Thus, as the bobbins increase in diameter by the addition of successive layers of the roving, they adapt their velocities to that increase, and taking it up just as fast as it is produced, and no faller, so that the roving, as it passes from the end of the flyer tube to the bobbin, is never stretched, and never becomes slack. The intelligent mechanism will readily perceive that this is practicable, but at the fame time he will be sensible of the accuracy requisite in the adjustment of such a machine to its work, and the difficulty of making this adjustment for different sizes of roving. This, perhaps, is the only bar to its general use, that it requires a skilful mechanic to attend and take charge of it, because every different size of roving, which is made in it, will require a different rate of increase or decrease of motion, by means of the lever m., for a large thread causes the diameter of the bobbin to increase more rapidly than a small one, and therefore the quantity of twist which the lever m., makes every time on the two cones K, H, must be determined by the size of the roving, as is also the height at which the lever shall stand when the machine is first let to work, and the bobbins are all empty. These adjustments are made in the lever snail, and other connecting mechanism, which are omitted in our plates. We have attended for a long time to the action of several double speeders of this kind, made by Mr. Smith, and adjusted by him, which performed their work in the most perfect manner, making a roving so loose and soft, that it would part with the lightest force, but at the same time as regular and even as possible, and the yarn spun from it was greatly superior to any which could be produced from the same material by any other means we have seen. We venture to prognosticate that the general introduction of this machine, when a sufficient number of managers are instructed how to make it work properly, will be a great improvement of a most essential department in cotton spining.

The rovings, thus prepared on bobbins, are carried to be spun, either, as before explained, in the water-frame, or mule. We shall describe the former first: it is constructed in two very different forms; and though in both the operating parts are the same, the machinery which actuates them are very different. One is called the water frame, being the original spinning frame, as first constructed by Mr Richard Arkwright, whilst the other is a more modern construction, and is known by the name of the throttle frame. Their comparative advantages we shall speak of after having described them both by the aid of drawings made from the most improved machines of both kinds. See Plate IX. which contains a drawing of

A Water spinning frame, taken by the writer of this article from Meffrs. Strutt's mill, Belper, Derbyshire, whose works are the most complete for the water-spinning trade of any in the country. Fig. 1. is an elevation in front of the whole frame; fig. 2. an elevation endways, and fig. 3. is a plan: the remaining figures are the parts on an enlarged scale. In all the three first figures, the same parts are designated by the same letters of reference: a is a bevelled wheel, fixed upon the horizontal axis, which extends through the whole length of the mill. This turns a smaller bevelled wheel upon a vertical axis B, which has a drum, C, at the lower end, and by a lever, a, actuates the whole machine. Another lever, b, goes the other way, and works another frame on the opposite side, the drum, C, being common to both. The spindle, B, passes through the drum, C, with a circular fitting, so that it flips freely round within it, without giving motion to the drum, except when it is cast into gear. This is done by two locking bolts, shewn by dotted lines pacing through the drum, and both fixed into a collar or socket-piece d, fitted to slide up and down the spindle. It has a groove formed round it, in which a fork, at the end of a lever e, is received, so that the fork embraces the piece, d, in the groove, and when lifted up, raises the two locking bolts with it. This lever is raised by the power of a second lever D E, the extremity, E, of which, being depressed, raises up the lever e, and unlocks the drum from the spindle B, by withdrawing the locking bolts from their contact with an arm, f, of a wheel, g, which is fixed fast on the spindle B, by which the drum, and therefore turns with it; but the locking bolts being let down, that their ends may project through the drum, and intercept the crofs arm, f, of the wheel, the drum and all the machinery are put in motion.

The end of the lever, a, e, passes, as shewn in the figure, the whole length of the frame, makes a turn round the pulley m., and comes back again. Other pulleys, 1, 2, 3, of the fame dimensions as e, are situated, at intervals, in a direct line between the drum e, and the pulley, m., to bear the lever, and in the intermediate spaces between these pulleys, the vertical spindles marked a are placed in pairs, exactly opposite each other. On the lower end of these, small wheels, x, called binders, are fixed, and the lever, a, e, pressing against them, as shewn by the figure, turns them round, the object of the pulleys 1, 2, 3 being to bend the lever out of the straight line sufficiently, to make it apply to the surfaces of the several binders and turn them round. The half pulley, m., is fitted in a frame, and can, by a screw, 4, be moved to strain the lever tight. Above each binder, and on the frame spindle, a wheel, is fixed: it receives two belts, b, (fig. 3.) which turn four of the spindles b, h, h, h, each belt giving motion to two spindles. The binders, x, (see fig. 5.) are fitted to slip round on their spindles n, but can, at any time, be united thereto, to give them motion by a locking bayonet q, which is cast in or out of action, at pleasure, by a small lever r, in exactly the same manner as the locking of the principal drum: therefore, by the lever r, any four spindles can be detached from the machine at pleasure. The spindles, n, of the binders have each at the upper end a pinion, which turns a face or converse wheel p, fixed upon the spindle of the front rollers which give out the cotton to the spindles. The rollers are arranged in distinct heads or frames, containing four lengths in each, which supply four spindles.
The construction of one of the heads is shown in figs. 4, 5, and 6; fig. 4, being a section of the rollers and spindle; fig. 5, a front view of the rollers; and fig. 6, an end view. In these, p still denotes the face wheel, and 4 the lower front roller. Upon this, which is fluted in the acting parts, the upper rollers 5, made in two separate lengths, are placed down upon the lower one by two heavy weights, 6, 6, which are suspended, by means of hooks, 7, from the necks or small parts of the upper rollers, and thus keep them firmly down upon the flutes of the front roller 4.

On the opposite end of the front roller to the wheel, p, a pinion, r, of eleven teeth is fixed: this turns a wheel, i, of 28 teeth, which is mounted on a flud or pin, and has a pinion, t, of 16 teeth fixed to it, which works a wheel, o, of 32 teeth, fixed on the end of the middle roller, shown in the section, (fig. 4,) at 12, whose motion will be the same as that of the roller nearest in five to one. On the other end of the roller is a pinion of 10, which turns another of 15, on the back roller, 13, by means of an intermediate wheel, so that this turns only once for one and a half turns of the middle roller; consequently, the roving 14, (fig. 4,) which is introduced between the back rollers, from the bobbins or cops set up in a frame F, (figs. 1 and 2,) above the machine, is, in passing between the back and middle rollers 12 and 13, drawn out one and a half times; then between the middle and back rollers 12 and 14, it is extended five times more, making a draught or extension of 7 / 2 times in the whole; and as fast as the rovings come through the front rollers, they are twilled into a thread by the rapid circular motion of the spindles. But these we have to explain; they are straight steel arbors, i, i, (fig. 4,) on the lower end of which the whirles or pulleys, which receives the band, i, for them, are fixed: these spindles are mounted in a frame common to them all, which consists of two rails 14, 14; the lower one supporting the points or toes of the spindles, and the other having bearings for the cylindrical parts of the spindles, and a strip of wood is screwed against this to keep them up to their bearings. Above this bearing the spindle is only a draught cylindrical wire, and on the upper end of it the flyer, 15, is fastened, either by ferreting it on, or it is &lt;f&gt;uck&lt;/f&gt; fall on by friction, which is sufficient to carry it about. The two arms or branches of the flyer are sufficiently distant for them to revolve round clear about the bobbin 16, which is fitted loosely upon the cylindrical spindle, and with liberty to slide freely up and down upon it. The weight of the bobbin is supported by reeling on a piece of wood 17, attached by ferreting to a rail M, which has a flow rising and falling motion, equal in extent to the length of the bobbin between its shoulders, by which means the thread, as it comes through the eye formed at the ends of either of the branches 15, of the flyer, and is wound by the motion thereof upon the bobbin, becomes equally distributed throughout, its length giving it a cylindrical figure, instead of having all the thread at one part, like a barrel, as would happen if the bobbin did not rise and fall. This motion of the bobbin is produced by aauloows or irones, r, (fig. 1) and 12, by revolving the rail M, with all the bobbins upon it, from the arm 16; the lower end of the other arm, 17, bears against it, and is moved by a heart or eccentric wheel 18, nearly of the figure of a heart, which is fixed on an horizontal axis extending the whole length of the machine, and at the other end it bears a similar heart 18, (fig. 1,) fixed on it, which operating upon another lever 16, suspending the other end of the rail M, thus causing it, when the hearts are turned round, to rise and fall equally at each end, or parallel, and move all the bobbins reeling upon it together. The motion is given to the spindle of the heart 18, by a small contrate wheel on the end of it, which is turned by a pinion on the lower end of the vertical spindle 19, receiving its motion by a pair of bevelled wheels from an horizontal spindle 20, in the middle of which is a cog-wheel 21, turned by a spiral piece of iron 22, which is fixed on the main spindle B, just beneath the great bevelled wheel. It operates in the same manner as an endless screw, turning the wheel, 21, round one tooth for every revolution of the main spindle, and this flow motion is communicated by the spindle 19, and wheel-work just described, to the hearts, which revolve with such a velocity, as will cause the bobbins to ascend and descend so fast, that they lie every turn of the thread close by the side of that preceding it, but not upon it, so that the figure of the bobbin, when filled with thread, will be nearly cylindrical.

The bobbins of the roving frame are put upon a wire, or temporary spindle, and in this state are set up in the frame, F, in two rows, one above another, so that they will all turn freely round when the rovings are drawn off from them. These rovings are conducted over wires, as shown in fig. 2, to lead them in the right direction, and are brought, two together, through wire flaps fixed in the board G, (fig. 4,) then through notches made in the edge of a piece of iron plate fixed on the edge of the board, and projecting up above the surface of it, and after passing through these notches the rovings enter the back roller 15, in fig. 4. The board, G, has a short traversing motion backwards and forwards, by which means it causes the roving to travel backwards and forwards between the rollers, or it would soon, if constantly conducted through the same part of the rollers, wear out the flutes at that part, making a smooth round round it; but by this traversing motion the wear is equally distributed over the whole length of the fluted rollers, and does not act partially at any one part. This motion is caused, as shown in fig. 4, where 18 is the spindle of the hearts 18, (fig. 2,) situated immediately beneath the board G: it has a 40-gear-wheel of 18 teeth fixed upon it, turning another, H, of 36 teeth, on the axis of which a small crank, K, is formed, and by means of a connecting rod draws the board, G, backwards and forwards every time it makes a revolution, by means of the cog-wheel, which will be once for every two turns of the hearts. The rovings, two together, as before stated, enter between the back rollers, and then pass forwards to the middle pair, receiving in the passage a draught or extension of one and a half; then advancing through the middle rollers to the front, they are, by the motion thereof, drawn out five times, and in this state delivered to the spindle L, which twirls the fibres round each other the instant their ends come out, before the rollers leave the other ends, or they would fall to pieces, being drawn out too fine, that the cohesion of the fibres is insufficient to bear any thing, and the twine given to the roving is entirely lost, for it was at first only one turn in 5 inches in length; and to 14 inches, being the draught of the roller drawn out to more than 13 inches, the twist of one turn in this length is imperceptible, and adds no strength whatever to the roving, so that it is necessary the spindle should, by the connection of the thread 41, passing down from the rollers to its flyer, give a twist to the fibres the instant they come through the roller, so that by twisting one end of each fibre round the other, whilst the opposite ends are held fast between the rollers, they will become a thread sufficiently cohesive to advance towards the spindle, and receive its full quantum of twist to become a hard and strong thread: it passes through a wire eye or staple fixed in a board at 34, which changes its direction.
direction into a line with the spindle, to which it is connected by passing through the eye formed at the end of either of the branches of the flyer, which revolves with the greatest rapidity along with the spindle, and thus give twist to the thread. The bobbin does not partake of the motion of the spindle, but is retained by the friction of its lower end rolling on the piece of wood 17, and this is increased by a washer of leather put under it: then, as before explained of the bobbin of the roving frame, the thread, by the motion of the flyer, drags the bobbin about after it with a velocity equal to the difference between the motion of the end of the flyer, and the motion of the thread as delivered out by the front rollers. When the frame has been so long at work, that the bobbins become filled with thread, the child in attendance, by the handle of the lever 10 (fig. 5), disengages the binder \( n \) of the four spindles from its axis \( n \), and then they, as well as the head of the rollers belonging to them, stop, and the child breaks the thread; then pulling off or uncerwing the flyer, he hits off the bobbin, puts on an empty one, on which the end of the thread is previously lapped to make a beginning: the flyer is next fixed on, the thread passed through the eye at the end of the flyer, and it is ready to work again: the eye of the flyer is made open at one part, being curved in the manner of a cork-screw just at the end so that the thread can be hooked in and out of it by the child, but is in no danger of getting out by the motion of the flyer in its work. When a thread accidentally breaks, it is not always necessary to stop the spindle to unite it, but the attendant takes hold of the broken end which belongs to the bobbin, and draws off a considerable length, a yard for instance, from the bobbin, and breaking it, throws away, because it has every chance of being unfound: then taking the end in the finger and thumb, and applying it against the end of the roving which is coming through between the rollers, leaving them overlapping a small quantity, and letting them go from the finger and thumb, the ends are instantly turned together, and united into one found thread. But this requires some dexterity, for if the end of the thread is held so long between the fingers in applying them together, that the roving coming through the rollers advances the length of the fibres of the cotton before it is let go, and suffers the spindle to twist it, the fibres will part and the thread breaks at the end, or is never formed at that part; it is therefore necessary to catch the roving as close as possible to the rollers, and apply the end of the thread quickly to it, then letting them go instantly, the fibres are twisted in with each other, and the union takes place so perfectly, that it cannot be afterwards discovered where the joint was made. The lower rollers are made of cast iron, turned extremely true, and fluted by an engine; the upper rollers are also cast iron, but are covered with leather in the acting parts, so that this soft sub stance holds the cotton more firmly upon the flutes of the lower one than any other material would, as the roving is not liable to lap round the rollers like the flyer of the drawing frame. No clearer is need; but instead thereof, a small wooden roller covered with leather is placed over, between the front and middle roller, but it merely lays upon them, having no pivots or support; its surface is rubbed over with chalk or whitening, and this it communicates to the leather of the upper roller, and is found to improve their action, probably by not suffer ing the cotton to slip beneath the rollers; fig. 4 shows, that the middle and back rollers have their weights to keep down the upper rollers upon them in the same manner as the front rollers; but the weights are very different, the front weight 6, being 20 lbs., whilst the middle weights are but a few ounces, and the back rolls have a weight of 5 lbs. The reason for the front roller requiring so great a weight is, that it is necessary for them to press and hold every one of the fibres of the roving while passing through them extremely tight; because if it only held a few in the middle of the roving, the others towards the edges of the roving might, by the twisting, be drawn out before their ends were fairly twilled into the thread, and this would render the thread fuzzy in its whole length; the infant the foremost end of a fibre comes through between the rollers, it should, by the twine of the spindle, be twilled over the middle of some other fibres which are coming through, and over the ends of others which have altogether escaped the roller, and the smoother of the surface of the thread altogether depends upon this being done instantaneously on the foremost end presenting itself through the rollers; for the effect of all the preceding operations has been to dif fer the ends of the fibres equally, so that they effectually break joints with each other, and then being equally twilled, it forms a thread of equal strength in all parts.

The numbers of the wheel-work for the rollers of the roving frame, are varied with every different number of cottons which is to be spun; the draught being altered, when requisite, to produce such an extension of the fibre in passing through the rollers, as will make the roving, when finished, 4 3 times the weight (length for length) of the yarn it is to be spun into. This is a pretty general rule in cotton-mills, and the roving is occasionally measured and weighed, to ascertain if the machines are drawing the proper quantity, and if not, the pinions are changed for others which will produce the proper degree of extension. It is in this stage that the size of the yarn is determined, and the spinning frames have, in general, the same draught; but the velocity of the spindles with respect to the roller, so that they will give a greater or less degree of twist to any given length, is varied in spinning different kinds of twist, whether hard or soft twist. The alteration is made by employing larger or smaller pulleys, or whirls, on the spindles which cause them to revolve with a slower or quicker motion. Neither do the rollers of the spinning-frame give out the same quantity of roving in a given time when spinning coarse or fine goods, or when spinning very high numbers, as No. 60: the front rollers are adapted by the wheel-work to revolve at the rate of 35 times per minute; but for coarser goods, some of them will turn 60 times per minute; this is because a fine thread requires more twist in a certain length than coarse.

The frame from which the drawing was taken contained ten heads, or forty spindles, on each side, the frame = 80, and the frame on the opposite side of the drum, to be driven by the irrup, by making 160 spindles, actuated by one cog-wheel A.

The construction of the locking bayonet \( d \), for connecting the drum with the main spindle, we have explained; but one circumstance was then unnoticed, viz. that the bar \( f \), fig. 1, is not permanently fixed to the wheel \( g \), but that the wheel has a groove turned in the edge of it like a pulley and an iron hoop or clip, made in two halves, screwed together, is fitted round the wheel in this groove, and to this clip the cross-bar \( f \), is united, by the ends of it turning down, and being received between the ends of the clip, the frame screw-bolts holding all together. The consequence of this construction is, that the machine is not suddenly jerked into motion when the bayonet is let down, and intercepts the arm \( f \), which is revolving rapidly with the spindle and wheel \( g \); instead of jerking the frame, the bar \( f \), for a moment becomes stationary against the point of the bayonet,
The "throttle spinning-frame" is delineated in Plate X. of which Fig. 1. is a section across the length of the frame; Fig. 2. is an end view, and Fig. 3. is an elevation of the machine in front. After the minute description we have given of the construction and operation of the roving-frame and water-frame, it will not be necessary to be very diffuse in our account of this machine, which has the same parts as those machines, but only differs in dimensions and proportion. The same letters of reference are employed in all the figures, and A A represents the live and dead pulley actuating the whole, fixed on the end of the spindle of a long tin cylinder B, which is called the throttle, and turns all the spindles and other machinery at once. On the main spindle of the throttle a pinion, a, is fixed: this turns a wheel e, which has a pinion, b, fixed on it, turning the wheels D and E (Fig. 2.) by the intermediate wheels, d, on one side, and e and f on the other. The wheels, D and E, are fixed on the ends of the spindles of the front rollers X, as is plainly shown in Fig. 3. These rollers are made in lengths, which serve fix spindles, and the lengths are united by connecting boxes, as shown at F, to other lengths, so that one train of wheel-work, a C b d e f E and D, will turn the front rollers for 112 spindles, or 66 on each side of the frame, and then the rollers are made in 11 lengths. Some frames are longer, others shorter than this. Our drawing only contains 12 spindles, and two of these at each end are removed, to show the works inside of the frame: at a a pinion is fixed on the spindle of the front roller, and turns a wheel on the face of the middle roller, by an intermediate wheel and pinion on a f; and at the opposite end of the middle roller is a wheel b, turning the back roller with its proper velocity by means of an intermediate wheel, so that the motion of the rollers in this frame is exactly the same as in the water-frame. The spindles, l l, are all driven by bands from the throttle cylinder B, the manner in which they cross being shown at k, Fig. 1. The bands are very loose, and, as the figure shows, are inclined, so that their weight tends to draw them tight, and turn the spindles, l l, about with the proper velocity; but still the child attending the machine can, by preying his knee against the whirl, as the pulley is called, flop the motion of any one spindle for a moment whilst a broken thread is repaired, the band slipping round it all the time. The spindles, being exactly the same as the water-frame, need little explanation, more than to enumerate their parts, which are, the bobbin m, the flyer n, fluek by friction, or else screwed on the top of the spindle, and its branches ending in a curled hook, through which the thread is passed to the bobbin. This is fitted quite loose on the spindle, and reaps its weight on a piece of wood o, fixed to the under side of a rail N, which rises and falls, to lay the thread regularly in a coil upon the bobbin, as fast as it is taken up thereby. The rifs and fallare thus produced: the two rails, N N, on opposite sides of the frame, are suspended by iron rods, p p, from horizontal levers G, which are mounted on an axis, extending the whole length of the frame, and having as many of the levers, G, upon it, as are necessary to suspend the rail, N, without bending g. It is an iron rod joined to the lever G, and coming down to a short lever I, which, at the opposite end to its connection with H, rests on the surface of the heart R, fixed on a spindle, which is turned by the following train of wheel-work. The pinion of the wheel and pinion, C b, passes through the frame, and by a pair of bevelled wheels, L (Fig. 3.), turns a vertical axis M, on the lower end of which is an end of the screw, giving a flow rotation to the spindle of the hearts by a tooth-wheel, m, thereon, which is turned round one tooth by every revolution of the ends of the screw. A heavy weight, P (Fig. 1.), is suspended from the lever, G, to counterbalance, and cause the end of the lever, I, always to press upon the surface of the heart R, which, as it turns round, elevates and depresses the bobbins on the opposite sides of the frame alternately. The joints of the levers, G and I, with the rods, H and p p, are made, as the figure shows, adjustable; that is, the centre pins are fixed to the levers by fitting in grooves, and are held in by nuts, so that they can be fixed in different distances from the centre, to accommodate the acting radius of the levers, so that the motion given by the heart, R, may be made to correspond with the length of the bobbin between the shoulders.

The bobbins for the roving are set up in a frame at S S T, between the two sets of rollers, X X, and the roving is conducted immediately between the back rollers: but, as it goes through the same process as before described in the water-frame, it is needless to repeat it. The traverse motion, to prevent the cotton wearing away the rollers in any one part, is sometimes omitted; but we have seen throttle-frames in which the whole of the frame S T, consisting of one board, S, below, and another, T, above, connected by proper pillars, together with all the bobbins of rovings, had a small traverse motion, which is found to be a great advantage in the wear of the rollers.

Respecting the comparative advantages of the throttle-frame and the water-frame, cotton-spinners are divided in their opinions: the simplicity, and consequently low price in the first erection of the throttle, is its recommendation, and it is generally stated to be driven with far less power, because it has fewer parts. To set against these advantages, it is said, that when the bobbins are filled, and require to be changed, the whole frame of 112 spindles must be stopped at once, by shifting the strap to the dead pulley A; whereas in the water-frame, any four spindles can be stopped together, by calling off their binder; and it is only necessary to stop the whole frame by the calling off the great drum, when the frame is to be repaired, or is out of use for a day, or longer period.

We have now explained the manner of spinning cotton into a thread by the water-frame, and shall proceed to describe the construction of the other method of spinning, viz.

The Mule.—This machine was introduced by a Mr. Crumpton, who lately received a reward of 5000l. from parliament for the invention, which, as before mentioned, consisted only in the combination of Hargrave's spinning-jenny with Sir Richard Arkwright's drawing rollers. Plate XI. contains drawings of one of the best constructions of this machine, in which Fig. 2. is an end view of the whole machine, and Fig. 1. an end view of the carriage alone. Fig. 3. is a front view, and Fig. 4. is a view of the operative parts detached: Fig. 5. a similar view in another figure of its operation. As this machine is extremely complicated in its movements, it will be difficult to explain these movements before entering upon the machinery which causes them. This is shown in Figs. 4. and 5., where W represents a bobbin of the roving frame let up in a proper frame, and the roving is conducted from it, through three pairs of rollers, A B, and C, which have the same Draught as the rollers.
MANUFACTURE OF COTTON.

rollers for the spining-frame, and are moved by similiar wheel-work: but the upper rollers, a, b, c, are weighed down in a different manner: thus, d is a piece of metal resting on the neck of the front roller, a, at one end, and the other end upon the middle of a second piece e, which bears upon the necks of the other two pairs of rollers, b and c; then an iron rod f, coming down from the piece d, holds all the three upper rollers a, b, c, at once, by means of a lever g, which is hooked beneath a fixed rail of the framing supporting the rollers at one end, and the other is made with a heavy knob, f, in the purchase, or leverage of this piece g, draws down the wire, f, with sufficient force to load all three rollers with their respective forces: thus it is plain the roller, a, must bear the principal weight of the lever, g, because the wire, f, is nearer to the roller a; but as it acts upon the piece, e, with a considerable length of leverage it bears lightly upon it, and this again bears upon two, and therefore still less upon either, the weight of the end of d being divided upon two rollers, b, c; but it bears more powerfully upon e, the point or end of d being nearest to that roller, so that the operation of all these pieces is to load the three rollers nearly in the same proportion as the rollers of the spining frame: but this proportion can readily be altered by shifting the acting lengths of the levers.

The roving, after passing through the rollers, is taken up by the spindle D G: this is placed rather inclined, but without any bobbin or fly, like the spindle of the water frame; it is merely a plain conical arbor, supported at its point, or toe, in a slip made on the rail, E, of the frame, and is a bearing at F, against another rail. It has nothing to keep it up against this bearing, the draught of the band, which passes round the pulley b, and gives motion to the spindle, being sufficient for this. The end of the thread is merely lapped round the upper end of the spindle, and its accumulation upon itself soon forms a mafs G, which is called a cop, or coppin. Now it is evident that, from the inclined position of the spindle, it will, when turned round, give twill to that part of the thread which is between the end of the spindle and the roller A, although the spindle and the direction of the thread do not coincide, because, when the spindle is turned, the thread will slip over the top end of it and receive a twill, without winding up upon the cop; but when it is required to wind up, the thread, or wire H, is prefced down upon the thread. This removes it from the end of the spindle to the middle of the cop, as shown in fig. 5, and then the motion winds up the thread upon the cop instead of twilling it. The wire, H, is extended at the end of a lever H I, moveable on a centre f, in the manner shewn in fig. 5, but when left at liberty, the weight of the opposite end of the lever restores it to the position fig. 4, and then the spindle twills the thread instead of winding it up.

The operation of the machine is this: the rails E and F, supporting the spindle, are part of a carriage or frame carrying above 100 such spindles, and moving on wheels which traverse on railways to and from the rollers in a direct line, for the extent of a yard and a half. Now suppose it wheeled home, that the ends of the spindle are close to the front roller A, then supposing the rollers set in motion, they take in the roving from the bobbin W, and draw it out or extend it eight or more times, giving it out between the front roller A, to the spindle G, which, with its carriage, recedes, by the movement of the machine, from the rollers, taking up the thread as fast as it comes out between them; and, at the same time the machinery draws the spindle back, it turns it round rapidly, giving twist to the thread as fast as the rollers deliver it out, and thus producing such a compression of the fibres by twisting them round each other, as will form a thread of sufficient strength to bear stretching. This means, that when a yard of thread has been given out by the rollers their motion ceases, so that they deliver no more, but the spindle continues to recede from the rollers to the further distance of a yard and half, twisting the thread all the time it stretches itself length, till it forms a fair and strong thread. The twisting motion of the spindle then stops, as does also the drawing-out movement of the spindle, with its carriage. Thus one yard and a half of thread is made and finished. The attendant to the machine now thrusts the spindle, with its carriage, home to the rollers, holding the wire H, done in the manner shewn in fig. 5, and at the same time turning round the spindle at such a rate, that it will wind up the thread upon the cop-pin, and the wire H, which is held down by the hand, is fo humoured, as to make the thread wind up with regularity. The rotatory motion given to the spindle is, in this instance, done by the other hand of the attendant, and is so accommodated, as to wind up the thread just as fast as the advance of the spindle towards the rollers requires, and no more; but when it arrives close to them, the wire, H, is raised up, and the machinery is put in motion again, the rollers begin to draw out, and the spindles to recede, turning all the time. The mechanism by which all this is effected is described by figs. 1, 2, and 3; first, see fig. 2, where K is a live and dead pulley for the endles H I, actuating the whole by the power of the mill. The pulley is mounted on a short spindle, having a winch or handle, L, at one end, and on the other a large pulley M, which has a number of different sized grooves formed round it, to receive an endles rope: see also fig. 2: this rope, after making a half turn round M, passes under a wheel k, fixed on a pin or flud projecting from the frame. From this wheel the rope, l, proceeds to another wheel, i, at the opposite end of the frame, and returning from this goes over a wheel situated close behind k on the frame centre pin. The ends of the rope are then joined, and it forms an endles band, which, when the irnap is cast live pulley k, and the wheel, M, turned by it, the rope, l, constantly runs in a slant line from the wheel k to i; but in this passage the rope makes a quarter turn round a wheel m, upon a vertical axis, which is mounted on the frame or carriage E F, for the spindles D G, shewn separately in fig. 1. The rope, l, not only passes round the wheel on this spindle, but goes forwards until it passes over a groove, formed upon the upper end of a vertical drum, (not seen in the figures,) which has several bands upon it, each driving two spindles, D, by passing round the pulleys, k, of two of them, as shewn in fig. 3, in which it is also seen that the bands are all at different heights, that they may not interfere with each other upon the drum, but each take its proper place upon the length thereof. The carriage runs upon four wheels 1, 2, (fig. 2) two of which are placed at each end, and run upon an iron railway, so that the carriage containing all the spindles and drums runs backwards and forwards, to and from the rollers, for the length of a yard and half. But during this motion, the power of the mill is all the time conveyed to turn the spindles by means of the endles cord i, which, as before mentioned, making a slant line from the wheel k to i, will not be affected by the motion of the carriage, but will always circulate round the several wheels, and give motion to the drum which turns the spindles; 4, (fig. 1 and 2,) is an iron bracket, supporting the axis I of the lever, H, fig. 4, which supports the wire H, and as many of these levers are fixed on the axis I, as shewn in fig. 3, as are sufficient.
The force of this pulley, with its ropes, as we shall describe, is to make the whole carriage move parallel, or both ends equally, which, in a carriage of twenty feet long, requires some nicety. As the two wheels 1 and 2 cannot be placed very distant, and therefore give little leverage to a carriage of such a great length, the parallelism is thus preferred: a rope 8, is made fast at one end to a fixed part of the framing, then passes a quarter round the upper groove of the pulley 5, and runs along the whole length of the carriage, and turns a quarter round a similar pulley 7, fig. 3, and then goes forward parallel to its first direction, from 6 to 5, and is made fast to the frame in a similar position to 8, fig. 2, but at the farther end of the frame. In the same manner, another rope is fastened to the frame at 8, and making a quarter turn over the upper groove of the pulley 5, proceeds the whole length of the carriage, and turns a quarter turn over the pulley 7, fig. 3, and proceeds parallel to the first direction, from 8 to 5, and is made fast to the frame in a similar position to 6, but at the opposite side of the frame. The two ropes cross each other in the centre of the carriages, and they always pass over opposite sides of the pulleys 5 and 7. Their effect, which is not easily explained without a separate figure on purpose, is to make the carriage move equally at both ends, for it must do this, unless one or other of the ropes slip upon the grooves of its respective pulleys 5 or 7, and this they will not do if strained tight. We have clearly stated the passage of the two ropes 6 and 8, and the mechanic who knows this, will readily see the manner of its operation, though it is difficult to explain it by words only.

We must now attend to the wheel-work for the rollers: a bevelled wheel o, fixed close behind the wheel M, on the main axis, turns upon the end of an inclined axis p, fig. 2, at the opposite end of which is another bevelled wheel q, fixed under the extreme of the front roller; which being combined with the wheel M, forms the same wheel-work as the thrum frame, and the rollers bring of a similar construction, demand no further description, except what we have already given in fig. 4, of the weights for pressing down the upper rollers. When the rollers are to be cast off of gear, it is done by disengaging the wheel, p, from the wheel o; for purpose the bearing for the upper end of the inclined axis carrying the former, is made in the upper end of a lever r, which moves on a centre pin, fixed in the standard supporting the bearings for the axis of the wheel M: the lower end of this lever is connected with the end of a short lever s, moveable on a vertical centre pin fixed in the frame: this lever has an arm proceeding from the centre at right angles with that seen in fig. 2, and is therefore hidden behind the centre, its form being shown at Z, which is a plan of this lever. From this second arm a wire proceeds to the pendulous lever P, s, moveable on the centre pin t. Now by moving the end of the lever P, t, away from the wheel, M, it draws the wire in, and the arm of the lever, a, hence, which acting upon the lower end of the lever r, throws it inwards, throws the upper end outwards, and brings the wheel, p, in contact with the wheel o; so that the inclined axis, and the front rollers also, are set in motion, as long as the end of lever, P, is kept held towards the end of the frame. This holding is performed by its arm v, which, as in the figure, may be hooked under and kept down by a small tooth w, and from this point, upwards, proceeds back to the opposite end of the frame, and is then linked to a short lever, which is fitted loosely on the same centre pin, which connects the lower end of the lever, r, with the arm of the lever l. This lever is shown at z, in the separate figure Z, but its use is only to support the end of the wire q, and keep it up, so that a part of the carriage of spindles, in running back, may, by intercepting the end of it, draw the wire and the catch w, thus relieving the arm, v, of the lever P, and this, as before explained, throws the wheel, p, out of gear, and the motion of the rollers ceases. On the return of the carriage towards the rollers, a piece of wood, x, fixed to it, runs against the lower end of P, and moves it back so far that the catch, w, engages it. This fets the rollers in motion, which they continue, until, in the retreat of the carriage, a piece of iron p, fig. 1, projecting up from it, catches the short lever, z, near s, supporting the wire q, which being thus drawn, disengages the catch w, and then the wheel, p, is call out of the gear with o, and this is the motion of the rollers. The motion for drawing out the carriage from the lever P, is thus performed: a cog-wheel R, which has a pulley fixed on against it, receives an endless rope, m, passing round a pulley, n, at the end of the frame. One part of the endless rope is tied to an iron arm projecting from the carriage, so that when the wheel, R, is turned round, by engaging its teeth with a cog-wheel fixed upon the end of the front roller, the endless rope, m, travels, and moves or draws the carriage out with it. The wheel R, which is called the Mendoza wheel, is made to lock in or out, by setting it on a centre pin, which is fastened into the upper end of a lever T, (see the separate view,) moveable on a pin fixed in the frame. The lower end of this lever is moved by a horizontal lever, see endways near V, which represents its vertical centre pin or fulcrum. The end of this lever, which is before the find, or near the eye, is connected by a strong wire with the lever P, and therefore, when this lever is pulled by the motion of the carriage, it engages the Mendoza wheel, and draws out the carriage, at the same time that the rollers are put in motion, and give out the roving between them; but the carriage, being shut in, and the wire, while the roving, which is to have to stretch and spin the Mendoza wheel, is not disengaged, the moment the rollers are cast out by the wire q, and catch w, in the manner we have just described, because the lever, l, carrying that wheel, p, is provided with a catch, similar in its properties to w, that is, it holds the wheel, R, in its work until the carriage has run a yard and a half, and then it seizes a wire communicating with this catch, thus disengaging the catch holding up the lever T; the Mendoza wheel then falls back, and the drawing-out movement of the spindles ceases. This catch and wire are not shown in the figures, as it would produce much confusion, but being so exactly similar in this action to the catch w, and its wire q, they may be easily imagined.

We have now to describe the manner in which the rotation of the spindles is cast in and out. The reader, if not confounded by the complication of this machine, may remember that we explained the connexion from the wheel M, by means of the endless cord s, to the wheel m, and thence to the vertical drum turning the spindles. When this motion is to be thrown in and out, it is done by shifting the main trap, driving the whole machine on the live or dead pulley K, fig. 3. The trap is guided by passing through an eye or loop at the extremity of a lever, W Y, fixed on a vertical
MANUFACTURE OF COTTON.

vertical axis 12. On the lower end of this axis is a long lever 13, and at right angles to this a shorter lever, which being seen endways is not apparent, but it advances some distance forwards from the centre of the lever, and has a wire, 14, jointed to it, which is extended to a lever 15, against which the carriage runs when it is pushed home, and the spindles are close up to the front rollers. When this happens it draws the wire 14, which acting on the short lever of the axis, 12, turns it round, and the lever Y W with it, shifting the main flap from the dead to the live pulley K, and thus putting the whole machine in motion; at the same time that, by the operation we have before explained, the Mendoza wheel is thrown in, and also the movement of the rollers. The former of these draws back the carriage, till, as described, the catches are released, and the movement, first of the rollers, and then of the Mendoza wheel, are thrown out. At the moment before this happens, the carriage intercepts the end of the lever 15, which is formed like an inclined plane: it is therefore thrown outwards by the carriage running against it, and the end of the lever, W, being at the same time moved, it shifts the flap upon the dead pulley, and the motion of the whole machine ceases. The attendant to the machine now takes hold of the handle L, and pushes the whole carriage back again, till the spindle comes close home to the rollers; then by the carriage striking the levers 15 and P, it shifts the flap to the live pulley, and puts the spindles all in motion together, at the same time calls, in the motion of the rollers, to give out the roving; and also it calls in the Mendoza wheel, which traverses back the carriage and all the spindles to take up the roving as fast as it comes from the rollers, twirling it by the motion of the spindles all the time.

To describe the operation of this ingeniously constructed machine, will be only to recapitulate movements which we have repeated several times over; but this recapitulation will give the order in which they succeed each other. The man or woman who attends the mule stands in front of the spindles, at such a distance from the right-hand end of the frame that he can conveniently reach the handle L. In the other hand he holds the axis, 1, of the wire H. Suppose, to commence, that the spindles are closer to the rollers, then the movements succeed each other as follows:

1. The lever 15, being thrust back by the carriage running against it, draws the wire 14, and by the lever, W, shifts the flap upon the live pulley, putting the wheel M, and the wheels k, l, with the endless rope t, the wheel m, and all the spindles in motion.

2. The end of the lever, P, being pressed by the carriage, engages the wheel for the motion of the rollers, and they begin to deliver out the roving at the same time.

3. The Mendoza wheel is cast into gear, and begins to cause the carriage to retreat from the rollers as fast as they give out the roving. These first, second, and third motions, all happen at the same instant.

4. The spinning of the rovings is now performed by the above motions, the spindles twisting the rovings as fast as they are given out; but the motion of the rollers is so quick, that the twist now given is slight, but having thus extended, or taken out, a yard in length from each spindle to the roller, the piece of iron y, fig. 1, on the carriage, meets the end of the lever 15, and

5. Difengages the wheel-work for the rollers, which are therefore stopped, and deliver out no more roving; but the retreat of the carriage and the twine of the spindles continues for another half yard, stretching out the thread, and twirling it, till the piece of iron, y, meets the catch of the next wire, which is not drawn in the figure, and

6. Difengages the Mendoza wheel, consequently the carriage draws out no further. The thread being sufficiently extended and twirled.

7. The carriage takes hold of the end of the lever 13, and thus shifts the flap to the dead pulley K, fig. 3, and the motion of the whole machine ceases.

8. The attendant, by turning round the axis, I, of the wire L, depresses down all the threads together from the points of the spindles to the middle of the coppin, in the manner of fig. 5; then

9. Takes hold of the winch L, to regulate the winding of the thread on the coppins, when he

10. Drives the carriage home to the rollers. In this motion the spindles all revolve, and lap up the thread upon the coppins. The revolution is caused by the endless rope i, which may, when the machine is standing still, be considered as a stationary rope acting upon the wheel m, and the drum for the spindles, and as their centres traverse, turning them all round, on the same principle as a carriage wheel is turned by rolling on the stationary road. In like manner m is turned, by moving along while the rope, i, is immovable. Now the quantity of motion, or the number of revolutions the spindles will make during this return of the carriage, is, in all cases, the same, and the quantity of thread to be wound up is always the same; but it is evident that it will require a greater number of revolutions to wind up the length (1 1/2 yard) of thread, when winding upon the spindle, or upon the circumference of a small coppin, than when the fiance coppin is increased by the accumulated thread to ten or fifteen times the size of the spindle. To accommodate this, it is necessary for the spinner to have the handle, L, in his hand, because he can, by turning this one way or the other, add or diminish so much to the number of turns the spindle will make, as will just take up the thread as fast as the carriage advances towards the rollers. Thus, at first beginning, when the coppins are small, the handle, L, will require to be turned forwards a considerable quantity, to make them wind up the thread sufficiently fast; but as the size of the coppins increase, they will come to such a diameter, that the handle requires to be held quite stiff. The motion given to the spindles by the return of the carriage, being then jut equal to wind up the thread at the proper rate, any increase of the dimensions of the coppins after this will require the handle, L, to be turned backwards, to diminish the motion of the spindles, or they would wind up too fast, and break the threads.

The spinner accommodates the motion of the handle, L, so exactly by habit, as to keep the threads always to that degree of tension as will make the coppin compact, but not injure the thread; at the same time by the other hand, which holds the spindle of the wire H, he lays the thread regularly on the length of the coppin.

The carriage, having with these precautions been wheeled up close to the rollers, the several operations are repeated as before; and thus the mule continues to spin a yard and a half upon each spindle every time it is drawn out, and then wind it up upon the several coppins. A good spinner will draw out 3000 times per day of a mule with 240 spindles; and many women will attend two machines, having them placed opposite to each other; and while one is drawing out the other will wind the home other. This makes 108,000 yards per day upon each mule, or both together will make more than 1200 miles to be spun in one day by one woman; who, on the old method of the hand-wheel spinning, on which the mule is an improvement, would only have managed a single spindle, instead of 480; and this single spindle would not have spun half the quantity of any one in the mule; and with
with respect to the regularity and accuracy of the thread, no comparison can be drawn. A mule of 240 spindles has nine drums in the carriage to turn them; all the length, therefore, is nine repetitions of fig. 5, which only contains the spindles turned by one drum.

The motion of the mule can at any time be stopped, if a thread break, or any other accident happens, by means of a long wooden rail, Y, which is joined to the end of the lever W Y, and extends along over the whole length of the rollers, so as to give the spinner the means of stopping the mule when winding opposite to any part of its length; for it is evident, that by thrusting this rod one way or the other, the flap will be shifted either on the live or the dead pulley, stopping or putting the wheels in motion at pleasure.

The thread spun upon the mule is much softer, and has a smoother surface than the water-twist; this is owing to the manner in which the extension of the thread is made, after it has been twisted slightly, and the fibres thereby compressed together in some degree; for the effect of stretching a slightly twisted thread is, to draw all the ends of the fibres into it. All these fibres having assumed a spirally curved form in the thread, by drawing or stretching them out in the length of the thread one among another, the fibres are drawn along with a spiral movement, and all their ends are thus brought into, and concealed in the body of the thread. This operation, at the same time it makes the surface of the thread even and smooth from projecting fibres, increases the strength of the thread by bringing them all into use; and the strength obtained by this means does not require the thread to be twisted hard, but leaves it soft and pliable, which is the great recommendation of the mule-twist.

The thread thus spun, either by the water-frame or mule, has many other operations to go through to prepare it for the market, where it is to be sold to the weaver or manufacturer. The chief end of these operations is, measuring it out in lengths, weighing it, to ascertain the number, and packing it up for carriage. The first machine the thread is taken to after spinning is

The Reel; see figs. 1 and 2 of Plate XII. The former being an elevation of the end, and the other an elevation in front, a very short explanation of this machine will suffice; its framing and some other parts being evident. A is a row of the bobbins of the spinning frame, or for mule-twist, the copings of the mule flake upon pins, on which they will revolve freely and give off their thread. B, fig. 1, is another row placed behind the former, and arranged in the intermediate spaces between the bobbins of the first row, which arrangement is necessary, because the bobbins would touch each other if all placed side by side.

The threads for these bobbins are conducted between several pins or wires, bucked up in a rail of wood D, and each thread is twisted once round one of these pins, that it may be drawn off with such a degree of force, from the friction thus occasioned, as will cause the thread to lap or wind with a sufficient tension upon the reel E E, which confids of a horizontal shaft E, from which three sets of arms, F, proceed, supporting six rails, G, G, parallel to the axis, and upon these the thread is wound, as shewn in the figures at J. The dimensions of the reel is such, that it takes exactly a yard and a half of thread to make one turn round it: this, therefore, is the measure of length, and the mechanism which remains to be described is for the purpose of counting the number of revolutions it has made. The reel is turned round by means of a cog-wheel, H, on the end of the spindle; this is turned round by a wheel K, on the axis of which is a pulley M, to receive an endless rope, which is turned round by the mill; but the bearing for the pivot of the axis, E, is fitted in a groove, formed on the top rail of the frame, so that the wheel, H, may, by sliding in this groove, be disengaged from the teeth of the wheel K, and when the movement being thrown out of gear, the reel stops. One of the opposite end of the axis of the reel, a pinion, a, of 14 teeth is fixed, which turns a bevelled wheel of 28 teeth on the upper end of a vertical axis b, which has an endless rope upon it, turning a wheel, d, fig. 1, of 40 teeth, on the axis of which are eight leaves, turning a wheel, c, of 57 teeth. This wheel has a small circular ring fixed on the face of it, which is formed like a flail on the front edge, that its surface is not parallel to the plane of the wheel, but is inclined to it in such an angle, that in turning round it operates upon a lever, f, to move it backwards and forwards, and this motion is, by means of a vertical lever, h, communicated to the rails, A B and D, at the top of the reel, which carry the bobbin, and also the pins, D, that guide the thread, and having thus a short traverse motion parallel to the axis of the reel, the threads are laid regularly by the flake of each other, without overlapping each other in one place, as they would do without this motion, and by thus enlarging the diameter of the reel, the thread that winds upon the measure would be incorrigible.

By calculating the dimensions of the train of wheel-work, a, b, d, &c., which we have before explained, viz. by multiplying the number of all the pinions together, and the number of all the wheels together, and dividing one sum by the other, thus, 14 \times 8 = 112, the product of all the pinions; again, 28 \times 40 = 280, the product of the wheels. Divide 280 by 112, and the result is 560; therefore the wheel c, of 56 teeth, will make one turn for 560 turns, or bouts of the reel. The wheel d makes only one-seventh of this number, or once for 80 bouts; and a pin being fixed in the back of its rim, touches the tail of a bell, m, once for every turn it makes, consequently this bell rings at every 80 bouts of a yard and a half each, = 120 yards of thread wound upon the reel.

The reel, in beginning, makes the end of each thread fall to one of the rails, G, of the reel, then calls it on, and sets it going until the bell, m, rings; it will then have made 80 bouts, or reeled: 20 yards, which is called a ley. The reel is stopped the instant the bell rings, and every one of the leys of thread, r, r, fig. 2, is tied up by a piece of thread to keep these 80 bouts distinct; then the reel is set on again and another ley reeled, which is tied in its turn; and when seven leys have been thus done, it makes 560 bouts, or 840 yards, which length is called a knob: the seven leys composing it are tied all together, the ends of the thread cut off, and the hanks are removed from the reel. They are got off by what is called striking the reel, to do which, the arms supporting one of the rails, G, are divided across in the middle of each, and united by hinges. When the arms are detached, it produces 560 hanks, or 840 yards, which length is called a knob: the seven leys composing it are tied all together, the ends of the thread cut off, and the hanks are removed from the reel.

A reel usually winds 50 hobbins at once, and the principal care of the attendant is to watch the hanks, supplying others, and tying the ends of the threads as fast as they are exhausted.

The hanks are now twisted up into a knot, by catching one end of them over an iron hook, fixed to the wall, then putting...
thing a small iron rod in the other end, the hank is twisted up very hard, using the rod as a lever to turn it round. To prevent its untwisting again, it is taken by the middle of its length, and without fulfilling the ends to entwine it is doubled, then the ends are released, and the two halves twist over each other, forming a bundle or knot of thread, resembling a piece of thick rope, about eight or nine inches in length, and perhaps two inches girt. The hanks, being thus all knotted, are weighed, to ascertain their number. The weighing instrument consists of a short pendulum, from which an arm proceeds on each side, at top passing through the centre of suspension, so that it resembles the letter T. From one of the horizontal arms a hook is suspended, by which the hank is hung on; and at the end of the other arm is an index pointing to an arch which is divided, and has figures upon it, shewing how many of such hanks (as the index is brought to by hanging any one upon the hook) will weigh a pound. The divisions are made by experiment, and frequently verified by means of small leaden weights, which the overseer is provided with.

As fast as the number of the several hanks is determined by this method, they are thrown into different bins or shelves, and when they are to be made up for market, as many hanks of any number as will weigh ten pounds are counted out, weighed, as a check upon the weighing instrument, and packed up in paper, forming a small square bundle, which is made compact and tight in the bundling-press. This is a small square chest, of about eight and a half inches by nine and a half, formed of vertical iron bars set upon a table, and a lid of iron bars shuts down over the top, with bolts or other fastenings. The bottom of the chest is movable up and down by means of a rack and pinion, a screw or other means, which will enable the workman to give a great preasure upwards. The hanks, packed closely into this chest with paper round them, and the whole number being packed in, the lid is shut down and bolted upon them; then by turning a handle the bottom of the press is raised up, and compresses the bundle together into as small a compass as is required. The bundle in this state is tied round with several fringes, the interlaced with the iron bars composing the press, leaving sufficient room for the spaces among the fringes, and for the knot to be tied to confine the bundle. In these bundles the greatest part of the twist is sent to market; but what is called hard twist, must be twilled two threads together, as is called flocking-yarn. Such thread as is intended to be doubled for these purposes, is taken from the spinning-frame to the Doubling machine, instead of the rod. Here the threads, two together, are wound upon bobbins, as preparatory to twilling them round each other. See Plate XIII., figs. 1 and 2, which represent a doubling machine in front, and endways at fig. 2. A is the pulley which is turned round by the mill: this pulley is loose on its spindle, but has a clutch or locking-box at the back which connects it with its spindle, when the upper end of the lever, B, is moved towards the machine. But when it is moved the other way the machine hands still, though the pulley continues all the time to turn round. A wedge, C, being put on either side of the lever in its mortise through the piece of wood D, retains the pulley, A, either closed or locked in, with the spindle which is fixed in the end of a thread-cylinder, R, and by bands turns all the spindles, B, B, together. The bobbins of the spinning-frame are fluck upon pins in the top rail, E, of the frame, and the threads descend to wires, D, round which they make a turn, two threads in company, to produce a friction, as before explained, sufficient to lay the turns on the bobbin of the spindles, B, B, tight and even. The threads then go through wire flapes or eyes fixed in a rail, F; situated opposite to the bobbins, C, which are fluck fast on the upper ends of the spindles, B, B, and being turned thereby, wind up the thread from the bobbins at E: the rail, F, is adapted to rise and fall parallel to itself, being attached by radial bars to an axis moving on centre pins fixed in the frame. Its motion is occasioned by an iron rod, g, which is jointed to it, and connects it to a lever, f, fixed on an axis; and at the extreme end of this is a lever, h, g, 2, resting upon the circumference of a heart, which, fixed on the face of a cog-wheel i. This is turned by a pinion fixed against a wheel, k, which receives its motion from another pinion upon the end of the spindle of the thread cylinder, R. By this train of wheel-work, the heart is slowly turned round, and raises and falls the lever, h, at the same time giving a similar motion to the rail, F, and by that means regularly winding the thread upon the bobbins, C, which are turned rapidly round by the motion of the vertical spindles, B, B, which receive their motion from the thread engine. The rails, when before described. The bobbins are such as shown separate at X, and have a hole through them exactly fitting the conical end of the spindle, on which it flacks to fall, that the bobbin will, by the motion of the spindle, wind up the two threads together off the bobbins at E. When the bobbins are filled with double thread, they are removed to the twilling-machine, if it is intended to make flocking-yarn, or if it is to be what is called hard twist, for sewing, knitting, or mending-cotton, it is done in the water-frame, which, however, undergoes some alterations, viz. the spindles are made to turn about in a contrary direction to that in which they moved to spin the thread. It is done by turning the whole frame the other way about, but as this would make the rollers move the wrong way, the pinion at the upper end of the spindle of the binder is placed at the outside instead of the inside of the face-wheel on the end of the front roller. The rollers then turn the right way about to deliver the thread to the spindle, but the back and middle rollers are removed, as it is not required to draw out the thread, the roller being cylinder, R, by the hands, as before described. The lever it regularly to the spindle, which operates in the same manner as for the first spinning, except that it twills in the contrary direction; because when any two threads are to be turned together, it must be done by a contrary twill to that which composed the two separate threads themselves. After spinning this hard twist it goes to the reel, and is treated in all respects as other twist is. When it is merely required to twine the two threads slightly together for flocking-yarn, the bobbins of the doubling-machine, when filled with double threads, are carried away to the Twilling-machine, for Plate XIII., fig. 3, of which is an elevation endways; and fig. 4, another elevation taken in front. In this, A represents the live and dead pulleys turning the whole machine: the strap is conducted through an eye at the end of an iron branch a, affixed to a rod or beam B, which slides in guides beneath the machine, and can be moved endways by means of a lever, h, which comes out in the middle of the length of the machine, and the attendant, by applying his foot to the lever, and moving it sideways, moves the beam, B, and the eye at the end of the branch, a, guides the strap upon the dead pulley; the machine then hands still. The live and dead pulley is fitted on the end of the spindle of the throttle cylinder D, which, by bands going to both sides, turns a double row of vertical spindles on each side, F and E, the internal row on either side being placed opposite the spaces between the outer row, so that the
the spindles are not crowded too close together. On these spindles the bobbins are fixed in the same manner as those of the doubling-mall; and the threads proceeding from the bobbins are conducted through wire eyes, which are fixed in rails, G, of the frame, then each twisted thread makes a turn round a wire fixed in the rails, H, just above G, and these have a slight traverse motion backwards and forwards, by which they lay the thread evenly upon the reels, I, K, which take up the threads, as before described, of the reeling-machine. The reels are slowly turned round by a train of wheel-work from the main spindle of the pulley A. This train consists, first, of a pair of bevelled wheels, one on the main axis, and the other at the lower end of a vertical spindle L, which at the upper end has a pinion actuating another wheel, g, upon the middle of a horizontal axis, which at each end carries a pinion, turning wheels, M N, on the ends of the pivots of the two reels. The proportions of the wheels are such, that the reel turns once for about 24 turns of the main throttle D, or about one for every 72 revolutions of the spindles, and as the reel has 1 yard of warp about, the thread will be not always about 72 times that length by the rotation of the bobbin and the thread with it. The motion of the reel draws the thread off the bobbin as fast as above-mentioned, so that the proportion of the wheel-work determines the quantity of twist which shall be given in any certain length. The reels are provided with counting-wheel-work of the same operation as that before explained in the reeling-machine. Thus, on the end of the spindle of the reel is a pinion turning a wheel, i, on the axis of which is a sprocket turning a wheel, j, and this has a pinion on it turning a wheel, n, by means of the intermediate wheel, l. The spindle of this latter wheel has a nail fixed upon it, which operates upon a lever, m, the lower end of which presses against a cross-bar, connecting the rail, H, with its fellow. On the opposite side of the machine there is another similar cross-bar at the other end, and the rails being thus united, form a frame which is supported on iron radial bars, p, q, which move upon centre pins fixed in the rail, G, of the frame; so that the frame, with the rails H, I, has a free motion to traverse without friction, and guide the threads to lay regularly upon the reels I, K. At the opposite end of the frame a fitting is tied which pales over a pulley, and has a weight, r, fastened to it, which always draws the frame, or the other end, and tends to keep the upper end of the lever, m, in contact with the main upon the axis of the wheel, m. This axis has also a pin projecting from it, which every time the spindle turns round, rings the bell P. The motion of the wheel-work is so calculated, that the bell shall ring once for every 380 hanks of the reel, and the size thereof is such, that this 380 hanks shall measure 420 yards, being the length of the double thread yarn, small enough to half the length of the single thread yarn, which is, as before mentioned, 840 yards, and the number of double thread yarn, is according to the number of these hanks of 420 yards each to the pound. The reels, I, K, when filled, are secured, and the hanks taken off them in the same manner as the reeling-machine before described.

Hard twill, which is intended for sewing, knitting, or mending-cotton, after being twisted and reeled in hanks, is sent to the bleach-field, and bleached by some of the processes described in our article BLEACHING.

But the processes which is most generally in use for bleaching yarn, is thus conducted: an earthen-ware retort is filled with one quart of oil of nitroil, two quarts of fulfalt, and one quart of the ore of manganese. The head of the retort being put on and luted, it is let over a small florov or full-bath, and the heat being raised from it the oxygenated muriatic acid gas, which is received in a square wooden chaff, about seven or eight feet square, and as many deep, forming a small air-tight chamber, in the upper part of which the goods are suspended upon a rack or frame. The lower part of the chaff, for about three feet deep, is filled with water, sometimes impregnated with a ley of potash, and sometimes with lime-water, or water mixed with lime. The gas is introduced betwixt the fluid and the goods, amongst which it ascends, and by its action upon any colour they may contain, renders them white; at the same time, by occasionally immersing the goods in the fluid below, it is sought to modify the action of the acid, and prevent the operation proceeding too rapidly. This is effected by means of a pole or long rod connected with the frame on which the goods are suspended, the centre of which pole moves on a fixed in a hole in the partition, or lid of the chamber, which is occasionally flopped with clay, and enables a person to take the goods by means of a small crane, or, at pleasure, to let them down into the fluid as far as required, however, without inconvenience, which occasioned the name of the Bullum procures, as the workmen, if they inhale the gas, are flusted.

Previously to the yarn being subjected to the action of the gas, it is boiled in a ley of pearl-ashes, then milled for twenty minutes in a fulling mill, and the hanks are hung upon the racks or crofs rails of the square frame in which they are suspended, to be let down into the bleaching-chamber. This frame is, as before-mentioned, attached to a long pole, that suspends it from the crane, which being swung over the chamber, is let down therein, and the lid is closed over it, the joints being made tight with clay, and the pole coming through a hole in the lid, which is carefully made tight round it by a wet cloth. The gas is now admitted to the chamber, but the yarn is not subjected to its action more than ten minutes before it is let down and immersed into the liquor at the bottom of it, which thus defends it from the action of the gas for a few minutes, until it becomes thoroughly wetted, when it is drawn up again into the gas, and remains in it for half an hour to be bleached: it is then let down again, for a few minutes, into the liquor to wet it; it is then drawn up again, and in this manner the process continues, until such time as it is known, by experience, that the yarn will be sufficiently bleached. The frame is drawn up by the crane, and the cotton removed from the rails on which it hangs, and being rinsed in clean water, is carried out and spread on the grasses in the fields, to be subjected to the sun and air, by which the bleaching is completed. It is not the business of the present article to enter into the theory or chemical principles of this process, which will be found under the article BLEACHING.

After the hanks are returned bleached, the yarn is found to be much lighter, so that it will generally be two numbers higher: thus, cotton of N 48 hanks to the pound being sent to bleach, will return so much diminished in weight, as to require 50 of the hanks to weigh a pound. But this rule is not so exact as it is requisite; the thread must therefore be reeled over again, weighed, and packed. A great proportion of the sewing cotton is wound into balls of a very beautiful appearance by a curious winding machine. As a preparation to this winding, the thread must be wound off the hanks in which it was bleached to large bobbins. This is done in a machine provided with several spindles, like the doubling machine, upon which bobbins are fixed, and the thread wound on them from the hanks, when they are extended or stretched out between two pulleys.
MANUFACTURE OF COTTON.

Ball Winding Machine, see figs. 3, and 4, of Plate XII. the former being a plan of the acting parts, and the latter an elevation of the whole machine on a smaller scale. In fig. 4. A is the bobbin from the winding machine, which is slung upon a pin projecting upwards from the bench, and a small lead weight is laid upon the top of the bobbin, to lead it, and cause such a friction as will make the thread wind with a proper tension upon the ball. The principal part of the machine is a spindle B, which is perforated through its length, and receives the thread: it runs, in bearings, at the top of two standards, a, b, and at the extreme end of the spindle, beyond the front standard, a flyer or branch, D, is fixed, and the end of it therefore describes a circle when the spindle, B, turns round by the endless bands, which surrounds the pulley, E, and gives it motion from the mill. The spindle has an endless screw cut upon it, turning a wheel, G, at the upper end of the vertical spindle F, which, at the lower end, is acting upon an inclined spindle H: this, at the lower end, has a small bevelled wheel, h, turning another, f, on a small vertical axis, carrying, at the upper end, an universal joint, which communicates motion to an inclined spindle I, and this, by another similar joint at J, connects with a vertical axis, which has a pinion, k, turning a wheel, k, upon whose spindle, m, the thread is laid to form the ball, as shown in fig. 3: the spindle, m, is supported by a piece of metal, K, formed like the letter L, and moveable on a central pin n, which is situated exactly in a line with the short vertical axis of the wheel, j: M is a circular plate, on which the piece, K, rests, when turned about on the central pin m, and N is the handle by which it is turned about at pleasure upon it. The two spindles, B and m, are, as shown in fig. 4. on the same level, but are capable, as shown in fig. 3, of being set at any angle to each other by inclining m on its central pin n, and this being in the line of the spindle of f, the motion does not tend to lengthen or shorten the spindles I and J; but they always convey the motion, communicated from the spindle, B, by means of the axis M, to m, by the several wheels, G, h, f, k, and J, which have been described: they are so apportioned, that the spindle, m, turns only once for 48, 60, or 72 revolutions of the spindle B. These different numbers are used in different machines, and the appearance of the ball they will wind materially depends upon this circumstance.

To explain its operation, suppose the spindle, m, inclined to B, as in fig. 3, the rapid motion of the spindle, and its flyer D, (over the point, d, of which the thread is conducted) laps the thread round the spindle, m, in an oblique direction. At first, the ball thus formed has no regular figure, but as the thread accumulates and forms a cone, the lapping of the thread in a regular order begins and continues, as in fig. 3; here it is seen, that the motion of the flyer will lap the thread obliquely upon the ball from one end to the other, as the figure shows; but at every succeeding revolution of the flyer, the ball itself has made ⅔, ⅔, and ⅔, part of a revolution upon its own axis m, according to the proportion of the wheel-work, and thus the thread is not always deposited on the same oblique line, but on another parallel to it, and removed a small distance from the former. Now it is plain, that the thread on the underside of the ball must be inclined in a contrary direction to that lapped on the upper side; therefore, when the ball is looked at, the oblique threads of every alternate layer cross each other, in the manner of the figure. This will, however, be much more readily understood from an inspection of a ball of this kind, than from any verbal description. The length of the ball depends upon the angle which the spindle, m, makes with the spindle B: it can, therefore, by shifting the handle N, be wound off of any required figure; but the most general method is, when about one half the size of the ball is wound, to give the spindle a greater degree of obliquity: this occasions the ball to wind longer from that period, as well as a greater diameter; the consequence is, that when the ball is finished, on looking at the end of it a circular hollow is seen in it, as though it had been turned in a lathe, and sometimes a thin-membrane, consisting of about two or three layers of thread, is extended nearly across the end, leaving the hollow beneath, which can be seen into from a small hole in the end. This membrane is made by letting the handle, N, at the greatest angle it will make, the thread then not only lays over the whole surface of the ball, but is stretched nearly across the end of it; and the interference of a great number of these forms a transparent membrane, which has a circular hole in the centre. After laying this layer two or three times over, the handle N is returned to its original angle, and winds the ball as at first.

The bench or table RR, on which the machine stands, is made long enough to contain fourteen spindles, all placed in one row; and a throat cyliner, running along under the bench, gives motion to them all at once. Two children attend the whole fourteen, which they can readily do, having only to lap the thread, at the beginning, upon the spindle m, and then, when the ball has arrived at a certain size, to turn the handle N; but the period or quantity of this alteration is not of any great importance, as it only influences the figure of the ball, and, as we before described, those fancy ornaments within the hollow end: these may, by great attention in frequently and artfully shifting the handle N, be made very delicate and beautiful. The machine we have just described was made after a model of a machine invented by Mr. Brunell, who first devised the means of connecting the spindles, B and m, by wheel-work. The machines, before this, were turned by endless bands, from the principal cylinder which gave motion to the whole. The defect of this method was, that the parts of the wheels could not be so exactly proportioned, as to produce order of a for exactly forty-eigh, &c. of B, that the threads of the successive layers would lay exactly one over the other, because the leaf variation in this respect would greatly injure the effect of the ball. But in the machine before us, the motions are so accurate, that, on inspecting the ball, it appears honey-combed, or consisting of regular cells, which gradually diminish in size as they approach the centre; the partitions between these cells are only one thread in thickness, but consisting of a great number, stretched so exactly over each other, that they form regular plane sides to the interior of the several cells.

We have now presented our readers with all the operations of cotton-spinning; but these operations are conducted on so grand a scale by many manufacturers, that the system of their management, the arrangement of the buildings, the construction of their water-wheels, steam-engines, or other fast movers, and many other particulars, are no less admirable, and worthy of description, than the machines themselves. To describe all the curiosities of the cotton trade would fill a volume; but we must content ourselves with describing one plate, which contains drawings of one of the most complete cotton-mills we have ever visited. It is one of the four mills at Belper, in Derbyshire, belonging to Messrs. Struts, whose very extensive works contain almost every improvement in the cotton trade. The whole of, the
The crown, has each; nine be appropriated pales they fliał, also are one pair also with the a building the a one containing the built which winter; this, is the llrong "I'hc mill. wheel columns that school- Thus, like pinion /V. another two fliewn fup- bevilled third top the render the the mill. wheel.

The space of the mill, therefore, between the walls C and D, is appropriated to the machinery, as is also the wing, which consists of six arches, as shown in fig. 3, projecting from the middle of the mill, perpendicular to its length.

The width both of the mill and the wing is, as shown in fig. 3, composed of three lengths of arches, having three iron girder that they rise from, and two columns to support them. The arches in the ground-floor, or cave of the mill, are supported by very strong piers, v, instead of iron columns. These piers are founded very firmly in the earth, and every caution taken to prevent them subsiding, or settling under the great weight they have to carry. The columns of the first floor are erected immediately upon the top of these piers: on the top of these columns are those for the second floor; the third form the head wall, and to the top of the mill: the columns being thus erected, one upon another for the whole height of the mill, forms the Framebuilding that can be imagined.

We shall now proceed to describe the machinery of the mill. The whole motion is taken from the great water-wheel M, situated underneath the wing, in the cave, or lowest room of the mill, and as it is of so great a size, namely, 18 feet diameter, and 23 feet long, that no call-iron girder could be thrown across it strong enough to support the arches for the wing above it, a strong flue arch, N, is thrown across from the wall b, which is built up at the end of the water-wheel, to the wall, A, of the mill, which is the end of the other mill; and to refill the thrust of this arch, two strong iron bolts, x, are extended across it, and render it as strong as possible; so that the iron columns of the wing over it may be raised upon it as safely as they could upon foundation piers, w, like the others. But as a precaution against overloading the walls, b and A, which, as they include the water-wheel, would ruin every thing, if they settled in the leaf, the arches of the wing immediately over the water-wheel are built, instead of solid brick, with small pots like garden pots, so that they are light, but sufficiently strong to bear any thing which is ever required to be loaded upon them. These small pots are also used to build the arched floor, K, of the roof, that it may be light, and as it has nothing to bear but the school room, they are sufficiently strong to make the floor.

The great water-wheel has a cog-wheel, a, upon the end of its shaft, which turns a pinion, p, on a flong shaft, that carries a wheel q, and thus turns a pinion on a third shaft, r, this, at the end, has a bevelled wheel, which gives motion to a vertical shaft, s, proceeding up to the top of the mill, and turning the machinery in the several floors. The bevelled wheel on the shaft, r, also drives a horizontal shaft, t, extending the whole length of the mill, and having upon it, just beneath every arch, a bevelled wheel, turning another on a vertical flindel, which rises up through the two floors D and G. These are the main flindels of the spining frames, and the great frames are fixed upon them. The frames are all flwen endways in fig. 1; but in fig. 3, on the floor F, a pair of frames are flwen in front, as they flind side by side, and the floor, G, over it has just the fame, as has also the wing, though not put in the drawing; but these last are turned by a bevelled wheel, v, fig. 1, on the shaft s, in the floor G, which turns a horizontal shaft, v, fig. 3, extending the whole length of the wings, and turning the flindles of the several frames as it passes over them. The two lowest floors, F, G, which are appropriated to the spining frames, contain 28 frames on each floor, 56 and 12 more in the two floors of the wing, in all containing 4 356 flindles, a considerable proportion of which are, however, employed in spinning the hard twill. The two next floors, viz.
the 3d, 11, and the 4th, 1, are occupied in the body of the mill with carding machine, which stand in three rows; they are turned by flaps from a horizontal shaft, extending the whole length of the mill, over the machines. In fig. 1, they are shown endways, and fig. 3, shows them in front of the floor H, while that about it is just the same, though not drawn: in all these two floors are 63, breaking cards, and 72, withers. The same floors, H and I, in the wing, contain 16 drawing frames and four stretching frames or bales, in which the roving are prepared as described in our account of the different methods of making rovings. The fifth floor, I, contains the reeling, doubling, and twisting machines, i.e., as we have described; but the numbers of the different kinds of these last mentioned machines vary in every mill, according to the kind of cotton which is to be spun in it, and that branch of trade its proprietor intended to carry on: it is for spinning twist for weavers, only reels will be wanted in the fifth floor; or if it is for spinning yarn, doubling and twisting machines will be wanted. Indeed these last machines are altered every few years in cotton mills, according as the state of the trade varies from a demand of one article to another.

The space of the mill, between the walls C and L, contains, as before-mentioned, the flaxcase O, which is of flour, extending from one floor to the next, and also the shed P, P. This is a warm interior, and useful over it is the usual machine for hand cards in the Cotton mills, which has been adopted by Messrs. Strutt in all their cotton mills, and it is applicable to many other manufactories. The cradle consists of a large square basket, or cradle, four feet six inches square in the bottom, withinside, and six feet deep; it is open in front. The bottom is a floor of wood, and the sides wicker or basket work strongly bound with iron flaps. This basket or cradle is suspended by a rope in a well P, extending from the top to the bottom of the mill, through all its floors. The cradle exactly fills the well, and is guided by iron flaps in each angle, so that it may be readily drawn up from one floor to any other by the power of the mill, and dropped or set in motion, either up or down, at pleasure, by pulling two guide ropes, which are always in reach of a little boy who sits at the top of the cradle in a seat made for the purpose. Now the machinery for effecting this is the only difficulty; it is necessary, in such a crane, that the machinery, when set on to draw up the cradle, should move with a regular and equal velocity, without making any shock or jerk when it hits flats, so that it should not shake the flax it is required, other things being equal, to be very difficult to set the machine on its floor, exactly on a level with any of the floors of the mill, and if not so, it would be very inconvenient for the people to get in or out of it.

The cradle must also be let down by the power of the mill as well as drawn up, because if suffered to run down by its own weight, it would always run down too quick or too slow, and be dangerous and uncertain; it may, at the same time, be so contrived, that the cradle itself will stop the machine if drawn up too high, or let down too low, to prevent its being over-wound and breaking the works. All these conditions are effected, in the most perfect manner, by very ingenious mechanism, which was invented by Mr. H. Strutt, and has been adopted in all his father's mills, rendering these cranes as safe and manageable as possible. The rope suspending the cradle in the well is double, to endure greater strength, and is conducted over a pulley, or grooved wheel, situated in the roof of the mill. The other end has such a weight suspended from it, as will balance the weight of the cradle, together with half the weight of the usual load the crane is expected to carry. This weight, therefore, draws the rope tight upon the grooved wheel, that it will, by turning round one way or the other, elevate or depress the cradle at pleasure, and at the same time the balance weight, which has a small well of its own to work in, on the axis of the grooved wheel has a cog-wheer on the end of it, which is carried round by a small pinion fixed on the extremity of an axis on which the mechanism is placed: it confines, first, of a large wheel, like a coach wheel, shown at x, fig. 1, fixed on the middle of the axis, and on each side of this are two broad riggers or drums to receive the endless flaps, which give the motion against these riggers on the outside of each. A dead pulley or rigger is fitted loosely on the axis, and being exactly the same size as the live riggers or pulleys, the flap can be shifted from one to the other in a moment. The axis is actuated by two endless flaps coming from one drawn at y, fig. 1, which is turned by wheel-work from the shaft in the fifth floor of the mill, as the figure shows. One of these flaps is crossed between the two drums, and the other is not, so that the motion of the two dead pulleys on which these flaps act are always in contrary directions to each other, whilst the axis on which they run is stationary. The two flaps are guided by pulling through eyes attached to a side rail of a square frame, which includes the axis with both its riggers and great wheel, and is furnished with wooden rods, so that it has free motion to swing backwards and forwards in a direction parallel to the length of the axis of the pulleys, which motion is communicated by a crank formed on a pinrade, having a grooved wheel on the end of it. An endless rope passes over this wheel, and then descends to the bottom of the well, where it is strained beneath another wheel, so that the two sides of this rope are always in reach of the boy before-mentioned, who rides in a seat at the top of the crane, giving him the means of turning the wheel and crank either way about, for by pulling down one of these guide ropes, he turns the wheel and crank, and draws the suspended frame one way, or by pulling down the other guide rope it is drawn the other. The consequence of these movements is, that the endless flaps are shifted both together on one or other of their live pulleys, whilst the other flap will be shifted upon the opposite dead pulley; consequently, the flap which is upon the live pulley turns the axis round one way or the other, drawing the cradle up or down, as it happens to be the cradled flap, or the opposite. This is the live pulley, the axis on which is either side of the great wheel, which we first compared to a coach wheel. This is, in reality, a brake wheel, having a broad flap surrounding the lower half of it, both ends of which are conducted over two pulleys, and levers with heavy weights draw down the ends, so that it has a constant tendency to press downwards beneath the wheel, to break, or cause such a friction upon it, as will stop its motion, when the two endless flaps are shifted upon their dead pulleys: but when the swaying frame is shifted either way, by the boy pulling down one of the guide ropes, which go down to the bottom of the well, and either of the flaps are thus shifted upon the live pulleys, the frame forms the tail of a bent lever on each side the wheel, and relieves the weights which draw the flap against the wheel, and it hangs quite slack beneath the wheel, with a considerable space all round, so that its motion is quite free, and only under the influence of that flap which, being upon one of the live pulleys, gives it motion in either direction. The crane before-mentioned for shifting the swinging frame is faultless in its performance; it has a tendency, by means of a weight, to assume such a position, that it will direct the swinging frame, and the flaps, both upon the dead pulleys and the brake flap, being at the same time in contact with the lower half of the wheel, the crane will stand
but when the crank, by pulling one of the guide ropes which go down to the bottom of the well, is turned to shift the endlesss fraps either way, and consequently put the cradle in motion, the crank drops into a kind of hitch, or catch, which holds it in that position, but not so fast but that it can be relieved in a moment by snatching the guide or rope, and if left to itself it then assumes that position in which the crane will stand still. By this means the crane is in no danger of any accident, as it is always under the action of one or other of the endlesss fraps, which cause it to ascend or descend, or it is under the brake ftrap, which makes it stand still, and the great advantage of all these movements are, that they act so softly, without any sudden jerks or snatches in changing from one state to another. The well has a gate fixed at every floor to prevent people falling down into the mill, and if any person, on the fifth floor, for instance, wishes to descend to the third, he goes to the gate and calls the boy, who, with the crane, is perhaps below, to come to No. 5, which he does by snatching that guide rope which makes the crane draw up, when he leaves the floor of the basin come exactly opposite the floor of the mill No. 5. He snatches the opposite rope; this jerks the crane out of its hitch, and it shifts the fraps and brake, stopping the cradle in an instant, so that it is seldom half an inch out of level with the floor. The person who wishes to go down can now open the gate, which he could not do before, because the latch of the gate is lifted up by the crane, when its floor is level with the floor of the gate, and stepping into the cradle he mentions the floor he wishes to go to, and the boy pulls down that directing rope which lets him down, and stops it at the floor he wishes, by snatching the other rope; but if he should pull the wrong, no harm can ensue, because the brake will always act to stop the machine, if the fraps do not act to move it. The bobbins of the spinning-frame, and the cops of the mule, are set up in little frames mounted on wheels, and thus wheeled along by little children to the crane, and drawn up or let down as required, without any hard labour; in fact, the flairs are seldom used except for the people to go up and down when they begin and leave off work.

The stove which warms all the mill is situated down in the cave beneath the头脑: it is very ingeniously contrived with an iron cockle, or inverted conical vessel, beneath which a fire is made, and the smoke escapes by a flue behind into a chimney. The air is then brought in a current to strike upon the external surface of this cockle, and being thus warmed, rises up through flues into every floor of the building, where it is admitted in any quantity at pleasure by regulators, which are regulated to produce an agreeable warmth, but as the warm air escapes again with a draught through a proper ventilator, there is nothing of clockmenc connected with it.

Our limits will not permit us to describe more of the ingenious contrivances with which the millers, Struts' extensive mills at Belper abound, neither could the reader form a good idea of them without additional plates, and we have already exceeded our proposed number. Millers. Struts very liberally permitted the writer of this article to visit their works, for the purpose of compiling it, to take drawings of the principal machines, which are of the very best construction of any in the cotton trade. We could have appeared here, but that the first six plates of our series were drawn and engraved some years ago, being intended for the article Cotton, at a time when the machinery was not brought to that perfection in point of construction, that it is now. Indeed, the mechanical ingenuity called forth in the whole manufacture of cotton, is beyond the conception of those who have not visited the countries where it is carried on. The tools and implements employed in constructing the different machines are very curious; for as there are such immense numbers of each part of every machine to be made, it becomes, in the same manner as with the clock-maker, worth the machine-maker's trouble to construct complicated tools and engines to expedite the manufacture of the parts; thus cutting engines for forming the teeth of the numerous wheels, see Cutting Engine. And here we would remark, that Mr. George Gilpin of Sheffield has, since the printing of that article, invented a method of cutting wheels from solid cast iron, with as much accuracy and as good a finish as brass wheels have hitherto been cut, making a very great saving in the expense of brass for a large mill, and much more durable when done. Card wires are manufactured in a very extensive scale in Yorkshire, and many very curious machines have been invented to diminish the labour of cutting and bending the wire teeth, and prickling the leathers for them: but a patent has been lately taken out, by Mr. J. C. Dyer, for a machine which cuts and bends the wires, pricks the leathers, and puts them in all at one operation, and with such rapidity, that it completes four per second. It is one of the most ingenious and perfect machines we ever met with, and it will prick and stick any fort or size of teeth, by altering adjustments introduced for that purpose. Drawings and a full description of this curious machine are lodged in the patent office by the patentee, who brought over the invention from America, where it has been some time in constant use. Curious lathes for turning spindle, and various other circular work, are used in the workshops of the cotton mills and spinning machines, for cutting the flutes in the lengths of the rollers of the drawing and spinning machines: in short, such works as Melfa, Struts' at Belper. Mr. Arkwright at Crafford, in Derbyshire, Melfa, Phillips and Lees at Manchester, Mr. Peele's and many others, are schools for mechanics in almost every department of the science; and good ones too, as the cotton manufacturers in general are convinced, that it is their interest to attend to every minutia in the construction of their machines, which may render them more durable or their operations more perfect. Among these improvements we may mention, what is becoming very general, viz. the addition of governors, or regulating balls, to the water-wheel, which turn the cotton mills, as they always keep it moving at the fame speed, without which all the machines in the mill act irregularly, and it must happen that the velocity of the common water-wheel varies, when any number of machines are stopped, or cut in motion; but the regulated water-wheel always adapts its draught of water to the work it has to perform, preserving an uniform velocity in itself and all the machines it turns. This is brought to such perfection, that many such mills have a clock turned by the mill; close to it another clock, regulated in the usual manner by a pendulum, and the motion of the mill is so regular, that these two clocks will never vary more than two or three minutes. Both are made with dials and hands exactly alike, but one has a tick on the dial, mill time, and the other, clock time. We shall take an opportunity of explaining a regulated water-wheel, under WATER-WHEEL.

We shall here close this article, though we have only gone through the detail of cotton-spinning, because the subsequent process of weaving cotton-thread into cloth, dyeing, finishing, printing, &c., have been or will be explained.
planned under the following several heads: viz. for explanations of the weaving processes, see Draygent of looms, or CORDING, Draw-loom, DRAPE, DUNNOCK. Thoroughly the three last are rather linen than cotton, still the same processes apply in part to the weaving of cotton goods; see also FUSTIAN, and last, WEAVING. For the dressing of cloth after weaving, see CALENDAR, or rather PRINTING OF CLOTH, which precedes the calendar, except for some particular goods; and as a part of calico-printing see DIPPING; also BLEACHING, DYEING, DISCHARGING, and WASHING-WHEEL. And, as we have before mentioned, a full account of the wonderful rise and progress of the cotton manufacture, which is wholly founded upon the improvements in the machinery for spinning, will be found under COTTON. Under the head of SPINNING, we shall describe those variations of the cotton machines, which have been made to adapt them to the spinning of flax, wool, and worsted.

MANUFACTURERS. Persists enticing artisans into foreign countries incur the penalty of 500l. and twelve months imprisonment, for the first offence, for each person so induced, and 1000l. and two years imprisonment, for the second offence. (23 Geo. II. c. 15.) And such artisans not returning within six months after warning, shall be deemed aliens, forfeit all their lands and goods, and be incapable of any legacy or gift. (5 Geo. I. c. 27.) By 22 Geo. III. c. 60. if any person shall contract with, or endeavour to persuade any artisan concerned in printing calceous, cottons, muffins, or linens, or preparing any tools for such manufacture, to go out of the kingdom, he shall forfeit 500l. and be imprisoned for twelve months; for a second offence, 1000l. and be imprisoned for two years.

MANUGASTA, in Geography, a town of South America, in the province of Tucuman; 20 miles S. of St. Yago el Eleros.

MANULCA, in Antiquity, that part of the catapulta to which the cord was in working it was fixed.

MANULICA, in Botany, so named, as it should seem, from manulca, a covering for the hand, in allusion to the form of the corolla, the four segments of which point one way, and the fifth separate from them, suggest the idea of a glove, at least in Manulca Cheiranthus. Linnaeus, who gave this name, fearfully ever designed to give any explanation of the names he contrived, and we offer the above as a conjecture only. Professor Martyn leaves it unexplained. Linn. Mant. 82. Schreb. 416. Willd. Sp. Pl. v. 3. 327. Mart. Mill. Dict. v. 3. Thumb. Prod. 100. Julii. 100. Lanarck Illust. t. 520. Gaertn. t. 55. (Neinia; Berg. Cap. 460.) Cliffs and order, Didynania Anguiferrinia. Nat. Ord. Periconia, Linn. Pediculaires. Jull. Scrophulariaceae. Venten.

Gen. Ch. Cal. Perianth inferior, in five deep, linear, erect, equal, permanent segments. Cor. of one petal, irregular; tube cyndrical, contracted at the mouth; limb spreading, in five deep awl-shaped segments, the four uppermost of which are most connected at their base, the lower one being reflexed. Stem. Filaments four, very short; anthers of the upper two in the mouth of the corolla, those of the two lower rather oblong, within the tube. Pith. German superior, roundish; fyle thread-shaped, the length of the lower flaments; stigma simple. Peric. Capsule ovate, the length of the calyx, with two cells and two valves, which split when ripe are half cleaved; partition double, formed of the inflexed margins of the valves. Seeds numerous, small, affixed to an oblong, compressed, central column.

Eff. Ch. Calyx inferior, in five deep segments. Limb of the corolla in five deep awl-shaped segments, the upper four of which are most connected. Capsule of two cells, with many seeds.

Obi. The above characters are taken from the original species, M. Cheiranthus above-mentioned, but they by no means agree, at least in the limb of the corolla, with the generality of those subseqently referred to this genus in the Supplemetnum and elsewhere. Bergius gives as the essential character of his Nemina, which includes M. Cheiranthus and rubra of Linnaeus, that the two upper anthers are roundish, the two lower oblong. This however is probably variable, and certainly not very important. Thunberg indicates no generic character, but enumerates a great number of species, 50, in his Princomus Plantarum Caprifom, four of which have entire, 25 toothed or ferrated, and one unnotified leaves. Willdenow admits but 17 in all, not having, when he wrote, seen the second part of Thunberg's work. The chief difficulties are found in distinguishing between Manula, Erinus and Buchnera. Ventenat in his Jard. de la Mahnaifon, 15, suggests that the two former are most nearly allied, and differ only in the lobes of the corolla of Erinus being more or less notched or cloven, while those of the genus before us are entire. Buchnera, according to this writer, differs so essentially from both as to belong to a distinct natural order, the Pediculaires of Jussieu, as having the partition of its fruit, contrary to the valves; whereas the other two genera, having it parallel, belong to the Scrophulariaceae of that author. As the matter is so obscure, and the plants so little known, we shall take a view of all those in Willdenow, giving what illumination is possible from original specimens, and adding what we can that has escaped him.

1. M. Cheiranthus. Hand-flowered Manulca. Linn. Mant. 88. Willd. n. 1. (Lobelia Cheiranthus; Linn. Sp. Pl. 1319. Nemia Cheiranthus; Berg. Cap. 150. Cheiranthus africana, flore hideo; Commel. Hort. v. 2. 153. 1706.) Leaves oblong-oblong, ferrated, hairy. Stems nearly leafless, somewhat racemose. Segments of the corolla taper-pointed. Native of the Cape of Good Hope, and as are all the following species. Commelin cultivated it at Amsterdam in 1697, and named it Cheiranthus, from the resemblance of the flower to a hand, an etymology that confirms our explanation of the Linnaean generic name above. The stem is annual, spindle-shaped. Stems about a span high, erect or ascending, nearly simple, almost leafless, each terminating in a simple, elongated, bracteated clysters, of numerous yellow flowers, whose form is described in the generic character. The leaves are almost all radical, flaked, obovate or oblong, strongly ferrated, more or less hairy, paler beneath. The herbage, calyx, bracteas, and even the outside of the corolla, are befrinkled with silvery dots or granulations. The capsule is elliptical and smooth, its partition formed by the inflexed margins of the valves, and so far parallel thereto.

2. M. corymbosa. Corymbose Manulca. Linn. Sappl. 286. Thumb. Prod. 102. Willd. n. 2.—Leaves obvolute, toothed, smooth. Flowers on leaf-topped, somewhat umbellate, clysters.—We know nothing of this species but the above characters, given by Thunberg and the younger Linnaeus. The stem is said to be naked.

3. M. altissima. Tall Manulca. Linn. Sappl. 286. Thumb. Prod. 102. Willd. n. 3.—Leaves radical, lanceolate, somewhat toothed, hairy. Stem elongated, almost naked. Spike ovate-oblong. Lobes of the corolla rounded. The leaves are all radical, about four inches long, lanceolate, tapering down into a footstalk; their edges unequally

MAN
Manulea.

equally toothed; their surface clothed with short glandular white hairs. Stem two feet high, erect, hairy in the same manner, scarcely at all branched, terminating in a denfe, rather corymbose, spikes of numerous, large, and apparently handfome, flowers, the fegments of whole corolla are unequal, fpreading horizontally, of a rounded somewhat kidney-like shape; the mouth clofed. Calyx hairy, divided to the very bafe. Capsule of the structure proper to the genus.

4. M. plantaginea. Plantain-like Manulea. Thumb. Prod. 101. (M. Plantaginea; Linn. Suppl. 286. Wildn. n. 5.)—Leaves ovate, obtufa, flalked, entire or toothed, fmoother. Stems diffufe, nearly naked. Spikes ovate. Bracteae obvolute, longer than the fowers. — Root long, fibrous, apparently annual. Stems three or four, decumbent, divaricated, about two inches long, fimple, almost leafless, hairy. Leaves not unlike thofe of a daiy, ovate, obtufa, fmoother, flefhy, occasionally toothed, meafuring, with their fomblחצי, rather than an inch in length. Spikes mostly solitary, short, round and denfe, of many small fowers, separated by ovolute, obtufa bracteae, twice their own length, whole bafe only hairy. Calyx bell-shaped, hairy, not very deeply divided. Segments of the corolla rounded, and fome of them, if we miftake not, cloven, in which cafe this plant becomes an Erinus.

5. M. linifolia. Flax-leaved Manulea. Thumb. Prod. 100. —“Leaves linear, nearly entire, rough with minute hairs.” —We received from Kew garden in 1791, fpecimens by the name of Manulea, which answer exactly to the above characters of Thunberg, of whole plant we have no further information, it not being defcribed by Linneaus or Wildenow. Our’s has a fnder, branched, leafy, nearly smooth ftem. The leaves are oppofite, inferted, an inch and half long, about a line broad, bluntinf, rough with minute glandular pubefeence; their margin occasionally toothed; their bafe tapering into a fnder falfmouth. Flowers numerous, in loose, compound, terminal clusters, with small oblong bracteae. Calyx small, obtufa, smooth. Corolla fnder, above half an inch long, its tube glandular in the upper part, its limb of a rich deep yellow, in five oblong, obtufa fegments, whose edges are reflexed, and one of which feems more fpreading than the rest, as in the firft fpecies. —Can what we defcribe be Buchnera rifofa? Ait. Hort. Kew. ed. 1. v. 2. 357? L’Heritier’s figure has never appeared.

6. M. pinnafifolia. Pinnafifolat Manulea. Linn. Suppl. 286. Thumb. Prod. 102. Wildn. n. 4.—“Leaves ovate, pinnafifolat; their fegments toothed.” —This we have not met with.

flowers panicled. We have what feems to be this fpecies, gathered by Sparrmann in fady places at the Cape. The ftem is somewhat fhrubby, and very much branched, hairy. Leaves oppofite, hairy, ftrongly toothed. Inflorescence at firft corymbose, afterwards becoming more fiofe and panicled. Calyx hairy, with long fnder divisions, not quite feparate to the bafe. Segments of the corolla obovate.

10. M. argentea. Silver-leaved Manulea. Linn. Suppl. 286. Thumb. Prod. 102. Wildn. n. 9. —Leaves alternate, obovate, wedge-shaped, ferrated, beflowered with fiverly dots. Flower-flaks axillary, fingle-flowered, longer than the leaves. —Thunberg’s own fpecies, given to Linneaus, here leaves no doubt on our minds, though their definitions of it a little vary. The ftem is woody, with numerous curled leafy branches. Leaves falked, small, alternate, with little axillary tufts of fmall fmalier ones; their form obovate or round-iff, fhrubby ferrated, wedge-shaped and entire at the bafe; the under fide, more especially, clothed with glandular filverly dots, as is also the deeply-divided calyx. Segments of the corolla rounded. The flower-flaks are folitary, axillary, simple, fmoother, about an inch long, much exceeding the leaves. Capsule proper to the genus. The plant turns black in drying.

11. M. oppositiflora. Oppofite-flowered Manulea. Ven. Ten. Malmaif. t. 15. —Shrubby, downy. Leaves oppofite, ovate, deeply ferrated. Flower-flaks axillary, fingle-flowered, the length of the leaves. —M. Ventenat defcribes this as a native of the Cape, flowering profufely during the sunmer and autumn. It has the fhrubby habit and aspect of the lat, but the oppofite leaves and flowers clearly diftinguish it. If Buchnera pedunculata, Andr. Repof. t. 84, be, as Ven- tenat fays, generaifly diftinft, and even effentifally different in its capsula, from these two fpecies, it must be allowed their habit is too similar to make such a difference credible in all the force he allows it.

Buchnera ethiopica and caprifus of Linneaus if, as Thunberg now makes them, fpecies of Manulea, should follow here, the former being nearly akin in habit to the two or three fpecies defcribed. But as habit seems treacherous with regard to these plants, we dare not decide. See Buch- neria.

12. M. tomentofa. Woolly Manulea. Linn. Mant. 429. Wildn. n. 10. Jacob. 1c. Rar. t. 498. Curt. Mag. t. 422. Thumb. Prod. 101. (Selago tomentofa; Linn. Sp. Pl. 87?) —Leaves obovate, downy, bluntly toothed. Stem leafy. Clutter compound, terminal, many-flowered.—Mr. Maffon is faid in the Hort. Kew. to have introduced this fpecies into the gardens of Britain in 1774. It is we believe naturally fhrubby and perennial. The branches are round, leafy, and they, as well as the foliage, inflorescence, and even the outside of the fowers, are clothed with denfe hoary pubefeence. Leaves mottly oppofite, an inch or more in length, obovate, very obtufa, unequally and bluntly toothed. Flowers very numerous, in a dense, compound, hoary cluffter, produced from May to November, having, according to Mr. Curtis, "a fingular but unpleafant smell, not perceptible at a distance." The outside of the corolla is pale yellow, as is the upper fide of the limb when firft expanded, but the latter gradually assumes a deeper and deeper orange. There is a great affinity between thefe flowers and thofe of our M. infiifolia, n. 5. 3 N
s] The stems, or branches are smooth. The leaves are "linear, toothed, rough, felted; the lower he had not seen. Clyther terminal, very long and slender, its branches alternate, dilant and erect, the flowers nearly felted. Calyx fringed. Tube of the corolla long, flender, pale red, thickened and hairy upwards; segments of the limb linear-ovate, obtuse, hairy beneath, spreading, nearly equal, revolute in the margin, deep scarlet.

15. M. cuneifolia. Wedge-leaved Mantula. Linn. Suppl. 285. Thunb. Prod. 101. Wild. n. 13—Leaves elliptico-ovate, toothed, nearly smooth. Spikes at length oblong. Calyx fringed.—The stem is shrubby, much branched, leamy, round and downy. Leaves nearly opposite, flat-topped, about half an inch long, ovate, obtuse, with coarse blunt ramifications; both sides occasionally slightly hairy, often smooth. Spikes terminal, solitary; at first dense and almost capitulate, with a linear, obtuse, fringed bracteae to each flower, longer than the flower itself. Segments of the calyx very deep, linear, obtuse, fringed with soft hairs. As the fruit advances, the spike becomes very long. The lobes of the corolla are rounded, obtuse and entire. Capsule elliptical, narrow, obtuse, with a strong furrow at each side. 16. M. cordata. Blue Mantula. Linn. Suppl. 285. Thunb. Prod. 101: Wild. n. 14—"Leaves linear, opposite, downy, toothed. Flowers racemose." Linn.—Thunberg defines the leaves as lanceolate, the flowers axillary and solitary. We have seen no specimen.

18. M. integrifolia. Entire-leaved Mantula. Linn. Suppl. 285. Thunb. Prod. 100. Wild. n. 16—Leaves opposite, ovate, nearly entire, smooth. Flower-flanks axillary, single-flowered, the length of the leaves.—This is perhaps next akin to our tenth and eleventh species, though essentially different in its leaves, being at most but slightly ferrated. They greatly resemble those of Thymus Acretus, and the species might well have been named thymofolia or ocygynofolia. The stem is shrubby, round, much branched. Leaves opposite, on short downy footstalks, which embrace the stem; nor are they by any means scattered, as Linnaeus defines them. Calyx smooth, its segments long and narrow. Tube of the corolla swelling upwards; segments of the limb rounded, obtuse.

19. M. microphylla. Small-leaved Mantula. Linn. Suppl. 285. Thunb. Prod. 100. Wild. n. 17 (Pink. Phyt. t. 272. f. 7.)—Leaves densely tufted, ovate, entire, smooth. Flower-flanks lateral, solitary, single-flowered, downy, much longer than the leaves.—Gathered by Sparrmann as well as Thunberg at the Cape. Stem woody, with very numerous branches, along which are arranged crowded dense tufts of innumerable, extremely minute, leaves, each tuft seeming the rudiment of a future branch. The flower-flanks, scattered here and there, are about half an inch long, solitary, simple, ascending, rigid. Segments of the calyx oblong, obtuse, downy, deeply separat. Plukenet perhaps represents the calyx, not the corolla; the latter we have not seen. His figure was truly indicated by Linnaeus himself on the specimen, though omitted in the Suppl.

We subjoin the remaining species of Thunberg, without regard to the order in which they ought to come, as we have no means of correctly ascertaining it.

20. M. revoluta. Revolute Mantula. Thunb. Prod. 100.—"Leaves linear, entire, revolute in the margin. Flowers axillary."—This he places next after his linifolia; see n. 5.

27. M. eordata. Heart-leaved Mantula. Ibid.—"Leaves heart-shaped, ferrated. Stem decumbent, creeping."—In MANUMISSION, MANUMISSION, an act whereby a slave, or villain, is set at liberty, or let out of bondage.

The word comes from the Latin manus, hand, and mittère, to send; quia furores uitæbatur extra manum, feu potestatem domini sui.

Some authors define manumission an act by which a lord enfranchises his tenants, who till that time had been his vassals, and in a state of slavery, inconsistent with the facility of the Christian faith.

Among the Romans, the manumission of slaves was performed three several ways. 1. When, with his master's consent, a slave had his name entered in the census, or public register, of the citizens. 2. When the slave was led before the praetor, and that magistrate laid his hand, called vin- dicit, on his head. 3. When the master gave the slave his freedom by his testament. Servius Tullius is said to have set free on foot the first manner; and P. Valerius Publicola the second. A particular account is given of the third in the Institutes of Jusjtimian.

It was not necessary that the praetor should be on his tribunal to perform the ceremony of manumission; he did it anywhere, indifferently, in his house, in the street, in going to bath, &c. He laid the rod on the slave's head, pronouncing these words, "Dico cum liberum eel me quo Quiritum," "I declare him a free man, after the manner of the Romans." This done, he gave the rod to the hétró, who struck the slave with it on the head, and afterwards, with his hand, on his face and back, and the notary or scriber, entered the name of the new freed-man in the register, with the reasons of his manumission.

The slave had likewise his head shaved, and a cup given him by his master, as a token of freedom. Tertullian adds, that he had then also a third name given him; if this were so, three names were not a token of nobility, but of freedom.

The emperor Conoantius ordered the manumissions at Rome to be performed in the churches.

Of manumission there have also been various forms in England. In the time of the Conqueror, villains were manumitted, by the master's delivering them, by the right hand, to the vicarout, in full court, shewing them the door, giving them a lance and a sword, and proclaiming them free. Others
Others were manumitted by charter. There was also an
implicit manumission; as when the lord made an obligation
for payment of money to the bondman at a certain day; or
fued him, where he might enter without fuit; and the like.

MANUPELTA, in Geography, a town of Naples, in
Abruzzo Cita; eight miles S. of Civita de Cicha.

MANURE, in Agriculture, that sort of fibulence or ma-
terial, whatever its nature may be, that has the property or
effect when applied on, and incorporated with a soil, to in-
crease its fertility, and thereby promote the growth of dif-
ferent kinds of plants, such as those of the grain, grafts,
and other descriptions.

It may be noticed that the fibulences capable of being
made use of in this way, are extremely numerous, and of
different natures and properties. It has been flated by a late
writer, that on account of the changes that are continually
taking place among bodies in nature, and the new combina-
tions that are formed in confequence of them, a vast variety
of matters are unfolded, elaborated, and prepared for the
nourishment and support of vegetables; some of which
possess a high degree of fluidity and volatility, as water,
various gaseous materials, as oxygen, hydrogen, azote,
and carbonic acid, in different states of combination, with other
more subtile and elastic fluids, which are principally formed
and applied in or upon the foils on which the plants grow
and exiit; and in larger or smaller proportions, according to the
season of the year, the nature of the climate in respect to
heat or cold, and the state or condition of the land in regard
to its properties; while others exiit in a more gross and heavy
state of connection with the different materials, and require to
be applied and blended with the foils, or spread out upon
their surfaces, in order that they may exert their influence in
promoting vegetation. But it is the laft, as being the chief
means of supporting various sorts of plants, as crops, that
are considered as manures, though it is plain they must un-
dergo different changes to fit them for the purpose. In
addition it is likewise remarked, that in the various fibulences
applied in this way, there are great differences; "some are
found to yield the matters which are necceflary for the
support of plants much more readily, and more abundantly
than others, as animal, vegetable, and all such fibulences as
are rich in mucilage, facecharine matter, and calcareous earth,
and readily afford carbon, phosphorous, and some aerial fluids,
such as have been mentioned; while others that are greatly
deficient in all or many of these principles, or do not readily
part with them, are found to be of much less utility, when
employed in the way of manures." It is supposed that this is
"a principal reason why some sorts of manures or fibul-
ences, when put upon grounds, are fo greatly superior to
others, and the value of the same, and in the name manner
and proportion." But besides these there are "other ways in
which fibulences, when applied to foils, may render them
more fertile and productive, and contribute to the aid of
vegetation. Some, besides furnishing such matters as are
suitable for the purpose of promoting the growth of plants,
are known to add considerably to the quantity of vegetable
and other matters contained in the foils on which they are
placed, and thereby provide a more suitable and convenient
bed for the reception of the roots of plants; others con-
btrute little in this way, but operate chiefly upon such ma-
terials as are contained in them, breaking down their organi-
sation or texture, and thus fetting at liberty different vola-
tile and other ingredients, by which new compounds are
formed, and brought to such states as are the most adapted
to the support of vegetable life; others again act principally
by producing certain changes and alterations in the constitu-
tion or texture of foils, such as rendering them more open
and porous, or more flill and compact, and by such means
bringing them into the most proper conditions for the bearing
of different vegetable productions; and there are still others
that contribute in all or several of these ways at the fame
time."

By different inquirers these fibulences have indeed been
conceived to "operate in all the different ways by which
vegetation is promoted: by imparting to the foil with which
they are mixed the vegetable food which they contain; by
communicating to it a power of attracting this food in greater
plenty from the air; by enriching the vegetable matter: by
diffolving the vegetable food which it is already poffefed
of, and fitting it for entering the roots of plants. Some
afford nourishment only; as rape-duft, foot, malt-duft, pi-
egons' dung, and in general all top or hand-drillings. Others
give nourishment, and also add to the foil; as animal dung,
and all rotten animal and vegetable fibulences. Others
again open the foil, and do not nourish in their own nature
as lime, light marles, fand, &c. And lally, other manures
shift the foil, and at the fame time nourish a little; as clay,
clay marles, and earth." Matters of this kind have also been
"considered by different agriculturists as simple and com-
posed; as natural and artificial; nutritious and stimulating,
or solvents and mucilages; mechanical or chemical; as ani-
mal, vegetable, and mineral, &c." All which diftincions
may have their ufe, but are each attended with difficulties,
and liable to objections. "Some of them operate in all the
ways above-mentioned; and there are probably none that
do not operate in more ways than one. It is a fundamental
miffake to fuppofe with Tull, that tillage may be fubli-
tuated in the place of manure. Manures will indeed be of
little avail without it; but although good tillage, by sepa-
rating the foil, may bring a great number of nutritious par-
ticles within the reach of the crop, yet the foil cannot poifi-
ibly continue to be fo completely divided as it is by the ferme-
ntation excited by dung and other manures; which are found
to enrich the bell pulverized foil again and again, after it is
exhausted by crops; and therefore promote vegetation by
increasing the quantity of vegetable food. Some manures
lofe part of their strength by being long exposed to the air.
Thus after dung is sufficiently fermented, the longer it lies,
the lefs is its value. Cow-dung dried on the paffure, ga-
ered and laid upon other land, has scarcely any effect;
whereas the fame quantity carried from the cow-houfe, or
collected by folding the cattle, enriches the land. Hence
this kind of manure contains the vegetable food in itself,
and does not receive it from the air. Other manures, on the
contrary, operate sooner, and with greater violence, the
longer they are exposed to the air, before they are used.
Lime and marles are of this kind. They are obferved to have
a frong power of attracting certain qualities from the at-
mosphere; and operate by communicating to the foil with
which they are mixed a power of attracting vegetable food
from the air. And further, "some manures exhaust land of
its vegetable food, and do not restore it again when im-
mediately applied. This is thought by some to be the cafe
with lime. Land thoroughly limed, after having carried
many very good crops, seems to be exhausted, and reduced
to a worse situation than before. When in this cafe lime
has been applied a second time, its effects have been found
to be far inferior to what they were when first applied. This
manure, therefore, seems to operate by dissolving the vege-
table food which it meets with in the foil, and fitting it for
entering the roots of plants. It may however be noticed,
that the exhaustion of land by lime, is owing to bad manage-
ment and unmerciful forcing it with continued white crops.
It is not certain that land will not bear a second liming.

But
MANURE.

But it is certain that the effects of the lime may be long kept up by the proper application of dung and other fertilizing manures; and there have been instances of the effect of lime continuing forty, fifty, or even a hundred years." It is certain that almost "all kinds of manures contribute to open the foil. Any person may be convinced of this, who will take the trouble to compare a piece of land on which dung or any other manure has been laid, with a piece contiguous that has not been manured; he will find the former much softer, much more free and open than the latter. It must be allowed, therefore, that all manures operate by enlarging the vegetable pature of plants."

Hence, on account of the great differences that are thus met with in the properties and principles, as well as in the agency of the matters that are made use of as manures, it is difficult to bring them into any sort of practical arrangement. That which tends to show the nature and qualities of the materials from which they are derived, seems to be the most advantageous in the cultivation and improvement of land.

Manures of the Animal Kind.—It may be observed, that the materials which constitute this sort of manure, are of very different kinds, but they may be conveniently distinguished into such as are of a soft and hard quality; the former comprehending all sorts of animal dungs, and various other animalized materials of a soft nature; the latter including all sorts of hard animal matters, such as bones, horns, hoofs, and different other substances of a similar kind. It has indeed been remarked by a late practical writer, that "all substances of the animal kind, when reduced by the process of putrefaction or other means into a loof, pulpy, or mucilaginous condition, have been flown, by the experience of the most correct and able cultivators, to afford those matters which are suited to the nutrition and support of plants, with greater readiness, and in a more copious manner, than most other bodies. And chemical analysis has demonstrated, that the chief component materials of such substances, so far as agriculture is concerned, are principally water, jelly, or mucilage, and fæcherine oleaginous matters, with small portions of saline and calcareous earthy substances. Hence animal dungs well prepared, though they agree, in some circumstancies, with vegetable productions, each being in common water, fæcherine and calcareous matters, are far more compounded; and in animal substances none of these materials are in large proportions, while in vegetables they only exist in a very small degree; and the jelly, which in some measure resembles the gum and mucilage of plants, differs likewise from them, in its having much less tendency to become dry, as well as in its property of attracting humidity from the atmosphere, and of running with great rapidity into the state of putrefaction and decay." And in addition, "all these principles of animal substances are, it is added, resolved by their ultimate decomposition into other matters, such as the different gaseous fluids that have been mentioned above, carbon, phlogorous, lime, &c." It is likewise supposed, that "in animal substances of different sorts, there may be differences in regard to the proportions of these several ingredients or principles; some kinds affording one or more of them in greater abundance than others; while others again are deficient in these, but abound in some of the others. On this supposition, the different effects of substances of the same class, when applied to soils of the same kind, may, it is conceived, be easily accounted for."

It is found, that all substances of this kind, "on being deprived of their vital principle, have a quick tendency to take on or run into the state of putrefaction, a process which is considerably affected and influenced by the circum-

flances under which it is produced. But in the horny and more compact animal matters, this tendency to putrefaction and decomposition is, under similar circumstances, much less rapid than in such as are of a left firm and dense texture. The process of putrefaction is, however, greatly expedited by the conditions under which it takes place being favourable; such as the sub stance, of whatever kind it may be, possessing sufficient moist ure, being exposed to the free action of atmospheric air, and a moderate degree of heat. On various accounts it would likewise appear, that the decomposition of such substances may be promoted by moistening them with water, slightly impregnated with common salt; and perhaps some other saline substances, such as the muriats of magnesia and soda, or sea-salt, as ingeniously suggested by the Earl of Dundonald." And it is thought probable, also, "that the decomposition of some of the more hard and solid substances of this description, such as horns, bones, hoofs, and rotten rags, &c. might be greatly promoted, and rendered more immediately useful, by being reduced into much smaller particles than they are usually reduced. Besides, as well as by the application of higher degrees of heat than that of the atmosphere, when it can be done with convenience, and in a sufficiently cheap manner. It is likewise further stated, that "as the diffusion of animal as well as vegetable matters, is known to be much impeded by their being excluded from the air, or exposed to such degrees of heat as are capable of drying up and taking away their moisture, and by the mixing of such earthy substances with them as are capable, from their open and porous textures, or vitriolic and other qualities, of depriving them of the fluid matters which they contain; it is evident, why under certain circumstances of their being mixed and applied as manures, they may prove less beneficial than in other influences."

There are other circumstances, besides those which have a tendency to render the decomposition of all such matters more quick and expeditious, as those of their being lightly deposited together, and not in too large heaps, or with too much earth mixed with or deposited upon them, by which the air is prevented from acting upon them so extensively as might otherwise be the case. The practice of sprinkling common water over them frequently, especially in hot and dry seasons, and where they are of the more hard and compact kinds, in many instances might, probably, be useful in promoting their diffilution, and rendering it more sudden and complete, consequently, to supply the food of plants more readily, and in greater abundance in any given time.

But the principal substance, and that which is most commonly applied as a manure, is the excremes produced by various kinds of animals, which is found in very different conditions, or states of restitution and richness, in some measure according to the kind of food on which the animal has been fed, and the materials with which it is incorporated or intermixed. The writer of the Middlesex Report says, that "the dung of fat animals is unquestionably more rich, and, consequently, poifesles greater powers of fertilization, than the dung of lean ones; and that the quality of the dung of every sort of animal will, in a great measure, be proportioned to the goodness or poverty of its food. This is when the animal is fed on oily feeds, such as lin, rape, and others of a similar nature, it will be the most rich; when kept on oil cake, or those feeds which have been deprived of part of their oily matter, the next so; on turnips, carrots, and such like vegetable roots, the next; on the beit hay, next; on ordmary hay, next; and on straw, perhaps,
MANURE.

It may be noticed, that the foil of privies is sometimes met with in a flat state to be applied to the ground, when not mixed with fluid matters, such as urine, and forms a most excellent manure. It most frequently happens, however, that it is in such a liquid state, as to require other more solid substances to be blended with it, before it can be conveniently applied to the soil. In doing this, a late writer suggests, that "too little regard seems to have in common been paid to the choice of the most proper materials; but it is obvious, that such as can be the most fully acted upon, and the most readily converted into the state suitable for affording the nutrition of vegetables, by the principles of the matters thus employed as manures, must be the most adapted for the purpose, as well as the most beneficial. When, therefore, the manure made use of in this way, is either wholly or principally constituted of such animalized matters as, from their fluidity, are in an improper state or condition to be set on land, without having other substances previously mixed with them, such as peaty, boggy, or black vegetable earths should be chosen, as contain large proportions of matter, which the ammonia or volatile alkali so abundantly provided by the decomposition of such substances may exert itself upon, and reduce into that state of solubility which is suitable for promoting the growth of plants. By duly attending to this practice, which has been scientifically handled by the earl of Dundonald, much advantage may be gained, not only in the quantity, but likewise in the quality of the manure. The refults of experiments attentively made in this way, indeed clearly demonstrate, that an inconceivable loss is incurred by the inconsiderate practice of excreting human excrement, as well as the negligent custom of permitting the liquor or fluid parts of dung heaps to run away. The trials which he has been enabled to make, also lead him to suspect, that it is a much more walleful practice, to apply these liquors to the ground in their uncombined state, than in conjunction with such earthy matters as have been mentioned above. Besides, much of them must be imperceptibly carried off by the procefs of evaporation, even when they are carried out in the most favourable seasons of the year; and they cannot, in this way, always be made use of on those soils that contain a sufficient quantity of those earthy materials, or principles, with which they can readily form combinations, and exert their moft beneficial and full effects."

And it is further stated in the fame practical work, that "most of the later practical writers on agriculture are decidedly of opinion, that the foil of privies is a manure of the most enriching kind, but that its effects are not so lasting as those of many other substances. In the trials which have been lately made with it by Mr. Middleton, "it is paid to have produced such astonishing fertility, as to induce him to conclude that it exceeds all other arts of manure that can be put in competition with it, for the first year after its application. The second year he supposes it of some service, but as the third its effects nearly, if not quite, disappear."

The circumstances which render this form of manure so immediately active in promoting vegetation, and so quickly deprived of its beneficial influence, would seem to be the great quantity of elastic principles which it contains, in a loose state of combination, and the small quantity of earthy matter which it is capable of supplying to the soil, by the last stages of decomposition or decay. This also further shews the advantage of mixing and incorporating with it such kinds of earthy substances as it may be capable of acting upon, and uniting with. From the causes just noticed, its most active and nutritious properties are almost immediately set at liberty, and either directly contribute to the growth of plants, or form such new combinations as readily become useful for the purpose, while but very little of the earthy material is left behind for further decomposition, and the durable aids of vegetable increafe. Mr. Middleton also farther remarks, that this matter is not only prepared in the most suitable manner for the purpose of perfect vegetation, but that the herbage produced by it is capable of fattening the largest cattle in the shortest time than any other. And the first of these writers knows from repeated experiments, that the finest garden vegetables may be produced by it, when properly employed, without the least injury to the root, even in the most delicate of them, such as cauliflower, white broccoli, &c. Instead of a bad taste being communicated to herbage by the use of this manure, it would seem probable, that it considerably improves its own, as it has been observed, in the Annals of Agriculture, that the patches of such pastures as had been manured with this substance, were constantly eaten quite close by horses, cows, and young cattle, while in other places there was much longer grass."

From these facts it is therefore concluded, that "the importance of this substance as a manure is such, that every possible means should be contrived to prevent its loss, which is shamefully permitted, at present, to take place in large towns, to the astoniffing extent of more than two-thirds of the whole, and some method made use of to render its conveyance and application more general and convenient. See Night-soil."

It is further noticed, that it is not only this, but the dung of all those animals which feed on such foods as constitute either wholly, or in a great part, the food of man, as has been suggested above, that are, from the experience of practical farmers, found to be more effeclual in promoting vegetation, when applied as manures to the ground, than those of fish animals as are fattened by such kind of matter as are field or ever made use of in that way; "hence it is obvious that the dung of carnivorous birds, dogs, fwine, horses highly fed, poultry, pigeons, and such like animals, must be more powerful in their effects as manures, than those of horses when fed only with hay or grass, neat cattle, sheep, and other animals that live in the same manner. On the same principle, too, it is suggested as not improbable, but that the excrement of insects may be less efficacious as manures than their bodies, as it is well known that by their deftruction and decomposition the fertility of land is considerably increased in particular instances. It is probable likewise, that the dung of some animals may, from the state of their stomaches, and other caufes, as well as the nature of their food, be more completely reduced and animalized in its passage through their bodies. That this is the case, at least in granivorous birds, in which the food is subjected to considerate trituration in the course of its digestion, there can be little doubt, and thereby they perhaps become, in some measure, in a condition more suitable to form new combinations, or afford the support of vegetation. It is conceived, that this view of the nature of the manures afforded by different animals, should lead the practical agriculturist to be more attentive to the subject, in order that he may render them more abundant, and be capable of employing them under the most favourable circumstances, which cannot be the case while they are, as at present, indiscriminately mixed and blended together in the common dung-heap. That they should not be used in this way is clear,
clear, from the contradictory accounts of them that have been presented to us by various writers and experimenters, which would seem to have been caused by employing them in flates of mixture with other substances. By some it is asserted that one load of *soil dung* is nearly equal to two of most other forts, and that it is the richest of all animal manures; in this, however, they would seem to be mislaid, as from trials made by others, it has been shown that *night-soil* is certainly to be ranked much before it. In one of the ingenious experimental attempts of Mr. Young, it is also shown, that the dungs of rabbits and poultry are superior to that of pigeons, and greatly more durable. But poultry-dung, in the comparative experiments of Mr. Arbuthnot, was found to be more effectual than that of rabbits, and that of the latter greatly superior to wood-ashes. *Pigeon's dung* has, notwithstanding, been proved by much experience to be a powerful and efficacious manure, and probably, from its abounding with volatile alkaline principles, been conduced to be of a hot or stimulating quality. But it is "from the larger animals that the farmer derives the principal part of the dung that is made use of as a manure in the cultivation and improvement of land; the dung of horses as highly fed being found, as has been already seen, to be much more valuable for the general purpuses of agriculture, and some uses in horticulture, than that which is made by horses when fed with hay or grass only. Where the animals are kept in the latter way, it is probably not so good as that of well fed cows and neat cattle in general, as in these it may, perhaps, become more animalized from the circumference of their food being more intimately blended with the *faeces*, or other juices, during the ruminant state of feeding in such animals. The dung of horses is, however, in common, much more disposed to take on the procures of putrefaction, and cause more heat, than that of cows and other neat cattle, and indeed these are the chief disturbing circumstances between them as manures. The dung of neat cattle may also, on account of its less disposition to run into the state of putrefaction, contribute more of the earthy material to the land on which it is applied. Hence, probably, its superior utility on the leaner and poorer, or thinner forts of soil. The dung and urine of animals, when newly voided, are not, except when the animals are morbid, in a putrefuent condition, the length of time in which they remain in their bodies being too short for its fully taking place; but some degree of, or tendency to putridity, is constantly necessary to their discharge; and the means which are further fitted to promote it in these substances have been fully described and explained above, when speaking of the nature of animal substances in general.

With respect to the experiments that have been made with the dung of sheep, they shew "that it is equally valuable with that of many other animals that feed in the same way, but agriculturists have not yet turned their attention sufficiently to the means of collecting and preserving it, so that it may be used alone as a manure. The method by which it is at present applied to land, is by folding the animals upon it, under which method of management, on many fols, a great part of the advantage must be derived from the operation or action of the ammonia of their urine upon the vegetable matters contained in them, as well as from the condensation produced by their treading upon it. See Dung.

Besides the above, there are many other soft animal substances that may be of use for the purpose of improving land as manures, some of which have yet been but little attended to by the farmer. Of this sort are *graves*, or the residuum which is left after making of candles, and the *sewage* which is collected in the boiling or refining of sugar. The author of a late practical work observes, that "different trials upon a small scale, with the former, have fully convinced him, that it is a substance that possest great powers, when employed as a manure. And although it is a substance which is generally procured at a high price, from its going a great way, and being a lasting manure, it may, probably, be more frequently had recourse to than has hitherto been the case. It is mostly procured in the state of hard compressed square cakes, though sometimes in a soft condition, without having undergone any pressure. When, in the former state, the cakes must be broken down, and reduced into as great a state of division as possible, which may be rather a troublesome and expensive procurs, except a mill or some proper machine for the purpose be employed. But when it has been even reduced to the finest state possible, it will still be improper for application as a manure, until it has been mixed and incorporated with a pretty large proportion of some rich earthy substance with which it may combine. In the attempts which he has had an opportunity of making with this animal substance, after being much reduced, it has always been blended in the proportion of three or four parts of good vegetable mould, according to the condition of the land, to one of the graves, and then sown as a top-dressing on grass land, where it has never failed to produce a full crop of hay, considerably greater than that by the usual dressings of dung, and a rich forest after-grass, or such as cattle are remarkably fond of feeding upon.

At Enfield, Dr. Wilkinson found, in his trials, that the animal kingdom furnished the strongest manures; among which, graves was the most powerful and durable in its effects. "From one ton to a ton and a half, he considers as sufficient for an acre, according to the state of the land. The cakes, in his practice, were minutely divided, which, on account of their hardiness, is an expensive and laborious operation; and that even in this state of minute division, unless mixed with mould, they frequently prove too strong for corn, as he found by experience, on applying them to barley, the strain of which being injured by the rankness of the straw. They are, he conceives, peculiarly adapted to promote the growth of grass, turnips, and the leguminous plants." And it is further stated, that "eight acres of pebbly loam were manured by him with dung, at the rate of ten loads of the common Middlesex carts per acre, except one acre of the poorest and most gravelly, which was dressed with a ton and a half of graves. The turnips where the graves were spread, and the succeeding barley, (which were the crops on the whole piece,) were thicker and more vigorous than where common dung had been laid. He has observed graves rendered so rank, by the use of graves as a manure, that cattle would not touch it till mellowed by the winter's frost; and even in the succeeding years he was able to trace, by the superior verdure of the graves, to what extent this manure had been spread. He has also used, with success, salted fish provisions, particularly herrings, which had been spoiled on ship-board, and has found them equal to the graves. In the same manner he has used salt meat, that has become putrid in a long voyage. His general mode of application has been to mix them with mould raised from the head-lands of the field, where they were intended to be spread. By letting them lie for some time, the earth imbibes the strong smell and virtues of the animal manure. Over these he has spread with advantage the liquor drawn from the graves, and the washings of the casks of salted meat, which has been spoiled. When sprinkled immediately over
ever grafts in the former, he has also observed this liquor attended with considerable efficacy in producing a plentiful crop of hay." He adds, that last year (1800) he used with success a combination of lime and graves, mixed with mould from the head-lands, in the proportion of about fifty bushels of lime to a ton of graves. This composition refines sugar fum, which confines of lime and bullock's blood." On the whole, "from the large experience he has had of the benefits arising from sugar fum, he thinks this combination of lime and animal matter deserves further investigation." On this it may be observed, that "there can be little doubt but that by combining lime with animal substances, they may be rendered highly active as manures, especially when applied on soils that have a sufficiency of those earthly manures, on which they can exert their full influence. In this way they seem frequently to be rendered more active, than when employed in a simple uncombined state: but experiments are perhaps wanting to fully ascertain the utility and best means of employing such matters."

It is however further added, that "lime might thus be combined with bones or woollen rags, or with a compossip of earth and night foil, and would certainly greatly facilitate their conversion into manure, as well as render them more active in producing their effects in the support of vegetable crops: and by some of their properties being absorbed by the lime, during the time of their decomposition, and afterwards parted with more slowly in the soil, they may also by such means be probably rendered more durable and lasting as manures."

It has been objected by Dr. Wilkinson, that "the Arabsians, who take great pains to improve their lands, are accustomed to make large pits: these are put in animal manures, and cover them with calcareous or clayey earths; and afterwards these earths, which of themselves are fertile, acquire the properties of the richest manure." He adds, that "he once ordered a heifer, which died in a field at a distance from his house, to be buried in a compossip of lime and earth: and does not affirm that this was not the most profitable application; he had, however, no reason to complain of his compost." And "Mr. Wright, in his Survey of the Husbandry of Scotland, he observes, mentions a compost of two parts lime, and one part pigeon's dung, to remain mixed until a considerable fermentation takes place, which is known by the effluvia. Six bullocks of this compost, it is said, is sufficient for an acre, and will work itself for many years after it has been applied."

There are various other combinations of this nature, which may be successfully made use of for the purposes of agriculture, when properly made and applied to the soil.

There are still other materials of these class, that may be employed as manures on land, such as the refuse of glue-makers, the cuttings of felt-mongers, the chippings of furriers, the scrapings of oilcloth-leather, and the chips or rags of shoe-makers, where they can be collected in sufficient quantities. These, from their abounding in mucilage and oil, their great attraction for moisture, and their being readily soluble in water, contribute quickly to the support of vegetation, but are not probably so durable in their effects upon land as many other substances: hence they should only be made use of with a view to the immediate crop, which, it is believed, is pretty much the case in those places where they are capable of being obtained in such quantities as to be employed for the purposes of the farmer.

There are also of the fish kind many manures that may be applied in this way, as the bladders, remaining after the preparation of oil from the whale, and other large fishes, and different sorts of small fish, both of the salt and other kinds; likewise the offals of such animals, where they can be procured in large quantities, as in large towns, sea districts, and where they are cured or prepared in great numbers for the market. These may be found beneficial in various cases.

All these substances may be readily reduced to that state which is proper for manure, by mixing with them a small portion of the carbonat of lime, and afterwards, according to circumstances, a quantity, two or three times more than the whole, of good vegetable mould. Shell-fish, such as mussels, or commonly applied without being mixed with earthy matters; but this is certainly a wasteful practice, as much of their valuable principles is diffipated and lost, as is evident from the highly disagreeable flemch that affails the neighbourhood of the ground on which they have been applied." By mixing good vegetable mould, scrapings of ditches, or peat earth with them, the quantity of the manure would not only be greatly increased, but the offensive odors attending the use of such manures, in a great measure, corrected, and the effects of them, in promoting the growth of vegetables, probably rendered more extensively advantageous to the farmer. And the wafte and refuse of slaughter-houses and butchers' shops are likewise capable of being prepared and made use of in a similar manner to that of fish; but as the manures formed from these animal materials are capable of affording much elastic volatile matters, during their decomposition, they of course require to be well mixed and blended with such earthly manures as they can combine with, and render soluble, and in proportions suited to their powers, in order to produce the most beneficial effects on vegetation, and afford the greatest advantages to the cultivator.

The different sorts of woollen rags, hair, feathers, and such like substances, though frequently made use of as manures to land, from their having a less portion of oily or mucilaginous matter in their composition, are probably in their effects inferior. These manures must be cut up or chopped into small pieces, before they can be advantageously applied to the ground as manures.

And the author of "Practical Agriculture" concludes, "from the experiments that have been made with such animal manures as manures, that it may be inferred, that their effects continue longer than those of many substances of other kinds;" and that they are highly useful materials, in many cases, for being applied to the soil.

It may be noticed, that among the harder sorts of animal manures, that are capable of being employed as manures, there are considerable differences in respect to their texture and firmness: some being quite firm and solid, such as bones, horns, hoofs, flavings of horn, and some other similar substances; while others are more soft and pliable. The bones of all animals are capable of affording much nutritious matter to plants; but those which are procured from cattle, that have been killed when fat, are said to be the best for the purposes of manure. Those which have been boiled are not inferior, in this view, to those which have not undergone that process, as by such means they are principally robbed of their oily and mucilaginous properties, and consequently yield much less nourishment to the immediate crop, whether it be grass or graze. All these sorts of manures require to be ground down in mills constructed for the purpose, or otherwise reduced into small pieces, before they are laid on and mixed with the soil, or formed into composts. It is stated, that "the usual method is to reduce them to about the size of large sifters, but that there can be little doubt but that they would sooner run into the flate of putrefaction, if they were reduced into still smaller particles."
MANURE.

ticles, and thus be made to afford their nutritive properties much more expeditiously, as well as more abundantly; by which means, much less quantities would probably produce equally full effects with the large ones at present made use of: as, where the pieces into which they are broken are left large, they remain a great length of time in the soil, and are only gradually decomposed, without yielding that full supply of nourishment which is necessary for the supporting of crops. And when they have been even prepared in this way, too much earthy matter should not be mixed with or applied upon them; as, where this is done, by preventing the free operation of the air, their decomposition is greatly retarded. Nor should they, upon the same principles, when intended to be incorporated with the soil, be ploughed in too deeply; as, by such a practice, the crop will be deprived of much of the advantages which it might otherwise have obtained from such manure.

It is now well known, that these substances are constituted of a considerable proportion of mucilaginous or gelatinous matter, a flight portion of fat, and an earthy salt composed of the phosphoric acid and calcareous earth. If great heat be applied, they afford a large quantity of hydrogen gas, carbonic acid gas, and a volatile alkaline liquor. From the nature of these different principles, it is evident that some sorts of substances may be blended and united with the reduced particles of bony matters so as to promote their effects, as manures, in a considerable degree, such as lime, chalk, peat earth, and good vegetable mould, in suitable proportions, as by such means new combinations may be formed highly favourable to the processes of vegetation. And that the confuming of bony or horny substances, by means of fire, for the purpose of obtaining their ashes, is a wasteful dissipating practice that ought never to be attempted by farmers, as by it the mucilaginous and oily materials are driven off and lost, and nothing remains but a phlogist of lime, which can be of but little use in promoting the growth of vegetable crops. Dr. Hunter found, from the application of reduced bones to a poor calcareous soil, with a grain crop in the proportion of 60 bushels to the acre, that the crop was much superior. where this was used, to that which had not been drested in the same way, and the grazs crops afterwards for some length of time, on the same place, displayed a superiority, and appeared more early. He also found the same superiority in turnip crops in different fields, when drested in the same way. Mr. Young likewise found the effects of bone manures to be very great; but they did not correspond to the quantities employed, as with 25 cart-loads the crop was better than with 50. This curious fact is, however, explained in the opinion of the first of the above writers, by his observing that the soil was an extremely poor one, as in such a case there could only be a small portion of earthy matter for the ammonia and other substances afforded by the decomposition of the bone to act upon, and reduced to that state of solubility the most adapted to the support of vegetation. Hence the immediate benefit that was derived from the manure probably depended solely on the oily and mucilaginous materials that were afforded on their being first applied.

But where bony substances are not broken down into very small particles, it is supspected, from some few trials that the stirft of the above writers has been enabled to make, that the effects of such substances will be equally, if not more apparent the second than the first year, whether they be used on grazs land, or that which is under the plough. The trials which Dr. Hunter made with ground and unground bones, seem likewise to support this opinion, as he found, that for the immediate crop the unground bones were of little or no service, but the ground ones of much benefit. What effect the unground ones had the second year is not exactly known; however, from his concluding that these substances are in general, upon grazs land, more effectual the second than the first year, it may be easily supposied to have been the case. See Bones.

Manures of the Vegetable Kind.—There are many different sorts of vegetable matters, when deprived of their living property, by undergoing the processes of decomposition, that have become proper for the nutrition and support of new plants, and fit for being applied as manure. Their reduction into this state is greatly promoted by their being exposed to the full influence of the air, moisture, and a suitable degree of heat. Under these circumstances different substances are evolved, and new combinations formed that become useful in the support of vegetation. These processes or decompositions have been commonly suppsed to succeed one another with regularity, from that which is productive of sweetness, to that which is the ultimate result of putrefaction. But Dr. Darwin has suggested, that it is more probable that different sorts and parts of organized matters, when dead, may undergo many different sorts of chemical changes, and that these may be different according to the differences in the degrees of heat, the quantity of water and of air to which they are exposed.

He was led to this supposition from the faccharine processes preceding the vinous fermentation, which takes place in certain slates of animal stomachs; and from what happens in the germination or sprouting of grain, by which the mealy matter is converted into sugar. And from observing that the acerb juices of some kinds of fruits are rendered sweet by baking, he conceives that the faccharine processes may take place in a degree of heat which is about that of boiling water, and that by it the processes of fermentation may be altogether prevented from occurring. By destroying or injuring the life of fruits, it is also supposed, that the faccharine processes of their juices may be promoted, as is found in many instances; such as the ripening of fruits after being plucked from the trees; their being sooner ripened after being injured by insects, or other means; and after partially cutting, or otherwise injuring the branches of the trees on which they grow; and this, which is termed the faccharine processes, it is conjectured, may take place either beneath or upon the earth, in the incipient state of vegetable decomposition, before the vinous fermentation, and thus afford a very nourishing matter to plants.

And further, that in the vinous, or processes which commences after the faccharine, carbon becomes united with pure air in a large proportion; and that probably at the moment of their combination, while they are in the form of a liquid, and before they assume the gaseous state, they may be taken up by the roots of vegetables. And that, as in the processes of putrefaction, carbon is not only changed into carbonic acid, but water decomposed, as is evinced by the smell of hydrogen, it is suspected that these inflammable substances may combine with carbon, as in the cafe of hydro-carbonate gas, and thereby become capable of being taken up as food by the roots of plants, without their passing into the acid or gaseous states. The union of azote with pure air, towards the close of the putrefactive processes, by which nitrous acid is produced, it is likewise conceived, may possibly tend to promote vegetation. This, however, may be promoted from the circumstance of the pure air or oxygen adhering more closely to its bafl, the azote, in the formation of this than other acids, and on that account yielding it more readily to the absorbent roots of vegetables.
besides these means of supplying the nutrition of plants, as in the decomposition of vegetable substan ces by the process of putrefaction, the constituent principles of the water which they contain are, as has been just observed, in some measure let at liberty, and the hydrogen, one of them, uniting with the azote which is afforded by the dilution of vegetable matters, though not in such large proportions as by animal substan ces, forms ammonia, which, from its rapid union with fat and oily matters, and thus rendering them capable of being taken up by the absorbent roots of vegetables, may contribute to the support of vegetation. And, in some instances, where saliva, in soluble, earthy matters, or metallic salts are contained in the soils to which manures of this kind are applied, or in which ammonia may be formed, it may decompose them, and by that means contribute to the formation of other new and less noxious compounds, or such as may be more capable of contributing to the growth of vegetables." It is added, that there is another substance which generally prevails in vegetables, and which is supposed to be a simple material, obtained in great abundance from the recr ements not only of putrifying vegetable, but animal substan ces, and calcareous earth, the latter of which is supposed to have been of animal origin in the early periods of the world. This matter, it is thought, when met with in the flate of solution, may be taken up entirely by the absorbent roots of vegetables, as well as occasionally formed and elaborated by them. It is therefore probable, that different matters fitted to the nutrition and support of plants, as crops, are formed and evolved during the different processes and stages of decomposition of vegetable as well as animal substan ces. But that in vegetable productions the changes are less rapid than in those of the animal kind, and probably much more varied, according to the various flates and textures of the particular substan ces; as it is obvious, from numerous facts and circumstances, that the more luxuriant and juicy vegetables are much more readily decomposed than such as are dry, and have a licentious structure. Hence it is, that fresh vegetable matters are much more quickly converted to that flate of decay, which is suitable for the supplying vegetable nourishment, than such as straw, hay, wood, and other dry materials of the same nature. It is not improbable, but that some vegetable matters may yield some of the substan ces that are taken up by the absorbent roots of vegetables in much larger proportions than others; as it has been found that different sorts of grain vary considerably in the proportions of mucilaginous, and what is termed vegeto-animal matter, which they contain; and that grain, potatoes, carrots, and many other roots of the same kind, on being confined in the open air, afford much larger quantities of alkaline salts than hay, straw, or wood.; it is undoubtedly from these and similar causes, that some sorts of vegetable matters, when reduced by means of putrefaction, are found to be so much more effectual as manures than others, when applied under the same circum stances, and to soils in every respect of a similar nature and quality. There is likewise a further circum stance to be attended to in substan ces of this nature, which is, that in general, when resolved by the ultimate process of putrefaction, they yield larger proportions of earthy materials to the soils on which they are deposited, than most matters of the animal kind, and consequently add more effectually to the substan ce of the land. And as this vegetable mould, or earth, from various causes, is constantly becoming more extensively and more intimately blended with the other materials of the soils, and, of course, forming new combinations, by which some of these matters which serve for the nutrition of plants are set at liberty, and brought into the flate most proper for being absorbed by the roots of vegetables; it is evident why those manures, which are principally composed of vegetable substan ces, are more durable in their effects than such as are prepared from many forms of animal materials.

It is stated that the substan ces of this kind which are capable of being beneficently converted to manure, are extremely numerous; and consequently suggested that "all kinds of green vegetable productions may be employed in this way; such as the luxuriant weeds of rivers, lakes, ponds, and ditches, fern, and the refuse of different kinds of garden vegetables. Where green materials of this nature are made use of, they should always be cut down while in their juicy flate, just before their flowers begin to appear, in order that they may be in the most suitable condition for becoming quickly putrid, and to prevent the injury that might otherwise be sustained from the vegetation of their seeds. They are afterwards to be collected into heaps of a moderate size, and their putrefaction promoted by their being thrown together as lightly as possible, and the occasional sprinkling them with water, if the air be hot and dry; and as lime is found, when applied to vegetables in their green moist flate, to difengage from them both hydrogen and azote, by the combination of which volatile alkali is produced, it may be advantageous to blend a portion of lime at first with the heaps, and afterwards add a suitable quantity of peat earth, or good vegetable mould, for the alkali thus formed to act upon. By this method, the quantity of manure from such substan ces may be greatly augmented, and rendered more valuable. But when dry materials, such as hay, straw of different kinds, fern, and rushes, are made use of, such additions cannot be had recourse to with equal success, unless where much of the dung and urine of animals have been incorporated with them." Their resolution and decay may, however, be greatly promoted by their being kept in a moderate flate of moisture, and not permitted to be trodden down too much by cattle, or other means in the farm yards, or other places where they are provided. And another means of supplying vegetable manure, not sufficiently practised, is that of providing full succulent crops of green vegetables; as clover, buck-wheat, tares, vetches, sainfoin, peas, beans, turnips, and many other similar plants, to be turned down by the plough, in order that they may undergo the putrefactive process under the ground, and by that means be converted into manure, and supply the food of plants. "In this practice it is suggested as probable by a late writer, that a great advantage might be obtained, on the principles which we have just alluded to, by the spreading of a small portion of lime and peat, or rich vegetable earth, over such crops, and then rolling them down, that they may be completely turned in and buried by the plough; an operation which should be performed as quickly as possible afterwards, and where the crops will admit of it, in the summer or early part of autumn, while the sun has the power of promoting the decay of such vegetable matters. By this means, it seems probable that the putrefaction of such crops would not only be much expedited, but the principles thereby set at liberty be capable of exerting their influence much more extensively than where the plants themselves are only employed, and little additional expence be incurred by the farmer in executing the work."
MANURE.

advantageous practice, especially where manures of other kinds are scarcer, than that of obtaining it by consuming them by the feeding or foiling of cattle, which, under other circumstances, is certainly an excellent mode, and one which should never be lost sight of by the farmer.

Before it be completely rotative, the manure, which is capable of being employed as a manure with great advantage, and which should never be overlooked when it is within the reach of the farmer. This is sea-weed, *fucus marina.* In the management of this substance there is considerable diversity; in some districts it is the practice to spread it upon the land as soon as possible after being cut from the borders of the rocks on the different sea-coasts, or collected after being left by the tides, and to plough it in: where this method is adopted, it is advised that as little time as possible should be suffered to elapse after the cutting, or collecting of the weed, before it is ploughed down; for as the plant in its green or succulent state readily decays and becomes putrid, if there be any considerable delay in the performance of the bufners, especially when the weather is hot, much of its valuable properties as a manure is dissipated, and carried away by means of evaporation, as is sufficiently shown by the pungent and disagreeable smell that issues from it, on its being thrown upon the land and undergoing the processes of putrefaction; and, besides, when it is suffered to become dry and hard before it is turned into the ground, the parts that remain are considerably longer before they become decomposed and reduced into the state suitable for affording the nourishment and support of vegetable crops. It is believed to be, on these accounts, as well as that of the weed affording but little earthy matter in proportion to its bulk, on its decomposition, that it is found, in general, to be less permanent in its effects as a manure, than some other vegetable matters. Something may likewise depend on the goodnefs and luxuriance of the weed itself, and the state which it is in when gathered from the shores, or cut from the sides of the rocks. As in most other plants, this will undoubtedly be in the most proper condition for the purposes of being converted into manure, when cut or collected in the most succulent state of its growth, before it has become too old. Another method of practice with this weed, is that of collecting it into large heaps, and letting it remain exposed in that state to the influence of the weather, on the land, where it is completely rotten, and in a condition to be put upon the land; but as the plant maintains in its composition a large proportion of fibrous matters, which, during the state of its decomposition, or decay, are brought into activity, it is plain that by such a method of proceeding much less must be putrefied, not only from the dissipation of the volatile and more fluid active parts, by the action of the sun and wind, but by the rains dissolving and carrying down the saline materials that may have been formed. When it is not immediately to be applied as a manure, it would therefore seem to be the most economical and advantageous mode, especially where the weed is fresh, to first blend a portion of quick lime with the heaps, and then have a sufficient quantity of fresh good earth, mould, or other similar material, placed beneath them, as well as mixed with and covered over them, in order that the substances afforded by the dissipation of the weed may have something to mix with and act upon, and be prevented from being washed away by rains. In this way, the quantity of manure may be much increased, and at the same time its effects rendered considerably more lasting in the land. It is the custom in the islands of Jersey and Guernsey, where this weed is extensively employed as a manure, to cut it in the early part of the spring, and about the month of July; the first cutting, in most cases, being immediately made use of as a manure for barley and pature lands, and the latter principally converted to the purpose of fuel, the ashes only being employed as manure. In the practice of confuming the plant in its dry state, however necessary it may be there from the great scarcity of fuel, the lofs in manure is extremely great, as the quantity of ashes thus produced are very small in proportion to the weed which is consumed. Such weed as is collected after having been thrown upon the shore by the tides, is found to be much inferior as a manure to that which is cut from the rocks and made use of in its green juicy state. This should, therefore, be well attended to where this plant is in use.

Another material of the vegetable kind, that may be had recourfe to as a manure, is that of such barks as have been made use of for the purpose of tanning leather. This substance, when made use of in this way, should be collected into moderate sized heaps, before it has become dry by too much exposure to the heat of the sun and wind; and then have a quantity of lime mingled with it, and be kept slightly moistened with water, as by this means its putrefaction and decay may be greatly promoted. When intended to be applied to grafts lands, it should be considerably more reduced towards the state of vegetable mould, than when laid on land for the purpose of supporting crops of the green kind. There is another point that ought to be regarded in this material, which is, that as during its decomposition much heat is produced, and many offensive matters set at liberty, it would seem as a manure to be more adapted to the stiff, cold, and heavy soils, than those of the lighter kinds; a fact which the experience of agriculturists has shewn to be well founded in general.

And mud taken from the bottom of rivers, ponds, and other places where water has stagnated for some time, fresh or maiden earth from the borders of fields or other places, and the scourings of old ditches, are other substances that may be occasionally employed with advantage as manures, as being principally composed of the remnants of decayed vegetable matters. They should not, however, be put upon grounds, especially those in the state of grafts, until they have been reduced into a considerable degree of fineness, by means of frequent turning over, and the mixing of portions of lime, rotten dung, or other materials of the same kind, with them, in order to promote and render the way of the more solid parts complete. In the application of manures prepared from substances of this sort, as top dressings to land, in the state of grafts, they should not be spread on too thickly, or in too large proportions at one time, as where that is the case great injury is often done to the succeeding crop, the grafts not being able to spread itself completely over the surface of the ground.

There is another material in the duff which is separated from malt in drying, mixed with the tails, usually denominated coombs, which, where they can be procured in large quantities, as in the making distilleries, may be made use of for the purpose of manure. In a paper, by Mr. Farey, in the Annals of Agriculture, it is remarked, that the black malt-duff, such as falls through the kiln-plate in the operation of drying, is greatly preferable to the white, on account of the seeds of charlock, with which it abounds, being destroyed by the heat, and rendered fit for manure. The heat thus applied, by destroying the vegetative principle of such seeds where they exist, probably renders them the dust more readily disposed to take on the proceeds of
of decay and become putrid, and thereby afford the nutri-
tion of vegetables more quickly as well as more abundantly
than in other circumstances. It is well hinted by a late
writer that this, as well as sawdust, where they can be
had at a cheap rate, may be considerably improved as ma-
urses by incorporating them, in pretty large quantities,
with the dung and excreta of animals, as by throwing them
in the bottoms of poultry and pigeon houses, dung heaps,
and cesspools; and also in the bottoms of referries into
which the urine of cattle, and the loo-fuids after washing
are emptied; from the action of these matters upon them,
they are found to become more quickly in a flate to be used
with advantage as manures." And it is added, that "ma-
nures of this kind have been found very beneficial when ap-
plied in the proportion of four quarters to the acre, from
with the crop for which it is employed. See MALT DUST.

The husks, or cakes, which are left after different oily
seeds, such as those of rape, cole, &c. have been subjected
to preffure in mills in order to obtain their oil, are other
materials that may be converted to the purpose of manure.
These substances are generally prepared for application
by being reduced into the flate of coarse powder, by mills or
other suitable means, and then forced by the hand, and
harrowed in with the seed of the crop for which they are used.
Some farmers, likewise, advise their being mixed, when thus
reduced, thinly, with the materials of such dunghills as are
deficient in riches, as where they have been made by lean
locks with a large proportion of litter. On turning over
heaps of this kind, about a ton of cake is recommended to
be well and evenly incorporated with every twenty or thirty
tons of the dunghill compost; by this practice a rich and
good manure is said to be formed. It is asserted, that "the
success of these substances, when made use of as manures,
have been found to depend, in a great measure, upon the
falling of rain soon after they have been put upon the land,
as in dry seafons little benefit has been derived from their
application." The reason of this seems to be, according
to a late author, "that as the cake when used is moist in
an extremely hard and dry flate, it does not undergo that
decomposition which is necessary, until it has been moistened
by the rain, by which it is rendered capable of running
quickly into the flate of putrefaction, and consequently of
affording such matters as are suitable for the support of
plants." And it is added, that "when applied without
being incorporated with any other substancc, it is moystly laid
out on to the amount of four or five quarters to the acre, accord-
ing to the condition of the land.

And there is still another vegetable matter found in
the refuse or pulp of pears and apples which have been ground,
and the liquor squeezed from them, that may likewise be
converted to the purpose of a manure, in the districts where
cider is prepared in large quantities. But it is advised that
some heavy substances, such as good earth with a little dung,
should be mixed with it before it is put upon the foil, as by
being blended with such materails it may be more conven-
iently and more extensively applied to the land, and pro-
bably with better effect.

Manures of the Earthly or Fossil Kind.—It is well known
that there are a great many different sorts of materials of
this nature that may be brought into ufe for the purpose of
improving the condition of lands. The chief of the sub-
stances of this description are of the calcareous kind, which
are found to "produce effects more or less powerful in pro-
miting the growth of vegetable crops, in some measure,
according to the flate and quantity in which they are ap-
plied, the nature of the soils in which they are employed,
and the properties of the matters with which they are com-
bined. For though calcareous materials have been made ufe
of as manures for a very great length of time, and have been
applied in various ways, difficulties still remain concerning
the manner of their application, in many cases, which seem
principally, however, to proceed from the want of proper
discrimination in respect to the flate of the different cal-
careous substances at the time of their application, and their
being made ufe of to different soils without a sufficient dif-
tinction as to the properties of the materials of which they
are conftituted or composed." The inquiries of a late ex-
perimental writer "have likewise shown it necessary to
attend to another circumstance, which is, the substances
the calcareous material is combined with; as he has found that
where magnesia is in union with the calcareous matter, it is
not by any means so beneficial for the purpoles of manure
and promoting vegetation, as where no such mixture or com-
bination is present, especially when used in the same pro-
portions." This is, however, a point that requires further
examination, and which is by no means fully decided. It has
also been observed, "that from sand entering largely into
the composition of lime-flour or other calcareous matter, in
some cases, as it is a substancc of much greater specific
gravity than pure calcium lime, considerable differences in its
effects as a manure may be produced." On these accounts
it is concluded, that though lime may be produced from
chalk, marble, different lime-flours, coral and shells, by
subjecting them to such degrees of heat as are neccessary
to expel or diluence the carbonic acid or fixed air that they
contain, which is apparently of the same quality, it may
vary in its effects when employed for the purposes of the
farmer. See LIME and LIME-STOKE.

It is evident that lime, when newly burned, or before it
becomes loaded or faturated with the mofturc and carbonic
acid, or fixed air, contained in the atmoferca, which, from
their strong tendencies to combine or unite with it, gene-
 rally soon takes place, is in its great flate of activity, and
from the power which it posffees of breaking down and
destroying the texture and organization of such animal and
vegetable substances as come in contact with it, termed
caulif or quick lime. When, under these circumstances, it is ap-
plied to grounds which abound either with fresh vegetable mat-
ters, or such as have undergone some degree of change, by
being buried in the foil, as in moory and heathy mountain-
land, peaty or boggy earth, and all such soils as have
long remained in their original uncultivated flate, covered
with a variety of coarse plants, it is said to be "found to produce beneficial effects; in the first cafe probably by its
ready action on the different materials of the green plants,
by which it diffuses them hydrogen and azote, from
the subsequent combination of which ammonla or volatile al-
kali is produced, a substancc which has great power in pro-
moting vegetation, as is seen in cafes where substanccs that
contain this matter in large quantities are used as manures;
and in the second place, by its combination with the car-
bonaceous matter of such foils, or with that of various
animal and vegetable matters which are contained in them,
in some of the flages of their putrefaction or decay, and by
this means rendering it soluble in water, and thereby ca-
pcible of being taken up as food by the absorbent roots of
vegetables." And, "that though lime in its pure or caufic
flate retards, in some degree, the proccss of putrefaction,
especially when used in any large quantity, it is probable,
that by its power of corroding and dissolving the hard and
fibrous parts of vegetable and other matters, as is shown
by its quickly reducing the lignaceous particles of bark, which
has been employed in the process of tanning, to the flate of
mould, it may bring the abundant vegetable and other ma-
terials;
terhls contained in such forests of land quickly into that
earthly condition, in which they afford the nourishment and
support of crops, which by the process of putrefaction,
and insect digestion, could only have been performed in a
very slow and gradual manner." Further, from its well-
known property of destroying different kinds of insects,
such as worms, ants, flies, gnats, grubs, &c. which are mostly
abundant in rich fresh soils, it may furnish much nutritious
matter for the purpose of promoting the growth of plants as
soon as its leaves, etc., are cast off, and its branches that
may be reduced in the same manner, as is evident in the case of
new plastered walls, it may be
of considerable utility when applied to the dry and sandy
forests of soil, by affording moisture and such aerial matters
to the roots of the vegetable crops; which it is capable of
supplying in a very equal and extensive manner, from the
extreme state of pulverization to which it is reduced when
flaked by the dampness of the atmosphere, or by a very gentle
fall of moisture. And in addition to these modes of pro-
moting the growth of vegetable crops, it has been profited
by Dr. Darwin, that calcareous earth, by containing phos-
phorus, may be useful, as by its union with it a kind of
phosphoric acid may be produced, and the phosphorus thereby
rendered soluble in water, without becoming an acid by means
of its combination with oxygen or vital air. It is conceived
that phosphorus is probably as necessary an ingredient in
vegetables as animal bodies, as is evident, it is supposed, from
the phosphoric light seen on rotten wood, in some of the
flags of putrefaction; in which, it is believed, the phos-
phorus is set at liberty from the calcareous earth, or from
the fixed alkali, or the carbon of the decomposing wood,
and acquires oxygen from the atmosphere, both warmth
and light being emitted during their union. And it may,
perhaps, more frequently exit in the form of phosphoric
acid in vegetables, and be thus readily combined with their
calcareous earth, or be separated from its acid by the carbon
of the vegetable, during the time of calcineration, as well as
in the process of putrefaction. It is, therefore, plain, from
this account of the nature and properties of lime, that it
may be made use of in one or other of its states more gene-
 rally to soils, than has been commonly profited. But it
should never be applied without duly attending to the nat-
ure and quality of the soil on which it is to be laid, as
upon this circumstance, its success in a great measure de-
pends in all cases.

It may be noticed, that the trials that have been made by
farmers with this manure, sufficiently show, that the more
minute hile is blended and incorporated with the mould of
the land on which it is applied, the more full and complete
are the effects which it affords in supporting the growth of
different sorts of crops. In support of this, it has been
remarked by Dr. Anderson, that "if a heap of lime of a con-
derable thickness shall have been ever so long on one spot,
and be afterwards carried clean away from it, so that none
of the particles of the hile remain to be mixed with the
soil, that spot will not be richer, or carry more luxuriant
crops, than the places around it; which, every one knows,
is not the case with regard to dung." And further, that
"if lime be spread upon the surface of the soil, and allowed
to remain there without being ploughed in, its effects will
leisurely be perceived for several years, till it has had time
gradually to sink through the stward, and mix with the
soil; after which its effects begin to be perceived, although much
less sensibly than if the lime had been intimately mixed with
the soil by means of the plough and harrow." The same
writer adds, that he is not a stranger to the improvements
that have been made in Derbyshire by means of lime, with-
out the plough; but this, he thinks, is no exception to
what he has said. The effects are slow, though certain.
"Those who inhabit counties that do not admit of the
plough, are often advised to lay lime upon the grasses,
and are made to believe that their pasture will be immediately
mended by it, nearly in the same perceptible manner as if
it had been dunged. This he has tried, and has seen it tried
by others; but always found that the grass for the first
year was rather hurt than benefited by it; nor was it so much
improved in succeeding years, as if the same quantity of
lime had been applied and immediately mixed with the soil.

MANURE.
MANURE.

In this mode of applying lime, it is long, he conceives, before it yields a proper return, and is not to be recommended to a poor man, unless where necessity obliges him to practise it." On this supposition, it is conceived, that lime may be employed much more advantageously when made use of, even in small proportions, than such calcareous substancess as have been reduced into the state of powder without calcination; but much must depend on the mode in which lime is laid on. "If it is spread as soon as it is flaked, while yet in a powderly state, a very small quantity may be made to cover the whole surface of the ground, and to touch an exceedingly great number of particles of earth; but if it is suffered to lie for some time after flaking, and to get so much moisture as to make it run into clods, or cake into large lumps, it may never be again divided into such small parts; and therefore a much greater quantity is necessary to produce the same effect, than if it had been applied in its powdery state. But if the soil is afterwards to be continued long in tilage, (as these clods are annually broken smaller by the action of the plough and harrows,) the lime must continue to exert its influence anew upon the soil for a great course of years; it will produce an effect nearly similar to that which would be experienced, by annually flewing a small quantity of powdered lime over the whole surface of the soil; but as the price of the lime must, in the first case, be paid by the farmer altogether at the beginning, which only comes to be successively demanded in the other case, this deferves to be attended to, as it may become a consideration of some importance where lime is dear, and money not very plentiful.

With respect to the use of lime, there is another point to be considered, which is, the quantity that may be necessary. The opinions of practical farmers are much at variance in respect to this point, some contending that a small quantity only can be applied with safety and advantage, while others maintain that scarcely too great a proportion can be made use of. It is plain, a late writer thinks, "from the differences that take place in soils, that no particular proportion can be suitable in every case, but that it must be varied very considerably according to the circumstances, as well as from the situation or condition of the land on which it is laid, and the proportion of real calcareous matter that may be contained in the lime that is to be applied. As it has been shewn that lime, when in its most active state, soon becomes reduced so as to be perfectly mild by its property of absorbing moisture, and the carbonic acid from the air, there can be little danger of injury from its caustic quality, though it may, on its first application, have a tendency to unite with and deform such green or other vegetable productions as may be present." It is, however, the remark of an able farmer, that " molt kinds of flax-lime should be applied with a sparing hand, and with a considerable degree of caution, as the caustic quality is many times greater in this than in lime made from chalk." He has had many opportunities, he affirms, of seeing tolerable burnings induced by a too liberal use of it; very generally at the several places where the carts were flapped for the men to spread it, at the bottoms of every heap, and once an entire clod.

It is well known that lime has been made use of as a manure in different proportions, from one hundred to fix or seven hundred bushels on the acre, on different sorts of soil, by some under similar circumstances, with benefits in proportion to the quantities applied. Besides, accidental experiments in Dr. Anderson's practice have demonstrated that it may be used in still larger proportions, with advantageous effects. And he concludes, that " on soils which do not naturally abound with chalk, or other calcareous matter, there is less danger in giving too much, than too little, except in these cases where an over-luxuriance is dreaded in the land."

It may be observed, that the permanency of the effects of this material in promoting the growth of vegetable crops, must be different, according to the difference of circumstances in the land to which it is applied; the proportion of it that is made use of, the kind of crop that is cultivated, and other causes of the same sort. But from the facts that have been recorded by practical writers, in respect to its f making the powers of diloping lands on which it has been laid to the growth of particular sorts of crops in preference to others; of rendering the operation of other kinds of manure, and other methods of culture, more effectual than where it had never been used; that it affords useful changes in the soils to which it is applied. Of this we have an additional proof in the well-known circumstance of the quality of the grain, from such lands as have been limed being much improved, having a thinner skin, and yielding much more flour than that from ground where it has never been employed; which is fupposed, by a late writer, to proceed from its containing more flarch and less mucilage, on account of the tendency of the lime to promote the conversion of the latter substance into the former, by expediting the ripening of the grain. This is a circumstance which also shews the utility of this manure in those kinds of land that are late in bringing their grain crops to perfection, whether from the nature of their soils, situations, or other circumstances.

It is obvious that this substance, with proper care, may be useful on many different sorts of land, but in its active state it is laid on to the most advantage on those of the moony, peaty, heathy, and other kinds that abound in coarse vegetable matter. On which account it is, perhaps, that it has been found by experience to be equally, if not more beneficial, on poor than on rich soils; and its requiring to be mixed and incorporated with a small portion of earth or mould, to render it highly productive, is in favour of the same thing. From these facts it may be concluded, that this substance, besides being useful when blended with soils, in rendering the matters they contain proper for the reception of plants, is beneficial in supplying such materials as contribute to their growth and increase. See LIME.

Other materials, such as lime-lime, and various hard calcareous bodies, which, without being subjected to the processes of calcination by heat, may, in some cases, as where fuel cannot be procured to burn them into lime, be beneficially applied for the amelioration of land, as has been shewn by numerous experiments. When thus used they should be well pulverized, by such mechanical means as can be cheaply performed; much of the advantage to be derived from them probably depending upon their being reduced into a considerable state of fines, by which they may be more minutely blended with the mould of the soils on which they are applied, and of course act upon and afford nutritious principles more extensively, for the support of crops; and at the same time render the heavy and more cohesive soils lighter, by being more uniformly incorporated with their clayey and earthy materials. But as such substances can never be reduced, by any sort of machinery, to the fine powdery state to which they are capable of being carried by means of calcination, it is probable that, when employed upon land, they will be less beneficial in many cases, than when used in the state of lime. The same principle likewise holds good, probably, in respect to the磊ings of roads, made with calcareous and other substances, which are found beneficial in different manners, as the proportion of them is in the face or an entirely different matter.
MANURE.

from the attention caused in different ways. It has been sug-
ggested, by the experimentants of an able philosophical inquirer.
that even magnesian lime-stone is made ufe of in this flate of
reduction, without being converted into lime; it may not
be fo friendly to vegetation as that which is perfectly calca-
reous, efpecially when employed in the fame proportions;
but fuch circumftances may, in some degree, account for the
difference which has been obferved in the utility of fuch sub-
fances as manures." It is obvious that fuch lime-stones as
contain the largest proportions of argillaceous earth in their
compositions, when employed in this reduced flate, muft be
the moft proper for the thin light fols; as by that means
the depth and texture of them may be increafed to the great
advantage of the crops. In the application of this fort of
material to land, the farmer fhould be attentive to the flate
or condition to which it is reduced, as well as the nature of
the foil, and adapt the quantities as much as poffible to them.
See LIME-STONE.

Lime-stone gravel is another ftufiance of this nature, which
has been fuccefsfully employed in Ireland; it is a kind
of flony marle, which might probably be equally or more
beneficial, in much lefs quantities, by having the flony lumps
which it contains firit more perfectly reduced; as it has
been found that where the pieces are large, a much greater
proportion is required, and the effects are flower than when
made ufe of in a more reduced flate of powder. See Lime-
stone Gravel.

And chalk is another material of the fame fort, capable
of producing beneficial effects on land, when applied in a
proper manner in its uncalcined flate. From the portion
of argillaceous or clayey matter united with it in fome cafes, it
partakes of the nature of marle. It has been flated that,
where it is made ufe of to the more fliff, clayey, loamy, and
heavy forts of foil, it fhould, in moft cafes, be as much pul-
verized and reduced as poffible before it is laid on, in order
that it may be fpread with greater effectness, and be more
regularly mixed and blended with the fliff and compact ma-
terials of fuch lands; from which they may be rendered
more capable of admitting the fibrous roots of vegetable
crops to fhread themfelves in them, and thereby take in
more perfectly the nutritious matters which are prefented to
them." That this is an ufeful practice, is evident from the
circumftance of farmers, in moft of the countries where chalk
is employed as a manure, finding it more beneficial when
made ufe of in the spring, after having been dug up in the
autumn, and fpread to the frott and moifure through the
following winter, as by that means it is much pulverized and
broken down. The advantage of breaking down the large
lumps is alfo in favour of the fame opinion. It is flated
by the author of Practical Agriculture, that "it would prob-
ably, however, be a still more advantageous practice to
break it down, and apply it as quickly as poffible, after
digging it out of the pit; as by leaving it fpread to the
atmophere for foine length of time, it not only becomes
hard, but likewife lefs folicile, and therefore lefs proper for
the purpofes of manure. Hence it probably is, that far-
ners, where the chalkiulbndary is practiced, find the dreff-
ings more efficacious when the chalk is dug from a confi-
derable depth, than where it lies near the surface of the
ground. In the dry and light fols too it may, probably,
be more ferviceable in this reduced and powdery flate, from
the circumftance of its poffeffing more moifure, on account
of a more extended surface being fpread to the air, and the
parrtles of the foil, from which it may abforb and attract
it, and afterwards part with or afford it in a more regular
and uniform manner, to the aberrent roots of the growing
vegetable crops. The obervations of practical farmers,
however, invariably fhew, that on fuch fols it is much more
beneficial when made ufe of in the form of compoft, either
with rich peat, or vegetable earth and mould, or with good
dung; as by this means a great deal in fuch kinds of land,
the want of well reduced vegetable matter, is remedied, and
a greater proportion of nutritious materials afforded for the
support of crops."

But in uing it upon wet and powdhy kinds of ground,
there is not, probably, the fame neceffity for its being re-
duced to a great degree of fineness, as it may be apt, under
fuch circumftances, to difolve, and fink down too much by
being too greatly diluted with water, while in the rougher
flate it may be retained near the surface, and thereby be
capable of abforbing and taking away the per-abundant
surface-moifure more effectually. In fuch fols, where the
principal intention is the deftruction of mofs, ruleys, and
other coarse plants, the growth of which depends upon a
great degree of superficial wetness, it may, however, be
employed to moft advantage in a flate of coniderable re-
duction, as from its greater readiness to fpread down, it may
the more quickly take away from their roots the exellece
moifure that supports them. When acids exit under cer-
tain combinations in fuch fols, it may, probably, also neu-
tralize them more readily when applied in its pulverized
flate, than in the lumpy one in which it is moftly laid on
fuch lands.

It may be flated, that the quantity or proportion in which
it may be applied, muft depend, in a great meafeure, upon
the flate of the foil, the nature of the crop, and the inten-
tion with which it is employed. In the fotheren diltricts
it is laid on the fliff clayey fols in large quantities, as from
twelve to fourteen or fifteen waggon loads, or from fifteen
to twenty hundred weight each to the acre; and on the
fandy fols in fome parts of Kent, at the rate of one hun-
dred and fifty buflheis to the acre. On deep and strong
kinds of foil, the practice is moftly either to lay it on the
clover keys while feeding off, or upon the flummer fallows.
And it is frequently ufed in the form of compoft on light
foils, to the wheat ffalls, as weal as grafs founds. But
as it cannot be reduced to the flate of powdery fineness of
lime, and cannot of course be fo equally fpread out, or fo
minutely blended with the foil, much larger proportions muft
be employed to produce the fame effects upon the foil;
and in fome farts the quantity is in molt cases requifite.

On this account it has been fuggelted, that where it muft be
carried from a great distance in its wet, heavy flate, it may
be the moft economical practice to have it firft converted
into the flate of lime, as it will thereby be much more
eafily conveyed to the places in which it is wanted. See
CHALK.

There is another ftufiance of this nature, in fome forts
of marle which may be made ufe of as manure to different
forts of foils with great benefit, according to the difference
of their nature.

Where ftufances of this kind are laid upon land, for the
purpofe of supporting immediate crops of either corn or
grafs, the moft crumbley, or thofe the moft readily redu-
cible into a powdery flate, are the moft proper; but where
they are laid on with the intention only of affiling future
crops, or of producing more letting effects, thofe that are
more hard, and lefs diluted to fall into pieces, may be more
advantageously employed, the firft of which is thrown to be
the cafe, by the obervations of practical husbandmen in
maling diltricts, that it does not exert its full effects on
the foil until it has been well mixed and incorporated with
it by frequent aration, and by the practice of letting it re-
main some time on the surface of the ground before it is
turned
turned down, from which it becomes much reduced into a powdery flake: and the latter, by the circumstance of the harder forts remaining a great length of time upon, or within, the ground, before they are fully decomposed, or broken and carried down into the soil to be blended with it.

It is clear that substances of this kind produce beneficial effects on most forts of soil in their different forms; the flake, bone, and those kinds of marl which abound most with calcareous earth, or which have in their composition, are the most adapted to the strong, flinty clayey soils, as by the infusion of such matters they are not only rendered more light and friable, but a great part of the injurious moisture which they contain is removed. While those in which clay considerably predominates, are found more advantageous in the light, dry, sandy, gravelly, and loamy soils, as by such substances the defects of lightness are remedied, and the necessary moisture in some measure preferred. The writer of the Middlesex Report states, that "the stronger forts of loamy soil, clayey marl will mortly be improper, as it has much tendency to render such forts of land more wet and adhesive, by which they may be greatly injured. These have been found to be the effects resulting from the application of it even upon a temperate loam, in some parts of Suffork. And, besides, it is sometimes apt to bring up coltsfoot, a weed which is difficult to be eradicated." It depends, then, upon the quantity or proportion of these substances which is applied, it differs considerably in different districts, which in some degree depends upon the nature of the soils; the heavy, clayey, or loamy, demanding in general a much larger proportion than the light, sandy, or gravelly forts. The average quantity employed may be estimated at from about one to four or more cubic roods of sixty-four yards to the statute acre, according to the state of the marl, and particular nature and condition of the ground upon which it is laid. According to the Survey of Lancashire, "it may in many cases be the most advisable practice not to apply too thick a covering at one time, but to have recourse to light dressing more frequently, as by such a method the fertility of the land may be better preferred and kept up, and the crops be rendered more full and abundant."

It is stated in a practical work, that manure of this fort is employed on lands in a course of tillage, as well as in grazes. On the former it is often made use of as a preparation for barley, turnips, and other similar crops, or applied upon clover or other new leys, previous to their being ploughed up for wheat; in which modes of making use of it, the common practice is to leave it spread out upon the surface for some length of time before it is turned in, in order that it may be well reduced into a powdery form; for the more perfectly the marble is broken down and spread out, the more effectual it is found in promoting the growth of the crops. It has been noticed, that in its application in the latter case, "it is frequently laid on in too large quantities, or left too long in its lumpy flake; from both which circumstances disadvantages are produced to the growth of the crops. It has been noticed, that in its application in the latter case, it is frequently laid on in too large quantities, or left too long in its lumpy flake; from both which circumstances disadvantages are produced to the growth of the crops, unless to be cut for hay, or fed off by cattle; as by the former, when the marl contains much of the argillaceous material, a kind of crust is formed that prevents its springing, as happens where the flint mud of ponds, and such like manures, are too thickly laid on lands; and from the latter, the marl is not only injured by the small vessels, as is experienced when imperfectly reduced clayey earth is applied, but the effects of the manure are prevented from being fully exerted on account of its not being well broken, and carried down to the absorbent roots of the grasses, by the frequent rains that may take place after its application." And that "when employed in large proportions, whether upon the heavier or lighter forts of land, a considerable space of time appears, from experience, to be required to elapse before it can with advantage be had recourse to again; for if this circumstance be not properly attended to, or too many white crops be successively taken, a very great degree of exhaustion is soon produced, as has been experienced in many of the marling counties of England, and in Forfarshire in Scotland. These injurious consequences are, however, found to be easily prevented, by adopting the alternating system of corn and grasses, or other green crops." And it is further suggested as probable, "that by taking corn and grass crops in succession, or, after having one or two grain crops, letting the land be laid down for two or three years with artificial grasses, the application of marl in small quantities might be more frequently renewed, to the great advantage of the farmer, and the improvement of the land. In some of the places where this kind of manure is made use of, as in Lancashire, something of this practice is adopted with much benefit. And when mixed with dung and other substances, in the form of compost, it is generally found capable of being repeated, at short intervals, with the most beneficial effects." From these facts, the writer therefore concludes, that such injuries are rather to be ascribed to the mode of cropping, than to the nature of the manure. Something may also, he urges, depend on the manner in which it is applied, as it has been found to be more efficacious when well mixed and incorporated with the soil, than where this has not been the case; and that, as it has been found highly advantageous in promoting and bettering the condition of the grassy lands in some districts, while in others it has been objected to as injuring them, it is still further probable, he conceives, that much depends on the state and manner of its being put in or upon lands, and that it is only where it is laid on in a moderate suitable proportion, and after it has been well broken down and reduced into a fine powdery form, so that it may be very minutely and intimately blended with the soil, that its best effects can be exerted upon the land.

And the general method of digging it up in the summer season, and spreading it over the ground in its lumpy flake, in order that it may be acted upon and reduced by the heat of the sun, and the frosts during the succeeding winter, is a proof of the same conclusion. See MARLE.

Another useful material as manure, is found in the shelly sand, found in beds in the hollows, and other parts of the sea-coast, in different districts, as containing not only calcareous matter, in a state of confiderable frieness, but a portion of animal and vegetable substancess, with a small quantity of the muriate of soda or sea-salt; the salt of which, from its well-known property of promoting the process of putrefaction in animal and vegetable matters, when in such proportions, and that of destroying different kinds of living insects, may contribute greatly to the good effects experienced from it. This is rendered highly probable, from the circumstance of that which is taken from underneath the water, or from such banks and places as are daily covered by the tides, being the most efficacious when applied to the soil.

The proportion of calcareous matter contained in substances of this fort vary very much, according to the particular circumstances of them. It has been observed, that "where the quantity of calcareous matter is large, and in a very reduced or attenuated state, it is by much the most valuable; as when there is much sand amongst it, a much larger quantity will be required, and the expence of application be of course much increased." It is conceived that this substance
MANURE.

"more proper for the clayey or loamy soils than tho' of the lighter kinds, especially where the proportion of the calcareous ingredient is large. When equally spread, and well incorporated with such lands, it is generally found to produce good effects for a great length of time." And it has been observed by Dr. Anderson, that "a considerable fewer quantity of calcareous matter, when in this fine state, will have a more sensibly effect, than when it is in that of any kind of earthy marl, as it admits of being spread over the ground with greater equality, and of being more minutely and intimately blended with the soil."

With regard to the quantity employed, it must obviously be different, according to the nature and circumstances of the soil, as well as the land; but twenty tons to the acre is, for the most part, considered as a proper dressing. It is laid to be frequently applied on the summer fallows for wheat, and sometimes as a preparation for barley; and may likewise be laid on clover or other leys, before they are ploughed down for grain crops, but in such cases so large a quantity is not requisite. When put upon grass-lands, in not too large a proportion, it commonly produces great and sudden effects, the crops quickly becoming very luxuriant." And it is also observed, that such lands as have been treated in this way, when again brought into tillage, mostly produce abundant crops of the grain kind. It has been stated by Dr. Anderson, that "the effects of this fort of manure on the well-coated of the northern parts of the island have been very extraordinary, especially upon the heathy or moily soils; and it is supposed that such kinds of land are more common on the clay coats than has been generally supposed from the little attention that has been bestowed by the farmer in such situations to procure it for use."

Although common sand cannot be properly considered as a manure, it is often found useful in the flint, clayey, and loamy soils, in lessening their tenacity, and rendering them more light and mellow. This substance has been laid upon rough pasture and meadow land, with the effect of rendering the surface more equal, and bringing up a close thick crop of grass with much white clover. In these cases, the quantity should be proportioned to the flintiness of the soils; but the best practice is, not to apply too large a dressing at a time, as injuries may be done where a very large portion is put on at one time.

Manures of the saline Kind.—There are various offerings of this fort, when in combination with earthy and other ingredients which are found beneficial as manures in many instances, when properly employed. The materials that are principally made use of in this way are the refuse of different manufactures, such as those of bleaching and soap-boiling, where in sufficient quantities, as in the neighbourhood of large towns, and where such nuisances are conducted on an extensive scale. The ashes which remain after the combustion of various green vegetable matters, wood, pit-coal, peat, &c., and some other substances, such as salt and sea-felt, are of the same nature. It is suggested in a late practical work, that "it is probably to the different alkaline principles contained in these offerings, from the great facility and power which they possess of acting upon and dissolving the parts of animal and vegetable matter, especially such of this kind as have been rendered infusible by the absorption of the oxygen, or pure air of the atmosphere, from long or frequent exposure to it, and even solid coal, under similar circumstances, and by this means forming new saline compounds which are fusible, that their beneficial effects as manures are chiefly to be ascribed." And "that as such inert or infusible vegetable or peaty matters, when decomposed or reduced into a state of solubility by alkaline substances, assume a brownish-red colour, and become infusible; the alkalies, in such cases, must enter into combination, and be neutralized by the acid or acids contained in them, which will be found to be the phosphoric and the oxalic, or acid of forset; from which will be formed, according to the nature of the alkali contained in the substance made use of, phosphates and oxalates of potash, soda, or ammonia, which are matters capable of promoting the growth of plants." But, besides their forming in the soils, or the earthy materials with which they are mixed, such compounds as are beneficial in promoting the growth of vegetables, they may be useful in many cases, when properly applied, and used in sufficient quantity, in correcting the acidity, in altering the state or condition of the land, as by taking away moisture from the surface where it prevails in an over-proportion in meadows and pastures, and thereby supports crops of coarse vegetables, and by rendering the texture of such grounds as are under the plough more open and mellow, consequently more suitable for the reception of the roots of grain, and other crops. But some of the flint clays, and the bleacher's refuse, contains vegetable and mineral alkali, in such proportions as render it incapable of being made use of without being previously mixed with other materials. For which purpose, it is suggested, that "fresh mould or peat earth should be procured; and after having been well mixed and blended with it in the quantity of about eight or ten parts of the earth to one of the refuse, a proportion of rotten dung, suitable to the purpose for which the manure is intended, may be added, by which means a good manure will be formed." And the waste of soapers is another manure that may be made use of in the same way; but in this, it is observed, there is a considerable portion of lime mixed with the alkaline matter. The bones or carcases, which are drawn off after making soap, as containing much alkaline saline matter, may likewise, where they can be procured in sufficient quantities, and at a reasonable rate, be made use of in a similar manner.

All these different substances, when combined with good rich vegetable mould, turf or peaty matters, and made use of as a manure, are constantly found to be the most beneficial upon the flint clayey and loamy soils; as in such sorts of land it is supposed that they probably not only contribute to the increase of the crops, by furnishing such fusible matters as can be readily taken up by their aborptive roots, but, by lessening their flintiness and tenacity, render them more proper for their reception."

In regard to the proportion or quantity of these manures which may be necessary, it must, as in other cases, vary according to the particular circumstances of the ground or soil upon which they are applied, and the views of the farmer in their application. But it is usual to apply them upon lands in a state of tillage, as well as under grass; in the first they are generally either put on in the state of compost, at the rate of about ten loads to the acre, just before the seed furrow is given or trowed over the surface, and harrowed in with the grain; in whichever mode they may be applied, it is requisite to have them spread as equally as possible, in order that they may produce their effects in the most extensive and perfect manner." In the latter it is observed, that "though they may in some instances be used alone, it is probably a much better practice to have them mixed with such earthy substances as have been just mentioned before they are laid on the lands, as by such a practice their effects as manure may be rendered more complete and permanent. Upon grass lands they are often used to the amount of from one hundred to one hundred and fifty bushels. And most grass lands are improved by the application of such manures, but especially such as are wet, and disposed to the production..."
tion of coarse four vegetables, such as rutab, wild forer, and various other plants of the same kind. But the ashes, or earthy saline matters, arising from the combustion of different fresh vegetable products, though beneficial as manures, are too wafeful and uneconomical in their production to be made use of, except in particular instances, as where wood and other vegetable productions are very abundant, and used commonly as fuel. Or where they cannot be readily cleared away by other more advantageous methods, as ten or fifteen parts, and in some cases considerably more, of such materials are dilipated and lost during the process. Where they are in sufficient quantities for this purpose, it is suggested that they may probably be employed to the greatest advantage by being mixed with a good portion of rich vegetable mould, or peat earth, and a quantity of well fermented dung; as, in such a compound state, they are capable of being applied more extensively, and at the same time in the most favourable condition for the support of vegetation. When made use of on the heavy soils, the quantity of ashes in the compost should be much greater than on those of the lighter kinds; they are, in general, the most effectual when applied as a top dressing to grass lands, especially such as are commonly termed sour, or have much tendency to the production of mohs on their surfaces." See Ashes.

And peat earth is another substance met with in different districts, which, after being cut and dried by the heat of the summer, is made use of as fuel. By the consumption of this fort of earth in this way, a considerable lofs in respect to manure is sustained; as it has been found, that, "in many cases, nineteen parts out of twenty of the material are dilipated and carried away in the process of combustion, which, as it has been shewn, that the inert vegetable or peaty matter, produced by the action of oxygen, or the pure air of the atmosphere for a great length of time, is capable of being rendered soluble, by mixing it in certain conditions with water, and still more effectually by alkaline saline substances, might have been preferred and rendered useful." However, in Berkshire it is the common practice to dig up peat earth, merely for the purpose of burning it into ash, in order that it may be used as a manure upon land in various cases.

But as it is only from fresh or green vegetable productions that alkaline saline substances can be obtained when burned, none being afforded by the combustion of dead or decayed vegetable matters, it would seem that the ashes of peat earth seldom contain much saline matter. It has, however, been observed by some, that all peat earths afford alkaline saline matters in a greater or less proportion when burned, and that in some it is from a twenty-second to a thirty-second part of their weight. It is stated, that "the ashes produced from the burning of peat about Reading in Berkshire, which long experience has shown to possess great fertilizing powers, are affected to contain no alkaline salts, nor, from the hasty analysis of them which was made by lord Dandonald, was any saline matter, except a small proportion of sulphate of magnesia, or Epiom salt, found. But it is added, that if the analysis had been more carefully made, and when the ashes were newly burned, they would most probably have been found to contain a hepar of lime, which is a saline substance soluble in water, while gypsum, the substance to which it returns on being exposed to the air, is indubitable." The fertilizing effects of these ashes may, therefore, it is supposed, probably materially depend upon this hepar, a circumstance which is rendered still more probable from the observation of Mr. Middleton, in the Middlesex Report, that "the hills on each side of the meadows which produce the Newbury peat-ashes, consist of chalk, easily diffolvable by heavy rain, which washes it off the ridges down the furrows, ditches, and streamlets, to the low grounds, where, mixing with the floods, it is floated over the meadows, and deposited in the peat. Consequentially the peat of this district differs from that of most others, by the quantity of chalk which it contains; and, when dug, dried, and burnt, the fire reduces the chalk to lime, and the rest to ashes. Hence Newbury ashes are a mixture of lime and vegetable ashes; and it is very probable that any common peat-ashes, or the ashes of rough grasses, land, of turf, heaths, furnes, ling, wood, &c. produced by the operation of paring and burning, being mixed with chalk lime in due proportion, would be as equally fertilizing as these noted ashes." But it has been suggested, that there is another circumstance that may produce a difference in the saline and other substances contained in the ashes of different peaty earths, which is that of the presence of mineral springs. When, by this means, an over large portion of sulphat of iron, or green vitriol, happens to be present in the peat, the ashes produced from its combustion must in consequence become injurious, or at least much less beneficial to the growth of vegetables, than in cases where such a substance is not present. Its prejudicial effects, according to lord Dandonald, may be corrected by the use of either lime, magnesia, alkaline salts, or dung; but that preference is to be given to magnesia and alkaline saline substances, as they not only decompose the vitriolic salt, but form other saline substances, which are found favourable to vegetation or the growth of plants.

And where dung is made use of in such cases, the vitriolated iron is brought into its metallic condition, and the sulphuric acid, thus fet at liberty, enters into combination with the ammonia or volatile alkali formed from the dung, and produces sulphat of ammonia; or, by uniting with the calcareous matter, and the additional affinity of the inflammable, or putrefactive matter of the dung, it may be converted into a heapar that may be beneficial to the growth of plants as crops.

Ashes of these descriptions may be used as a manure, either by being harrowed in with the grain-crops, or sown over them as a top dressing after they have come up. In the former case it is advised, that they should be employed in a somewhat larger proportion than in the latter; in which the best practice is to sow them over the crops before they are grown too high; and if the weather be rather inclined to wetness, it will be the more favourable; the quantities commonly employed in this way are from fifteen to twenty bushels the acre, according to the state or condition of the land. Where laid on grass lands, whether those of the artificial or natural pasture kinds, they often produce great improvements, rendering the grases thicker, finer, and more close and abundant, often removing much of the molyb matter which infects them. See Ashes.

And peaty substances, in the reduced state of dust, are sometimes made use of with great benefit; but it is suggested by lord Dandonald, that this fort of earth may generally be employed to most advantage by being well mixed and incorporated with such substances as contain alkaline salts, or with alkaline hapers, or by a mixture of sulphat of soda, with lime in its active state." It is likewise supposed that the powdery or dusty matter of pit-coal might, probably, be applied with the same advantage if prepared in a similar manner, and it is capable of being rendered soluble in the same way. And it is further alleged by the same writer, "as the result of experimental trials, that the effects of peat earth, mixed and incorporated with alkaline saline substances, are equal, if not superior, to those from dung, the weight of
of each being the same;" which, if it be well-founded, shews the superiority of employing peat earth in this way, instead of converting it into ashes, to be much more than has been already believed to be the case. See Peat-dung.

And the ashes obtained from pit-coal, when applied as manures, are found to be useful in many respects; but it is supposing, as they can contain saline matter only in proportion to the quantity of fresh vegetable products that may have been consumed along with them, little of the effect which is produced can depend upon it; much more, probably, arises from the portion of calcareous earth which they contain. It is also added that sufficiently small, in some cases, probably depends on the animal substances that may have been occasionally burnt, or afterwards mixed with them, before they are made use of as manure. And that "they may also be serviceable on the stiffer sorts of soil, by rendering them more open and disposed to admit the roots of growing vegetables." This "seems to be shewn by their utility in the stiff clayey grounds, from which brick earth has been dug, and on which are generally term four lands. On the more tenacious loamy soils, they may operate by giving friability, and at the same time the calcareous principle, in a small degree, where it is deficient, which is further supported by their having been found from experience to be much less useful in the poorer sorts of land, than those that are of a good quality."

It may be noticed, that the application of these ashes to stiff soils, from which brick earth has been taken, renders it sufficiently friable to afford good crops of beans, a sort of plant which, though it grows well on heavy soils, could not be produced on lands too stiff as the bottoms of brick grounds, without these ashes. However, except in such cases as the above, this manure is probably best adapted to grass land as a top-dressing, and it may be occasionally used in this way to young grain crops in particular cases.

With regard to the proportion in which it may be laid on, it must be different according to the views of the farmer, the nature of the crop, and the state of the ground, as well as other circumstances. See Coal-ashes.

Another saline substance is met with in foot, that experience has shewn to be of much utility, when applied to land as a manure. It is probably, that the beneficial effects resulting from the use of this substance depend, in a great degree, on the quantity of alkaline saline matter which it contains; which by its action on the rich vegetable mould of the soil or earth with which it is blended, may render it more capable of supplying the nutrition of vegetable; and it may bring the gross oleaginous matter of the foot into such a state as to be capable of solution or diffusion in water, and in that way render it fit to be taken up by the absorbent roots of vegetables. It is supposing, that "the earthy matter of this substance, as well as that of different kinds of ashes, may probably be rendered more suitable for the purpose of promoting vegetation, by their having been exposed to the action of fire, as is well known to be the case with clay." The great flake of linens in which foot is found, may, likewise, it is supposing, be serviceable, as by that means it becomes capable of being more regularly and more extensively mixed with the soils on which it is applied. And it is believed, that "the good effects of most substances employed as top-dressings depend, in some measure, upon this circumstance." It is thought probable, that this substance, as containing alkaline salt in a considerable proportion, may probably be used with greater advantage by being well mixed or blended in such mould, or peat-earth, and by such a method the quantity of manure would be greatly increased. This should not, however, be attempted where the defrutution of insects forms any part of the design of the farmer in its application upon his land.

Soot is a substance which is chiefly made use of as a top dressing to grain crops and grass lands. "On the former it has been found extremely useful in destroying the wireworm and other destructive insects. This is probably effected by the bitter oleaginous liquid formed from the union of the alkali and the oil of the foot, impregnating those parts of the plants on which they feed, and thereby causing them to be rejected by such insects." It may also produce some advantage in this respect, by promoting a rapid vegetation, and thereby rendering the texture of the plants, very quickly, too firm to be preyed upon by them, as has been observed by lord Dundonald. That it is very powerful in promoting the vigorous growth of vegetable crops, is shewn "by the change which takes place after sowing it over such young wheat crops as have a yellowish sickly appearance, as they frequently put on, in a very short time afterwards, the healthy green aspect. On meadow and pasture lands, experience has likewise shewn it to be highly useful, not only by encouraging the growth of a finer sort of grass, but by destroying or correcting the frequent distillation of such grounds to produce mofs, and some other coarse sorts of vegetable productions." In respect to the quantity or proportion that may be applied, this must vary according to the circumstances of the case; the most common quantity is generally from about forty to fifty bushels on the acre. See Scott.

It is advisable, where any of these or other materials that contain saline matter, are to be employed as manures, that "they should always be preferred in fields, or other convenient places, from rains, or the accidental application of water to them, as where this practice is neglected, the saline substances are soon dissolved and carried away in a liquid form. It is chiefly from this cause, that substances of this kind, which have been long exposed without being covered, are often found to inferior in their effects to those which are fresh or newly made. On this account also, if such substances are laid on land at too early a period of the season, they will be liable to have much of their valuable properties carried away by the rains that may take place." The muriat of soda, or sea-salt, is a substance, the utility of which has been already noticed, but which, "for the purposes of manure, seems not yet well ascertained, as by some it is considered as possessing considerable powers of promoting vegetation; while others have experienced little or no advantage from its application. But though it may prevent putrefaction when employed in large proportions by its antiseptic property, as has been shewn by different trials, when used in small quantities it has a tendency to promote the process. On this account, it may therefore, it is supposing, be serviceable when incorporated with farm-yard dung, and other animal or vegetable matters, in small portions."

The author of "Practical Agriculture" has suggested, that "as everywhere in the vicinity of the sea a ready means of obtaining this saline material in unlimited quantities offers itself, it may deserve more particularly the notice of the agriculturist; and more especially as many other substances that are known to contain, or be impregnated with it, such as the weed thrown up by the tides, and the sand over which they flow, can be easily procured." There is still another substance of this nature, that "exists in the bittern, waUey, or rrfufe of salt works, which generally contains muriat of magnesia in large proportions."
MANURE.

It has been found to possess very great septic qualities, and may, therefore, be highly beneficial when mixed with dung, or earthy matters. Experience has shown it to be capable of promoting vegetation in a great degree.

The above writer thinks, that "in whatever manner sub- stances of the saline kind may produce their effects in promoting vegetation, when employed as manures, it is evident, from their containing in themselves little or nothing of such matters as are capable of affording nourishment to plants, that they may, in most cases, be made use of to the greatest advantage, by being mixed and incorporated with such sub- stances as they are capable of acting upon and reducing to a state proper for the support of vegetable crops; such as rich earthy materials, imperfectly reduced dung, and other matters of a similar kind. Where substances that contain the muriate of soda, or sea-fall, are employed, they may probably be applied to much advantage, by being mixed with imperfectly burnt clay, when reduced to the state of powder. And if upon trial they should be found effectual in this form, they may be very conveniently made use of in the way of top-dressings to grass or grain crops in the spring."

"Manures of the mixed or compost kinds.—It is extremely evident, from what has been stated and explained in respect to the nature of the different substan- ces that are capable of being used as manures, that many of them may frequently be mixed and blended with each other, or with materials of other kinds, so as to be not only considerably increased in quantity, but often rendered more effectual and proper for application than in their simple states. At the same time, it is clear, that some of them may be thus mixed and incor- porated with each other with much more benefit than others; for although the constant experience of farmers has decid- edly shown the great importance and advantage of employing composts, till lately they have paid little regard to the mixing together of such matters as are, from the prin- ciples which they originally contain, or which are formed from them, in the changes which they undergo in the different stages of their decompositions, adapted to act in the most suitable manner for producing such combinations or alterations in the materials, as are capable of being benefi- cial in the greatest possible degree in promoting vegetation, when applied to the land or soil.

It is obvious, that the manure raised in the farm-yard is the most common application of any, and which, from its being formed by the gradual decay of various kinds of vegetable matters, as hay, straw, fern, and various other materials of a similar nature, with which the dung and urine of animals are incorporated and combined, it is to be con- sidered as a compound manure. And from the largeness of the proportion in which such vegetable productions enter into its composition, and the quantity of earthy materials that is in most cases added, especially where the manage- ment is judicious, by laying of suitable foundations or bottomts, it is less frequently requisite to blend it with other substan- ces than other manures. But as most of the vegetable materials that constitute the chief part of it are made use of in a dry and hard state, and do not so quickly ferment or run into the state of decay, notwithstanding the quantity of animalized matters that may be blended with them; it becomes useful to turn them over once or oftener, in order that their complete purefaetion may be promoted, and at the same time the different materials minutely blended together. And it has been suggested, that "in forming of this manure, care should also be constantly taken, that the heaps be so situated, as that they may not become too dry, or too much soaked in water, as in either case they must be greatly injured," and that "whenever it may be requisite to incorporate any earthy material with this sort of manure, the agriculturist should carefully attend to the state or richness in which it may exist in the yard, and proportion such additions accordingly." It cannot, however, ever demand a portion nearly so large as that of such ma- nures as are almost wholly composed of animal substan- ces of such earthy matters.

After observing that straw or litter is the basis of farm- yard manure, or what is often termed dung, a late writer maimed that, for light and heavy soils, the dung should be prepared in different ways, be used at different lengths, and applied to different crops. For light soils, he thinks, manure requires to be much more prepared than is necessary for clayey soils; and that every step of the previous prepa- ration, to be perfect, ought to be executed in a quite dif- ferent manner. "For soils of the first description, where tur- nips are taken as a fall crop, dung can hardly be too well prepared; because the nature of the crop, to which it is ap- plied, renders a complete incorporation with the ground absolutely necessary, without which the young plants might be starved at their very entrance into life. In the belt of farmed English counties, which have come under his ob- servation, dung is often kept over year, in order that it may be perfectly rotted; and the late Mr.BKawell was in habits of not applying it till it was reduced to a state some- thing like black fruit."
He does not, however, approve of such procrastination; for, when the preparatory steps are conducted with judgment, there is rarely any necessity for keeping dung over year upon turnip-farms; besides, such a delay causes a waste of the article, and most likely dissipates its strength; at all events, a year's interest of the value of the increased produce must be lost. In general soils, there is not much difficulty in preparing dung upon turnip-farms, because, in the dry season, from the nature of the food used, such a quantity of liquid passes from the animals, as to prevent burning, provincially fire-fanging, the greatest obstacle to the rottling of dung that can be experienced. If turnip dung is regularly removed; if it is properly mixed with the horse litter, and other excrementitious matter ac- cumulated upon the farm, it will be found an easy task to prepare all that is made by the middle of April, at which time the fold-yard should be cleared. What is produced after that time should be stored up separately, receive waterings, if the weather is dry, and be referred for clover stubbles, or other fields that are to be drenched in autumn."
But though the middle of April is mentioned "as a good time for clearing the fold-yard, this does not prevent the work from going partially forward through the winter, when suitable opportunities occur. When drove out of the fold-yard, the dung should be laid up in a regular heap or pile, not exceeding five quarters, or four feet and one half in height: and care should be taken not to put either horse or cart upon it, which is easily avoided by backing the cart to the pile, and laying the dung compactly together, with a grepe or fork. It is also useful to face up the extremities with earth, which keeps in the moisture, and prevents the fun and wind from doing injury. Perhaps a small quantity of earth threw on the top might also prove useful. Dung, when managed in this manner, generally ferments very rapidly; but if it is discovered to be in a backward state, a complete turn over, about the first of May, when the weather becomes warm, will quicken the process; and the better it is shaken andander, the sooner will the end in view be gained." A secluded spot of ground, not much exposed to wind, and perfectly secure from being floated with water, ought always to be chosen for the site of such piles.
piles or heaps. If the field, to which it is to be applied, is at hand, a little after-trouble may be saved, by depoiting it there, in the first instance; but he has always found it most convenient to prefer a piece of ground, adjacent to the home-flead, for such a purpose. There it is always under the farmer’s eye; and a greater quantity can be moved in a shorter time, than when the situation is more distant. Besides, in wet weather, and this is generally the time chosen for such an operation, not only are roads cut up, by driving to a distance, but the field, on which the heap is made, may be poached and injured considerably. This he conceives to be “the most approved method of procuring dung upon turnip or light farms.”

However, “upon clay soils, where wheat forms a principal part of the crop; where great quantities of beans are cultivated, and few turnips own, unless for the use of milch cows, the roting of dung is not only a troublesome, but an expensive affair. Independent of what is consumed by the ordinary farm-yard, the overplus of the straw must faine how or another be rotted, by lean cattle kept in the foldyards, who either receive the straw in racks, or it is thrown across the yard, to be eaten and trod down by them. According to the use of consumption, it is evident that a full necessity arises for a frequent removal of this unmade dung; otherwise, from the trampling of the beasts, and the usual want of moisture, it would compre very much as to prevent putrefaction altogether. To prepare dung sufficiently upon farms of this description is at all times an arduous task, but rarely practicable in dry seasons: for if it once gets burnt (fire-fanged), it is almost physically impossible to bring it into a fit state of preparation afterwards; and, at all events, its virtues are thereby considerably diminished. The straw flung out in considerable portions to the fold-yard, after being compressed by the trampling of the cattle, becomes rather like a well-packed stack, than a mass of dung in a preparatory state. The small quantity of water and dung made by the animals is barely sufficient to cause a slight fermentation, and this fermentation, when the heaps get into a compacted state, is sure to bring on the injury of fire-fanging. To prevent such an injury, no measure can, it is conceived, be so successfully used, as a frequent removal of this unmade dung, especially in the event of wet weather at the time. If people can stand out to work, you cannot have too frequent removals, in this operation; for there is always such a quantity of the straw, that has not passed through the entrails of the cattle, as renders it almost impossible to do injury in the first instance, by an access of moisture. What he would therefore recommend, upon every clay-land farm, especially those of considerable size, is a frequent clearing of the fold-yard; and that the greatest care should be taken to mix the stable or horse-dung in a regular way with what is gathered in the fold-yard, or made by other animals, in order that a regular heat or fermentation may be speedily produced. Where the materials consist of a small quantity of dung, or excrementitious matter, and a large floor of unrotten straw, only partially moistened, he is clear that no damage can ensue from putting horses and carts upon the heap; nay, he rather thinks that a positive benefit will be gained from this slight compreッション. He is, however, at the same time, well aware that the sentiments of many able and judicious farmers are different from his on this point; they being of opinion, that the natural prelude of the materials is quite sufficient; and that any more is attended with injurious consequences. He is, however, satisfied, that such ideas are unfounded; having tried both methods upon an extensive scale, and, from the results, feels himself justified in recommending the manage-
vented from escaping, as would otherwise be the case, and which, by combining with and acting upon the earthy materials, quickly renders them proper for the purposes of manure. And as substan-ces of the animal kind have been found to run very rapidly into the state of putrefaction, it has been remarked, that "they may frequently be incorporated with such vegetable materials as are little disintegrated, or with difficulty made, to rot or become putrid, and by such means good composts be more expeditiously formed. In making use of such earthy materials, it may be of much advantage to have them exposed to the influence of the atmosphere for a considerable length of time, frequently turning them over, before they are mixed with the manures, as by such means they become in a more pulverized state, and are capable of being more intimately blended with such materials, and afterwards spread over the land with much greater equality, a circumstance upon which their effects very much depend. And that when, in performing this business, the earthy substan-ces are formed in a state of ridge, about five or six feet in height, and nearly the same breadth in the bottom, they will be in the most proper situation for being united with dung or other matters that may be intended to be blended with them."

By a late writer it has been remarked, that "lime is a substan-cce that has often been too indiscriminately made use of in the formation of composts, but which, by attending to the following circumstances, may admit of being employed extensively and with more beneficial effects. Where the destruction or decay of green or fresh vegetable matters, especially those of the more coarce and hard kinds, is intended, it should be used in its caustic state in small quantities; as in this condition, thus sparingly employed, it reduces more expeditiously the numerous and hard parts of such matters to an earthy state; and as, during its action in this way on these substan-ces, such earthy matters are set at liberty, as by their subsequent combination afford ammonia or volatile alkali, it may frequently be a beneficial practice to blend the earthy substan-ces as have been just mentioned with them, and thereby prevent the earthy matters from being diffused and lost. If a portion of rich farm-yard dung be some time afterwards incorporated with the materials, a valuable compost will be formed." And it is added, that "quick lime is likewise found useful, sometimes in bringing the hard parts of dead vegetable matters, as tanners' bark, fern, straw, cabbage-faik's, leaves, &c. quickly into the state of earth or mould; but whenever it is made use of in this way, it should be had recourse to only in a very scanty proportion to those of the matters with which it is mixed, as when it is employed in large proportions, it is liable, from the heat that is extracted or diffused by its combining with the moisture of such substan-cce, being so augmented during its flaking, as to convert them into a coaly substance that is infallible, and at the same time to force off, in the form of gas, their elastic principles, except such a quantity of carbonic acid as may combine with the lime during the process."

It is evident that, "by the common practice of blending quick or caustic lime with farm-yard dung, much loss is frequently sustained; as by its violent operation upon such substan-ces, some of the elastic matters are not only set at liberty and quickly conveyed into the atmosphere, but, with what remains infallible lime, its pounds are formed which cannot afford vegetation. It is conceived that the complete putrefaction of such manures, when necessary, is best promoted by the use of lime in its mild state. But in cafes where it is to be blended with peat or earth, the most advantageous method is to use such lime as has been newly made and well flaked, in the proportion of about one part of the lime to five or six parts of the peat or mould, which should not be too much exsiccated, or dried, before it be made use of. By this means the heat which is generated will not be sufficient to produce any injurious consequences, either by forming a caustic matter, or forcing off the elastic principles in the state of gas. And the volatile alkali, which is composed in such cafes, by being allowed to enter into combination, as it is formed, with that part of the peat or mould which has not been acted upon by the lime, in consequence of its being employed in so small a proportion, and in its effete state, will form a soluble lime substan-cce, capable of promoting vegetation."

Lord Dundonald states, that there are other substan-ces that may be still more beneficially employed in forming composts with peat earths, when they can be procured in such quantities and at such cheap rates as render them capable of being made use of in this way," such as "alkaline earthy matters, or such substan-ces as contain them in any quantity; as by mixing these with the peaty materials as above, they are made perfectly soluble, while by the use of lime only, such a proportion of them is rendered soluble, as can be acted upon by the quantity of ammonia or volatile alkali formed during the time it is mixed with them."

And still farther, that insoluble compounds, such as have been noticed, are formed in the latter circumstance.

But the practice common, in different districts, of making composts with lime and mould on the headlands, or other parts of the fields on which they are to be applied, which cannot be done to advantage, except where the surface mould is rich in vegetable matter, is not to be much recommended, but wherever such composts are to be formed, the land should always be ploughed or dug up to a great depth, and be reduced into as perfect a powdery state as possible; fresh lime may then be deposited in small heaps, along the middle ridge of the headland, and the earth in this fine state be thrown over them, in the proportion of about four parts of earth to one of lime, being kept close by being beaten down with the back of the plade. It is observed, that this gradual flaking of the lime in this situation, by the moisture of the earth, elastic matters are set at liberty, which combining with the mould or earth, render it still further reduced, and by being afterwards very intimately blended by means of the spade with the very fine particles of the lime caused by the flaking, a valuable compost is made for the different forts of soil, especially if a small quantity of good rotten dung be well incorporated with them some time afterwards.

Although farm-yard manure is seldom in a state to admit much addition of earthy matter, yet where there is much liquid oozing from such composts, or flagrating about the bottoms of them, some of the earthy materials which have been mentioned may be laid around them in order to absorb or take it up, and prevent the great waste that much other-wise take place, as may often be observed in the situations where dung composts are made. And it is advised, that "this should be more particularly attended to, where such composts are laid in situations that have not been properly formed as dung-ideas." In such cafes, it may often be an useful practice to place a considerable thickset of such materials in the bottoms, before the farm-yard compost is carried out, and laid upon them, as by that means the manure heap may be greatly increased, and at the same time a proper substan-cce for the volatile alkali contained in such liquors to act upon supplied. This method is fully confirmed by the practice being in use wherever any attention is directed to economy in the forming manures of this kind.

With regard to the application of this sort of manure, the nature of the soil, the state or condition of the land, and
and the goodness of the matters, are circumstances which render a difference in the quantity of such manures necessary. The heavy forts of soil, such as those of a clayey or deep loamy nature, require composts constituted of the lighter forts of earthy materials; while the thinner and more light forts stand in need of those which are formed of clayey, loamy, or the more tenacious matters. But "in general, the allowance of such manures should be from sixteen to twenty loads to the statute acre, each containing seventeen or eighteen hundred weight. On many occasions, however, a much larger proportion may be required, and in others a less may answer the intentions of the farmer." It is added, that "the mixture of dung and litter, and other materials which are gradually collected and formed into heaps in the farm-yard, is, in general, when employed without having any other substances incorporated with it, laid on such lands as are under preparation for wheat, turnip, or barley crops. It is likewise in some places laid on for a pea crop, where wheat is intended to be the succeeding crop."

The compost manures, which are collected from the streets of large towns, are formed of a great variety of substan ces, as the reccrments of decayed vegetables, putrid animal matters, and ashes; but from their abounding for the most part with substan ces of the latter kinds, they may, on the principles just stated, be in many instances greatly increased by having rich surface mould or peat earth blended with them; and by such a practice, where the manure heaps are in a condition to admit of it, the rill of waste by the escape or dilution of their more fluid contents in the aerial or gaseous state be effectually prevented. But such additions can only be advantageously made where the proportion of animalized materials in the manure is large; in other cases it is better to employ them in the state in which they are met with when collected.

It is found that compost manures are capable of being used with great benefit on different soils, and in preparation for different forts of grain crops, as well as those of the grass kind. It is flated, that "what when applied in the proportion of fifteen or twenty tons to the acre, should generally produce great fertility. They should, however, be applied according to the particular circumstances of the soils, and the nature of the crops for which they are made use of."

It may be noticed, that the result of practical trials fully proves that the most beneficial composts are all those which are formed by the combination of earthy materials with animal matters. See Compost.

Manures. Means of increasing and preparing them.—After what has been already advanced, the belt means of augmenting, preferring, and managing manures may be considered, as upon this in a great measure depends the general fertility of farms, and the goodness of the crops that are raised upon them. It is of course a matter of great interest and importance to the farmer to see that nothing is destroyed, wasted, or thrown away, that can in any way be converted to this purpose. It has been remarked by a late writer, that "there are many substan ces that may be rendered useful in this way, which have hitherto been little regarded by the cultivators of land, there can be little doubt, when the daily waste of animal, vegetable, and other matters that take place in every country, from their being carried away by rivers, or confounded by fires, is fully considered." By greater attention to the cutting of grain, so as to preserve as much straw as possible, as well as care in getting together the fluke, in many instances vast advantage may be gained in this view. And that "another great cause of loss in the production of manures is from the want of adopt-

ing or putting in practice such modes of management, in respect to different substan ces, as are capable of rendering them fit for the purpose of application in the most quick and expeditious manner; for it is obvious, that if by properly attending to such means, the same quantity of manure can be prepared in a short space of time, which under other circumstances must have required a long one, much increase of manure may be effected, and consequently great advantages be gained by the cultivators of the ground." It is flated, that what is necessary to be done in order to facilitate and hasten the decomposition and reduction of different materials into the proper flakes for being applied to the soil are, as has been seen, "in some measure, the free admion of atmospheric air, a quantity of moisutre suited to the condition of the matters made use of, and a due degree of heat. And also the proper blending of animal with vegetable substan ces, in the incipient states, and the addition made, into which not only the drainings from all the different fields and places where animals are fed or kept may empty themselves, but likewise the urine from the necessaries, the fae from the wash-houses, and the washings of the various utensils employed in the family. Without these advantages in the construction of farm-yards, much lofs of manure must daily occur from the liquid matters of such places continually running away, and being otherwise wafted, as well as from their not being made use of to forward the conversion of other substan ces into the condition of manures." But that, where these and other suitable accomodations have been provided, the farmer will have little more to do than "be careful in saving or providing such matters as are suitable for the purpose, and causing them to be properly placed and removed, in order to have them speedily reduced into the state of manure, and the quantity of his dung-heaps thereby greatly increased and extended. With the fame design, various vegetable matters, such as hay, straw, fern, leaves, rushes, coarse grases, flags, and many other aquatic plants, should be collected and stored in large quantities as possible, by allowing nothing of the kind to be fold or carried from farms, except in some particular instances, as where they are fitted near large cities or towns, where such articles can be advantageously disposed of for the purpose of feeding and littering horses, or other animals, and at the same time an equivalent in good manure be brought back to the farm; by moving and raking together the wheat or other flukes, the fern from the commons, and leaves where they can be obtained, as in the vicinity of parks and other wood-lands, and by cutting the coarse grases and
and aquatic vegetables at such periods as they are in the moit juicy and succulent states. The whole, after being sufficiently dried, should be carried to the farm-yards, and stacked up in convenient situations, either in or near them, for the purpose of being made use of as litter, and by that means being converted into manure. And in addition to these means, every leisure opportunity should be taken, before the commencement of the foddering season, to bring into the farm-yards such quantities of peat or boggy earth, rich surface mould, marly, dry mud from ponds or ditches, cropings of roads, loam, and other subfusibles of the same kind, as can be conveniently obtained, for the purpose of being applied as bottoms for the ab sorption of the liquid matter.

It is farther stated, that when such materials as are necessary have been thus procured, "the bell mode of proceeding seems to be that of covering the whole of the yards where the cattle stand and tread, and even the pig- 

flies, in some cases, with layers of these earthly matters, eight, ten, or more inches thick, according to the number of cattle and other circumstances; and also to di- 

posit in the referrors before the dung-yards proper quanti- 

ties of the same subfusibles, for the liquid matter which come into it act upon. Upon these earthy bottoms, at the time the cattle are confined, pretty thick litters of one or more of the materials that have been collected and stacked up may be placed, and the flables, cow and ox- 

ittas, pig-flies, &c. cleaned out upon them. Where it is the practice to tie up and confine the cattle in the night-time, the straw or other subfusibles, after having been broken down and reduced by littering them, may be used for cov- 

ering the bottoms of the yards, by which means their decay may probably be rendered more quick and convenient. It appears also probable, that where flabelle, fern, rushes, leaves, or other vegetable matters, the textures of which are hard and ligneous, are employed, their decay or reduc- 

tion into the flate of manure may be greatly expedited by means of a flight portion of lime, in its active state, being spread over the earthy bottoms before they are applied, as has been found to be the cafe with tanners' bark."

And that, "where the matters made use of in the way of ma-

nures are liable to be rendered too dry by the weather, their putrefaction and decay may be much promoted, by having them sprinkled over occasionally with water, which may be, conveniently and readily performed by having a pump with 
	

troughs fixed properly for the purpose, or where there are 

wanting, from a pond in the yard." And in order to re-

nder the plan the most effectual it is capable of, the whole 

of the cattle should be strictly confined to the fold or fod- 

dering yards during the winter, and not turned out, as is frequently the case, into the pastures, by which the making of much manure is prevented, great injury in many situations done to the grass-hands, and the flock, from being much exposed to cold and other causers, benefited in a far less degree than is commonly imagined. By pursuing this me-

thod, from the great confusion of straw and the outer forts of food by the young lean cattle, and of hay and luxuriant vegetable roots of plants by the others, such quanti- 

ties of animalized matters are voided, as by mixing with the bottoms of the yards hinders their putrefaction, and affords not only an immense increase of manure, but of such as is of a very valuable kind. If there be not a sufficient proportion of animal dung and urine incorporated with the other matters, which can seldom be the cafe where the cattle are not regularly confined to the fold-yards, the manure, though it may be nearly as large in quantity, is found by experience to be very inferior in its effects when applied to land." It is likewise stated, that "where the number of 

cattle confined in the fold-yards is great, it may be need- 

fary, occasionally, to remove the bottoms, and the matters 
littered upon them, to the dung-yards, after they have be- 
come in some degree manures, by being well saturated and 

blended with the urine and other animalized matters. These 

must be immediately replaced by others in the way just no- 
ticed. And farther, "the earthy subfusibles from the re-

ferrors should also be occasionally emptied out upon the 
dung-yards, and replaced by quantities of fresh materials of the same kind, and the items of different grofs vege-
table products from gardens or other places."

Besides, "at the close of the season, when the cattle are 
turned out of the yards, the heaps of manure which have 

been thus collected and thrown together, should be turned 
over, in order that the animalized matters may thereby not 

only be still more intimately incorporated with the earthy sub-

stances, but, likewise, that more of the pure air of the at-

mosphere may be retained among the clofs, from their being 

rendered much smaller by such means, and the putrefactive proc- 

esses be thereby more perfectly produced." And, "af-

ter this business has been well performed, as little delay as 

possible should be suffered to take place before the manure is 

applied to the foil; as, from the combination of oxygen or 

pure air with the carbonaceous material of the dung, and 

of azote with hydrogen, under these circumstances, such fluid matters are formed as constitute its most beneficial pro-

perties, but which are afterwards continually waiting, 

so long as it remains unsapplied to the ground or foil."

Hence, "on these accounts, as well as those which have 

been already stated, manure heaps should not be made too 

large, but of such fizes only as that they can be expeditiously 

turned over, and put upon the land. And another advantage 

which attends the having different heaps, and their not being 

large, is, that one can be prepared and carried away at a time, 

without the other's being in the least injured by any delay 

that may happen from unforeseen causes of any kind."

It is noticed in an useful periodical work, that "in many 
situations where the above-mentioned articles are plentiful, 

they are suffered to go to waste, though they may be used 
to great advantage for littering the flables and fold-yards. 

Ferns and rushes do not rot so soon as straw, but make a rich 

manure, and if well turned over in the spring, are sufficiently 

rotten in June." In winter and spring, when dung is taken 

from the flable or fold-yards to the fields, it is conceived better 
to throw it up with forks than allow the carts to be taken 

upon the dung-hills, a practice which prevents a speedy or 

complete fermentation. At these times, the quantity of 

manure may be much increased by mixing with the dung 

large quantities of rich earth, taken from old dykes, sedi-

ments of ponds formed by running water, and such other 

places as were most likely to afford it, well mixed with fresh 
or diffused vegetable matter." But it is well observed, 

that the practice of mixing earth with dung requires to be 

managed with a delicate hand, especially in forming a dung-

hill with materials that have not been previously subjected to 
fermentation, for, as in carting upon it, by precluding and 

condensing the outs, it greatly retards, and, in some in-

stances, almost entirely prevents, fermentation; indeed, by 
mixing any considerable quantity of soil with dung in an un-

fermented state, by precluding the straw and other matters into 

a small space, it so effectually excludes the air, that the 
dung, at the distance of several months, is found in a flate 

very little different from what it was when put in the heap: 
and, after all, when it is in common language said to be ro-

ten, it is, upon examination, found to be only decayed, and 

the produce, in place of abounding in rich mucilaginous 

fusibles, 

"
MANURE.

SUBSTANCES, which all well-fermented dung does, is found to consist almost entirely of vegetable earth. There is, however, it is said, a mode of applying earth to dung-hills, that is not only safe, but highly beneficial: "It consists in covering the whole surface of the dung-hill lightly, either with common earth or broken peat, every time the stables or fold-yards are emptied; a covering of that kind not being heavy enough to press materially upon the mafs, does not retard the fermentation, and has the great additional advantage of preventing the lofs daily sustained about most farms by evaporation, and the dissipation of the greatest part of the valuable gasses generated during the process of fermentation, all of which are entangled and retained by the earth; which, by that means, not only acquires high fertilizing powers, but renders the dung more valuable." And then, "though a proper system is followed of carrying out the manure from the stables and yard to the dung-hill—as once a mouth, if it is spread equally over the whole, and a covering of the kind just mentioned laid above it, a considerable addition may be made to the quantity of manure upon every farm yearly, not only without risk, but with very great advantage." This sort of manure has been found upon light gravelly hills, or fertile clays, particularly useful. It is supposed that "the rich earth alone would have made very much improved such ground, but by being mixed with dung, it probably became impregnated with something of a fertilizing nature, which would otherwise have been lost." In some cases, "instead of mixing as above, the earth has been occasionally laid on a foot or two deep, as a foundation to build dung-hills upon; at other times in situations where the drainings of fold-yards, or the urine of fat cattle, could easily be conveyed into it, and no doubt considerable advantages may be reaped from these methods of increasing the quantity of manure. In regard to the propriety of mining rotten or rank dung, the latter is supposed very impalpable, though purfued by some farmers, who do not wish to have partition in being led out and turning, not only because these operations are troublesome and expensive, but because they believe that the quantity of dung is thereby lefened. They certainly leffen the bulk, but probably not the quantity of good manure. Perhaps they prevent the loss of some very fertilizing particles, which are exhised by the solar heat, or otherwise injured by the weather, when the dung is applied in its rough state, and consequently not properly covered in. There can, however, be no doubt of a small quantity of rotten dung making land more productive than a much larger one of such as is rough or half rotten.

And it is believed that, "by mixing lime with manures composed of earth, and dung in the more advanced stages of their preparation, some increase of quantity may likewise be produced; and at the same time, by its uniting with the nitrous acid during its formation, may prevent that fulfance being thrown off into the atmosphere in a gaseous form, or readily wafted down by the storms by rains; and therefore preserve a material that has long been used useful in promoting the growth of plants."

As great value of manure is continually taking place from the evaporation of the more liquid parts of manure heaps, where they are much exposed to the influence of the sun or winds, and the waftings of the ris, it would tend greatly to the saving of much matters, and at the same time considerably promote their complete putrefaction and decay, to have them placed in situations that are much shaded by trees or other means. It is suggested, that, in farm-yards, movable coverings of some light kind of material might probably be highly advantageous for this purpose. By means of this nature, the manure heaps, in such places, may be effectively screened from the action of the sun in the summer, and prevented from being injured by the heavy rain or snow that falls in the winter season. And as a further inducement to adopt such methods, the manures which have been preferred from the effects of the weather in this way, are said to have been found, by practical trials, to be far more efficacious in promoting the growth of crops, than under other circumstances; and of course capable of going much further in their application to soils.

In order to procure manure from the articles of food and other matters produced on the farm, different modes have been purfued in different situations. Some have strenuously contended, that the most advantageous plan is to have the whole of the hay and straw confumed by the different animals, without employing any of them in the way of litter, floors or flanimals; for them being conducted in such a manner, as that they can be tied up, and kept clean and dry merely by sweeping, without being littered with straw or other similar materials; while others maintain, on the ground of actual experience, that the method of eating the hay by the flock, and employing the whole of the straw, as well as other matters, in the way of litter, is by much the most certain and effectual in promoting the increase of manure. On these different opinions, it has been observed, that "though each of the methods may be practiced with more or less advantage, according to the nature of the farms;—as there is much graft and little tillage land, the former may be preferable; but where the quantity of grafts is small, and that of arable ground large, the latter;—it is probable, that a judicious combination of both may be the most benefical, especially where, in addition to the common arties, coarse vegetable and rich earthy matters are produced, and made use of in the way which has been mentioned, as by such a combination the full effect can only be produced. In the former method, the lofs of cattle in digestion and annihilation is probably much greater than has been generally suppos'd by those who have maintained the superior utility of the practice."

In the feeding of horses, and different kinds of cattle, with rich green food, as clover, lucern, summer tares, and other artificial grasses, cut fresh every day during the summer season, and placed in cribs in the fields or foddering-yards, the bottoms or floorings of which have been prepared and littered with earthy materials and litter, in the manner already directed, there is another way of making great additions to dung-hills, as the evacuations of cattle fed in this way are very considerable. The Earl of Dundonald has suggested, "that experience only can teach or warrant the belief of how few acres of ground, under the culture of artificial grasses, when cut green, and daily given to working horses and other cattle, will suffice for their maintenance. The artificial grasses, or plants best adapted to this purpose, are, he supposes, red clover, tares, and fainfouflage. None of those succulent plants with large flours and leaves the former to be well dappled as to be的模样; not only on account of the injury they receive in being bruised by the treading of cattle, but, by being confantly cropt and kept short, they are deprived of the nourishment which they principally receive by their ftems and leaves. Saintfain is, he thinks, well suited to chalky or dry soils, and to the southern parts of Britain. It has often been tried without success in the northern parts of England and Scotland. Winter tares have also been known, but have not been found to answer any valuable purpose. Clover and summer tares, therefore, should be the only plants of which the cultivation on a large scale should be in these parts be attempted; and every prudent farmer will take care to have a full supply of them, as in the event
event of a superabundant quantity for green food, these crops are equally proper for hay. Tares should always accompany the culture of clover, to supply the deficiency of herbage between the first and second cuttings of the clover.

And the quantity of manure that may be formed in this way is, probably, much greater than can be supposed by those who have not actually made a trial of the method. By some French writers it is stated, that from three to four hundred sheep, kept in this mode, manure sufficient for nearly an acre of land may be daily procured; and the manures, thus obtained, are likewise asserted to be preferable to dung procured in the common method. It has likewise the advantage of preventing the great waste that unavoidably must take place in feeding off fitch crops, and of bringing the whole of them immediately into use; besides, the manure, thus produced, becomes of a superior quality, from the vast quantities of worms and other insects that are generated during the hot summer weather, where it is going on to any great extent.

And the author of "Practical Agriculture" states, that it is by means of covered sheep-folds, a great increase might also be made annually to the flock of manure. If this neglected, but highly beneficial, practice were regularly employed here, as is the case in many other countries, by having proper fitches and inclosures for the purpose, constructed of any flight materials near to the fold-yards, or other more convenient places of the farm, so that the sheep might have fresh air, and sufficient liberty to run about, and, at the same time, have the means of being sheltered from rain, snow, and the coldness of the winter weather, the advantage to the flock would likewise be considerable, besides the great supply of manure that must be provided. In order to promote the latter advantage, the bottom or floors of such folds and inclosures should be covered with such earthy materials as have been recommended for the cattle yards, and also littered upon in the same manner; all of which ought to be removed and cleared away to a heap, or the common dung-heaps of the farm-yards, as often as they become perfectly faturated and blended with the dung and urine of the sheep, and fresh materials of the same kind supplied. In bad weather, it will be advantageous to keep them constantly in the covered folds, and feed them with hay in standing racks; but when it is fine, they may be suffered to go into the pastures in the day-time, and only be put into the folds during the night. It is added, that the practice of keeping fhee in covered folds is made use of in Flanders, for the purpose of raising manures, with great success; and very dry sand is sometimes employed for the bottom of the folds, instead of litter. And that, where the house-lamb is kept on any extent, the preparation and littering of the fitches and yards, into which the ewes are occasionally put, and the lambs kept and suckled, might be practised with great advantage, in respect to the production of manure; as animals, under such kinds of management, are constantly found to void urine and dung in much larger quantities than in the ordinary courses of feeding. Where deer are kept, the same management may likewise take place, and much good dung be raised.

See Sheep-Fold.

The ploughing down of full rich green crops of different kinds, in their most succulent states, is also another means of increasing manure, that may occasionally be adopted with great advantage.

And the practice of feeding off different green crops on the land by sheep, bullocks, or other animals, is another method by which much fertility may occasionally be given to the soil at a cheap rate, as the expense of carriage is prevented, and a considerable saving of manure effected. Mr. Middleton states, that, by this mode of management, the great loss of urine and dung, that unavoidably occurs in the other methods, may be most effectually prevented; "for in the stables, cow-houses, steds, fold-yards, and dung-hills, even under the best management, there is a great waste, perhaps of half, including dung and urine: under ordinary management, three parts of this manure is lost; but in the feeding of tares, turnips, cole, clover, &c. in the fields, there is no loss; the whole is immediately applied, without the cost of carriage, to the enriching of the soil."

In this way there must, however, be much more waste than is here supposed; by evaporation, from the action of the sun and wind over to extensive a surface, much of the valuable matters of the manure, in such situations, must be daily carried away; and the more fibrous or ligneous parts of the materials, which are rejected as food by the cattle, from their being thinly scattered over a large surface, become dry and hard, and must be longer before they decay, or are rendered fit for the purposes of manure, than where they are collected together in large quantities, and in more confined situations.

Another mean of increasing manures to a very great extent, is by adopting such methods as may effectually prevent the soil and urine of privies, and the various animal and vegetable materials that are continually thrown into them, in cities and large towns, from being uselessly retained in deep pits, or places constructed for the purpose, or inconfiderately washed away and wasted, by being conveyed into rivers or ponds by fewers and drains. Mr. Middleton has stated, that, from want of suitable means of preserving such fubstances, the annual loss, in this country, is probably not less than five millions of cart-loads, which, if turned to the uses of agriculture, would be worth to the cultivators of the soil two millions and a half, and to the community five millions of pounds sterling! And the eagerness which is manifested in many other countries to preserve and promote the increase of fuch manure, shews that it is a fubflance of vall utility, and that an abundant fource of fertility is thus neglected, and lost to the public. It is suppoled, by a late practical writer, that the most easy and convenient methods of preserving fubstances of this kind, in the country, would be, probably, by having pits formed for the reception of them, as near as possible to the dung-heaps in farm-yards or other places, and prepared with floors of clay, or some other material, through which the liquid matters could not readily pafs; these might be connected with the privies by proper drains, and have covers fitted to them, in order that a quantity of mould, peat-earth, sawdust, lime, bricks, or other substances, of the same sort, might be occasionally placed in them, and removed to be blended with the common dung-heaps, as often as they become fully reduced by putrefaction, and well faturated and impregnated. But in large towns or cities, where such manures are produced in great quantities, refervoirs or basins of large sizes should be constructed with floors of the above kind, and be connected with the privies of different parts, by means of fewers or drains. Such refervoirs ought to be fo situated as to be capable of being emptied with ease and facility, as often as necessary, by persons appointed for the purpose, and their contents carried away in the night-time. Where there is the convenience of rivers, however, as in London, and many other populous cities and towns, a large proportion of such manures might, in most cases, be readily emptied from basins of this sort, formed on their banks for the pur-
MANURE.

... or perhaps from the extremities of the common fowlers themselves, by means of proper flumes, into covered boats or barges, and thus cheaply carried to a distance, for the advantage of agriculture; a method, in some respects, practised with success in Sweden. See Communications to the Board of Agriculture, vol. i.

But as this kind of manure is extremely liable, from the agitation of the carriage in which it is moved, to become fo liquid as to be conveyed with great difficulty, it is probable that, by having such earthly or other substances as have been mentioned above, or as could be conveniently procured in such large cities or towns, such as the long littery dung from livery stables, lime rubbish from the pulling-down of old houses, and the fresh earth dug up in preparing the foundations for new ones, mixed and bledded with it in the pits orreferowes, for some time before they are cleared out, the difficulties attending the carriage of it might not only in a great measure be obviated, but the disagreeable smell issuing from it be much corrected, and the quantity of manure greatly augmented. By some method of this nature, under the management and direction of proper persons, vast stores of fertility might, it is conceived, be provided in such places for the neighbouring districts, which inattention or popular prejudice at present withhold from the use of agriculture. See NIGHT-soil.

Besides, in particular situations, as near the sea, where shell and other small fishes can frequently be procured in large quantities, by having them well mixed and incorporated with good surface-mould, turf, or peat-earth, or other matters of that sort, a vast increase of good manure may also be provided. The weeds cut from the sides of the rocks, and which are thrown up by the tides, when collected into heaps, and mixed with small proportions of lime and suitable quantities of mould or earth, may likewise contribute greatly to the increafe of the compost heaps in such districts and situations.

Another material, capable of augmenting the manure heap very much, is the rich vegetable mould, and other matter, contained in the bottoms of ditches, and in boggy, hollow places, where water frequently flagrantes, and large crops of aquatic or other plants alternately vegetate and decay. This should be occasionally dug up and applied to the soil, for which it is proper, either in the flate in which it is found, or after having been formed into compost heaps with dung, lime, or other substance of a similar nature.

And clay, though not actually a manure, is a substance that may also be employed with great advantage on sandy and other light soils, and by that means fave the more valuable manures. It has been made use of with great effect in its crude state, in the practice of an improving Suffolk farmer, but it would seem to be the most serviceable for this use after being imperfectly burnt in clamps and kilns, probably from the production of oxygen or pure air that is thus combined with it, or with the metallic matters which it contains. It is well remarked, by a late writer, that "it is necessary, in order to increase the flock of manures on farms to the greatest possible extent, to be careful that none of such animal or vegetable substances as are capable of being converted into manure, be thrown away or consumed by fire, but that they be all conveyed to the dung-leys in the farm-yards or other places, or laid in heaps of themselves, and suffered to pass into fermentation, by which they may be speedily reduced to manure. Where the matter thus made use of chiefly consists of weeds and the limbs or roots of coarse plants, such as peas, beans, cabbages, docks, nettles, &c., their decay may be greatly promoted by a little quicklime being blended with them. Such heaps should also be covered over pretty well with some of those earthly matters that have been mentioned above." It is added, that as "the different materials which are made use of for the purpose of manure, pass through different stages of decomposition and decay, in each of which such matters of the solid or fluid kinds are formed, as are capable of contributing to the nutrition and support of vegetable crops, but which are liable to be diffus'd or carried away by the agency of various canals, it may be necessary to guard against such waste by keeping the dung-heaps covered in every situation, as much as possible, with earth or foil, both in the early periods in which heat is evolved, and at the latter ones, when ammoniacal or volatile alkali is formed; as by such management the process of decomposition, when too rapid, may be restrained, and the clastic matters that are gradually set at liberty be absorbed by those coverings, while the more fluid ones are detained by the earthy bottoms on which they had been placed, and thus the whole of the valuable properties of the manure be preserved."

MANURE, in Gardening, a term used to signify all such substances or materials, whether of the dung, compost, or other kinds, as are useful in the improvement of garden ground, so as to produce good vegetable crops of various kinds.

It is obvious that materials of this kind are necessary to all soils to recruit them when exhausted by the growth of vegetables, and to cure their defects; being thus beneficial in enriching and fertilizing such as are poor, and in rendering such as are strong or stubborn more light, loose, and friable, as well as those which are very light, loose, and dry, more compact and nitrous, and those that are too wet, drier, &c.

In these views most stiff land is the most improved by light manures, which open and loosen its particles; very light land by the more heavy and moist soils; and wet land by dry light composts. Some garden soils also require manure annually, and others only once in two or three years. See DUNG, &c.

On the whole, the most proper forts of manure for the use of the kitchen-garden are those of the flable, cow, sheep, pigeon dung, foot, lime, leamy marle, shell marle, sea-weed, wood, whin, fern, and coals; the vegetable mould of decayed tree-leaves, and decayed vegetables of all kinds, as cabbage leaves, hauhn, weeds, &c. And to these may be added the fluid substance which drains from dung-hills, which is capable of affording the nutrition of plants in a very high degree, from the large proportion of carbonaceous matter with which it is loaded.

All these several materials may be applied either in a simple or compound state; but the latter method is probably in general the most eligible; as it is suppos'd by some, that if they have not undergone a proper degree of fermentation, they have the effect of giving a rank and disagreeable flavour to some fruits and vegetables; and when a large quantity is applied, of producing a considerable degree of unwholesomeness, tainting the juices of the plants. This effect is, however, much to be disputed, since the different substances are changed and elaborated in the vesicles of the vegetables before they become fit for the purpose of their increase.

It is ascertained by the author of the Scotch Forcing Gardener, that "a combination of flable dung, sea-wood, lime, and vegetable mould, which has lain in a heap for three or more months, and has been two or three times turned during that period, will make an excellent manure for most kinds of garden land." Alfo that of "cow dung and sheep dung, mixed with foot or any of the kinds of ashes," and that "pigeon dung, marle, and vegetable mould, well mixed, will make
MANURE.

make an excellent manure for heavy land; or even for lighter soils, provided the pigeon dung be used sparingly." But that "pigeon dung, lime, foot, ashes, &c. should never be applied in a simple state; the quantity of them required being comparatively small, and the regular distribution difficult without the admixture of other matters. It is further observed, that he has "witnessed the astonishing effects of whin ashes alone, in producing herbage in a five or six-fold degree; which was the more obvious, on account that the field on which they were applied was much alike in quality (a light, wet, clayey land), and the ashes applied partially. The effect was visible for several successive years. Also, on the timber trees with which the field was afterwards planted." He conceives that "marl is an excellent manure for almost any soil; and may be applied as a simple manure with as much propriety as any of the kinds of cattle dung, or even vegetable earth. The kind called shell marl is, it is supposed, much to be preferred; and should be freely applied to strong lands, but sparingly to light; the loamy kind being best adapted to light lands."

Whereable dung is used in a simple state, it "should not," it is supposed, "be applied in too rank a state, nor should it be too much fermented. It should generally lie in a heap for two or three months; during which time it should be turned twice or thrice. A ton of it in this state is worth three that has been used in the hot-bed, and are a year old. This manure, and indeed dung of any kind, when thus applied, should never be carried from the heap to the ground till it is to be dug in; as, by its exposure to the air, the virtues evaporate, and it is the least effective."

And when made use of in a simple condition, it is imagined "the necessity of the infant application of sea-weed after its landing, is even greater than in the above case; as it instantly corrupts, and its juices not only evaporate, but flow downwards, and are lost. If this manure be used as a compound, the heap wherein it is compounded should be more frequently turned on its account, that none of the juices may be lost, but that the other part of the compost may absorb them."

It is his opinion that "vegetable mould may either be used in a simple or compound state, and may be applied with equal propriety to all soils. None can be hurt by it in any degree; since almost every plant will grow luxuriously in it entirely, without the aid of any soil or manure whatever. It is conceived that manures have the effect of correcting tenacity, crudity, and porosity in soils, exciting their fermentation, communicating nutritive matter to them, and affording nourishment to the roots of plants, by which the vegetation and perfect growth of them are promoted and increased."

There are likewise considerable differences in the materials made use of as manures, in their affording their nutritious properties, some affording them much more readily and more abundantly than others. This is the case with animal vegetable, and all such matters as are rich in mucilage, the fuccharine principle, and calcareous earth, and which readily afford carbon, phosphorus, and some gaseous fluids, such as the carbonic acid gas, oxygen, &c. while others which are greatly deficient in all or most of these principles, or which do not part with them easily, are found by experience much less beneficial in promoting the growth of vegetables, fruits, &c.

However, the effects and importance of manure are now generally acknowledged and understood, it would appear to be the indispensable duty of the gardener and cultivator to be particularly careful in the collection of it, and also to distribute it with the most skilful frugality. "For this purpose, it is suggested that where it is capable of being formed, a well, sifter, &c. should be contrived for as to collect the dung-hill drainages; and that in the application of manure of any kind, the greatest care should be taken to divide it equally, according to the quantity to be applied." Also, further, that "the dung-hill may be considerably increased by throwing the haulm, stalks, and leaves of all vegetables into a common heap, letting them remain till well rotted, and afterwards, or, in the process of collection, mixing them with lime, marl, ashes, foot, &c. Watering the whole frequently with the drainings of the dung-hill would also greatly enhance its value."

It is likewise evident that the ground of gardens may often be greatly ameliorated and improved by proper draining, before the manures are applied, and sometimes by the use of sandy, gravelly, and other similar materials, that have the power of opening, and rendering it less close and adhesive. See MANURE, supra.

MANURING of Land, in Agriculture, the application of the various substances which are capable of being employed as manures to the soil, in such a way as to produce the most beneficial effects in the production of crops, whether of the grain, grasses, root, or other kinds. In this business various circumstances are necessary to be considered, such as the state or condition of the manures which are to be made use of, the nature of the ground on which they are to be laid, the kind of crop that is to be promoted by them, and the season of the year in which they are to be put into or upon the land; for as it has been shown that changes are continually taking place from the moment the materials of the dung-heap are thrown together, to the period in which they are reduced into a black carbonic earthy matter; and that in most of the different stages through which they pass in this process of decomposition, such substances are formed as are capable of contributing to the nutrition and support of vegetable crops; it is conceived "probable, that in cases where manures are to be turned into the ground, and such crops cultivated as require a supply of nourishment for a length of time, they should be employed in their long or more imperfectly reduced states, as by the heat which is evolved in the commencement of their diffilution, the precooks of early vegetation may be greatly promoted, and their gradual decomposition and decay afterwards, under the ground, afford a more durable and regular supply of nutritive materials, and thereby contribute more effectually to the growth of the crops; but that where they are to be buried in, or applied to the surface of the soil, and intended merely for the benefit and support of such crops as are of short duration, or quickly arrive at their full growth, they may be more advantageously made use of after they have been more fully and completely reduced, as in this state the manure is, in the case of grass lands, not only capable of being spread out in a more regular and uniform manner, by which it becomes more evenly as well as more generally carried down to the roots of the plants by rains, but it is in the most suitable condition for allowing the young plants the means of springing up with facility, and at the same time, whether used under or upon the soil, of affording the crops that abundant supply of nourishment which is necessary to their speedy growth and great luxuriance, and by these means to contribute most perfectly to the promotion of their increase." In addition to "these advantages of long, or imperfectly decayed manures; they have others that depend on the soil into which they are turned, and the nature of the crops that are grown or planted with them. Where they are employed in such fluff, clayey, or loamy grounds, as have a great tendency to become dry..."
and hard, and thereby incapable of admitting the tender fibrous roots of grains or other plants to spread or extend themselves, and draw in more abundant supplies of nourishment, they may be useful by keeping the earth around them in a more open and porous state, from the inflowes of their decomposition, and the gradual and continued manner in which the different elastic matters are fet loose and united with the soil. Hence, when barley, or such kinds of grain as require a rather light and open state of soil, and those bulbous or knobby-rooted plants, such as potatoes, that require much room to root and extend themselves, are cultivated on firm stiff soils, they are generally found to be the more productive, where such long or imperfectly reduced manures have been made use of in the preparation of the land." And that "as in the flow and gradual decomposition of the materials which are made use of for manures, when slightly deposited beneath the soil, there is much less waste of heat and those elastic matters which contribute to greatly to the support of vegetation, than where they are made to undergo the various proceedes of diffusion into large globes, as in dung-heaps, they may probably sometimes on that account be most advantageously employed in this state." Also "on this principle the ploughing down of fresh vegetable crops, in many cases, in their most succulent states, may be a more economical as well as more beneficial practice; especially in such light and dry kinds of soil, as will more readily admit of their gradual putrefaction and decay, than to cut and take them off for the purpose of being by other means converted into manure. It seems likewise probable, on the same grounds, that for the production of crops of the bulbous-rooted vegetables on the more stiff and tenacious soils, the materials made use of as manures may be employed with the greatest advance, when put into the earth before they have undergone any great degree of decay by means of putrefaction, as in this way there is no waste, the whole being ultimately converted and applied, though more slowly, to the support of the crops for which they are immediately employed." It has been stated as the opinion of a practical farmer, that flable dung never answers better than when carried on to the land as soon as made. He laid it on a piece of wheat in frosty weather, and at harvest the crop was laid to the ground. And on grafs lands, it is suppos'd, when laid on in the spring, to screen it from the cold winds, and occasion it to be more forward, and in that foundation of the strawy part protects the land from the sun; and in either case it is soon grown in and nearly lost to the eye. See Communications to the Board of Agriculture, vol. iv.

Manures, proper Season of Application.—In regard to the time or season of applying manures "with the greatest benefit and advantage, though in practice it must, in some measure, depend on the state of the land, the nature of the crop, and the convenience of the farmer, it should, in cafes where they are buried in the ground, as nearly as possible to the periods in which the seeds, or the roots which they are designed to support, are fown or placed in the earth; where they are to be laid upon the surface of the land, it ought probably to be just before the crops of grafs, or other vegetables, begin naturally to spring or fhoott forth." As in this practice of depositing and blending the manure with the soil, nearly at the time the crops are put in, there is scarcely any waste of the fertilizing property of such fulbarb, which, as they gradually proceed in their decomposition and decay under the ground, may otherwise be the cause, the roots of the plants not being in the most proper state for taking them up and converting them to their support. Besides, in stiff, loamy, or clayey soils, they have a tendency, as has been remarked above, to produce a degree of lightness and friability that is fatal to the early process of vegetation." The author of Phytologia has well remarked, that "the atmospheric air, which is buried along with the manure in the interstices of the earth, and which for many weeks, or even months, renders the soil loose and easily impressed by the foot on walking on it, gradually evolves, by its union with carbon, a genial heat, very friendly to vegetation in this climate, as well as the immediate production of much fluid carbonic acid, and probably of a fluid mixture of nitrogen with hydrogen, which are believed to supply much nutriment to plants."

The using of such manures as are made use of in the way of top-dressings in the early spring, is a practice by which "they are laid on at the most favourable period for affording their nutritious principles, and for their being drunk up by the roots of plants, and conseqently become useful at the time they are most wanted for the promotion of the crops, and the great waste which must otherwise be caused, either by the excessive falls of rains and fres in the winter season, washing down much of the valuable properties into the adjoining rivers and ditches, or the evaporation of their more volatile or elastic matters by means of the summer heats, is most effectually guarded against and prevented." It is hinted that the practice common in some places of applying manure to grasfs lands in the latter end of thesummer or beginning of autumn, after the first crop of hay has been taken from the ground, and the after-grasfs has begun to make shoots, is not by any means so favourable as that of early spring, as in the latter case the generation of these materials that contribute to the support of vegetation is greatly promoted by the continually increasing heat of the vernal and summer months; while in the former it is constantly checked and retarded by the increasing coldness of the autumn and winter seasons. Besides, the manure, by being spread out upon the surface of the land under such circumstances, must be the cause of great loss, by contaminating the after-grasfs, and rendering it incapable of being eaten off by cattle or other kinds of live flock. Yet, "where a second crop of hay is to be taken, it may sometimes be put on at such times with advantage to it, especially if the weather be not too hot, and the manure in a perfectly fine and reduced state, so as not to impede the mowing." It has been remarked by doctor Fenwick, in his ingenious reflections on manures, "that it is frequently possible, to foggeft a worfe mode of using manures on such lands, than that which is almost universally practiced in the neighborhood in which he resides; and it is the same in many other parts of the country, as is evident from the reports that have been lately published by the Board of Agriculture. "When," says he, "a severe frost has bound up the land in a rate of impenetrable cohesion, the farmers wheel on their dung, perhaps even when snow has covered it. While the frost lasts, the land can derive no advantage from the manure, and when a thaw supervenes, it is evident that the wash from the melting snow, or from the rains which generally fall in such weather, must deprive the mafs of every part that is soluble. The ground, in the mean time, retains the frost for many days, and is therefore incapable of absorbing the wet which falls upon its surface; and even when the influence of the milder air has reached it, it can imbibe but little, being in general presently filled with water, and the quantity which flows over it being too great for soil, under any circumstances, to drink up." It is believed by the same writer, that in support of this destructive and wasteful practice, however much it may have been defended on the ground of the farmer's leisure or convenience, and the little injury
MANURING OF LAND.

injury done to the turf or sward of the land, there can be
only one reason alleged, which is, that manure, when spread
early in the winter, may protect the roots of grasses from
the severity of frosts. And this, the author of "Practical
Agriculture" says, "is probably a mistaken notion, as it is
known to every one that the common grasses are seldom in-
jured by the severest frosts; and other kinds of grasses may
probably not suffer less injury from the application of manure
at such a season, than from the severity of frosts." It is
therefore concluded, that "on all these accounts, farmers
should confine as much as possible to apply the manures,
intended as top-dressings to grass lands, as early in the spring
as it can conveniently be done, which may be easily man-
aged on those that are dry, and on such as are inclined to be
wet and poachy, it may probably be greatly facilitated by
having small light carts constructed for the purpose, and
placed on broad cylinders as wheels." For he is convinced,
from the trials which he has made in applying manures to
grafts lands at such periods, that the trouble of the farmer
will not only be rewarded by much larger crops of hay,
but also by a considerable increase in the quantity of the
after-grafts; and, besides, his crops in both instances will be
more forward than in the ordinary methods of putting them
on, either in the autumn or winter months, which in many
causes is a circumstance of great importance." There are
others, however, who consider the early autumn as by much
the better season, as may be seen under the head of manuring
new laid down grafts lands at first. See Laying down
to grafts.

In Young's calendar of husbandry, it is stated, that "the
proper season for laying on several sorts of manure, such as
foot, coal-ashes, wood-ashes, lime, malt-dung, &c. and in
general all those that are spread in too small quantities to
require a whole winter's rains to wash them in," is in
February. "The use of these manures, and other light
dressings at this period, is, he says, very beneficial; but,
throughout the management of purchased manures, expe-
riements should be formed for a year or two, before the practice
is extended, to see which, at a given price, will suit the
land best. Without this precaution, a farmer may probably
expend large sums of money to little purpose. Nor would
he advise him to trust to the mere appearance of the effect
soon after the manuring; for some of them, particularly
foot and malt-dung, will lew themselves after the first heavy
flowers, in a finer green than the rest of the field; but the
proof of the effect does not arise from fine greens, but from
weight of hay; for he has himself found from experience,
that the latter is not always an attendant on the former.
Contiguous half-acres, or roods, should be marked out, the
prices of the manures calculated, and on each piece a sepa-
rate one spread, all to the amount of 20t. an acre, for in-
fances, at hay-time, the crops should be weighed. It will
then be known which manure, at the given prices, suits the
field best. This knowledge will prove true experience, and
a very different guide from general ideas." And "when this
is likewise, he adds, the feacon for spreading superficial
dressings on the green weeds, such as foot, ashes, malt-
dung, pigeons'-dung, poultry-dung, rabbits'-dung, &c. and
many other sorts in the neighbourhood of great cities. It
is very good husbandry; but the profit depends on the ex-
cuces." He therefore recommends "trying them in small
portions, (a rod, for instance, to each) before extending the
practice to whole fields, especially those which are not
dunged. As to the latter, provided the prices he not extra-
vagant, there can be no doubt of their answering to all soils.
Whenever a farmer has the choice of manures, never let him
hesitate about which to take. He may lay it down as a
maxim, that dungs of all sorts are excellent. Other ma-
ures may be the same, but they are not, he thinks, fo-
universally beneficial to all soils."

It is also stated, that furriers' clippings are sown by hand
from the feed scuttle, at about 3d. per quarter, in March,
on the land intended to be sown with wheat or barley, and
immediately ploughed in, after which the feed is sown and
harrowed in, when such pieces of the clippings are as left
above ground by the harrow, are pricked or shoved into the
ground by the end of a stick, to prevent their being devoured
by dogs or crows, who seize them greedily. From two to
three quarters are usually sown per statute acre. These
clippings are laid to answer well to light dry chalk or gra-
velly soils, where they are supposed to hold moiture, and
help the crop greatly in dry seasons, and they have little
effect on wet soils. And horn shavings, which are of two
sorts, small and large, are used in the same way and quan-
tities as the above article, except that they want no prick-
ing; and the large are generally ploughed into the land
three months before sowing wheat or barley. This sort of
shavings answers well in most soils and seasons, except very
dry ones, when they will not work. The small shavings
are much the most useful. Woollen rags are also sown by
hand and ploughed in three months before sowing wheat or
barley; the quantity used is from six to ten cwt. per
statute acre. Woollen rags, like furriers' clippings, hold
moiture, and are adapted for dry, gravelly, and chalky
soils, and succeed in dry seasons better than most manures,
but they do little good on wet soils. London rags are
found much better than those collected in the country; but
the danger of catching the small-pox in chopping and fow-
ing them, deter many farmers from making use of them.
Sheep's-trotters, and fellmongers' cuttings, are used in the
same way as furriers' clippings, from 20 to 40 bushels
per acre, and need pricking in dry seasons. They are very
fond of them. They do not answer on wet land, or in very
dry seasons; indeed nothing does succeed in excessive dry
seasons on these soils. Malt-dung is also sown by hand from
24 to 32 bushels per acre, at the same time as barley, and
harrowed in with the feed. It suits most soils and seasons;
but it quickly spends itself, and is therefore never sown
with wheat; as a top dressing to wheat in March, at about
30 bushels per acre, it would probably succeed on these
sorts of soils. Pigeons'-dung is used in the same manner
as malt-dung, and does good in any soil or season. Soap
boilers' ashes have also a great effect on cold foward. Hogs'
hair, when applied in the same manner as clippings, is said
to answer well. And hair, rabbits' dung, and lime, have
been tried upon these kinds of soils, but not found to
answer in any very advantageous degree.

Depths of Depositing Manures in Soils.—It is stated by a
late writer, that as "the putrefaction and decay of animal
and vegetable matters, whether above or beneath the
ground, is greatly promoted by the free admixture of air
and a suitable degree of moisture, it is evident that they
should not be buried so deep in the earth, as that they
may be prevented from readily receiving the aid of such cau-
ses in forwarding their decomposition; nor, as the process
is known to be much retarded by the fulness being
rendered too dry, should they be placed so near the sur-
fase, or he so thinly covered as to permit the action of the
sun and winds, before the crops have risen to such heights
as to prevent it from dissipating and carrying away their
nutritious properties. The introduction of the manure to a
mudding depth, as three or four inches, would of course,
on these accounts, as well as from its contributing more
expeditiously and more fully to the vegetation of the crops
that
MANURING OF LAND.

that may be put in with it; feeds, in general, to be the most advantageous practice; but on the lighter and more friable soils, it may be advisable to plough it into a greater depth than in such as are heavy and tenacious. In every case, however, whether the manure made use of be in a long or a more reduced state, it should be perfectly covered or ploughed into the earth. The practice of burying manures deep in the soil, has been defended by some on the ground of its being the nature of elastic matters to rise or force themselves towards the surface; but when they are placed to a considerable depth in the earth, as the processes of decomposition is thereby stopped, or suffered to proceed in but a very slow and feeble manner, little or nothing escapes for the support of vegetation, or it is furnished only for very slow and sparing a way, as to be of scarcely any service to the immediate crops. Thus, in the cultivation of such crops as are placed in rows or drills, where the manure is put into a great depth and covered pretty thickly with earth, on digging them up at the end of many months, it may frequently be observed near the same place it was when first put into the ground. And the same thing is often noticed by gardeners, where imperfectly reduced, or long dung is placed in deep trenches and covered to a considerable thickness with mould. It is also added, that "in order that manures may produce their effects in the most perfect manner, they should be spread over the surfaces of the grounds as evenly as possible, whether they be intended to be turned into the foil or left upon its surface as top-dressings," a point that "may be greatly facilitated by placing the manure out at first in very small heaps, as by such a practice it may be spread over the ground with much greater ease and exactness; and on grass lands much less injury will be done by the bottoms of the heaps."

And it is evident, that on tillage lands, manures should always be turned in, or otherwise covered, as soon as possible after they are spread out; for if this be neglected, much loss may be sustained, especially in hot seasons, by the quick evaporation that takes place in such cases. The best practice is, of course, not to carry more out from the dung-hill at a time, than can be conveniently spread upon and ploughed into the earth in a short time afterwards. It is observed in a periodical work, that the shortest possible space of time should be suffered to elapse between the spreading out the manure, and the ploughing it into the lands; as well as between this last operation and that of fowing the seed. And it has been suggested, that "in spreading manures employed as top dressings on grass lands, much advantage will be gained by breaking and reducing the cloths or lumps into as fine a state as possible, as by such means they are not only applied more perfectly, but washed by the rains much more readily to the roots of the grases. The springing of the young grasses is also less retarded, where the manures are reduced fine and powdery, than where they are left in a cloddy, rough state." The nature of the soil, and the purpose for which the manure is applied, should likewise be carefully attended to in this business, as no one method is adapted to every case that may happen.

It is fixed, in respect to the economy of their application, that "it seems not improbable but that some degree of favoring may occasionally be made, by applying them on lands under tillage, as well as others, nearly at the time the feeds and roots are put into the ground, or when the grases begin to shoot; as from the whole of the manure being in this way made to contribute directly to the support of the crops, a less quantity may be sufficient for the purpose; how far they may be safely diminished on this principle, can only be shown by actual experiments and accurate deductions made from them; but there are sufficient grounds, from what has been observed, for supposing that it may be considerably more than can be easily apprehended by those who have not adverted much to this circumstance. There is another economical mode of employing manure, which is, by placing it in the drills or hollows formed for the reception of different crops which are cultivated in rows, as peas, beans, cabbages, potatoes, &c.; by this method, that part of the ground which is intended to bear the crop, is only manured, the intervals or spaces between the rows not receiving any, from which, where the bulbous of putting the manure into the drills is properly performed, a great saving of course be made."

According to the conclusions of some, "the saving of manure in this way is so great, as to constitute one of the chief advantages of the drill system of cultivation. And the calculation of the experienced farmer is, that by "drills being made two feet wide, and each drill six inches wide at the bottom, there will be just one-fourth part of the ground covered with manure; for as six inches multiplied by four give two feet, which will be the distance from drill to drill, and as four multiplied by four makes sixteen, it follows, that if the whole of the land had been covered with manure, sixteen loads would have been required for what is as fully and beneficially performed by four, that is, by one quarter of the quantity used by the old method of dressing, supposing it of the same thickness and quality." Besides, from the manure being in this way kept more closely together, and the crops placed immediately upon it, they must, he supposes, receive the advantage of the dressing in a more full and complete manner than under other circumstances could be the case.

Dr. Dickson, in his work on practical agriculture, urges, that "as it appears probable that in the decay of different materials in the soil, all the nutritious matters as they are formed immediately become useful for the purpose of vegetation, without any waste being sustained, as must always be more or less the case where they are depoited together in heaps, it may be an economical practice, in cases where the crops to be benefited by them require a regular and lafting but not large supply of nourishment; or where the ground is required to be kept in an open and rather light state, for a considerable length of time, to employ such manures in their lea decomposed states, as by the ploughing down of green succulent vegetable crops, and the turning in of long strawy substancess. By adopting such means, the more perfectly formed manures of the farm may be refered for such crops of luxuriant vegetables as demand more speedy and abundant supplies of nutritive matters." And in what respects the advantage of using one fort of manure in preference to another, it may be remarked, "that as animal matters are found in general to undergo more speedily the process of putrefaction or decomposition than those of the vegetable kind, and as in most instances they afford those mucilaginous and elastic principles that contribute so largely to the support of vegetable life in greater proportions; such manures as are either wholly or in a great measure composed of them, must be the most beneficially employed, where quick and abundant supplies of nourishment are required, as in the growth of all the more grus and luxuriant crops, whether of grain, plants, or grases; and that as those vegetable substancess which contain saccharine, farinaceous, oily, fatty, or mucilaginous principles in the largest quantities are ascertained from experience to proceed the most readily into the state of dilution or decay, and consequently to afford more fully and more expeditiously the nutrient food of new plants, where manures
manures are principally formed from them, they should be preferred to such as have been made from the harder and more ligneous vegetable substances, that contain such properties in scarcely any, or much smaller degrees, for all the purposes of agriculture." Lastly, that "such substances as are found to contain those elementary materials of which vegetables are principally constituted in their more soluble or loosely combined states, as carboxaneous matter in the black earths or moulds, and oxygen, azote, and hydrogen, in burnt clay, radule, manganeese, and calyse, substances which hitherto been little employed, as well as in water and air, should be made use of in preference to those which contain the proportions of animal substances at all."

With regard to the particular modes of preparing and making use of the several articles that are capable of being applied to lands so as to ameliorate and improve them in the production of different sorts of crops, they will be more fully explained under the particular heads to which they immediately relate.

MANUS was anciently used for an oath, and for him that took it as a comparator. And it often occurs in old records: "teria quarta, &c. manu juris;" that is, the party was to bring to many to swear with him that they believed what he vouched was true: and we read of a woman accused of adultery: "nihil hae negat, purgatio festa manuis existit indita;" i.e. She was to vindicate her reputation upon the testimony of six comparitors. Reg. Eccl. Chrift. Cant. If a person swore alone, it was "propria manu & unica." The use of this word came probably from its being required at a person's hands to justify himself: or from laying the hand upon the New Testament, on taking the oath.

MANUSCRIPT, a book, or paper, written with the hand. By which it stands opposed to a printed book, or paper. A manuscript is usually denoted by the two letters MS. and, in the plural, by MSS. or Mss. What makes public libraries valuable, is the number of ancient manuscripts deposited in them. See ALEXANDRIAN, CAMBRIDGE, CLERMONT, COTTONIAN, HARLEIAN, VATICAN, &c.

MANUZIO, ALDO, the elder, in Biography, a celebrated printer and man of letters, was born at Baffano, in 1447. Having laid a good foundation, at his native place, in grammar learning, he was sent to Rome, where he pursued his classical studies under Gaspar da Veronaa, and removing thence to Ferrara, he had the advantage of learning Greek from Battista Guarino. During his residence at the latter city he was employed to give private lessons to Alberto Pio, prince of Carpi, and to Hercules Strozzi, afterwards a distinguished poet. In the war between the Venetians and the duke of Ferrara, in 1482, Aldo was obliged to quit that city, and he took up his abode with that patron of literature John Pico of Mirandola. He afterwards visited his pupil Pio, and it is probable, that with the assistance of those two enlightened nobles, he set up a printing office at Venice, for the purpose of giving correct and elegant editions of the Greek and Latin classics. His first work did not appear till 1494, after the press had been established about six years; but in the course of the next twenty years he had printed almost every Greek and Latin classic, as well as a number of other books. He was the inventor of the italic character, called for a considerable time the Aldine, and obtained from the senate of Venice, and the pope, patents for its exclusive use for a number of years. To render the editions that issued from his press correct, he procured the assistance of some of the best scholars of the age as editors. Aldo likewise established a kind of academy in his own house, at which the literati of Venice assembled, on fixed days, to discuss various literary topics. Aldo was very dexterous in rendering his academy perpetual, but it did not long survive him, though it was succeeded, not long after his death, by the Venetian academy. He married the daughter of Andrea d'Afola, from whom he obtained some pecuniary affinity, and with whom he entered into partnership. The wars of Italy impeded their labours, and by these Aldo lost a very considerable property, which he took much pain to recover, and in the attempt fell into the hands of the soldiers of the marquis of Mantua, by whom he was plundered and imprisoned; but on making himself known, he was liberated with much respect. This was in the year 1506, and during the six following years, he printed very little, but in 1513 and 1514 he returned his labours; and was closely engaged in his employment, when he was carried off by delirium in April 1425. Aldo Manuzio held a school in Venice for the Greek language: that his own learning was considerable, there are abundant proofs in the dissertations and prefaces of his own compositions, which are prefixed to his editions of the Greek and Roman authors; and also in his Latin letters that have been printed in various epistolary collections. He published a Latin grammar compiled by himself; and a treatise "De Metris Horatianis;" he translated various pieces from the Greek into Latin, and he compiled with great labour a Greek dictionary. He was visited by all the learned strangers who came to Venice; but to prevent a waste of time which he could ill afford, he put up an inscription over his study door, dehersing that visitors would make their stay very short, unless they had something important to communicate. Though his editions were not, and could not be expected to be, im- maculate, yet there are but few persons to whom literature is more indebted than to Aldo Manuzio.

Manuzio, Paolo, son of the preceding, an eminent scholar and printer, was born at Venice in 1512. He received the rudiments of an excellent education at Afola, whence he was early removed to a more learned instructor at Venice, under whom he made extraordinary progress. When he had attained to his twenty-fifth year, in 1533, Paolo re-opened the printing office which had been shut from the death of Andrea, and the business was conducted under the joint names of the heirs of Aldo and Andrea. In 1535 he paid a visit to Rome, on the promise of an establishment there, but his hopes were for the present entirely disappointed, and the only advantage which he derived from his journey was the friendship of some learned men in that capital. After his return, he opened an academy for the instruction of twelve young men of family, in polite literature: he continued in this employment about three years, and then made a tour through the important to communicate. Through his reputation for learning procured him several offers of professorships, but he did not engage in any of them, and his appointment to superintend a printing office set up by the academy of Venice gave occasion to his becoming distinguished in his proper profession, by several very elegant and accurate works: the inflatution was, however, but of a short continuance. About this time his eyes were too weak, or diseased, that he was obliged to quit his studies till he obtained complete relief by the assistance and advice of Fallopius. A liberal and magnificent plan had been formed at Rome for the printing of all the most valuable Greek MSS. in the Vatican. In the mean time, the progress of the Reformation, and the settling of the council of Trent, had rendered theological works in great request, and it was determined to give Vatican editions of the fathers and other ecclesiastical writers, which might furnish weapons to the
defenders of the church. To unite correctness with elegance in these editions, the pope, Pius IV., invited Paolo Manuzio to Rome; he accepted the invitation, and arrived in the summer of 1561. The press provided for him was in the Capitol, the palace of the Roman people; whence the works printed at it were inscribed "Apud Paulum Manutium in Editionibus Populi Romani." In 1575, other difficulties with his emoluments, or finding the air of Rome injurious to his health, he returned to Venice. From this period he spent much of his time in travelling from place to place, till at length pope Gregory Xlll. engaged him to stay at Rome by the offer of a pension, which allowed him to devote all his time to his studies. He died at Rome in April 1574, in the sixty-second year of his age. The learned world is indebted to Paolo for many valuable works of his own, besides those of others which he published into the world. He was the diligent annotator on the works of Cicero and Virgil; he was much attached to the study of Roman antiquities, and was the first who discovered the Roman calendar, which he published from his son's press with two tracts, "De veterum dierum ratione," and "Kalendarii Romani explicatione." He had formed the plan of a great work in which every topic of Roman antiquities was to be illustrated, but of this he only published "De curia Romana." He formed a collection of letters, as well as Latin as Italian, and among these, his own letters in both languages may be compared with the best of other writers. His Latin letters have frequently been reprinted, and are truly Ciceroan in their style: the Italian compositions are valued for their unaffected elegance and simplicity. He published many other works which were esteemed and applauded by the first scholars of his age: and as a printer he had merited high praise, as well on account of the beauty as the accuracy of his editions.

Manuzio, Aldo, the younger, son of the preceding, was born in 1547. His father paid the utmost attention to his education, and so extraordinary was the progress of the youth in learning, that he was enabled to give the world "A Collection of elegant Phrases in the Tuscan and Latin Languages," when he was only eleven years of age. Other juvenile works at different periods marked his advances in classical literature, and he soon became his father's assistant in his labours, both learned and typographical. He, when very young, conducted the printing business at Venice while his father was engaged at Rome. In 1572 he married a lady of the Giunti family, so well known in the annals of typography, and on the death of his father, in 1574, all the concerns of the Aldine press devolved upon him. He was, however, less calculated for the business of a printer, than for the profession of an author. In 1573 he was appointed professor of the belles lettres in the school of the Venetian chancery, in which young men desirous for public employments were educated. This office he held till the year 1585, when he was made professor of rhetoric at Bologna. In the same year he published the "Life of Cosmo de' Medici," which was so well received, that it was almost immediately invited to undertake the professorship of polite literature at Pisa, which he accepted, although he received an invitation at the same time to a professorship at Rome, which had been lately held by Muratus. During his stay at Pisa he received the degree of doctor of laws, and was admitted a member of the Florentine academy, on which occasion he delivered an eloquent oration "On the Nature of Poetry." He now paid a visit to Lucca in order to obtain materials for a "History of Castruccio Castracani," which he afterwards published, and which is much applauded by De Thou. The Roman professorship being reserved for him he removed thither in 1588, and intending to spend his life there, he caused his whole library to be brought to Rome from Venice, at a very great expense. He was in high favour with Sixtus V., who gave him an apartment in the Vatican, and a table at the public expense. He was also patronized in various ways by Clement VIII. He died in the fifty-fourth year of his age in the month of October 1597. He left no posterity, and with him ended the glory of the Aldine press. His library, containing 80,000 volumes, collected by himself and his predecessors, was sold to pay his debts. He was author of many performances besides those already mentioned, but the most celebrated of his works were his "Commentaries on all the Works of Cicero," in ten volumes. His "Familiar Letters," published in 1592, were highly esteemed.

Manwas, in Geography, a town of Hindoostan, in Boggicund; 30 miles S.E. of Makconda.

Manworth, in Old Law Books, denotes the price, or value, of a man's head.

In ancient times, every man, according to his degree, was rated at a certain price, according to which, satisfaction was made to his lord, if any one killed him.

Manzanas, in Geography, a river of Spain, which passes by Madrid, and runs into Haresen, about eight miles below that city—Allo, a river of America, in the Caraccas, which washes the city of Cumania. Its refreshing stream fertilizes lands otherwise sterile, which are thus rendered productive of fruits and vegetables in abundance.

Manzanares, a town of Spain, in the province of New Catalonia and district of La Mancha, the population of which is estimated at about 6766 persons. The houses are built with mud, and the poor are almost naked. It is one of the principal quarters of the royal Carabineers. The castle, with a considerable estate, and the tithes, belong to the knights of Calatrava, and yield a revenue of 3297, per annum. The land about it produces corn, saffron, and good wine. The vineyards are numerous, and this part of the country produces the best wine in La Mancha, and which is most esteemed at Madrid. It has the flavour of the richest Burgundy, with the strength and body of the most generous part.

Manzaneda, a town of Spain, in the province of Galicia; 20 miles E. of Orenfe.

Manzanello, a town of Spain, in the province of Leon; 23 miles S.E. of Valladolid.

Manzanilla Key, a small rocky island near the S. coast of Cuba. N. lat. 20° 54'. W. long. 72° 38'.

Manzat, a town of France, in the department of the Puy de Dôme; 9 miles N.W. of Riom.

Manzel. See Caravansera.

Manzinskoi, in Geography, a fortress of Russia, in the government of Irkutsk, on the borders of China; 30 miles S.S. of Selenginsk. N. lat. 49° 5'. E. long. 108° 44'.

Manzoli, Giovanni, in Biography, an opera singer of the first order, born at Florence, and gifted with the finest soprano voice which has been heard on our lyric stage in our memory. He was, during many years, the first singer in Italy; and when the court of Spain determined on having Italian operas performed under the direction of Farinelli, Manzoli was engaged for the principal man's part. From Madrid he went to Vienna, at the celebration of the emperor Joseph's first marriage. In 1764, he arrived in England, during the opera regency of Mezzfee, Gordon and Vincent, at which period the ferior opera acquired a degree of favour to which it had seldom mounted since its first establishment in this country.

The
The expectations which the high reputation of this performer had excited were so great, that, at the opening of the theatre in November, with the pulchris of Ezio, there was such a crowd assembled at all the avenues, that it was with very great difficulty we obtained a place; after waiting two hours at the door. Mazzini's voice was the most powerful and resounding sopranos that had been heard on our stage at the time of Farinelli; and his manner of singing was grand and full of taste and dignity. In this first opera he had three songs, composed by Pefce, entirely in different styles: Recogli quel' affocio, an animated aria parlante; Caro mio bene addio, an adagio in a grand style of cantabile; and Mi dono in renede, of a graceful kind, all which he executed admirably. The lovers of music in London were more unanimous in approving his voice and talents than those of any other singer of the last century.

The applause was hearty, unequivocal, and free from all suspicion of artificial zeal;—it was a universal thunder. His voice alone was commanding from native strength and sweetness; for it seems as if subsequent singers had poffessed more art and feeling; and as to execution, he had none. However, he was a good actor, though unwisely in figure, and not well made in person; neither was he young when he arrived in London; yet the sensations he excited seem to have been more irresistible and universal, than we have ever witnessed in any theatre. This great singer remained in England for a season, when, returning to Italy, he was succeeded by Elia.

In 1797 we heard Manzoli sing at Florence in a convent at the last consecration of a nun; he had quitted the stage, and his voice, though in a small chapel, seemed much less powerful than when he was in England; and it was then said by those who had heard him before, that, powerful as his voice appeared to all who heard him for the first time, it had been till better. This great vocal performer and worthy man died at Florence in 1791.

MANZOR, or Chirrera, in Geography, a river of Africa, which joins the Zambeze, S. lat. 16° 35'. E. long. 34°.

MANZORAL, a river of Hindoostan, which is a branch of the Godavery: this is a considerable river, which runs in the country of Amhedagur, and after a circuitous course, joins the main river below Nander.

MANZUREKA, a river of Ruffia, which runs into the Lena. N. lat. 53° 45'. E. long. 160° 34'.

MANZURSKA, a town of Ruffia, in the government of Archdinsk, at the juncture of the Manzureka and Lena; 32 miles S.E. of Vercholend.

MAO, or Mau, in Botany, a name by which some authors have called the magna Indica, or Indian mango-tree.

MAO, in Geography, a city of China, of the second class, in the province of Se-tchuen; 55 miles N. of Tching-tou. N. lat. 37° 38'. E. long. 105° 32'.

MAON, a small island in the Adriatic, near the coast of Dalmatia. N. lat. 44° 44'. E. long. 15° 1'.

MAON, in Ancient Geography, a strong city of Palestine, in the tribe of Judah, which gave name to the neighbouring wilderness. It stood on a barren eminence, at a little distance to the S.W. of the Dead sea.

MAOPOONGO, in Geography, a town of Africa, in Benguela, and capital of a district. S. lat. 10° 30'.

MAOUNA, or Massacre island, one of M. Bougainville's Navigator's islands in the South Pacific ocean, visited by La Perouse in 1787. This island is surrounded by a reef of coral, on which the sea breaks with great force; but the reef almost joined the shore, and the coast formed several little coves, in front of which were inlets where canoes could pass, and probably, says La Peroufe, our barges and long boats. At the bottom of each of these creeks were numerous villages, whence came out a number of canoes in succession laden with pigs, cocoa nuts, and other fruits, which were exchanged for glasses trinkets. When M. de Langle and several officers landed, night came on, and the Indians lighted a great fire to make the landing place clear; and, higher they brought birds, pigs, and fruit. Upon the first visit, the perfect tranquillity and apparent good humour prevailed, and whilst the effects of La Peroufe's frigates were filling with water, he entered a charming village situated in the midst of a wood; or rather, orchard, the trees of which were weighed down by fruit. The houses were placed in the circumference of a circle, about one hundred and fifty fathoms in diameter, the centre of which formed a large open place, with a grfs plat of the most beautiful verdure, and the trees which overshadowed it kept up a delicious freshnes. Women, children, and old men accompanied their new visitor, and invited him into their houses, where they spread the finest and freest mats upon the ground, formed by small picked pebbles, and which they had raised about two feet to protect them from the damp. In the handomest of these huts, probably belonging to the chief, was a large room of lattice work, equally well executed with those about Paris. This charming country, says our Navigator, united the twofold advantage of a foil fertile without culture, and a climate which required no clothing. Bread fruit, cocoanut, bananas, guavas, and orange trees furnished the inhabitants with abundance of wholesome nourishment; while fowls, pigs, and dogs, which live on the refuse of these fruits, afforded them an agreeable variety of food. They were so rich, and in want of so little, that they disdain'd our infringements of iron and flusses, and covet'd only some beads: burdened with real goods, they only wished for things that were useless. Our navigator was ready to pronounce the inhabitants of this richly stor'd and beautiful island the most happy beings on earth. But he soon found that this pleafant abode was not the maniften of innocence. Although no arms were perceived, yet the bodies of these Indians covered with fears, proved that they must be at war with their neighbours, or quarrel among themselves; and their countenances indicated a ferocit impromptible in the physiognomy of the women, whose perfons were agreeable, and mannersoft, lively, and engaging. Nature, says our author, had without doubt left this lamp on the figure of the Indians to denote, that man, almost wild and in a state of anarchy, is a being more mischievous than the ferceft of the animal creation. This first visit, however, did not pass off without private quarrels, which were terminated by prudent and wary conduct on the part of our navigators. The islanders became in proffes of time hold and inoffent, and regardles of every refraint to which they were subjected. The two frigates had during their stay trafficked for 500 pigs, a great quantity of fowls, pigeons, and fruit, and all at the expense of a few beads of glasses. La Peroufe gave orders for quitting the island before the storm burst, which he perceived to be gathering, and the harmonious intercourse that had subsisted was interrupted, which he faw likely to be the cafe; but M. de Langle, the poft captain, perifhed in his purpose of obtaining a few long-boat loads of water before he left the island: the confecration was difaftrous; the islanders became turbulent; and M. de Langle formed a body of 60 men from among the choiceft men of the crews, armed them with muskets and cutlaffes, and mounted fix swells in the long-boats, and thus prepared, they landed in order to ob-
tain water. The number of canoes increased, and the number of islanders, who were collected in hothe array on the shore, amounted to 10 or 1200. M. de Langle and his companions betook themselves to their boats amidst volleys of stones, and the Indians surrounded them within the distance of a toite: after a shower of stones, M. de Langle had only time to fire his musket twice, when he was knocked down, and unfortunately fell over the larboard side, 200 Indians immediately macerating him with clubs and stones. Of the 61 men who had engaged in this expedition, 49 saved themselves by swimming to the barges of the frigates, but the remaining number fell a sacrifice to the relentless fury of these savages, and all the others were grievously wounded more or less. M. de Lamantran, the philosopher and naturalist, was one of the number who lost his life on this occasion. Many of the Indians were killed or wounded in this conflict. M. de Vasquier closes his narrative of this event with the following general remark: "All those who were on shore can bear witness, like me, that no violence, no impiudence on our side provoked the attack of the savages. Our captain had, with respect to this, stifled the most riotous orders, which no one disobeyed." Captain Edwards calls this island "Otutuca." The anchoring place was in S. lat. 14° 22'. E. long. 189° 1'. Peroue's Voyage, vol. ii.

MAP, a plain figure, representing the surface of the earth, or a part of it, according to the laws of perspective. A map is a projection of the surface of the globe, or a part of it, on a plane surface, representing the forms and dimensions of the several countries and rivers; with the situation of cities, mountains, and other places. Maps are either universal or particular. Maps, Universal, are those which exhibit the whole surface of the earth, or the two hemispheres. Maps, Particular, are those which exhibit some particular region, or part of the earth's surface. Those of each kind are frequently called geographical, or land-maps, in contradistinction to hydrographical, or sea-maps, representing only the seas and sea-coasts; and properly called charts; which see.

There are three qualifications required in a map: 1. That all places have their just situation with regard to the chief circles of the earth, as the equator, parallels, meridians, &c. because on these depend many properties of regions, as well as celestial phenomena. 2. That the magnitudes and forms of the several countries have the same proportion as on the surface of the earth. 3. That the several places have the same distance and situation with regard to each other, as on the earth itself.

For the foundation of maps, and the laws of projection, see Perspective, and Projection of the Sphere. The application of these principles and laws, in the construction of maps, is as follows.

Constructions of a Map, the Eye being placed in the Axis. Suppose, v. g. the northern hemisphere to be represented with the eye on the point of the axis, v. g. the south pole; for the plane on which the representation is to be made, we take the plane of the equator, and, from all the points of the surface of the northern hemisphere, conceive lines passing through the plane to the eye; which points, connected together, constitute the map required.

In this case, the equator will be the limit of the projection; the pole, the centre. The meridians will be right lines passing from the pole to the equator; the parallels of latitude, &c. circles concentric with the equator; and all the other circles, and arcs of circles, as the horizon, vertical circles, &c. ecliptic, &c. conceived in that hemisphere, will be ellipses, or arcs of ellipses.

The better to apprehend the projection of the circles of the plane, conceive a radiant cone, whose vertex is the eye, its base the circle to be represented, and its sides the rays passing between the circle and the eye. Suppose this cone cut by the plane, it is obvious, that, according to the various position of the cone, there will be a different fiction, and consequently a different line of representation.

For the Application of this Doctrine in Practice.—In a plane, v. g. a paper, take the middle point P (Plate I. Geographies, fig. 4.) for the pole; and from this, as a centre, describe a circle of the intended size of your map to represent the equator. These two may be pitched on at pleasure, and from these all the other points and circles are to be determined. Divide the equator into 360, and drawing right lines from the centre to the beginning of each degree, these will be meridians; whereas that drawn to the beginning of the first degree, we suppose the first meridian.

For the parallels.—There are four quadrants of the equator; the first, 0°; the second, 90°; the third, 180°; the fourth, 270°; which, for the better distinction, we will note with the letters A, B, C, D. Taking one of these, v. g. B; from the several degrees of it, as also from 23 ° 56' and 66° 30' of it, draw obtuse right lines to the point D, marking where these lines cut the semidiameter A P C; and from P, as a centre, describe arcs passing through the several points in A P C. These arcs will be parallels of latitude. The parallels of 23° 56' will be the tropic of Cancer, and that at 66° 30', the arctic circle. The meridians and parallels thus described, from a table of latitudes and longitudes, lay down the places; reckoning the longitude of each place on the equator, commencing at the first meridian, and preceding to the meridian of the place; and for the latitude of the place choosing a parallel of the same latitude: the point in which this meridian and parallel intersect represents the place; and in the same manner all the other places may be determined, till the map be complete.

For the ecliptic, half of which comes in this hemisphere, we have observed, that it makes an ellipse; so that the points through which it passes are to be found. The first point, or that in which the ecliptic cuts the equator, is the same with that in which the first meridian cuts the equator, which is therefore distinguished by the sign of Aries: the last point of this half ellipse, or the other intersection of the equator, and ecliptic, viz. the end of Virgo, will be in the opposite point of the equator, viz. at 180°. The middle point of the ellipse is that in which the meridian 90 cuts the tropic of Cancer. Thus we have three points of the ecliptic determined; for the first, viz. for 1° and 15°, of Taurus, 10° and 15° of Gemini, 15° of Leo, 15° of Virgo; the declinations of those points from the equator must be taken from a table, and set off in the map. See Declination, &c.

Thus, where the meridian of 15° cuts the parallel of 5°, that point will be 15 degrees of Aries. Where the meridian 26° cuts the parallel 11°, will be the first degree of Taurus; and so of the rest. These points, being all joined by a curve line, will be a portion of an ellipse representing the ecliptic.

Maps of this projection have the first qualification above required; but they are defective in the second: the surface being shrunk farther, as it approaches nearer the equator. With respect to the third, they are still farther erroneous.
Maps.

By this method may almost the whole earth be represented in one map, placing the eye, e.g. in the antarctic pole, and assuming for the plane of projection that of a cone circle near it, e.g. the antarctic circle. Nothing is here required besides the former projection, but to continue the meridian, draw parallels on the other side of the equator, and complete the ecliptic; but this diffords too much for practice.

This projection is the easiest: but that where the eye is placed in the plane of the equator, is preferred for use. It is, in effect, of the latter kind that maps are ordinarily made. The former are added to them, in small, by way of supplemen
tment, to represent the intermediate spaces left between the two hemispheres.——Further, as the situation of the ecliptic, with regard to the earth, is continually changing; strictly speaking, it has no place on the earth's surface; but is used to be represented according to its situation, at some instant moment; viz. so that the beginning of Aries and Libra may be in the intersec
tions of the first meridian and equator.

Construction of Maps, with the Eye in the Plane of the Equator.——This method of projection, though more difficult, is yet much more just, more natural, and more commodious, than the former. To conceive it, we suppose the surface of the earth cut into two hemispheres by the entire periphery of the first meridian, each of which hemispheres we represent in a distinct map. The eye is placed in the point of the equator 90° distant from the first meridian; and for the transparent plane, wherein the representation is to be, we take the plane of the first meridian. In this projection, the equator is a right line, and the meridian, 90° distant from the first, is also a right line; but the other meridians, and all the parallels of the equator, are arcs of circles, and the ecliptic an ellipse.

The method is thus: From a point E as a centre (fig. 5) describe a circle according to the intended size of the map. This represents the first meridian, and its opposite; for drawing the diameter BD, there arife two hemispheres, the one of which, B A D, is the first meridian, the other, B C D, its opposite, or the meridian of 180°. This diameter, B D, represents the meridian of 90° degrees, of which the point B is the articulate pole, and the point D the antarctic. The diameter A C, perpendicular to that BD, is the equator. Divide the quadrants A B, B C, C D, D A, each into 90° degrees; and find the arcs of the meridians and parallels; proceed thus: divide the equator into its degrees; viz. 180° as being indeed only half the equator; through these several divisions, and the two poles, describe arcs of circles, representing meridians, as B 10 D, B 20 D, &c.——

How to find centres for describing those arcs, see under the word Chord. See also Geometrical Construction of the Globular Projection, infra.

Indeed the operation will be both more easy and accurate, if performed by a canon of semi-tangents.

Thus, by means of a sector, divide the equator A C into two lines of semi-tangents E A and E C, which will represent the degrees of longitude. Then with the fecant of 80°, as a radius, describe the arc of the circle B 80 D, which represents a meridian cutting the plane of projection at an angle of 80°; with the secent of 70° describe the arc B 70 D, which represents a meridian cutting the plane of projection at 70°; and proceed in the same manner with the rest of the meridians, which are usually drawn at every 10° of longitude, as the parallels are at every 10° of latitude.

To describe the parallels, the meridian B D must be in like manner divided into 180° degrees; then through each of these divisions and the corresponding divisions of the quadrants A B, C B, describe arcs of circles. Thus shall we have parallels of all degrees, with tropics, poles, and meridians.

The parallels may be drawn with the tangents for radii, as the meridians are with the secents, 1010 representing the parallel of 10°, with the tangent of 80°, that of 20° with the tangent of 70°, &c. The ecliptic may be delineated two ways; for its situation over the earth may either be such, as that its intersec
tion with the equator may be over the place A; in which case the projection of its semicircles, from the first degree of Cancer, to the first of Capricorn, will be a straight line, to be determined by numbering 23° 30' from A towards B, and from the extreme of that number drawing a diameter through E; which line will be half the ecliptic in this situation, and may be divided, as before, into degrees, to which the numbers, signs, &c. are to be affixed. But if the ecliptic be so placed, as that its intersection with the equator is over the place A, in the first meridian, its projection in that case will be a segment of an ellipse; whereas two of the points are A, C; a third, that wherein the meridian 90 cuts the tropic of Cancer. The other points must be determined in the manner laid down above; viz. by taking the declinations and right ascensions of 15° of Aries, 15° of Taurus, 15° of Gemini, &c. For where the parallels, according to their several degrees of declination, cut the meridians, taken according to the several right ascensions, those points of intersection are the points of the 15° of Aries, &c. A curve line therefore being drawn, these will give the projection of the ecliptic.

Nothing then remains to complete the map, but to take the longitudes and latitudes of places from a table; and to let them off on the map; as was directed under the former method.

In this projection the whole surface of the earth may be represented in one map; if, instead of the plane of the first meridian, some other plane parallel to it, but very near the eye, be taken; for by this means the entire parallels and meridians will be described. But as this diffords the face of the earth too much, it is seldom used; and we rather make the two hemispheres in two distinct tables.

One great advantage in this projection is, that it represents the longitudes and latitudes of places, their distance from the pole and from the equator, almost the same as they really are on the earth. Its inconveniences are, that it makes the degrees of the equator unequal; being the greater as they are nearer the first meridian D A B, or its opposite B C D; and for this reason equal tracts of the earth are re
dented unequal; which defect may be in some measure remedied, by removing the eye far from the earth. And, lastly, the distances of places and situation, with regard to each other, cannot be well determined in maps of this projection.

Construction of Maps on the Plane of the Horizon, or wherein any given place shall be the centre or middle. Suppose, for instance, it is desired to have London the centre of the map. Its latitude we will suppose to be 51° 32'. The eye is placed in the nadir. The transparent table is the plane of the horizon, or some other plane, if it is desired to represent more than a hemisphere. Take then the point E (fig. 6.) for London; and from this, as a centre, describe the circle A B C D, to represent the horizon, which you are then to divide into four quadrants, and each of these into 90° degrees. Let the diameter B D be the meridian, B the northern quarter, D the southern; the line of equinoctial east and west shews the first vertical, A the west, C the east, or a place of 90 degrees from the zenith in the first vertical. All the verticals are represented by right lines drawn from
MAPS.

the centre E, to the several degrees of the horizon. Divide B D into 180 degrees, as in the former methods; the point in E B, representing 51° 32' of the arc B C, will be the projection of the north pole, which note with the letter P. The point in E D, representing 51° 32' of the arc D C (reckoning from C towards D), will be the projection of the intersection of the equator and meridian of London, which note with the letter Q; and from this, towards P, write the numbers of the degrees, 1, 2, 3, &c. As also from O towards D, and from B towards P; viz. 51° 52'.

Then taking the corresponding points of equal degrees; viz. 99 and 99, 88 and 88, &c. about those, as diameters, describe circles, which will represent parallels, or circles of latitude, with the equator, tropics, and polar circles. For the meridians, first describe a circle through the three points A, P, C. This will represent the meridian 90 degrees from London. Let its centre be M in B D (continuing to the point N, which represents the south pole), P N being the diameter; through M draw a parallel to A C; viz. F H continued each way to K and L. Divide the circle, P H N F, into 360 degrees, and from the points P draw right lines to the several degrees, cutting K F H L; through the several points of intersection, and the two poles P, N, as through three given points, to describe circles representing all the meridians. The centre for describing the arcs will be the same K L, as being the same that are found by the former intersection; but are to be taken with this caution, that for the meridian next B D N towards A, the most remote centre towards L, be taken for the second, the other from this, &c. The circles of longitude and latitude thus drawn, infert the places from a table, as has been directed.

Construction of Maps on the Plane of the Meridian.—This projection is taught by Ptolemy, and recommended by him as proper for that part of the earth then known. In this the equator and parallels are arcs of circles, and the meridians arcs of ellipses; the eye hanging over the place of that meridian which passes over the middle of the inhabited world. But in regard the description of these ellipses is somewhat perplexing, and because this method seems calculated only for a part of the earth, it is not now used.

There is a second method, something akin to it, which represents the circles of latitude by right lines, and the meridians by arcs of ellipses, as must be the case; if lines be conceived to fall from the several points of each hemisphere perpendicularly on the plane of the first meridian, and the eye be supposed at an infinite distance from the earth, so that all the rays emitted from the places of the earth to it may be accounted parallels, as well as perpendiculars to the plane of the first meridian.

In his "Companion to a Map of the World," (London, 1794. 4to.) Mr. Arrowsmith has offered the following remarks on projection; and as they are immediately connected with the subject of the construction of maps, we shall here subjoin them.

"As the earth is of a form approaching very near to a globe or sphere, it is evident that the only map which can truly represent the figure of the various countries, and their relative bearings and distances, must be delineated on the surface of a globe. But as globes of a size proper to produce a map, sufficiently accurate, and containing all the information that is necessary or desirable, must be very bulky, and very expensive, it is necessary to have more portable and cheaper maps, executed upon a flat surface; these, since the art of copper-plate printing has been in use, have generally been made up a paper.

"It is obvious that such a map, wherein is attempted to represent upon a plane surface that which is really spherical, must depart considerablv from the truth; especially if it comprehends the whole, or a considerable portion of the world. It has, therefore, been an object which has engaged the attention of the most eminent geographers, to discover a projection (or arrangement of the proportional parts of the map) which should be liable to the fewest errors.

"The most natural method of representing a sphere upon a plane seems to be to divide it into two equal parts, and inscribe each of them in a circle: but as the equator and the polar axis, which intersect circle at right angles, and makes one of the meridians, must be supposed equal in length to the half of the superior (of which it is not quite two-thirds), it follows, of course, that the countries delineated upon or near these lines must be reduced to somewhat less than two-thirds of the size of the countries of equal extent, which lie at the extremity of the world: and that the lines drawn to measure the latitude, which are parallel to each other, or nearly so, must, in order to preserve as nearly as possible their proportional angles at the points of intersection with the meridian, form segments of circles, of which no two are parallel or concentric.

"There may be as many different projections as there are points of view, in which a globe can be seen; but geographers have generally chosen those which represent the poles, at the top and bottom of the map: these, from the delineation of the lines of latitude and longitude, are called the orthographic, orthographic, and globular projections." See Projection.

"I do not propose to detain the reader with a description of all the projections; some of which are so numerous (for the purpose of constructing of maps) as to deserve being confined entirely to oblivion. But as projections of maps form a pleasing and instructive exercise, and, indeed, indispensably necessary to the right understanding of geography, by students, I shall describe the manner of constructing the map that accompanies this work; but first hint at the orthographic projection. (The great geographer, d'Avalis, has constructed his map of the world upon this projection, adopting it to Caffini's system of the figure of the earth, which makes the polar diameter longer than the equatorial.) Among the various positions as applicable to the eye, there are chiefly two that have been adopted, wherein the eye is placed either in the point D (fig. 7) or removed to an infinite distance; and hence this projection is liable to the great error of differing the form of the countries, represented upon it, much more than is necessary. The only advantage is, that the lines of latitude and longitude intersect each other at right angles.

"This being observed by the excellent astronomer, M. de la Hire (Hist. Acad. Sc 1701), he invented a remedy for the inconvenience, by aligning to the eye a position at the point O (fig. 7) the distance of which, from the globe at D, is equal to the right line of 45; and hence the right line, O G, which bisects the quadrant B C, also bisects the radius E C, and produces the familiar triangles O F G, and O E F; and thus the other parts of the quadrant B C, and, in like manner, of the whole semicircle A B C, are represented in the projection nearly proportional to each other, and to the eye perfectly.

"This projection, as coming the nearest to a true representation of the globe, is called the "Globular Projection;" it is equal to the orthographic in point of facility, and vastly superior to it in point of truth.

"Geometrical Construction of the Globular Projection.—From the centre C (fig. 8), with any radius, at C B, describe a circle; draw the diameters A B, and 90, 90, (being careful to draw them at right angles), and divide them into

2
Maps, Rectilinear, are those wherein both the meridians and parallels are represented by right lines, which by the laws of perspective is impossible; in regard thereto, there can be no such position ascribed to the eye and the plane, as that the circles both of longitude and latitude shall be right lines.

In the first method above laid down, the meridians are right lines, but the parallels are circles: in the fifth, the parallels are right lines, and the meridians ellipses. In all other perspective methods, both kinds of circles are curves: one method indeed must be excepted, wherein the meridians are right lines, and the parallels hyperbolas; as when the eye is placed in the centre of the earth, and the plane, through which it is viewed, is parallel to the first meridian: but this method is rather pretty than useful.

Rectilinear maps are chiefly used in navigation, to facilitate the estimate of the ship's way. See Chart

Conflation of particular Maps.—Particular maps of large tracts, as Europe, Asia, Africa, and America, are projected after the same manner as general ones; but the observer, that for different parts, different methods may be chosen. Africa and America, for instance, as the equator passes through them, cannot be conveniently projected by the first method, but much better by the second. Europe and Asia are most conveniently represented by the third; and the polar parts, or the frigid zones, by the fifth.

To begin, then, draw a right line on your plane, or paper, for the meridian of the plane over which the eye is conceived to hang, and divide it into degrees, as before, which will be the degrees of latitude. Then from the tables take the latitude of the two parallels, which terminate each extreme. The degrees of these latitudes are to be noted in the meridian; and through them draw perpendiculars, bounding the map towards north and south. This done, meridians and parallels are to be drawn to the several degrees, and the places to be inferred, till the map is complete.

For particular Maps of less extent.—In maps of smaller portions of the earth, the geographers take another method. A tranverse line is drawn at the bottom of the plane, to represent the latitude of the furthest part of the country, to be exhibited, terminates. In this line, so many equal parts are taken as that country is extended in longitude. On the middle of this same line erect a perpendicular, having so many parts as there are degrees of latitude between the northern and southern limits of the country. How big these parts are to be, may be determined by the proportion of a degree of a great circle to a degree of the parallel represented by the tranverse line at bottom. Through the other extreme of this perpendicular, draw another perpendicular, or a parallel to the line at bottom, in which are to be seen as many degrees of longitude as in the lower line, and these, too, equal to each other, unless the latitudes happen to be remote from each other, or from the equator. But if the lowest parallel be at a considerable distance from the equinoctial, or if the latitude of the northern limit go much beyond that of the southern; the parts or degrees of the upper line must not be equal to those of the lower, but left, and that according to the proportion which a degree of the more northern parallel has to a degree of the more southern.

Maps, General, are the hemispheres; which are for the most part constructed stereographically.
veral degrees of the perpendicular erected on the middle of the first transverse line, draw lines parallel to that transverse line; these will represent parallels of latitude. Lastly, at the points wherein the meridians of longitude and the parallels of latitude concur, insert the places from a table, as before directed. But though there are various modes of constructing these maps, they are, in general, defective, so as not to be applied with accuracy and facility to the purposes intended, in determining the courses or bearings of places, their distances, or both.

Suppose it were required to draw the meridians and parallels for a map of Britain. This island is known to lie between 50° and 60° of latitude, and 2 and 7° of longitude. Having therefore chosen the length of your degrees of latitude, you must next proportion your degrees of longitude to it. By the table of degrees of longitude corresponding to every degree of latitude, under Degree, you will find that in the latitude of 50°, the length of a degree of longitude is to one of latitude, as 39.354 is to 60; that is, a degree of longitude in lat. 50°, is fome part more than half the length of a degree of latitude. The exact proportion may be easily taken by a diagonal scale; after which you are to mark out seven or eight of those degrees upon a right line for the length of your intended map. On the extremities of this line raise two perpendiculars, upon which mark out 10° of latitude for the height of it. Then, having completed the parallelogram, consult the table for the length of a degree of longitude in lat. 60°, which is found to be nearly one half a degree of latitude. It will be always proper, however, to draw a vertical meridian exactly in the middle of the parallelogram, to which the meridian on each side may converge; and from this you are to set off the degrees of longitude on each side. Then having divided the lines bounding your map into as many parts as can conveniently be done, to serve for a scale, you may by means of these set off the longitudes and latitudes with much less trouble than where curve lines are used. This method may always be adopted where a particular kingdom is to be delineated, and will represent the true figure and situation of the places with tolerable exactness. The particular points of the compass on which the towns lie with respect to one another, or their bearings, cannot exactly be known, except by a globe or Mercator’s projection. Their distances, however, may thus be accurately expressed, and this is the only kind of maps to which a scale of miles can be truly adapted.

The Rev. T. Bowen has just published an excellent apparatus for delineating the lines of longitude and latitude on maps, on a scale adapted for the use of schools. In like manner, these lines may be described on maps of any size with unerring accuracy.

The apparatus consists of a scale and a pair of compasses sufficiently large to be referred to with safety, with a book to explain the method of using them. The short lines at each end of the scale represent the equators, the meridians, the north, the south, the east, and west lines graduated; from which the outlines of the maps are to be constructed, and the degrees laid down. The lines extending the whole length of the scale on the other side, contain the centres of the different circles which compose the lines of longitude and latitude mathematically found. The radius of each line to be described on the map, is the distance between that line and its corresponding number on the scale; consequently, by placing one limb of the compasses on the central point on the scale (when adjusted according to the directions given), extending the other to its corresponding number on the meridian, and then moving it from east to west, the parallel of latitude is formed; from north to south through its corresponding number on the equator, and the line of longitude is described.

For an abract of La Croix’s paper on the projection of maps, see Pinkerton’s Geography, vol. i. Introd.

For Maps of Provinces, or small tracts, as parishes, manors, &c. we use another method, more sure and accurate than any of the former. In this, the angles of position, or the bearings of the several places, with regard to one another, are determined by proper instruments, and transferred to paper. This constitutes an art apart, called surveying.

Maps, the Use of, is obvious from their construction. The degrees of the meridians and parallels show the longitudes and latitudes of places, and the scale of miles annexed, their distances; the situation of places, with regard to each other, as well as to the cardinal points, appears by inspection, the top of the map being always the north, the bottom the south, the right hand the east, and the left the west; unless the compass usually annexed to the contrary.

Maps of Estates, in Agriculture, such plans or outlines of lands as are necessary to direct their management in the most easy and economical manner. In an useful work on “Landed Property,” it is advised that the different distinct parts or farms into which they are divided, should be outlined, coloured, and introduced on a general map, as well as each separately delineated, more particularly on a small pocket one, so as to show the farms with distinctness, or the lands intended to be laid into them, with the wood-lands, waters, &c. that are in hand. The pocket maps should exhibit at once the outlines, the names, and the contents of the different fields, or pieces of land of which they are severally constituted, which being coloured according to occupancy, the several fields of the exiling farms (or intermixed parts of farms intended to be united), though scattered, may be readily distinguished. And if separate columns of contents be inserted on the backs of the maps, one of them of the intended farm, the other of the exiling farms or parts of farms, with their totals subjoined; all the doubts and perplexities which are wont to arise on large estates, from the intermixture of farm-lands, will be avoided.

And these maps of farms should be of a portable size, as ten inches by eight, and be bound up in volumes corresponding to the general maps; so that the superintendant-manager in going over any part of the estate, may have with him the maps that belong to it. Each map should be folded double, and be hung in loofely within flexible covers, by a guard or flip of paper paled on the back, in order that when opened each may lie flat and fair, and be conveniently portable when shut.

Maps, Geographical. The idea of exhibiting in maps, by means of signs or illumination, the principal geographic features of a given tract of country, the aspect of its surface, the nature of its rocks, their alternation and relative position, is as new as the science which teaches us to distinguish from each other the manifold materials that compose the crust of the earth as far as we are acquainted with it. Several methods have been lately adopted for accomplishing the above object; all of which that of colouring the spaces occupied by the different rocks appears by far the most convenient. It is this method which has been improved and carried to a high degree of precision by the celebrated Werner, who has happily removed all those obstacles which hitherto prevented its general adoption. We are indebted
to professor Jameson for an account of the Wernerian method of colouring maps, communicated in the first volume of the "Transactions of the Wernerian Society" lately published.

The following rules should be observed in illuminating maps for the above purpose: 1. In every case such colours are to be used as will allow the ground-work of the map or delineations of the mountains to appear through them distinctly. 2. The colours should agree as nearly as possible with nature; they should correspond with the most common colour of the rock, or, at least, differ from it as little as possible, and agree with the transition tint of the colours. 3. The use of all bright colours must be avoided. 4. The colours must not be too pale or too deep, and they ought to be laid on as much as possible of the same intensity: perfectly dark and light coloured rocks are exceptions to this rule. 5. The colours of mountain-rocks must form suites or transitions, in order to express the transitions of the rocks into each other; at the same time they must be sufficiently distinct from each other.

The following colours are employed by Werner for distinguishing the particular rocks:—quartz; reddish-white, inclining a little to yellow;—copaz-rock; pale brick red;—granite; pale cochineal red, approaching crimson-red;—white;—pale flesh-red;—grays;—blue;—mica flake;—pearl-grey;—primitive clay-flake;—greenish-grey, approaching to blue;—alum-flake; pale blueish-black, approaching to grey;—flint-flake; deep ash-grey;—grey-wacke-flake and grey-wacke;—greenish-grey, falling into yellow;—trap-rocks, such as granular primitive trap, greenstone, flintstone, hornblende flake, blackish-grey inclining to blue:—bafalt; greenish-black;—porphry-flake; pale greenish-black;—amethyst; pale greenish-black, slightly inclining to brown;—terpenite; pale piacthico-green;—talc and chlorite-flake;—pale grafs-green;—porphry;—pale reddish-brown, slightly inclining to yellow;—fusinite; pale reddish-brown, inclining to blue, that is, close-brown passing into blueish-red;—granular primitive lime-flake;—pale Berlino-blue;—compact primitive lime-flake;—small-blue, faintly inclining to red;—transitien lime-flake;—indigo-blue, slightly inclining to grey;—flint-flake;—pale blue-grey;—chalk;—blue-stone;—calcaceous tuf;—smoke-grey;—gypsum;—pale sky-blue;—rock-salt, and rocks from which salt-springs issue;—pale verdigris-green;—coal-formation;—pale blackish-brown, approaching to yellowish-brown;—alum-earthe and brown coal;—liver-brown;—conglomerate and clay-flake;—pale orange-yellow, slightly inclining to reddish-brown;—sand-flake;—raw-yellow;—loam and clay;—yellowish-grey passing into ochre-yellow;—iron-clay and calamine;—pale ochre-yellow;—turf and peat;—liver-brown streaks;—bog-iron ore; ochre-yellow streaks. All these rocks may, likewise, be distinguished by particular signs or symbols; for which, if they should be deemed useful, we refer to the Wernerian Transactins.

Not only particular rocks, but also formation suits, may be represented in colours. Thus, the slate formation suite will be red shaded into blue, the blue into grey; this latter into green, and the green into yellow. The inflammable fossils, subordinate to these formations, will be dark brown. The limestone formation suite will be blue, which passes into grey, and finally into white. The salt and gypsum formation suites, which are allied to the preceding, will be greenish-blue and blueish-grey; the trap suite, greenish-black and blackish-green, shaded into blue; the porphyry suite, light brown; the tale and terpenite suite, pale yellowish-green.

The relation of the different rocks, Werner ex-
about the rivers Aourney and Orapu in Guiana, where Aublet found it flowering in June. One of his specimens is before us. Root perennial, creeping, firm, throwing up several simple, triangular leaves, about two feet high, rough with manifest hair points or prickers, and clothed at the base with several feathery, imbricated, membranous, reddish scales or leaves. The rest of the flemis naked, but its top is crowned with the three spreading involucral leaves, each five or six inches long, obvate, pointed, ribbed, entire, smooth, green, and lollaceous, in whose centre is flattened a round feffile head of several flowers. Vahl, who had examined a specimen, judicious remarks, that the leaves of the calyx are not toothed, as Aublet describes them, but entire.

MAPELLA, in Geography, a town of Italy, in the department of the Mincio.

MAPLE, in Botany. See Acer.

MAPLE Tree, in Agriculture, the common name of a tree of the deciduous kind, cultivated for the purposes of timber and ornament in plantations and other grounds. There are several species and varieties of this tree, as the great maple or sycamore, the common or smaller maple, the aft-leaved Virginia maple, the Montpelier maple, the plane-tree like Norway maple, the scarlet flowering maple, the sugar maple, the Tartarian maple, the Italian maple, the Pennsylvanian mountain maple, and the Cretan maple.

And there are two varieties of the great maple or sycamore, one with broad leaves and large keys, the other with variegated leaves: the latter, when blended in large plantations, affords a pleasing variety. This tree is frequently known by the name of sycamore, mock plane, and plane tree. See Sycamore.

The common maple is a tree of much humbler growth than the great maple, and by no means so ornamental; it may, however, be useful in extensive plantations and pleasing grounds. It is also very good for timber, being clofe in the grain of the wood. When cut down, it affords an excellent underwood.

The aft-leaved maple should be made use of in situations that are not much exposed to the winds, as it is fad to be apt to be split by them. The wood is soft and brittle, and of course less useful as timber.

The Montpelier maple is chiefly useful for the variety it affords in ornamental plantations.

And the Norway maple is principally useful for affording shelter, and also as a timber tree. There are two varieties, one with variegated or striped leaves, and the other with cut leaves.

There are two varieties of the scarlet-flowering maple, the Virginian scarlet-flowering maple, and Sir Charles Walker's maple. Both of them are chiefly propagated for the sake of the flowers, which are of a scarlet colour. The fort called Sir Charles Walker's produces larger clusters of flowers than the other, on which account it is in more estimation.

In America, the inhabitants tap the sugar maple in the spring, and boil the liquor, which affords an useful sugar. The sycamore, the afleaved, and the Norway maples also abound with a fuccharine juice, from which sugar might probably be prepared with advantage in some situations.

The Italian maple is common in many parts of Italy, and is a lofty tree, and, from its having a spreading head, adorned with large and beautiful foliage, deferves the attention of ornamental planters. It may be also useful as a timber tree, in fore cafes.

The Cretan maple is only useful as an ornamental tree. There is a variety of it, in which the leaves continue green most part of the year, when sheltered, and which is denominated the evergreen Cretan maple.

It may be noticed, that all the sorts and varieties of the maple are of easy cultivation; each being capable of being raised by seed, and many of them by layering, cuttings, and budding. They thrive well in mott soils and situations, provided they be not too moist: the common sorts succumbing the best in such as are deep and inclined to moisture, but not hard or stifl; and the American kinds in those that have a dry and rather close state of mould or soil. In raising them in the first method, as the seeds do not, in all the sorts, ripen well in this country, the best way is to procure them from the places where they grow naturally. A cool shady place is the most suitable for this purpose. The mould being made fine, and nursery beds marked out four feet wide, with length proportionate to the quantity, in these the seeds are to be regularly sown in the autumn, lifting over them the finest mould to the depth of half an inch. When the plants are come up, they must be kept clean from weeds, and frequently watered during summer. In the spring following, the strongcill may be drawn out and planted in nurseries, in rows two feet asunder, and at the distance of a foot from each other in them, leaving the others to gain strength. In the second spring, these also must have the fame culture; and they may remain in the nursery, without any other trouble than keeping the ground clean in the summer, digging between the rows in the winter, and taking off all strong and irregular side-shoots, till they are fit to be planted out. The trees raised in this way grow fuller, and arrive at greater heights, than those from layers; but they do not in general produce such quantities of flowers, which makes the latter mode more eligible for those who want these plants for low shrubbery uses. In these cases, they should always have four or five years growth before they are finally planted out. It is, however, advised by some, that the seeds of the common or Norway maples should not be put into the soil immediately after becoming ripe, but be dried and preserved in sand till February or March, as the season may prove favourable, when they may be sowed in drifts or beds eighteen inches broad, with alleys the same width, and covered three quarters of an inch thick with mould. In the following February or March, the alleys should be dug, and the roots of the plants cut about five inches under ground, which may be easily performed by means of a sharp spade, drawing the plants out where too thick. These may be replanted in any good mellow sot, in rows eighteen inches asunder, and eight or nine inches from each other in the rows. In October, when the plants in general will be about two feet high, both the seedlings and those that were transplanted should be railed, shortening their tap-roots, cutting off any crofs lateral branches, and removing them into rows two feet and a half apart, and fifteen inches distant in them, in order that they may continue for a year or two. Remove them again at the same feason the succeeding year, and plant them in rows five feet asunder, and two and a half from each other, that they may continue four years. These will now be from twelwe to fifteen feet high; and if required of a still larger size, they may be removed, and planted again eight or ten feet asunder; when, any time after two and not exceeding eight or ten years, they may be finally planted out where they are to remain. The use of removing these trees frequently when young is, that they are apt naturally to grow with tap-roots, which this management prevents, and makes the plants root better, and become more easy and certain in their growth, when transplanted at a large size. The timber sorts are best raised from the seeds, without being removed at all. Though all the
the species are capable of being propagated by layers, it is never practiced for the common maple. In this method the young shoots may be laid down at any time, in the autumn, winter, or early in the spring; but the first is probably the best. By the same time in the following year they will have struck root, and have become good plants, when the strongest may be set out in the places where they are to remain; while the weakest may be planted in the nurseries, in the fame manner as the seedlings, for a year or two, in order to gain strength.

But in propagating by cuttings, though all these trees are capable of it, it is a method chiefly practiced on the ash-leaved and Norway maples, as they take root this way more readily. The cuttings should be taken from the bottom part of the last year's shoots early in October, and be planted in rows in a moist shady place. In the spring and summer following they should be watered, as often as dry weather makes it necessary, and be kept perfectly clean from weeds. In the autumn they will be fit to remove into the nursery; though if the cuttings are not planted too close, they may remain in their situations for a year or two longer, and then be finally set out without the trouble of being previously planted in the nursery. These trees are also to be raised by budding and grafting, but as the other methods are more eligible, these are seldom or ever practiced, except for the variegated sorts and the large broad-leaved kind. The latter indeed is to be continued in no other way than by budding or flocks of the common sycamore; as the feeds, when fown, afford only the common sycamore. But the feeds of the variegated kinds produce variegated plants; which renders the propagation of these sorts very expeditious, where plenty of feed can be had. But where it is not to be obtained. in order to propagate these varieties, recourse must be had to budding; in performing which some plants of the common sycamore one year old, are to be taken out of the feed-bed and placed in the nursery in rows a yard asunder, and about a foot and a half distant from each other in the rows. The ground must be kept clean from weeds all summer, and be dug, or, as the gardeners call it, turned in the winter; and the summer following the flocks will be of a proper size to receive the buds, which should be taken from the most beautifully striped branches. The best time for this operation is about August; as, if it is done earlier the buds will flourish the same summer, and when this happens a hard winter is apt to kill them. Having budded the flocks the middle or latter end of August, the eyes, or buds, being infected on that side the flock which faces the north towards the beginning of October, the bals by which it was tied may be removed, as it will begin to pinch and confine the bark as well as the bud too much. In the spring, just before the fab begins to rise, or the trees begin to shoot, the head of the flock should be cut off in a slanting direction just above the infected bud; by these means, and that of rubbing off such shoots as come from the flocks, the shoots from the infected bud will be rendered more strong and healthy. The trees thus budded may remain in their situations for a year or two longer, or be transplanted into the places where they are intended for, in the autumn or spring following; care being constantly taken to keep the land between the rows well dug, so as to prevent their being injured by the growth of coarse weeds, and the fide buds trimmed from their flocks occasionally.

In respect to the time of planting, the autumn season is upon the whole the best time for planting these and other deciduous trees, when they are strong and well rooted; yet when very young they are apt to be injured by frosts, and to be thrown out of the ground in severe winters, when planted in that season of the year. In such cases the spring is better.

**Maple Sugar**, a kind of sugar made from a species of the maple, called by Monsieur Sarazin, Acer Canadense saccospermiss fructu minori. M. Sarazin, a physician at Quebec, intending to inquire at large into the nature of this sort of sugar, observed that there were four species of maple common in the places where it was made, all which he sent over to the garden at Paris. One of these species, distinguished from the rest by the smallness of its fruit, is called the sugar-maple; this grows to fifty or eighty feet high, and its juice, which is very redundant in the months of April and May, is easily made into a very good sugar. They procure this juice from the tree by piercing a hole into the trunk, and placing vials to receive it. This juice, being evaporated, yields about one-twentieth part of its own weight in pure sugar. A middle-sized tree of this species, will yield sixty or eighty pints of this juice, without receiving any damage as to its growth; and much more than this may be drawn, but then the tree manifestly suffers for it.

M. Sarazin observed some very remarkable particulars in regard to the faccharine quality of this juice, without which it never had it in the proper perfection. 1. The tree, at the time that the juice is drawn out, must have its bottom covered with snow; and if it is not naturally so, the Indians know so well the necessity of it, that they always bring snow from elsewhere, and heap it up round it. 2. This snow must afterwards be melted away by the sunshine, not gradually thawed by a warm air. 3. There must have been a frosty night before the opening of the hole in the trunk. It is remarkable that these circumstances are such as custom and experience alone could have contrived, since they seem contrary to reason; and so is it in many of the operations in chemistry, where the most seemingly rational means fails, while those which should seem quite contradictory to reason succeed. It is observed, that if the juice of the maple be not in a condition to become faccharine while the snow lies at its root unh thawed, that it almost immediately becomes so on the melting of the snow, and its penetrating into the earth. Mem. Acad. Par. 1750.

The juice of the maple, unboiled, has been drank as an antifcorbic; the sugar and molasses, which are said to be less sweet than those extracted from the sugar-cane, are supposed to be more medicinal in disorders of the breast.

**Maple Islands**, in Geography, two small islands of America, in lake Superior, near the E. coast. N. lat. 46° 44'. W. long. 84° 52'.

MA-POU-IOTUN, a town of Corea; 46 miles E.N.E. of Peking.

MAPOIUIRA, in Botany, Aublet. Guian. v. i. 175. t. 67. A shrub of Guiana; found by Aublet on the banks of the river Sinamori, flowering in September. It is called by the natives Mapouria-rebelle. Lcucifolia, or wild maple, are fond of the leaves and branches, and thence the above name was constructed. The root throws up many feitt, brittle, juicy fants, about eight or nine feet high, clothed with a greenish bark. Leaves opposite, each pair crowned by the next, oval, pointed, entire, pliable, smooth and shining, with one rib, and numerous transverse parallel veins; each leaf eight inches long at most, and about half as broad, supported by a footstalk an inch in length. Stigmas intrastamenous, in pairs, ovate, large, deciduous. Panicle terminal, trichotomous, many-flowered, with opposite minute bractlets at its subdivisions. Flowers small. Calyx superior, of five teeth. Corolla white, of one petal, 5 S.
its limb in five segments, about twice the length of the tube. Stamens five, as long as the tube, inserted into the tube between the segments. The mouth of the tube is befit with white hairs. German inferior, oval; style simple, as long as the filaments; stigma of two oblong lobes. Fruit unknown.

Juffieu. Gen. 255. presumes this plant to be of the same genus with the Simarac of Aublet, t. 65, and perhaps with his Polycarya, t. 66. The latter is the Stephanium of Schreber, of which we shall speak in its proper place, and was sold later by Solander to Mufflera. They appear to us very near to Pseahoria, at least to some plants referred to that genus. They all belong to the Pentandria Monogaonia of Linnaeus, and to the seventh section of Juffieu's great natural order of Rubiaceae.

MAPPAUS, an officer among the Romans, who, in the public games, as thefe of the circus, and of the gladiators, gave the signal for their beginning, by throwing an handkerchief (mappa) which he had before received from the emperor, confid, prator, or other supreme officer then present.

MAPPA, in Botany, received its name from Schreber, in memory of Mark Mappi, M.D. formerly a physician and botanist at Stralsbourg, who in 1691 published a famous catalogue of the plants in the public garden of that university. He also published, as Professor, some inaugural dissertations on tea, coffee, and chocolate, and on the robe of Jericho. His Historia Plantarum Altiarcarum appeared in 1742, after the author's death, by the care of Dr. Ehrmann, of the same place. This is a quarto volume of 335 pages, with a few plates, dipped in alphabetical order. Mappi died in 1701, at the age of 69. Schreb. Gen. 806. Mart. Mill. Dict. v. 3. (Soraria; Aulib. Guian. 552. t. 219. Juff. 433. Lamarcq Illutr. t. 468.) Clafs and order, Polysandra Monogaonia. Nat. Ord. uncertain, Juff.

Gen. Ch. Cal. Pernath inferior, of one leaf, in five deep, roundish, concave, permanent segments, coloured on the inside. Cor. Petals five, roundish, spreading, scarcely longer than the calyx, supported by short claws. Stam. Filaments numerous, (about 60,) the length of the corolla, capillary, dilated upwards, inserted into the receptacle; anthers ovate. Fil. German superior, globot; flily cylindrical, inclosed; stigma capitate. Peric. Berry ovate, of one cell. Seed solitary, large, ovate, involved in a thick fiddic tunic.

1. M. sceanda. (Soraria guianensis; Aulib. Guian. t. 219.)—Found by Aublet on the banks of the river Sinemari, bearing flowers and fruit in May. The stem is shrubby, with tuberculated branches, and twines about the trunks of trees, climbing to their summits, where the ultimate foliage becomes very long and pendant, bearing alternate, obovate, entire, smooth, fiddic leaves, six inches long at the utmost, and about half as wide, each supported by a footstalk an inch in length. Flowers white, in small, lax, axillary or lateral, corysnbo-calis clustered. Stamens about 60, according to Aublet's French description, which is always the most authentic: the Latin one, made it from other hands, says 632, an error which Schreber has ineffectually adopted. Berry red, the face of a cherry, crowned with the permanent flyle; its substance firm, fiddic, slightly acid. The tunic of the fruit is thick, white and fiddic. Permanent calyx fiddic and deep red.

MAPRONEA, the barbarous name in Aublet, who gives no account of its meaning or derivation, for a small tree of Cayenne, the Aegopriuon betulina, Linn. Suppl. 63.

413. Sm. Plant. t. 43. (Maprouena guianensis; Aubl. Guian. 805. t. 342.) See Aegoprius. We beg leave to correct one of our predecessors as to the origin of this name. It seems to be formed of a, a goat, and no, dung, in allusion to the shape of the fruit, which resembles the dung of goats or sheep. It ought rather therefore to have been Aegoprius.

MAPUNCO, in Geography, a town of Africa, in the kingdom of Angola.

MAQUALBURY, a river of Africa, which runs into the Atlantic, about 10 miles S.E. from the Scherbro. N. lat. 6° 50'. W. long. 15° 50'.

MAQUEDA, a town of Spain, in New Castile; 32 miles S.W. of Madrid.

MAQUEDAPA, a town of Mexico; 15 miles S.W. of Chiapa.

M. In. Rural Economy, a provincial term signifying a river or small lake.

MARA, in Mythology, a name of the Hindoo god of love, Kama, which see.

MARA, Madame, in Biography, born Schmelting, a native of Germany, arrived in England in 1765, with her father, during childhood, when she acquired a very correct pronunciation of our language, which is never done by foreigners but in youth. She could not be more than nine or ten years old when she came hither, yet she was then a notable performer on the violin; and as there were several children at that time in London of uncommon proficiency on different instruments, a concert was made for them at the Little Theatre in the Haymarket, in which they felicily displayed their talents; Baron and Schmeling on the violin; Mrs. B. on the harpsichord, and Coretto on the violincello.

After staying two or three years in England, and, we believe, performing on the violin in different parts of the kingdom, to the great surprize and pleasure of the lovers of music, she returned with her father to Germany, and we heard no more of her till the year 1771, when we received from a very intelligent musical friend at Hambro' the following letter.

"At Berlin there is now a German opera finger, that allures every one who hears her. People who have been a long time in Italy, and who have formerly heard Paulina, Cuzzon, and Aricaut, afford me that she surpasses them all. Indeed, when I heard her at Leipsie, two years ago, I was enraptured. I never knew a voice so powerful, and so sweet at the same time; she could do with it just what the pleasured. She sings from G to E in allegro with the greatest ease and force, and both her partiture di voce, and her volatility are, in my opinion, unrivalled; but when I heard her, she seemed to like nothing but difficult music. She sung at sight, what very good players could not play, at sight, on the violin; and nothing was too difficult to her execution, which was easy and neat. But, after this, she refined her taste, informing me that she was able to perform the part of "Tibé," in Hail's opera, which requires simplicity and expression, more than volubility of voice; and in this she perfectly succeeded, as Agricol, the translator of Toft's "Arte del Canto," and our best singing master in Germany, affirms me. The king of Prussia, a great connoisseur, was astonished at it. Her name is Schmeling, she is about twenty-four years of age, and was in England, when a child, where she played the violin; but she quitted that instrument and became a finger, by the advice of English ladies, who disliked a female finger." The next year, in travelling through Germany, this account was fully corroborated by several intelligent musicians who had heard her; and previous to our arrival at Berlin, we were informed that his Prussian majesty,
M A R A.

majesty, who, at first, with difficulty was prevailed on to hear "a German finger," exclaimed, "I should as soon expect to receive pleasure from the neighing of my horse." However, after his majesty had heard her sing one song, he was fain to have fought among his manuscript music for the most difficult airs in his collection, in order to try her powers, as much as to gratify his own ear; but she executed, at sight, whatever he commanded her to perform, in all styles, as well as if she had practised each of these compositions during her whole life.

When, afterwards, we had an interview with her at Berlin, we find in our journal the following account of her person: "She is short, and not handsome, but is far from having any thing disagreeable in her countenance; on the contrary, there is a strong expression of good nature impressed upon it, which renders her address very engaging. Her teeth are irregular, and project too much, yet, altogether, her youth and smiles taken into the account, she is rather agreeable in face and figure."

We found that she had preferred her English; indeed she sometimes wanted words, but having learned it very young, the pronunciation of those which occurred was perfectly correct. She was prevailed upon by a friend, who had procured us this interview, to sing soon after our entrance. She began with a very difficult aria di bravura, by Traetta, which we had heard before at Mingotti's in Munich. She sung it admirably, and fully answered the great idea which we had formed of her abilities, in every thing but her voice, which was a little cloudy, and not quite so powerful as we expected. However, she had a slight cold and cough, and complained of indisposition; but with all this, her voice was sweetly toned, and the sung perfectly well in tune. She has an excellent thake, a good expression, and a faculty of executing and artfuling rapid and difficult divisions, that is astonishing.

Her second song was a larghetto, by Schwanenburg, of Brunswick, which was very pretty in itself; but she made it truly delightful by her taste and expression; she was by no means lavish of grace, but those she used were perfectly suited to the style of the music, and idea of the poet.

After this, she sung an andante, in the part which the had to practice for the ensuing carnival, in Graun's "Merope; " and in this acquitted herself with great taste, expression, and propriety.

In a second visit to Mademoiselle Schmelting, she favoured us with several songs of uncommon rapidity and compass; her powers in this particular were truly admirable; but we found that she was frequently compelled to abate those powers by the airs which were given her to execute, in which she had passages that degraded the voice into an instrument; indeed such as a player of taste would be ashamed to execute an instrument.

Breaking a common chord into common arpeggios of no meaning, such as may be seen in the second allegros of Corelli's first and third folios, does not seem to reflect much honour, either upon a composer or performer. Geminiani, in transforming these folios into concertos, omitted these violin folseggios or exercises for the hand in private practice.

We found in this second visit to Mademoiselle Schmeling, a little want of brightness in the middle of her voice; and we then imagined it possible for her to fill to improve in singing adagios, though not in the execution of allegros. She did not then indeed seem to be placed in the best school for advancement in taste, expression, and high vocal finishing.

In the spring of 1784, Mademoiselle Schmeling arrived in England under the name of Mara, having been some time married to a performer on the violinola, in the service of prince Henry, brother to the king of Prussia, with whom she was connected in 1772, when we saw her at Berlin. There had been a correspondence opened between this admirable finger and the proprietors of the Pantheon, who wished much to engage her as a successor to the Aguado, but the king of Prussia would not let her quit his capital; and after she had executed an article which engaged her in the service of the Pantheon, and money had been remitted to her to defray the expenses of her journey, on his Prussian majesty's return from Rome, that she intended to quit his service à la feurde, he had her arrested and thrown into prison; and it was with extreme difficulty that she contrived, by means of our ambassador, Sir James Harris, to let the proprietors of the Pantheon know that she could not fulfil her engagement, and entered them, for God's sake, not to write to her any more. She, however, very honestly returned the money that had been advanced to her by the proprietors of the Pantheon.

At length, however, she obtained her diffusion, and engaged herself to perform six nights at the Pantheon; 1784 was not an auspicious year for the Pantheon. The dissolution of parliament and general election happening soon after her arrival, the audiences to which she sung were not very numerous, nor had her performance the effect it deferred, till the sung at Weltinginer Abbey; where she was heard by near three thousand of the first people in the kingdom, not only with pleasure, but extacy and rapture.

In the opera regency, after a bankruptcy, being settled, and Sir John Gallini recovered with the love of judging himself and others, "Didone Abbandonata," a patricious serious opera, was brought out previous to the arrival of Rubinelli, and had considerable success. But this must be wholly ascribed to the abilities of Madame Mara, who sung on our opera stage for the first time. Indeed, she was so superior to all other performers in the troop, that she seemed a divinity among mortals. The pleasure with which she was heard, had a considerable increase for her choice of songs, which, being in different styles by Sacchini, Peccon, Mortellari, and Gazzaniga, were all severally encored during the run of the opera; a circumstance which we never remember to have happened to any other singer, except Manzoli.

The manner in which she sung Handel's oratorio music in Weltinginer Abbey, and continued to sing it elsewhere, had gained her more applause and favour with the English public, than her astonishing execution.

This great vocal performer, except a few short excursions to the continent in France, continued to reside in England, and to enjoy the favour and admiration of the public, till the latter end of 1822; when she returned to Germany, and is said to have been received at Berlin, and heard with the same enthusiasm which she had excited 30 years ago. We have done ample justice to the talents of this extraordinary finger on many occasions. But we cannot quit this article without a few discriminative reflections, not to injure or extend her fame, but to manifest our sincerity as well as candour in drawing characters.

We have never been able to discover of whom the Mara, after quitting the violin, learned to sing; but we are inclined to think that it was not of an Italian matter; and that if it was of a German, it was of an instrumental performer. Perhaps the whole of her study in singing was to imitate the ingredients of great performers. In the tuneful flute in which she had traveled with her father, she could have had no opportunities of hearing fine Italian singing by performers of the first order. And it has often been observed by those accustomed to exquisite Italian singing, that her cadences, expression, and execution, however excellent, favoured more
of instrumental perfection than vocal. Her recitative was not spoken with Italian energy; and when we consider what a good performer she had been, early in life, on the violin, and what a good player the afterwards became on the pianoforte; or, in other words, what an excellent musician the was, and with what facility she could execute all kinds of difficulties, we have been often surprised at the little novelty, variety, and refined taste, there was in her clothes. Indeed it will perhaps be said, that she brought here, and left behind her, in this country, fearfully a new vocal passage; as all other great singers, such as in our own memory, Mingotti, Ehi, Manzoli, Pachierotti, Rubini, and Marchesi had done; but all these remarks only confirm old proverbs, that neither human nature, nor human art, are ever to be perfect, and that we cannot have perfection in one and the same individual.

Maracaibo, a mountain of Maracaibo, near the Straits. N. lat. 1° 55'. E. long. 104° 30'.

Maracaya, a town of Turkellia, on the Sirr; 130 miles S.S.E. of Andugar.

Marabá, a town of Peru, in the province of Segallia; 120 miles N.N.E. of Zarang.

Maracay, a town of Arabia, near the Red sea, formerly a sea-port, but since the harbour has been filled up, most of the inhabitants have settled at Loheia; eight miles N. of Loheia.

Marabona Bay, a bay on the N. coast of Jamaica. N. lat. 18° 31'. E. long. 77° 21'.

Marabo, an inlet of the harbour of Alexandria, in Egypt, situated at its western extremity, commanding one of the channels, and separated from the continent by a range of rocks 140 yards in extent. The length of the inlet is not above 300 yards, and its breadth 150. The French, during their abode in Egypt, constructed a strong regular fort on this inlet round a tower, which was formerly a mosque.

Maracaibo, a small island in the Atlantic, near the coast of Guiana. N. lat. 2°. W. long. 51° 26'.—Aloś, a town of South America, in the government of Caracas; 50 miles S.W. of Leon de Caracas.

Maracaguaco, a branch of the Amazons' river, which joins the main stream; 40 miles S.W. of Pauxis.

Maracaibo, in Zoology. See Felis vincina.

Maracaybo, a province of South America, in the government of Caracas, surrounding a lake of the same name, bounded on the N. by the Caribbean sea; on the E. by Venezuela; on the W. by the government of Rio de la Hacha, dependent on the vice-royalty of New Granada; and on the S. by Barinas, and the kingdom of Santa Fé. This province covers a small extent from E. to W., but stretches more than 100 leagues towards the south. The soil of Maracaibo is, for a certain distance from the capital, ungrateful; on the eastern bank the lake is dry, unhealthy, and unfruitful. On the west bank of the lake, the land does not begin to be fertile at more than 25 leagues to the south of the city. All that lies to the south of the lake may live with the belt lands of South America. The population is estimated at 100,000. In this province are 300 European regular troops, 100 artillery-men, and 810 militia.—Aloś, a town of this province, lying from N. to S., communicating at one extremity with the sea. Its length from the bay to its most southern reefs, is, according to Oviedo, 92 leagues, its greatest breadth 35, and its circumference upwards of 150. This lake may have owed its formation to the flow and gradual excavation occasioned by numerous rivers, which, flowing from E., W., and S., here terminate their course. It is easily navigated, and carries vessels of the greatest burden. All the produce and provisions of the interior, intended for consumption or shipping at the town of Maracaibo, are conveyed by the rivers which discharge themselves into this lake. Hurricanes are not unfrequent in this lake, and yet there is always a kind of undulation on the surface of the water, so that, on particular occasions, its waves are sufficiently agitated to bury under them the canoes and small craft. At this time the waters of the sea force themselves into the lake, and give a brisk salt water thus far as Maracaibo; but at all other times it is fresh and fit for drinking as far as the sea. The baths which are used here, and which the intense heat of the country renders indispensable, are attended with very salutary effects. All the different kinds of fish furnished by the rivers of South America abound in this lake. To the N.E. of it, in the most barren part of the borders, and in a place called "Mena," there is an inexhaustible mine of mineral pitch, which, mixed with eel, is used for gravel vessels. The bituminous vapours issuing from this mine are easily inhaled, and in the night luminous coruscations are visible, which resemble lightning, and which are denominated the lanterns of Maracaibo, because they serve for a light-house and compass to the Spaniards and Indians who navigate the lake. The fertility, and also the noxious atmosphere of the borders of the lake, discourage culture and population. The Indians are so unhealthy, that they prefer dwelling on the lake itself to taking up their abodes on its borders. The Spaniards found on this lake several villages, built without order, and without apparent design, but with solidity. Hence they gave them the name of "Venezuela," a diminutive of Venice, which they have not retained, but which has since been applied to the whole province. Four of these villages remain, and the Indians who inhabit them have a church, which is under the care of a curate, who is entrusted with the charge of administering spiritual aid among the aquatic Indians. The great resource and chief employment of these people is the hunting of wild ducks, which they take by thrashing their heads into empty calabashes, closed so that they may see without being seen, and swimming to the place where the ducks are, which they lay hold of by the legs, before they are alarmed, and tying them to their belts, thus bring them to the shore.

The goodness of the soil at the western part has induced French and Spaniards, regardless of the infalubrity of the air, to fix their habitations there, in order to raise cocoa and provisions. These settlements, which were very much dispersed, were not able to command sufficient funds for laying the foundation of a village, much less of a city. There is but one chapel, placed nearly in the centre of the scattered habitations, and a curate for performing divine service, and administering the sacrament. The southern extremity of the lake is uncultivated and uninhabited. The northern part is quite as hot as the other parts, but much more healthy.—Aloś, a town or city which is the capital of the province of the same name, situated on the left bank of the lake to the west, at the distance of about six leagues from the sea, on a sandy soil, and in a hot dry climate, chiefly experienced from March to October; but in July and August the air seems to proceed from a furnace. The only antidote is to bathe in the lake; and endemical disorders are unknown. The thunderstorms and torrents are here terrible; and if they fall, earthquakes certainly follow. Although many houses are built of lime and sand, and with considerable tafe, most of them are meanly covered with reed, and there is no water but that which is derived from the lake, which is fishous, though not unpleasant, especially in March and April, when the strong breezes impregnate it with sea-spray. The principal part of the city is on the shore of a small gulf, one league in depth, which
which forms the lake towards the west. The other part is
to the north, in the neck of the lake, which at this place is
two leagues wide, whence it begins to extend towards the
south. The point where the city begins is called "Mar-
acaibo Point," where the gulf commences "Point
Arica," situated almost opposite to "Point St. Lucia."
According to an enumeration in 1801, there were about
23,000 inhabitants; and they were visited by the Spanish
refugees from St. Domingo. With this accession, the pop-
pulation was raised to about 24,000 persons, who are dis-
tributed into four claffes; the nobility, consisting of about thirty
families; white planters, composed of Europeans or Creoles,
who apply to agriculture, navigation, commerce, the filleries,
&c. and live comfortably; slaves and freemen, who execute
tall kinds of trades, joiners, tailors, shoe-makers, carpenters,
masons, and smiths. Theslaves do not exceed 5000. The habit
of failing on the lake encourages the spirit of navigation,
and many of the natives become iamen. Even in the dry Sa-
vannas they contrive to feed numerous herds; and the youth
are celebrated for intelligence and ingenuity; but the in-
habitants are rather noted for want of probity. The women
are fond of the harp, which refounds in the streets in the
evening. In their youth they are distinguished by their
modesty, and, when married, are faithful affectionate wives
and excellent mothers, directing their attention to domestic
cares, and the education of their children. Here is only one
church, aided by a chapel of cafe, and a convent of
Franciscans. At Maracaibo they adore a virgin, which
bears the surname of "Chiquinquira," which was the name
of a village in the kingdom of Santa Fe, where she made
her first appearance. Her passion is to paint herself on
diff-clouts, and in the midst of it. A temple, on the dis-
covered of her in 1556, was dedicated to her; and, as the
fabulous tradition reports, a fountain rose under the altar
where she was placed. She communicated to its waters
miraculous virtues, which have given to her permanent reputa-
tion among the Spaniards. The image of this virgin is
placed in the chapel of cafe of St. Juan de Dios, where she
is invoked by all mariners as their imaginary protecttres.
The foundation of this town was laid, in 1571, by captain
Alonso Pacheco, an inhabitant of Trujillo, under the name
of New Zamora, now known only under that of Maracaibo.
At the entrance into this port is a bar of quick-land, ten or
fifteen feet under water, which excludes large vessels, and
admits small ones with difficulty, and not without the conduct
of a skilful pilot. As soon as the bar is cleared, there is
plenty of water and a good harbour, which is defended by
three forts. The manufactures and merchandise that are
brought hither from places near the lake are put on board
Spanish ships that come hither to purchase them. Maraca-
ibo is the seat of a governor, who enjoys the same salary,
and exercises the same functions, as the governor of Cumaná.
This place is very convenient for ship-building : 270 miles
E. of Carthagena. N. lat. 10° 30'. W. long. 71° 46'.
Depons: Traveis in South America.

MARACAIBO, a town of Barif, in the government of
Para, on a river which runs into the Atlantic; 80 miles
N.N.E. of Para. S. lat. 0° 27'. W. long. 49'.

MARACAIBO, in Ornithology, the name of a bird of the
parrot-kind, but larger than the common species, and covered
all over with blueish-grey feathers. It is very common in
the Brails. See Psittacus Centurus.

The natives also call another bird of the parrot-kind by
the same name, which is of a fine green on the head, neck,
and back, but the crown of the head looks a little blueish;
the tail is mixed of red and a blueish-green; the under part
being red, as is also the under part of the wings; at the
origin of each wing, it has also a red spot; and on each side
of the head a brown one. The noise this bird makes is ce, ce,
etc. See Psittacus Sciriops.

MARACANDA, in Ancient Geography, a very consid-
erable city of Asia, and capital of Sagdiana, which was cap-
tured by Alexander the Great, who, after leaving a strong
garrison there, burnt and laid waste all the plains. See
SAMARCA.

MARACAPA, in Geography, a town of South America,
and capital of a district of the same name, in the province
of Cumana; 42 miles W. of Cumana.

MARACAXAO, in Ornithology. See Fringilla
Melba.

MARACAY, in Geography, a beautiful new village of
South America, in the government of Caracas, situated in
the rich vales of Aragoa, 40 miles S.W. of Caracas; fa-
mous for the culture of chocolate. The industrious in-
habitants, mostly Bífayans, have been computed at more than
8000, and the vicinity is crowned with numerous plantations
of cotton, indigo, coffee, and grain.

MARACCI, Lewis, in Biography, a learned Italian, was
born at Lucca in the year 1612: in his youth he applied
himself most diligently, and with great success, to the study
of the eastern languages, particularly to the Arabic. His
skill in this tongue led to his appointment to the professorship
of Arabic in the college of Wisdom. He was also elected
by pope Innocent XI. as his confessor, which mark of high
confidence and honour would have been followed by a car-
dinal's hat, but the humility of Maracci led him to decline
that distinction. He died in the year 1700, at the great age
of eighty-eight. He had a considerable share in editing the
"Arabic Bible," which was published at Rome in the
year 1671, in three volumes folio: he is known also for a
work which he printed in Padua but two years before his
death, entitled "Alcorani Textus Universus Arabice et
Latine," in two vols. folio. This version is accompanied
with notes, a refutation of the Mahometan doctrines, and
a life of the Pseudo-Prophet. The work, though not wholly
free from errors, is highly applauded by the learned. Mar-
acci was author also of "The Life of Father Leonard,"
the founder of the congregation to which he belonged, and
of numerous other pieces.

MARACU, in Geography, a river of Brazil, which runs
into the Atlantic, S. lat. 2° 40'. W. long. 45° 31'.

MARACURANUM, a town of Hindoostan, in the
circle of Circacle; 15 miles N.E. of Tickley.

MARAKA, in Ichthyology. See Salmo Marana.

MARAGA, MARAGA, or Murga, in Geography, a town
of Persia, in the province of Dorbeitzan; 30 miles S. of
Tabriz. N. lat. 37° 20'. E. long. 46° 22'.—Also, a town of
Egypt, on the left bank of the Nile, the environs of which
are said to yield the best wheat in Egypt; 6 miles S. of
Tabriz.

MARAGAL, a town of Persia, in Dorbeitzan; 42
miles S. of Tabriz.

MARAGHA, a town of Syria, in the Desert, where an
observatory was erected by order of Hulaku, one of the
defendants of Jenghiz Khan, and furnished with instruments
for astronomical observation; 75 miles E.E. of Aleppo.

MARAGNON. See Maranon.

MARAH, or MARRA, a town of Syria, in which the
Roman Catholics have a church, and the Greeks a church
and convent; 15 miles N.E. of Damascus.

MARAHIBUTS, or MARRIOUTS, derived from a word
which signifies a monk, or a man engaged to the performance
of his vow, denote Mahometan priests, who are dispersed
through various parts of Africa. Thofe of the Mandingo
nation
nation apply themselves, besides religious matters, to the study of physic, as far as it depends on mere experience, without entering into the investigation of the causes of diseases. They are also often called upon by the kings and chiefs to give their opinion in cases of law and equity. Most of them are well versed in the Arabic language of the Maurusian dialect, and they are the only people of letters among the blacks; for none of the black nations about Senegal and Gambia have even an alphabet, much less any writings in their own languages. The telling of charms is said to constitute the greatest part of their revenue; and the more reputation any one of them has acquired, the nearer is it said.

These charms usually consist in nothing but a few lines taken from the Koran, written on a little piece of paper, which, after being nicely sewed up in leather or cloth, are worn by the purchasers about their necks. They are designed to protect and defend them in danger; but as one charm has only the power of preventing them from one kind of danger, they are obliged to have many of them; so that many of the blacks are covered with them in different parts of the body; and they have such a strong faith in them, that when they are surprised in the night-time by an enemy, they will not take up arms for their own defence, though in the most imminent danger, till they have adorned themselves with these charms, and then they will meet him undauntedly. This faith in charms, however, is a corruption of the Mahometan religion; and the Moors, who live on the north side of the river Senegal, observing it in its purity, make no use of them.

The Marabouts of the black nations, as well as those of the Moors, are also the principal merchants, and the most opulent people among them; and the gum trade on the river Senegal is chiefly carried on by those of the Moors. The Marabouts are also the only people who can travel with any safety into distant kingdoms, which no layman can well do without running the risk of being made a slave. Their religious profession protects them everywhere; they are even respected among those nations who are not Mahometans; and they are considered by them as a godly and virtuous people, and men of wisdom. They make peregrines everywhere to the Mahometan religion, and are industrious in spreading it all over Africa. Some Marabouts of the Foulah nation who visit Senegal, are pretty well versed in the Old Testament, and are partly acquainted with the infallibles of the new one. The Marabouts reason very well on such subjects as they are acquainted with, but their manner, like that of the calumniators of that of adorning parables or similes in their arguments, which do not always bear the slightest resemblance to the case in hand; though they are very persuasive with such people as are not capable of investigating the points in which they differ from the case in question. Their conversation is instructive and pleasing. The Marabouts of the Moors are more learned and ingenious in every respect than those of the black nations. Phil. Trans. vol. lxxii. p. 90.

Mara', a town of Hindoostan; 45 miles S.W. of Allahabad.

Marajo, an island between the mouths of the Amazon and Para rivers, resembling in its form an oval and triangle; about 146 miles in its greatest length, and 120 in its greatest breadth.

Marajon, a town on the east coast of the island of Marajo; 24 miles N.W. of Para.

Marais, a town of Tunis, near the sea, with the remains of a small harbour.

Marakunda, a town of Africa, in the kingdom of Badelu.

Maraldi, James Philip, in Biography, a learned mathematician and astronomer, was born at Perinaldo, in the county of Nice, in the year 1665. It is not known where he was educated, but at the age of twenty-two we find him at Paris, pursuing his maturer studies under his uncle, the celebrated Cassini, to whom he implicitly resigned the direction of his pursuits. When Cassini found that the young man's advancement in science, his extraordinary diligence, and above all his accuracy, had qualified him to become an useful assistant in his astronomical labours, he, by the leave of the Royal Academy of Sciences, associated him with himself in making observations on the celestial bodies. He soon opened the way to celebrity, by important discoveries with regard to the planets, particularly with respect to Jupiter; he found likewise that the parallax of the planet Mars was less by one second, than had been determined by Cassini in 1672. He spent the whole of the year 1674 in observations on the planet Saturn, and showed how the disappearance of the ring, at that particular period, confirmed the theory of Huygens. He hallowed incredible industry in perfecting the tables of Jupiter's satellites, and found that the eclipses of these bodies were of different durations, even when the distance of their nodes was the same. He applied himself to the constructing a catalogue of the fixed stars, and by his long and accurate attention to this object, became so well acquainted with these bodies, that on being shown any one of them, however small, he could immediately tell to what constellation it belonged, and its precise place in the constellation. Maraldi would sometimes relax in his astronomical labours, and apply freely to objects of nature history, on which science he drew up a number of interesting papers, which were inserted in the different volumes of the memoirs of the Academy of Sciences, of which distinguished society he was a member. In the year 1700, he was employed by Cassini in prolonging the French meridian to the northern extremity of France, and had a very considerable share in that important undertaking. When his business was finished, he paid a visit to Italy, where the astronomers gladly availed themselves of his advice and assistance in making their observations. At Rome, on the invitation of Pope Clement XI., he assisted at the assemblies of the congregation then sitting in that city, for the purpose of reforming the calendar. He also took a part in constructing the great meridian line at the baths of Diocletian. While at Rome he had a fine opportunity of observing an eclipse of the fourth satellite of Jupiter, from which he was led to the conclusion, that its inclination is three minutes less than that fixed by Cassini. He returned to France in 1705, with a rich treasure of subjects in natural history, chiefly collected at Verona, which he presented to the Academy of Sciences. In 1718 he was employed, with three other academicians, in prolonging the French meridian to the southern extremity of that kingdom. Amidst his various labours the greatest part of his time was occupied within the walls of the observatory of Paris, where he was incessantly employed in astronomical pursuits, and in completing his catalogue. This last great work he did not live to finish; he died in December 1729, in the sixty-fifth year of his age. He is characterized as a man of great erudition, integrity, and purity of morals, and possessing an interesting simplicity of manners. He published nothing but papers in the transactions of the academy; these, however, are very numerous and very valuable, and are to be found in almost every volume that was printed between the years 1698 and 1730. Moretti.

Marambaya, in Geography, a small island near the coast of Brazil. S. lat. 23° 10'.

Mara-
The text is a historical description of various geographical features and events, discussing geographical locations such as Marana, Mano, and Marano, among others. It mentions historical events and geographical details, including the discovery of new territories, conflicts, and the role of explorers and adventurers. The text is rich in historical and geographical details, providing insights into the landscapes, cultures, and events of the time.
MARANON.

Quillabamba, Urubamba, &c. The Mantaro, or river of Juan, so called from the province it pervades, but by La Cruz erroneously flyled the ancient Maranon, joins the Maranon at 12° 6', and seems to propel the chief river towards the north-east, the course having previously been towards the north-west. The great river Pauca tambo, called by La Cruz Yuambari, joins the Maranon at 10° 45'; the Perene, which rises about two leagues from Tarma, runs through that town, and receives many streams from the heights of Bombom and Paeco, having joined it on the opposite side or west, at 11° 15'. From the confluence of the Perene to that with the beautiful river Pachita, at 8° 26', that is an interval of 2° 52', or 172 geographical miles, though by numerous windings inclosed probably to 500, the Maranon receives no less than 40 copious rivers; but more particularly two of prodigious power, the Pauca tambo already mentioned, and the Beni, the most remote springs of which lie east of the province of Sicasica, in about 19° of latitude. This river runs from south to north, with some inflections, receiving various rivers from the mountainous territory which it intersects, among the most remarkable of which is the Coroyoco, rising from the province of La Paz, and entering it on the east. The Beni, pursuing its course in 15° of latitude, throws off a branch, in an easterly direction, which enters a considerable lake, named Rogagado, that extends upwards of 10 leagues E.W., and of 5 N.S. From the eastern side of this lake rises an arm, which runs to the Mamori; and three others are thrown off in a northern direction, viz. the Yutay, the Tefi, and the Coari, which pursuing a north-east course, empty themselves into the Maranon. The Beni, having supplied this arm, flows to its incorporation with the Apurimac, which it enters with an aperture of half a league, and by the name of Para. Three leagues beneath the junction of the Pauca tambo, the Maranon is joined by a river, about two British miles, or half a Spanish league in breadth, of such force that the course of the Maranon is changed for a certain distance, and bent towards the chain of the Andes. This river, however, wide and powerful as it is, is only a branch of the grand river Beni, already mentioned. Indeed it has been queried whether the Beni or the Apurimac be the principal stream forming the Maranon. The source of the Beni, near Sicasica, is about 200 farther to the south than that of the Apurimac, but as its course is far more direct, the actual length of the navigation bears no comparison with that of the Maranon, which at this junction acquires the name of the Grand Para or Para. The navigation of the Beni might conduct the adventurer to the mines of Poto, and that of the Apurimac to Cuco and Lima. At 8° 26', the Pachita joins the Maranon. The Pachita is esteemed the most beautiful of all those tributary streams: it rises in 10° 45', first running east, then north, and in the early part of its progress is called the Pozuez, especially at its confluence with the Mayo, where it forms a noted haven, whence there is an open navigation to the Maranon. The next remarkable stream that joins the Pachita is the Piachiz. The course of the Maranon here varies from due north to north-east; so that the map of La Cruz must be erroneous in the great westerly inclination of its course, thereby approaching the Gualaga too near, by one-half. The Agayara also joins the Maranon from the west, at 5° 35'; the Manoa or Cusniabatay, at 7°; the Sarayacu, at 6° 45'; the Tapichi or Canepocachi, opposite to San Regis, at 4°, which latter seems also to communicate with the Tunguragua. This Tunguragua, Lauricocha, or Jefuitic Maranon, falls into the Maranon at 4° 55', where the latter is divided into three branches, the chief of which is not less than 55 fathoms in depth. The course of the Maranon now turns to the east. The true Maranon, or Ucayalí, as it is also called in part of its course, is the most important of all the streams which descend from the grand chain of the Andes. In 1794 it was explored by Father Girival, who navigated it from its junction with the false Maranon to its confluence with the Pachita, and found it of a serene current, and abounding with fish, while animals of chase swarm on the shores. The savage tribes on this upper river are generally pacific, and seem to speak dialects of the same language. From its junction with the river Beni to that with the false Maranon it is navigable for large vessels more than 400 leagues, and in the course of 300 leagues presents 132 islands. The true Maranon, or Ucayalí, is navigable at all seasons. The first Portuguese navigation that occurs is Capiata, and the next San Pablo. Loreto, a Spanish fortres, lies at the distance of 12 leagues from Sapatinga; from which latter Pevas, a Spanish village, 1674 leagues, Napo 164, Tiquipoy 155, Omaguas 154, the junction of the Ucayalí 166, the village of San Regis 184, the mouth of Ururanas 224, and the mouth of the Gualaga 234.

See GUALAGA.

The banks of this large river are generally crowned with vast forests of lofty trees, among which are many of a rare and medicinal nature. Serpents of prodigious size are found in the marshes, and alligators are also common. It seems certain, from the disquisition of Condamine, that some female warriors still exist toward the north of this great river. Near its mouth the Bore rises from 12 to 15 feet in height; and the noise of this irruption is heard at the distance of two leagues. This effect, called "pororoca," is chiefly observable towards the cape del Norte, on the mouth of the Arayona. See BORE.

The succcessive voyages of Father Girival are rendered interesting, not merely by his having explored the Ucayalí or genuine Maranon, but by the account he has given of the different tribes of Indians who inhabit the adjacent territory. Embarking on the lake of the great Cocama, he proceeded to Omaguas, at the confluence of the Maranon and Tunguragua, commonly called St. Joachim, as distinguished from St. Pablo, or St. Paul de Omaguas, one of the first Portuguese settlements at the linear distance of about 3', or 180 geographical miles to the E. Having two canoes with 14 Omaguas Indians, robust and dextrous rowers, he soon passed from the Tunguragua into the Maranon, which he ascended with resolute and laudable perseverance, though he sometimes met with little fleets of canoes filled with Indians of unknown tribes, whom he terrified and escaped by his prudence. The "Conibos" will employ a whole year to hollow out a canoe from one tree, 16 or 20 yards in length, and from five to seven quarters broad, which they accomplish by means of sharp flat stones and fire. The poop is square, and the prow drawn to a pyramidal point. Among their slaves were some of the Mayoruna tribe, who dwell towards the sources of the river Tapiqui, and are called Barbudos, because their beards are as long and abundant as those of the Spaniards; but they are believed to be descended from Spanish solders, scattered in these forests in consequence of a former expedition. After a long series of navigation, they appeared on the W. a chain of mountains, running S.E. and N.W. Two days after they arrived at the little settlement of Saraícu, among the "Panos," and soon after reached the habitation of Anna Rofs, an Italian lady, educated at Lima, who greatly lamented the tragic death of the missionaries in 1767, committed by the "Chapeos," who had been severely chastised by her nation. Continuing the ascent he reached the river Manoa, also called by the Indi-
M AR A N O N.

Their ruling passion is war, and it is the business of the whole tribe, presided by the cazique or intended general. The tobacco tubes are lighted; the jars of "mazo" pafs round; and as soon as drunkenness begins, this important subject becomes the matter of deliberation: the first and moft solemn question being, "with what nation shall we go to war?" And the next is, "what fhall be the caufe of quarrel?" The caufls are generally fome petty robbery or offence; and the weakest tribe is generally fecled as the moft convenient enemy. When the expedition is refolved upon, the "moans," or priests of the evil Spirit, take charge of their defign, and treat them with fuch abfufition and artificial horrors, that at the end of fame days they come forth rather dead than alive. These favages impute all fucces in war to the evil Spirit, and carefully conceal from their deity their proceedings on fuch an occasion. Hence the "moans" are held reponsible for the refult of the expedition; and if it be adverfe they receive a thousand maledictions, and are beaten almost to death, because their prayers to the evil Spirit had not been acceptable. As their petty warfares are inexpensive, their villages, or large house, are prepared for defence; being conftrued in the form of a creffent, with the convex part towards the wood, and with one door towards fome hill and another to a plain. When the enemy attack at one door a party oppofes; while the others turn the wings of the house, and attack the foe on the plains.

Father Girval, in his second voyage 1791, entered the mouth of the Ucanal, or true Maranon, and though accompanied by any fowler, or white perfon, he was received by the favages with great cordiality, though he was afraid of encountering the "Caibos" on the eastern shore, who are reputed the moft ferocious tribe in those regions. The chief navigators of this part of the Maranon are the "Conibos," who are more humane; and the found of their rude flutes or cornets is the signal of peace and hospitality. Canoes of the "Panos" afterwards appeared; and the Father arrived at Sanaicau with a bark and 60 canoes of friendly favages. The cazica, Anna Rofa, conducted the procifion to a little convent which he had founded, and the Indians obeyed her orders with great punctuality. A tribe called the "Piro" inhabit the borders of Maranon, in the latitude of Torna, being about 20 days navigation from Sanaicau or the Manoa. He found abundance of cinnamon trees, and began to inculcate the natives in its cultivation, hoping that this precious spice would soon become an effential article of commerce. This settlement was thought of importance, as it prevented the Portuguese fhips from purifying their excursions on the Maranon; and with the fort on the Mayo, included the "Pampas del Sacramento" on both fides, fo as to render it a decided Spanifh provifion store. The "Panos" and "Conibos," and even the "Chipeos," who had murdered the firft millonaries, began, it is faid, to hew fome defaption for embracing the faith. Some "Piros" were exported from the vicinity of the Mantaro, and the frontiers of Guanta and Jauja, paffing in their canoes on the Maranon; but the "Caibos" near the Mayo, and on the banks of the delightful Pachita, a ferocious race, were fearfully expected to become amicable; having no intercourse with any other nation, and never leaving their own country, as they have no utensils for making canoes. They surprife and kill any strangers whom they find within their boundaries; and having cooked them with great care, eat them with correlponding comfort, fo that a traveller rarely returns to publish any account of foreign parts. These favages form the only obstacles to impede the navigation from Manoa to Mayo; but a few regular troops would easily extirpate their irrelifable tigers. Of the million-

Maran, Fals or Jefuit's, called by the natives Tunguragua, and also Lauricocha, a river of South America, which rises from the lake of Lauricocha, about eight miles to the N. of Pafco, and after pafting the Pongo, becomes navigable till it falls into the Ucaial or true Maran. We may here observe, on the authority of Father General, the reasons alleged by thofe who affign the meffure to the Ucaial. In the firft place, its fources are far more diltant than thofe of the Tunguragua, or pretended Maran of father Fritz: fecondly, the Beni, Pascantambo, and the Apurimac, are navigable up to a latitude where the falfe Maran has no meffure: thirdly, becaufe the Ucaial, far from being inferior in the quantity of water, is on the contrary fmoother, and forces the falfe Maran out of its coure: fourthly, becaufe all the ancient historians of the kingdom have acknowledged the Apurimac as the genuine Maran; fifthly, becaufe, till the year 1587, the very name of Ucaial was unknown, that river being called Apoparu, i.e. the great Paro, which is the name also given by the natives to the Maran, or the river of Amazons, after it is joined by the pretended Ucaial. In the far above-mentioned, a law-fuit arose between the Francisians of Lima and the Jefuits of Quito, for the village and millions of San Miguel de los Conchos. The Royal Audience demanded maps in order to determine with greater certitude; upon which father Fritz drew the map, which was afterwards engraved at Quito in 1707, and in which the Tunguragua is filyed the Maran, and the Paro is ridiculoufly called "Ucaial," a word, which merely signifies a confuience, and fpecially applied by the tribe of the Maynas to that of the Paro and Tunguragua: whence originated the error of father Fritz; while father Acuna affifted, with equal boldnefs, that the Napo was the Maran! The great credit of the Jefuits led people blindly to follow the nomenclature of father Fritz. Upon the whole it is sufficiently manifefl, that the great river Maran is that denominated the Ucaial by a mere manufon of the Jefuits, in oppofition to the moft palpable facts and the ancient hislory, traditions, and prefent accounts of the natives; and that the river Ucaial or Apurimac ought to retain to its very fource the real and juft appellation of the Maran: while to the falfe Maran, in fact a tributary flream, and recent appellation confedently erroneous, whether arifing from artifice or miftake, the ancient name of Tunguragua ought to be re-flored. This new Maran, Tunguragua, or Lauricocha, was navigated by Condamin from near the town of Jaen, where it begins to be navigable; thence pafting N. E. it arrives at the exterior ridge of the Andes, which it clieves at a pafs called the Pongo, a word which in the Peruvian language signifies a gate. This sublime scene defpays the Lauricocha confined between two parallel walls of an almofl perpendicular rock. From a breadth of 250 fathoms the river is here contracted to 25; but the rapidity is not ex- treme. and a raft paffes the two lages in about an hour. Pinkerton's Geog. vol. iii.

Marans, a town of France, in the department of the Lower Charente, and chief place of a canton, in the district of Rochelle; fitted in the middle of fat marshes, on the Sevre, about fix miles from its mouth. The trade of the inhabitants is confiderable in fat, malt, corn, and meal; 12 miles N. N. W. of La Rochelle. N. lat. 46° 18'. E. lang. 0° 54'.

Marant, or Amaranth, a town of Peru, in the province of Adiribitza, containing 2500 houfes, each of which has a garden, situated near a river, and watered by canals. Cochinchina is found in the neighbouring. Tradition reports, that Noah was buried here; 50 miles N. of Tabris.

M AR AN T A.

yard high, branched, slender, finely hairy, leafy, rather knotty at the joints, dying down to the root every year. Leaves alternate, solitary at each joint, with long, sheathing, ribbed, somewhat hairy footstalks; ovate at their base; lanceolate or tapering towards the end; entire, with one rib and numerous transverse parallel veins; paler and somewhat hairy beneath; each about four inches long. When dry they are involute, marked, on the upper side, with fine streaks parallel to the veins, and on the under, with equally fine transverse corrugations, contrary thereto. 

Paniculate terminal, long, lax, and spreading, their flalks flender, tumid and hairy at the base, furnished at every ramification with a solitary, long, linear, narrow, ribbed, at first sheathing, bractea. Germen somewhat hairy. Calyx green, smooth. Corolla white; its tube about half as long again as the calyx; lip above half the length of the tube, its segments separate to the base, obovate, slightly emarginate. Fruit nearly globose and equal, with three oblate angles, the size of a small currant, the surface corrugated when dry.

2. M. gibbon. Gibbous-fruited Arrow-root.—Stem branched, shrubby, perennial. Leaves ovate, taper-pointed, smooth. Flowers panicked. Germen silky. Fruit gibbous at one side.—Native of Barbadoes, from whence it was sent by the Earl of Seaforth, when governor of that island, to the botanical garden at Liverpool. The curator, Mr. Shepherdt, favoured us with a fresh specimen, flowering in November, 1808. The latter observes, that the kind does not die down in winter. In general appearance this much resembles the foregoing, but the leaves are quite smooth, except the kind which combines them with their footstalks, which is, as in the former, very hairy upwards. The flowers are smaller; their germens beautifully silky, with dense silky hairs, though the bract below, and calyx above, are perfectly smooth and naked. All the fruits we have seen, five in number, were so gibbous at one side as to be semi-globose. They lose their pubescence in ripening. A plant was raised from the seed of this species, ripened at Liverpool.

3. M. fukwatica. Wood Arrow-root. Roscoee Tr. of Linn. Soc. v. 8. 340.—Stem much branched, shrubby, perennial. Leaves ovate, acute, smooth, with a hairy central line above. Flowers panicked. Germen hairy upward.—This is likewise sent from Barbadoes to the Liverpool garden, by lord Seaforth. It flowers late first: the leaf, and had not in 1808 thrown any sign of forming fruit. The kind is hard and knotty, somewhat in the style of a bamboo. Leaves numerous, about two inches long, ovate, scarcely taper-pointed, smooth, except a confluent hairy line, close to each side of the nerve, above. They are striated above and below, and in this last, exactly as in M. arundinacea. The knot between the leaf and the footstalk is thick, short, hairy upwards. Flowers few and small. Calyx-leaves broader, and not half so long as in either of those before mentioned, being quite elliptical. Corolla not twice the length of the calyx. Germen clothed in its upper part only, with a few long white hairs, which appear soon to fall off.

4. M. Tonchat. East Indian Arrow-root. Willd. n. 2. (Donax Arundinatum; Leveil, Cochinch. 11. Arundatrum, vet Tonchat Seytan; Rumph. Amboin. v. 4. 22. t. 7.)—Stem branched, shrubby, perennial. Leaves elliptic-ovate, pointed, smooth. Flowers panicked. Germen silky. Fruit globose. Corolla five times the length of the calyx.—Native of woods, plains, and vales in the East Indies, from whence it was brought us by lord Viscount Valentia. Rumphius says it is more plentiful in Cera and Celebes, than in Amboyna. Loureiro gathered it in the woods of Cochinchina. (See Donax.) The kind is eight feet high, shrubby, hard, round, smooth, and solid; simple and naked in the lower part; branched and leafy above. Leaves broad-ovate, with a small point, scarcely three inches long in our dried specimens; Rumphius describes them as a span in length, and the breadth of five or six fingers. They are smooth, with many lateral veins, but not striated lengthwise or transversely as in the three foregoing. The knot at their base is cylindrical but short, somewhat hairy, sometimes curved. Panicule erect when in flower, drooping in fruit. Bracteae large and long. Flowers white, considerably larger than any of the former. Calyx-leaves tapering from a broad base to the point, strongly ribbed, a quarter of an inch long. Tube of the corolla scarcely exceeding the calyx; segments of the outer limb above an inch long, linear; lip still longer, flaked, with broad dilated rounded lobes, whose number and position we cannot, from the dried specimens, ascertain. The germens is few and broad, very densely clothed with white silky down. Fruit, according to Rumphius and Loureiro, nearly globose, exactly agreeing with our generic description. This species is, as Ventenat has observed under M. arundinacea, very different from M. Tonchat of Auberget, which may be merely a variety of the first species; but this we have no means of determining.

5. M. lutea. Yellowish Arrow-root. Jacq. Collect. v. 4. 117. L. Kar. t. 201. Roscoee Tr. of Linn. Soc. v. 8. 339.—Stem branched, shrubby, perennial. Leaves ovate. Branches of the panicle somewhat spikèd. Bracteae ovate, imbricated, coloured.—Native of moist woods in the Caraccas. It flowered with Jacquin, in the flore, from June to August, ripening fruit in September and October. It has the tuberous creeping root, and general habit, of the four foregoing species. The kind is several, six feet high, perennial, branched, smooth, and shining. Leaves several, in two ranks from the root; those of the kind alternate, ovate, about a foot long and four inches wide; their footstalks about the same length. Panicule erect, of a few alternate zigzag branches. Bracteae two-ranked, imbricated, ovate, folded, about an inch long, each enfolding a two-flowered partial flalk, with a much smaller internal bractea. Calyx-leaves elliptical, of the same dirty or tawny-yellow as the bracteae. Corolla white; the lip three-lobed. Germen smooth. Coat of the fruit firmly adhering to the nut. Our account is taken from Jacquin’s works, but a specimen brought, we believe, from the Brails, by the late Sir G. L. Staunton, agrees with it, as far as we can examine.

6. M. gracill. Slender-spiked Arrow-root. Rudge Guian. 8. t. 3.—Stems simple. Leaves ovate, pointed. Spikes terminal, solitary. Bracteae imbricated, sheathing, cylindrical.—Native of Guiana, communicated by T. F. Forster, clq. This has the habit of a bamboo, except that the kind are simple, and only a foot high. They are slender, smooth, and leafy. Leaves near three inches long, light green, taper-pointed, rounded at the base, smooth, except a hairy line along the nerve on the upper side; their veins transverse, as in the other species, not parallel to the rib, as in the above plate; the knot at their base very slender, hairy on its upper side; sheath ribbed, smooth, dilated upwards. Spike solitary at the tops of the kind, about four inches long, thrall, erect, slender, cylindrical, acute, being closely enveloped in five, six, or more, cylindrical, imbricated bracteae, about an inch long, from each of which, in succession, sprang a couple of flowers, whose tube is very long, inclosed in the bractea; the outside of their calyx hairy; their lip, as far as we can discern, undivided.
7. *M. obliqua.* Oblique-leaved Arrow-root. Rudge Guian. 8. t. 2.—Leaves elliptical, oblique at the point, on very long footstalks. Spikes clustered. Bracteas crowded, sheathing, cylindrical. Found by Mr. Alexander Anderson in the West Indies, according to the Bankian herbarium. Mr. Rudge had it from Guiana. Of the form of the whole plant we are uncertain, but by our specimen it appears herbaceous, the leaves being radical, on footstalks two feet long, sheathing in their lower part, and crowned with a cylindrical, fearedly swelling knot, above an inch in length. The leaf itself is about a foot long, and fix inches broad, elliptical or somewhat ovate, terminating in a very short, oblique or lateral, curved point; smooth on both sides; the veins transverse, extremely numerous and close, five times as numerous as in Mr. Rudge’s figure. Spikes apparently terminal, three together, either accompanied by a sheathing-footstalk, leaf, as in the figure just mentioned, or by one common bracteas larger than the root, as in our specimen. Each spike is about a foot long, almost perfectly simple, slightly zigzag, slender, cylindrical, acute, closely enveloped in numerous, alternate, cylindrical, crowded, but fearedly imbricated, hard, downy bracteasabove an inch long, each containing two flowers. About half a dozen lanceolate cartilaginous bodies are seen projecting just beyond the point of each bracteas, looking like the anger of a gras. These appear to us the tips of a number of linear, membranous, internal bracteas, about three of which surround each flower, and which might be taken for the calyx, were they not inferred below the germen. There are also two or three broad membranous bracteas, external with respect to these, but inclosed within the common sheathing one. Of the real calyx or corolla our specimen gives no opportunity of judging. The germen appears to be turbinate, crowned with dense upright hairs. Style compressed, the length of the bracteas, with the proper insedent stigma of the genus. Mr. Rudge represents the corolla as about twice the length of the external bracteas, with a long slender tube, and a structure analogous to the preceding species. The lip, it seems, is undivided.

8. *M. spiralis.* Long-footed Spiked Arrow-root. Aubl. Guian. 4.—Leaves ovate-oblong or unequal-sided, oblique at the point, on long footstalks. Spike simple, solitary, on a long stalk.—Gathered by Aublet in a boggy forest in Guiana. One of his leaves was given by Sir Joseph Banks to the younger Linneus, who has, in his herbarium, accompanied it with a rough drawing of the spike of flowers, and a note in Swedish, saying he had “seen four leaves, all of the same strange shape.” These materials, though imperfect, are valuable, as Aublet has given no figure of this, any more than of his *M. Aromus, hamillus, or lutus,* about which therefore following botanists have been much in the dark. Our leaf of *M. spiralis* is a foot long and three inches broad, smooth and thin, with numerous principal, as well as intermediate, transverse veins; the base is rather unequal, and the two halves of the leaf upwards much more fo, one margi being curved, the other straight; the midrib running up perfectly straight till it reaches the former margin, when it turns suddenly into the very short lateral or oblique point. The footstalk is, perhaps, as long as the leaf, bordered or sheathing below; crowned with a cylindrical, finly downy knot, an inch long, where it joins the leaf. Spike erect, three inches in length, supported by a very long, round, simple, erect, naked stalk (which we may presume to be radical), and subtended by a large ovate sheathing bracteas. Each flower, or perhaps pair of flowers, appears also to have an appropriate much narrower bracteas, an inch long, and these bracteas are about ten in all, imbricated in several rows. Aublet says they are firm and coriaceous, and the flowers white.

9. *M. Allomia.* Lateral-tufted Arrow-root. Aubl. Guian. 3. (Nara kila; Rheedee Mahb. v. 11. 67. t. 34)—Leaves radical, ovate, acute, on long stalks. Head of flowers sessile, from a lateral leaf in the footstalk. We venture to adopt this species from Aublet, because the figure he cites in the *Horatius Malabaricus* gives an idea of what he intends. He found his plant in the same marfy forest with the laft. The root is furnished with knobs of various sizes, good to eat when roasted. Leaves radical, large, on long footstalks, some of which bear a lateral tuft of numerous white sessile flowers; a mode of flowering analogous to that of the *Acorus.* The genus however of this species must depend on Aublet’s authority. His three others above-mentioned, see n. 8, we must leave in the uncertainty in which we find them.

10. *M. comosa.* Leafy-headed Arrow-root. Linn. Suppl. 80. Wildl. n. 4. Rofcoe Tr. of Linn. Soc. v. 8. 349. (Coreuma nova; A. Moen. Acad. v. 8. 251.)—Leaves radical, elliptical, on long stalks. Flowers in a terminal tuft, crowned with leafy bracteas.—Sent by Dalberg from Surinam. The leaves have the habit of the last. Both species seem to want the knot at the top of their footstalks, which is a strong presumption of their being no true *Maranta.* Indeed Linneus himself expresses his doubts of the present plant. The flower-stalk is radical, three feet high, round, simple, smooth and naked, except at the top, where it bears a fine crown of elliptic-lanceolate leafy bracteas, like that of an *Eucodon,* under which the flowers are illated, in sessile drooping tufts. We find their habit and structure very unlike what are proper to this genus, and the flowers are more like that of an *Alpinia,* to which we should, at a venture, remove this plant, without much scruple.

We omit *M. malacensis,* Wildl. n. 3, adopted by that author from Bornian (Gallanga malaccensis; Rumph. Amb. v. 5. 176. t. 74. f. 1.), as the figure of Rumphius fows it to be, in habit and character, an *Alpinia,* to which genus Mr. Rofcoe has referred it in Tr. of Linn. Soc. v. 8. 243. S. *Maranta,* in Gardening, contains plants of the herbaceous, perennial, exotic kind, of which the species cultivated is the Indian arrow-root (*M. arundinacea*).

The root of this plant, when washed, pounded fine, and bleached, makes a fine nutritive powder, which is made use of as food in many cafes where the stomach is weak and incapable of digesting more solid kinds.

Method of Culture.—All the plants of this species may be increased by dividing the roots and planting them in pots of light rich earth, in the spring, just before they begin to shoot, plunging them in the bark hot-bed of the ilove, where they must be kept in general, being frequently refreshed with water, when in a state of growth, having free air, after they become of some strength, admitted to them.

Ornament and variety are afforded by them in flowe collections among other tender plants.

*MARANTABUAN,* in Geography, a small island in the East Indies, n. of Borneo. N. lat. 6° 55'. E. long. 117° 20'.

*MARASCH,* or *MERASCH,* a town of Alaric Turkey, and capital of a Sangiace, under the pacha of Carama.
nia, and the see of a Jacobite bishop: 140 miles W.S.W. of Diarbekir. N. lat. 37° 24'. E. long. 36° 35'.
MARASIND ISLANDS, two small islands in the East India flea. S. lat. 5° 15'.
MARASKER, a small island on the E. side of the gulf of Bothnia. N. lat. 63° 21'. E. long. 21° 25'.
MARASMUS, in Medicine, from præsumus, to ex-20, is a term applicable to every chronic disease, in which great emaciation of the body is the only apparent change. A marasmus is said to be present in the last stage of every species of consumption or decline; but the term is more especially used to denote the miscellanea consumption, or that species of decline which occurs in children, and originates in derangement of the abdominal viscera. This disease will be found described at length under the article INFANTS, Diseases of, § 4.
MARASNA, in Geography, a town of Africa, in Wangan. N. lat. 14° 52'. E. long. 10° 12'.
MARAT, John Paul, in Biography, a native of Switzerland, who became a prominent actor in the French revolution, was born in 1744; he went to Paris to study physic, and, probably, not having patience to pursue the profession in a regular course, he became an empiric, selling his medicines at an extravagant price. On the breaking out of the revolution, he took the lead among the most violent and savage of all the factions that disgraced the capital. He published a periodical paper, entitled the "Publick's Parnass," in which he, without scruple, and without any regard to decency or truth, attacked the virtuous Necker, and other men eminent for their integrity and public talents. This journal did not last long, but the author had other projects in view, and he next set on foot a paper, entitled "The Friend of the People," in which he unburthened the people to revolt, pilage, and murder. He excited the troops to use their arms against their generals, the poor to plunder the rich, and the people at large to rise against the king. After the deposition of Lewis XVI he was named a deputy of the department of Paris, to the convention, in which assembly he appeared armed with pistols. In April, 1793, he publicly denounced the leaders of the Brissotine party, accusing them of treason against the state; he was supported by Robespierre, a violent turntuist, edited, but Marat and his friends were subdued, and himself impeached and protected; in a few days being brought to trial he was acquitted. The triumph of his party was now unbounded, and they soon gained such an ascendancy over their enemies, that they murdered or banished all that attempted to obstruct the progress of their nefarious projects. till at length their leader Marat fell a victim to the most barbarous rage of a female, Charlotte Cordet, who had travelled from Cen, in Normandy, with a determination of revenge, as the hoped, her country from the hands of barbarians, by the assassination of one of the chief among them. He died unpitied by every human being who was not of the atrocious faction which he led, having, for some weeks, acted the most fiage parts, and been the means of involving many of the most virtuous characters in France in imminent ind irrevocable slaughter. Previously to joining in revolutionary politics, he was known as an author, and published a work "On Man, or Principles of the reciprocal Influence of the Soul and Body," in two volumes, 12mo: also, some tracts on Electricity and Light, in which he attacked the Newtonian System. N. w. Ana Reg 1793.
MARATE, in Geography, a low desert island in the East India sea, about eight miles from the coast of Africa, four miles in circumference. On the S. coast is a good haven, secure from all winds, formed by two points of land, enclosing a spacious harbour, narrow at the mouth, where lies a very long flat island with some sand-banks; the depth is three fathoms in the shallowest place. N. lat. 18° 35'.
MARATHON, in Ancient Geography, a small city of Attica, near the sea, about 40 miles from Athens, famous for the victory of the Athenians over the Persians. The Persian army commanded by Datis consisted of 100,000 foot, and 10,000 horse; that of the Athenians amounted in all to 10,000 men. This latter had 10 generals, of whom Miltiades was the chief; the Persians had the command of the whole army, each for a day, one after another. It was a subject of great dispute among these officers, whether they should hazard a battle, or expect the enemy within their walls. The latter opinion was that of a great majority; Miltiades and Aristides were for risking an immediate engagement, and this measure was adopted. Aristides, well knowing that a command which changed every day must necessarily be feeble and fluctuating, judged it prudent to veil the whole power in a single person, and in order to induce his colleagues to adopt this plan, he himself set the first example of resignation. When his day of command occurred, he resigned it to Miltiades, at the more able and experienced general. The other commanders followed his example; so that Miltiades had the sole command. When the day of battle arrived, he endeavoured, by the advantage of the ground, to gain what he wanted in strength and number. Accordingly he drew up his army at the foot of a mountain, that the opposing army might not be able to surround him, but to charge him in the rear. On the two sides of his army he caused large trees to be thrown, in order to cover his flanks, and render the Persian cavalry useless. As soon as the signal for battle was given, the Athenians ran against the enemy with all imaginable fury, which was the first influence, says Herodotus, in which the Greeks thus began an engagement. The battle was fierce and obstinate. Miltiades had made the wings of his army very strong, but had left the main body more weak and not to deep. As he had but 10,000 men to oppose to a very numerous army, it was impossible for him to make a large front, or to give an equal depth to his battalions. He therefore concluded that he could succeed only by the efforts which he should make with his two wings, in order to break and disperse those of the Persians; not doubting that when his wings were victorious, they would be able to attack the enemy's main body in flank, and complete the victory without much difficulty. This was the plan which Amabili afterwards followed at the battle of Cannae. The Persians attacked the main body of the Grecian army, and made their greatest effort upon their front. This was led by Aristides andThemistocles, who supported it for some time with superior bravery, but were at length obliged to give way. At that instant came up the two victorious wings, and totally routed the Barbarians. The Athenians pursued them to their ships, set many of them on fire, and took leave. They had not above 200 men killed on their side in this engagement; whereas on the side of the Persians above 60,000 were slain, without reckoning those who fell into the sea as they endeavoured to escape, or those that were confused with the ships set on fire. The Persians had thought themselves so sure of victory, that they had brought marble to Marathon, in order to erect a trophy there. The Greeks took this marble and cast a statue to be made of it by Phidias, in honour of the goddess Nemesis, who had a temple near the place where the battle was fought. The memory of those Athenians that were slain in the battle was honoured by illustrious monuments erected to them in the place where the battle was fought; upon which their own names, and that of their tribes, were recorded. Miltiades was afterwards
eread in the same place. All the honour that was paid to
Mikdaes, the great deliverer of Athens and of all Greece,
was, that in a picture of the battle of Marathon, drawn by
order of the Athenians, he was represented at the head of the
10 commanders, exhorting the soldiers, and setting them an
example of their duty. This picture was painted gratis by
the celebrated Polygnotus, of the isle of Thasos, one of the
finest painters of his time, and it was preferred at Athens in
a gallery, adorned and enriched with different paintings,
excellent in their kind, and done by the greatest masters.

The battle of Marathon was fought in the 3d year of the 72d
Olympiad, B.C. 490.

In the plain of Marathon, and N.E. of it, was a large
lake, which received a river, that ran from the N.W.
There was also a mountain of Attica of the same fame.
Marathon, once so famous, is now an inconsiderable village
of European Turkey, in Lividus, confining only of a few
houses, but retaining its ancient name. The spot where the
brave Athenians were buried is situated near a lake, from
which a river runs into the bay of Negroponte; nine miles
N.N.E. of Athens.

MARATHUS, a large and rich town of Phoenicia,
situated between Batanea and Carmaea, according to Strabo.
This town obtained liberty from one of the successors of
Alexander, with the privilege of being governed by its own
laws. A war occurring between this city and that of Arad,
the inhabitants of the latter place took it, razed it, and
divided its territory among themselves.

MARATHUSA, a town in the interior of the isle
of Crete.—Also, an island of Asia, upon the coast of Asia
Minor, near Ephesus, according to Pliny, but according to
Thucydides and Steph. Byz., before Clazomenes.

MARATROCAMPO, in Geography, a town of the
island of Samos; six miles W. of Cora.

MARATTA, Carlo, in Biography, a historical
painter, and one of those fortunate men who receive during
their lives their full portions of praise and esteem. He
was born at Camurano, in the marquisate of Ancona, in
the year 1625. He was the disciple and friend of Andrea
Sacchi, with whom, to the death of the latter, he purified
his studies, and continued his attachment.

Although he enjoyed during his life, and perhaps deferred,
the reputation of the best painter in Europe, yet when com-
pared with the truly great, he never rose above mediocrity.
It is very seldom that enlarged and grand conception reigns
in his compositions; but a certain fluavity and loveliness in
his madonnas, which he seems to have acquired from Cor-
reggio's works, of grace in his angels, and devout character
in his saints, render his pictures always agreeable, and are
the source of his renown. From his first performances being
chiefly madonnas, his contemporaries treated him with the
appellative of Cartoccio delle Madonnì, and probably by
that very circumstance excited him to employ his talents upon
more extended and difficult subjects, in which he exhibited
his superior taste and skill. He evidently appears to have
studied the works of Raphael, but never felt the beauty of
his simplicty, nor underflood the principles of his design
and composition. For the well underflooded draperies and
judicious introduction of folds which we fee in the best pic-
tures of that great master, Maratta referred to a fulnes and
overwhelming quantity; arranged in the style of Sacchi; but
hiding too much of the figures, and giving them by that
means a heaviness, and often a bad proportion. His co-
louring is in general clean and freely wrought, but some-
times his shadow colour partakes too much of red, which
does not unite in a friendly manner with the lighter tones,
and destroys the brilliancy of effect which he generally
aims at.

There is a great number of his works in the churches
and palaces of Rome, which bear testimony of his popu-
laritv, and they were fold at prodigious prices during his
life. Of late, since a more just taste in art is arisen, they
have fallen in the eale to their proper level; but still are, as
they deferve to be, held in much estimation.

He lived to the advanced age of 88, and practifed his art
to a very late period of his existence.

MARATTA, in Botany, was so named by Dr. Swartz,
in commemoration of John Francis Marattì, abbot of Val-
 lumbera, lecturer on botany, and superintendent of the
botanic garden, at Rome. He published three small Latin
tracts in that city.

First a description of the flowers of dor-
fertous ferns, in 1760, which is rather a description of their
fruits; for the author certainly has in some cafes miltaken
the latter for the former; in others delineated as organs of
impression, what are, at moist, very doubtfully fuch.
Yet this effay occasioned Dr. Swartz to choose a genus of
ferns to bear his name; and he has certainly fallen on one of
the most singular, difficilt, and elegant, in nature. Mar-
atti's second work, printed in 1772, is a definition, with
figures, of two suppos'd new genera, entitled 'Romulea' and
'Saturnia'; the former of which is 'Sisian Bulboorum,' the latter
'salivum Comaenolym.' His last publication, dated 1776, is
on the Zoophytes and Lithophytes of the Mediterranean;
which, confidered as plants, he treats fyltematically, in the
Linnaean fyle, with synonyms. All these tracts are of
Sprengel Crypt. 180. Mart. Moll. Dict. v. 3. (Myriotheca;
and f. 15. Lamarek Illutr. t. 866.)—Clas and order, Crypt-
ograma Filices; fct. exanamatus. Nat. Ord. Filices du-
fifer.

Eff. Ch. Capulis oval, scattered, burling longitudi-
nally on their upper fide, difclofing a row of cells in each
divifion. Involucrum none.

This very remarkable and beautiful genus ranges next in
affinity to Dancia; fee that article. It differs however
effentially, in the capulin being formed of two lobes, at first
cohering longitudinally, by what afterwards becomes their
upper surface, and difclofes a row of from four to ten cells
in each lobe, opening each by a feparate orifice, smaller than
the internal diameter of the cell, in the fald upper surface.
The entire capsule therefore is oval, with a determinate
number of cells, very different from the indefinite aggre-
gation ofingle-celled capulics, seen in Dancia. Nothing
is known of the flower, or mode of impregnation.
The capulis fland feperately on the veins of the frond, without
any involucrum, and in a young flate appear like little
smooth grains. When mature they are generally the fize
of half a multard-feed. Their fruds are inconceiveibly mi-
ute.—Five, or at moist fix, fpecies are known.
128. Sm. Plant. Ic. t. 46.—Frond doubly pinnate. Leaflets
sharply ferrated. General falk fefy; partial ones winged.
Native of Jamaica, where it has been gathered by several
boatawils. This appears to be an herbageous fern, perhaps
three or four feet high, but we have not feen either the root
or the lower part of the frond. The upper part is doubly
and opputaneously pinnate, with fquare fcaly filks, the whole
of which in the branches, and the upper part of the main
frond, is winged with a leafy entire border, contracted at the
infection of every leaflet. The leaflets are fefile, an inch
long, more or less, very nearly, if not entirely, oppoite,
ovate-oblong, bluntish, sharply and rather deeply ferrated, especially towards the extremity, veiny, the veins always dividing soon after they leave the mid-rib, each branch ending in one of the ferrations. The upper side is smooth, with a prominent rib; under side paler, minutely fuscous about the rib and veins. The lower leaves are often lobed or pinnatifid; the upper ones diminished gradually, become confluent, and form an elongated ferrated point to each branch. The truly remarkable capsules are three, four, or five on each side of the mid-rib of most of the leaves, towards the margin beneath, each flattened on a branch of a vein, and about the size of a garden-poppet seed, externally pale brown. When the leaves separate, their upper side appears of a pale sulphur-colour, fritated transversely where the cells are to open, and more or less crenate at the edges. At length the whole capsule becomes brownish, and the cells open by about five oval-oblong orifices in each lobe.

2. M. levis. Smooth-foiked Maratta. Sm. Plant. Ic. t. 47. Frond doubly or tripinnately pinnate. Stalks smooth; the terminal ones winged. Leaflets entire, the uppermost confluent.—Gathered by M. Thierry de Menonville in Hifpaniola, not in Dominica. This has a general resemblance to the foregoing, but is partly tripinnately pinnate, and quite defteite of seales on the stalks or veins. The ferrations of the leaflets are blunter; partial stalls of the lower ones very broadly winged; and the capsules are shorter, almost globule before they open, having but four, rarely five, cells in each lobe. Their margin moreover is quite entire, neither crenate nor crarked. Seeds extremely minute, white. It may also be remarked that the principal subdivisions of the frond in this species are more generally alternate, and the veins of the leaflets are most of them simple, not divided.

3. M. fraxinea. Ash-leaved Maratta. Sm. Plant. Ic. t. 48. Frond doubly pinnate. Stalks smooth, simple. Leaflets alternate, lanceolate, ferrated, all distinct.—Native of the island of Mauritius. Our specimen was given by the celebrated M. Thouin to the younger Linneas, when at Paris. It is one of the most magnificent, as well as curious, of its whole natural order. Bluntly ferrated, the uppermost confluent of the branch of the frond, which shears the whole to be at least doubly pinnate, in an alternate order. This branch is above a foot long, and much resembles the leaf of some sort of ash, consisting of 22 alternate spiny leaflets; besides the terminal one, which is not larger than the others. The leaflets are very smooth and naked, simple, except a very slight wing near the very top. Leaflets two or three inches long, or very short stalks, smooth, bright green, lanceolate or slightly ovate, scarcely an inch wide in any part; their point elongated; their margin copiously, sharply, and pretty equally ferrated; their base wedge-shaped and entire; their transverse veins numerous, parallel, more or less simple, sometimes forked, quite defteite of seales. Capsules disposed near the margin, not very abundantly or irregularly, rather larger than those of the first species, roundish-oval, brown; each lobe quite entire at the edge, and furnished with about six cells. Dr. Swartz erroneously quotes the author of the present article, as saying the branches (pinnæ) are opposite. Opposite leaves. Service-leaved Maratta. Bory de St. Vincent's Voyage, t. 207. "Capsule, Frond doubly pinnate. Branches alternate. Leaflets lanceolated." Sm. Native of the isle of Bourbon.—We know this merely by what we have here copied from Dr. Swartz, not having access to the book he quotes. The author we follow supposes this to be the very species figured by Lamark in his Illustrations of Genera, tab. 866; but we should rather suppose that figure to be taken from M. fraxinea, except possibly the separate leaflet. The capsule and its defteites are all copied from Sm. Pl. Ic. t. 48.

5. M. oppulifolia. Opposite-leaved Maratta.—Frond...—Leaflets opposite, linear-lanceolate, sharply ferrated. Native country unknown. We have a mutilated specimen of this, without any mark whatever, in the herbarium of the younger Linneas. It consists of near four inches only of the rachis, or stalk, which is as thick as a goose-quill, smooth, convex beneath, marked with a narrow furrow above. This appears to be but a very small portion of the branch, or whole frond, we cannot tell which. It bears four pair of opposite leaflets, all nearly of an equal size, not quite four inches long; almost an inch wide, linear-lanceolate, taper-pointed, finely, sharply, and equally ferrated throughout, except at the base, veined like M. fraxinea, and supported on very short stalks. The upper surface is smooth; the under paler, its veins rough with fine linear scales. Capsules very numerous on every leaflet, rather larger than those of the fraxinea, but otherwise like them, without containing the fame, or occasionally a greater number of cells. These capsules form a continued line near each margin, except at the base and point, being from 40 to 50 in each row. We should, by the name, have supposed this the forkyolus tili mentioned, had the leaflets of the branch been described as opposite. The shape and size of each leaflet well agree with Lamarck's fraternate one, fig. b, but his footstalk is too long, and capsules not sufficiently copious or crowded.

6. M. falcata. Willow-leaved Maratta.—Frond simply pinnate? Stalk smooth, simple. Leaflets alternate, firm, linear, very slightly crenate, with ferrated points.—Our specimen of this nondescript fern was communicated by the late Rob. Moleworth, eq., as a native of New South Wales. As it was accompanied by a large collection of other plants, undoubtedly the produce of that country, and by no others, we presume the account must be correct; yet there being no Maratta mentioned in Mr. Brown's Prodromus, cannot but induce some suspicion. It is however a most curious and distinct species. We cannot positively say whether our specimen be the whole plant, from the root; in which case the frond is simply pinnate; or a branch rudely torn from a more complex frond. The stalk is two feet long, smooth, simple, and even, sometimes quadrangular, very firm and strong. Leaflets numerous (about 40), on short stalks, alternate, spreading, linear, sharp-pointed, four or five inches long and half an inch broad; smooth and of a fine green above; rather paler, and having capillary scales on the lower part of the rib, beneath; the margin is so very slightly and obtusely crenate it might almost be called entire, but the short taper point, beyond the capsules, is ferrated; the veins are much like the foregoing. The leaflets are excessively numerous, forming a close row, along each edge of the leaflet, every vein bearing one, so that there are near in every row. They are larger than in any other known species, and have nearly a double number of cells, whose orifices are linear, and crowded close together.

When we consider the possible rate of increase in such a plant as this by seed, it is as stupendous as that of the Ling-fish, whole progeny, if uninterrupted, would, according to the calculation of Linneas, in 20 years fill the whole ocean. Here are perhaps 160,000 capsules, each having about 20 cells, which makes 3,200,000, and we can hardly conceive the quantity of minute seeds in each cell; at least it is impossible to count them with any degree of exactness. The number of seeds however in some ferns, is probably much greater.

Not having yet been able to procure the volume of William's...
denow's Sp. Pl. which treats of ferns, we know not how far our new species may accord with any of his. S.

MARATTOUR, in Geography, a town of Hindooslan, in the circar of Guntoor; 28 miles N. of Mootalpi.

MARATUBA, an island in the East Indian sea, about 24 miles in length from N. to S. Its breadth varies from 12 miles to 4. It is the largest of a cluster, to which it gives name; the next in size is Kakababan; the rest are very small. N. lat. 2° 14'. E. long. 118° 30'.

MARAU, a town of Arabia, in the province of Yemen; 16 miles N.E. of Hodeida.

MARAUDING, from the French, marauder, in Military Language, is a term applied to a party of soldiers, who, without any order, go into the neighbouring houses or villages, when the army is either in camp or garrison, to plunder and deftroy, &c.

MARAVEDI, a little Spanish copper coin, worth somewhat more than a French denier, or half a farthing English.

The word is Arabic, and took its rise from the Ahmaravides, a dynasty of Moors, who, passing out of Africa into Spain, imposed their own name on this coin, which by corruption was afterwards changed into maravedi—Mention is made of it in the decreals, as well as in other Latin writers, under the name of marubiniti.

The Spaniards also count by maravedis, both in commerce and in their finances, though the coin itself is no longer current among them. Thirty-four maravedis vellon are equal to the real vellon, which is the most general money of account. Madrid, and all Cadiz, with most of the adjacent provinces, and also Bilboa. Malaga, and Galicia, keep accounts in reals and maravedis vellon. The real of new plate is double the real vellon, and is also reckoned at 34 maravedis of new plate. This real is represented by an effective coin of base silver; but books are not kept in any part of Spain in this money. The real of old plate is also reckoned at 34 maravedis of old plate. Cadiz and Seville keep accounts in reals and maravedis of old plate. The real of old plate is worth about 5d.; and the real vellon 2/3d. nearly; or, more accurately, 1l. sterling = 48 reals 2½ maravedis of old plate, or 91 reals 17 maravedis vellon.

Sec Real and Spain.

This smallness of the coin produces vast numbers in the Spanish accounts and calculation; and, though a stranger or correspondent would think himself indebted several millions for a commodity that cost but a few pounds.

In the laws of Spain, we meet with several kinds of maravedis; Alphonse maravedis, white maravedis, maravedis of good money, maravedis Combrenos, black maravedis, and old maravedis. When we find maravedis alone, and without any addition, it is to be understood of those mentioned above. The reals are different in value, fineness of metal, time, &c. Mariana asserts, that this coin is older than the Moors; that it came from the Goths; that it was anciently equal to a third part of the real, and consequently of twelve times the value of the present maravedi. Under Alphonse XI. the maravedi was seventeen times; under Henry II. ten times; under Henry III. five times; and under John II. two times and a half the value of the present maravedi.

MARAVI, in Geography, a country of Africa, with a city of the same name, built on the S. side of the lake, about 250 miles from the Indian sea. S. lat. 13° 15'.—Also, a lake of Africa, in S. lat. 10°, of great extent, laid down by M. d'Anville as more than 350 Britisli miles in length, but of inadequate breadth; some 9130 miles. This lake may perhaps, like that of Baikal, lie at the foot of the Table land on one side, as that of Aquilanda, of much smaller extent, does on the other.

MARAUTSCH, a town of Upper Carniola; 11 miles E. of Stein.

MARAUGUIR, a town of Hindooslan, in Myfory; 30 miles E.S.E. of Outfloor.

MARAWA, a town on the east coast of the island of Banca. S. lat. 2° 15'.

MARAWAR, a country of Hindooslan, bordering on the coast opposite to Ceylon; about 60 miles in length, and 40 in breadth. It was conquered by the British troops in 1773, and the rajah killed. It is covered with thick forests, and little cultivated. In the flourishing state of the empire of Hindooslan, Marawar yielded a revenue of five crores of rupees.

MARAWIL, a town of the island of Ceylon, on the W. coast; 14 miles N. of Negombo.

MARAYAN, a town of Hindooslan, in Bahar; 25 miles E. of Bahar.

MARAYAT BAB, a bay on the W. coast of the island of Luzon. N. lat. 14° 37'. E. long. 120° 21'.

MARAZION, or Market Jew, a market-town in the parish of St. Hilary, hundred of Penwith, county of Cornwall, England, is situated on the side and at the bottom of a hill, near an arm of the sea, called Mount's bay, three miles E. of Penzance, and 280 W. from London. It derived its principal support, if not its origin, from the resort of pilgrims, and other devotees, to a neighbouring sacred edifice on St. Michael's Mount; but that attraction being counteracted by the changes of opinion which commenced at the Reformation, and the then new town of Penzance drawing within its vortex many merchants and tradesmen, with their connections and dependants, the consequence of Marazion decreased. By some authors its name is derived from the Jews, who are reported to have traded here several centuries ago, and have held an annual market for selling various commodities, and purchasing tin and other merchandise in return. Richard, king of the Romans, granted two fairs to this town, for the benefit of the priory at St. Michael's Mount; but this charter was superseded by another in the thirty-seventh year of Queen Elizabeth, by which the government of the town was vested in a mayor, eight aldermen, and twelve capital burgesses, with power to hold one weekly market and two annual fairs. In the preamble to this charter it is stated, that "Marghafew was a trading borough of great antiquity;" from which expression, and from a corroborating correspondence between the sheriff of Cornwall and the mayor of Marazion during Cromwell's protectorate, it seems probable that this town was anciently represented in parliament. Two members were actually elected and returned in Cromwell's time; but they do not appear to have taken their seats: the endeavours of the inhabitants to regain their dormant rights proved ineffecual. In the Survey of the year 1801, pursuant to act of parliament, Marazion was rated to contain 224 houses, occupied by 1000 persons. The trade confisls chiefly in the importation of timber, coals, and iron, for the use of the inhabitants of the place, and for the neighbouring mines. The parish-church of St. Hilary is nearly two miles distant from the town: but here is a chapel of ease, supported by private subscription. Quakers and Methodists have also their sequehtive meeting-houses.

Between Marazion and St. Michael's Mount is a place called the Chapel Rock, where the pilgrims who came to visit the priory of St. Michael performed certain devotional ceremonies, in a kind of initiatory chapel previous to their admission to the more sacred Mount.
The peculiar situation of St. Michael's Mount, and the singular character it assumes from appearing to rise immediately from the waves, interest the imagination of the observer; though, when viewed from the land, its magnitude is apparently diminished, from the vast extent of the horizon, and the expanse of water which surrounds its base. At high tides it appears a completely isolated ambleague of rocks, rising to a considerable height, and gradually decreasing in size, till, affixed by the tower of the chapel on the summit, it assumes the form of a perfect pyramid. At low water it may be approached from the shore over a causeway of sand and rock, which is submerged by every rising tide, and the Mount again rendered a perfect island. Some of the masses of rock in the intermediate space are very large, and are composed of granite of a clove texture, with a film of a pink colour. The Mount itself consists of a hard granite, in which transparent quartz is the preponderating substance. The origin of the Mount, and its first consecration to religious purposes, are unknown: the earliest time in which it appears on record, as a place of devotion, is the fifth century; though it seems probable that it was then highly celebrated, as St. Keyna, a holy virgin, daughter of Braganus, prince of Brecknockshire, is flated to have come thither on a pilgrimage about the year 490. Upwards of 500 years afterwards, Edward the Confessor founded on this spot a priory of Benedictine monks, on whom he bestowed the property of the Mount. This priory was held in high estimation, and was formed with peculiar privileges by pope Gregory, in the year 1070. King Henry VI. granted the priory to King's college, Cambridge; and it was afterwards bestowed by Edward IV. on the monastery of Sion, Middlesex. At the dissolution, its revenues, valued at 1191. 12s. 7d. per annum, were conferred, together with the government of the Mount, then a military post, on Humphry Arundel, esq., a branch of the family from which the present lord Arundel is descended. After several transfers, it was, about the close of the seventeenth century, sold to John St. Aubyn, esq., whose descendant, Sir John St. Aubyn, bart. still possesses it. The Mount has been the scene of several military transactions: the earliest recorded was in the reign of Richard I. when it was fortified in support of prince John, then earl of Cornwall, in his endeavours to suppress the throne during the king's absence in the Holy Land, or his subsequent imprisonment in Germany. "From this time forward," Carew says, "this place continued rather a school of Mars than a temple of peace." It was a long time defended against Edward IV. by John, earl of Oxford, in behalf of king Henry. During the Cornish insurrection in the reign of Edward VI. the Mount was the refuge of many of the superior families, who were here besieged by the rebels. The civil contentions in the reign of Charles I. were the cause of the fortifications of the Mount being increased, till, according to an historian of that time, they were "impregnable, and almost inaccessible." They were, however, reduced, after a vigorous defence by the king's adherents, in April 1646, by colonel Hammond, who obtained great celebrity by the service of such difficulty and danger. This was the last military occurrence that took place on this romantic spot, whose inhabitants appear to have been then driven away; for at the commencement of the last century, here was but one dwelling-house besides the fortres. The improvements that have since been effected, and the increase of the buildings, are to be ascribed to St. John St. Aubyn (grandfather of the present baronet), who, about the year 1726, rebuilt and enlarged the pier, so as to contain upwards of fifty small vessels. The security thus given to fishing-boats, induced several inhabitants of Marazion to erect some houses at the bottom of the rock: the number has been since augmented to seventy, occupied by about 250 persons. The circumference of the Mount is rather more than a mile; and its height, from the land to the top of the chapel-tower, as ascended by Hadley's quadrat, is 250 feet, being 48 feet higher than the Monument in London. The distance from the shore at Marazion is about 400 yards. The ascent to the top of the Mount is by a steep and craggy passage fronting the north, defended against the midway and near the top by batteries. The whole summit is occupied by the remains of the ancient monastic buildings, which have been improved and beautified by the present proprietor, under whose direction the chapel has been repaired. Beauties of England and Wales, vol. ii.

MARBA, a town of Arabia; 10 miles W. of Mecca. MARBACH, a town of Saxony, in the circle of Erzgebirg; 8 miles N. of Freyberg-Apfel, a town of Austria, near the Danube; 90 miles S.W. of Aiggbach.

MARBCN, a town of Sweden, in the province of Smaland; 20 miles E.S.E. of Jonkiping.

MARBASIS, in Botany, a name given by fome to a kind of plant which they say climbed up trees, and there hung down from their branches in form of long jointed and naked filaments.

The word seems to be only a corruption of the word anabasis of Pline, which he calls also ephedra, and gives the same character to.

The marbas of the ancients seems to mean our ubiqua.

MARBECK, JOHN, in Biography, organist of Windsor. The premature reforming zeal of this musician nearly made a martyr of him, in the time of Henry VIII. He had indeed the honour of being brought to the stake, with three other persons, who were actually burnt for heresy; but was pardoned at the intercession of Sir Humphry Forder.

Fox, in his "Acts and Monuments," and Burnet, "History of the Reformation," give a circumstantial detail of the troubles in which Marbeck was involved, on account of religion. He however survived Henry, and not only saw the reformation completed, but in 1550 was the first, in publishing the whole English cathedral service, including the prayers, psalms, and responses, set to musical notes under the title of

The Book of Common Prayer, dated 1550. Translated by Richard Crichton, Printer to the King's Secretaries, cum privilegio ad impressio num folium. Marbeck was admitted, in 1549, to the degree of bachelors in music, at Oxford, according to Anthony Wood (Facts Oxon.) who erroneously calls him James Marbeck. He is honourably mentioned by Bate, because he had been perforated by the Catholics; and his name is omitted by Pitts, for the same reason. See Music a Cappella, and Chanting.

MARBELLA, in Geography, a sea-port of Spain, in the province of Granada, on the coast of the Mediterranean, beautifully situated in a valley, with its harbour screened from the E. wind by a promontory, and defended by a castle, which is furnished with some guns. The exports from this town are wine, dried raisins, leather, black horse, charcoal, and wood. In its neighbourhood is a small fine sugar plantation. 26 miles S.W. of Malaga. N. lat. 36° 51'. W. long. 4° 59'.

MARBEUF, a town of the island of Corsica; 10 miles W.S.W. of Vico.

MARBLE, in Technical Mineralogy, those finer varieties of granular and compact limestone, which, being of a closer grain, are susceptible of a superior polish, and are remarkable either for their whiteness, or the beauty and variety of their colours. In former times the appellation of Marmor (derived
Marble.

rived from the Greek μαρμάρος, to fhone, or glitter, and afterwards corrupted to marmol, marmel, marble, marbles,) was in
discriminately given to many flony maftes that admit of
being polished, and accordingly we find alaballer, ferpen
tine, basalt, porphyry, &c. defcribed under that name,
which is now confined to fuch maftive carbonats of lime
as come under the above definition; which, however, does
not exclude the varieties containing foreign fubstances im
belded in, or mixed with, the principal calcareous mafts,
such as ferpentine, hornblende, quartz, &c.

Molt of the external, physical, and chemical characters of
the pure marbles are, of course, the fame as thofe of compact
and granular Limetone; which fee.

Marbles are easily diftinguifhable from gypfous and cal
careous alabaffers, with which they are frequently con
founded; from the former by the application of some
diluted nitric or muriatic acid, which produces a ftrong
effervefcence, by expelling the carbonic acid; from the
latter (which belong to flatalitical limetone, and are, there
fore, acted upon in the fame manner by the acids) by infe
rior hardnefs, a flighter degree of tranfmutivity, and, if co
oured, by the aprence of regularity in the &ries and un
dulations that characterife the calcareous alabafTer; nor is
the latter ever found in mafts of confiderable dimenfions.

The fpecific gravity of marble varies in the fame manner
as that of the different varieties of common limetone, whence
no diftinctive character can be derived from it: Wallerius
and Gmelin flate the fpecific gravity of the former to be 2.72,
while others confider it as greater than that of common
limetone; but, according to Gerhard and other writers, it is,
in the whole, equal in both.

Some granular marbles, when cut into thin flabs, exhibit a
degree of elaticity or flexibility, fimilar to that of the well
known fandstone found in Brazil. This phenomenon was
firt obtained in fome pieces of marble preferved in the pa
cife of prince Borghafe at Rome. But afterwards another
marble, (of the variety called Dolomite,) having the fame
property, was discovered by Fleuriau de Bellevue, in the
Val-Levantine of mount St. Gothard. Dolomieu (who de
cribed the Borghafe marble) is of opinion that this pro
perty is owing to a flate of deforation which has defiened
the adherence of the molecules of the flones; and Fleuriau
de Bellevue has proved this conjecture to be well founded,
not only by the appearance and nature of the ffone he dis
covered on St. Gothard, but also by his imparting the fame
property to feveral inflexible varieties of marble by merely
expofing them to fuch a degree of heat as produced complete
deforation. Some wrought granular (flatuary) marbles acquire a fimilar property after a long expofure to
the action of the atmosphere and the solar rays; a circonfumnce which fometimes takes place in flates, cauing
thereby the more projecting parts to exfoliate, and to crumble
to pieces. Dolomieu has firt made this obfervation on an
Italian marble called Retullio.

The various tints of the uni-coloured and variegated mar
bles, are generally produced by oxys of iron, the solution of
which has, either wholly or partially, penetrated the mafts
previous to its complete induration. Blue and green mar
bles often owe their tints to minute particles of hornblende;
this is the cafe, for infance, with the flate blue variety called
turchino, and with fome green German marbles. The black
varieties are coloured by charcoal, and allo by bitumen,
when they pafs into flinkflone. In marbles containing petrif
tations, thofe appear fometimes to have derived their colour
from the fame fluid which coloured the mafts; while at other
times the colour of the ground is quite different from that of
the petrifations it contains.

All that has been faid of the fracture of granular and
compact limetone, is applicable to marbles; but it is
often difficult to draw the line between the two former.
In general it may be faid, that the white flatuary marbles
belong to the granular, and many of the variegated to the
compact. Nor is it in all cafes easy to determine whether a
given fpecimen belong to the older or newer formation of
limetone. It is, therefore, evident, that the division of mar
bles into primary, with flining fracture, and into fexadary,
with dull fracture, is far from being practically ufeful; in
deed, many varieties of marbles, as for infance, most of
thofe of the Hartz, &c. cannot be referred to either.

Baumer, Bertrand, Scopoli, Daubenton, Gmelin, and
others, have arranged the varieties of marble after the colours
they prdent; but this fility muft necessarily alignt two or
more different places to one and the fame kind of marble,
variable in the number of its colours, and is, therefore, ap
licable only to small fpecimens. A far more convenient
and ufeful distribution is the one adopted in the "Traité
des Pierres précieufes, &c. " by Brard, whom we fhall follow in
the prefent article. The marbles are by this author
divided, according to their localities, into claffes, and thofe
subdivided each into eight diftinct divisions, &c.

1. Uni-coloured marbles: this division contains only the
white and the black marbles.

2. Variegated marbles: thofe with irregular spots and
veins.

3. Madrepore marbles: this division, etablfified by
Faujas, comprehends all marbles containing remains of madre
pores, or of related animals which generally prefent them
elves in the fhape of white or grey spots, with regularly
difpofed dots and flars in the centre.

4. Shell marbles: thofe that contain only a few fells,
and are not, like

5. Luminalla marbles, entirely composed of fells.

7. Breccia marbles: formed by a number of angular frag
ments of various marbles united by a cement. Thofe are
subdivided into small breccias, with fots having generally
les than an inch in diameter; and into large breccias, with the
generality of fots exceeding that dimension.

8. pudding stone marble: formed, like the breccias of
fragments united by a cement, but which, inftead of being
angular, are rounded.

A. Antique Marbles.

Antique marbles are fuch as were made use of by the
anceints, and the quaries of which are no longer known.
The moft remarkable of thofe, both on account of their
beauty and the ufe made of them in the arts, are

Parian marble (Lycnithes of the ancients). Of a
yellow-white colour; texture fine fcaly; fcales fhining
and placed in all directions. Dipenus, Seyllis, Malas,
and Mieciades employed this marble, and were imitated by
their fucceffors. The ancients called it lychnites, becaufe its quaries were wrought at lamp light. The
principal statues of Parian marble till extant are, the Venus
of Medicis, Diana venatrix, Venus leaving the bath; the
coloffal Minerva (called Pallas of Velletri), Ariadea (called
Cleopatra), Juno (called Capitolina), &c. It is alfo Pa
rian marble on which the celebrated tables at Oxford are
incribed. See Arundelian and Parian Marbles.

Pentelic Marble, from mount Pentelus near Athens. This
marble much refembles the preceding, but is more defne
and fine-grained; it fometimes exhibits faint greenifh zones,
produced by greenifh tale, whence the Italian name Cipolin
flaturio. The principal monuments of Athens were of Pen
telic
tetal marble, such as the Parthenon, the Propylæes, and the Hippodrome. Among the statues of this marble in the Napoleon Museum, at Paris, are the Torso; a Bacchus in repose; Jason, (called Cincinnatus); a Paris; the Difcobolus repose; the bas-relief known by the name of the Sacrifice; the throne of Saturn; the tripod of Apollo; and the two beautiful Athenian inscriptions known by the name of "Nointel Marbles," because M. Nointel caused them to be brought from Athens to Paris in 1672.

Greek white Marble. The marble to which the statues of Rome give the name of Marmo Greco is of a very bright snowy-white colour, close and fine-grained, and of a hardness which is rather superior to that of other white marbles. It takes a very fine polish. This is one of the varieties which is found near the river Coralis, in Phrygia, were called coralic or coralic marble by the ancients. According to Pliny it was found in Asia, in masses of small dimensions; and Argive hill that a similar kind occurs on mount Caputo, near Palermo, in Sicily. The Greek marble was obtained from several islands of the Archipelago, such as Scio, Samos, &c.; that of the island of Lefbos or Metelin sometimes presents spots on its surface. Among the statues of this marble in the Napoleon Museum, the most remarkable are: a Bacchus, Zenon the philosopher, as also the bull known by the name Faune à la tache. Brand observes that this latter bull appears rather to be of the true Coralic marble of the ancients; and that the spot at the neck, from which the bull has derived its name, is foreign to the marble, and caused by contact with a piece of copper. Some suppose the Apollo of Belvedere to be of Greek marble, but the general opinion is that it is marble of Luni.

Translucent white Marble (Marmo fluturato of the Italians). This much resembles Parian marble, but differs from it by its more considerable translucency. There are at Venice, and in several other towns of Lombardy, columns and altars of this marble, the quarries of which are perfectly unknown.

Flexible white Marble, of a beautiful white colour, and fine grain. There are five or six tables of it preferred in the houses of princes Borghese at Rome; their length is about two feet and a half, the breadth about ten inches, and the thickness a little less than three. They were dug up, as the abbé Fortis was told, in the field of Mondragone. Being set on end, they bend, oscillating backward and forward; when laid horizontally, and raised at one end, they form a curve, beginning towards the middle; if placed on a table, and a piece of wood laid under them, they make a faint curve, and touch the table with both ends. We refer to what has been said respecting this property.

White Marble of Luni, on the coast of Tuscany. It is of a splendid white, and of a fine and close grain; it takes a very fine polish, and may be employed for the most delicate work, whereas it was preferred by the Greek sculptors both to the Parian and Pentelic marbles. It appears to be even finer than that of Carrara, and is moreover free from those grey veins which are not unfrequently found in the latter. Most mineralogists coincide in their opinion that the Apollo of Belvedere is of Luni marble; but the Roman sculptors look upon it as Greek marble. Of the Greek statues of this marble in the Napoleon Museum, the most remarkable are, the Antonius of the Capitol; the Antonius in bas-relief; the bas-relief representing the ceremony of the consecration.

White Marble of Carrara, between Spezia and Lucca. Of a fine white colour, but often traversed by grey veins, so that it is difficult to procure middle-sized pieces without them; its fracture is granular and flinty, and its grain fine enough for the purpoises of sculpture. It is not so subject to turn yellow as the Parian marble. This marble, which is almost the only one made use of by modern sculptors, was also quarried and wrought by the ancients, as is proved by the great number of antique statues still extant in this marble. Its quarries are said to have been opened in the time of Julius Caesar. At present its two principal quarries are those of Pisaiello and del Polvazzo. In the centre of the blocks of this marble very limpid rock-crystals are sometimes found, which are called Carrara diamonds. It is also sometimes, like the Pentelic marble, traversed by veins of a greenish tinge, when it is called in Italy Dipolitano di Carrara. The average price of this marble is twenty-two livres the cubic foot.

White Marble of Mount Hymettus in Greece. This is not a very pure variety, but inclines a little to grey. Pliny informs us that Lucius Crassus, the orator, was expoused to the fea-crests of Marcus Brutus, because he had adorned his house with six columns, twelve feet high, of Hymettian marble. The statue of Mekeagre, in the Napoleon Museum, is of this marble.

These are the chief white marbles which the ancients used for the purposes of architecture and sculpture. The Thaian and Arabian are likewise mentioned as antique white marbles, but we are not acquainted with any monuments executed in them.

Black antique Marble (nero antico of the Italians). This differs from the modern black marbles by the superior intensity of its colour; so much so, that if placed beside those of Dinan and Namur, it makes them appear grey. It has been affirmed that the ancients procured this marble from Greece; what we know for certain is, that Faunias has rediscovered quantities of real antique black marble that were wrought by the ancients, and of which the remains are still to be seen at the distance of two leagues from Spé, towards Franchimont, not far from Aix-la-Chapelle. This marble is extremely scarce, and occurs only in wrought pieces.

Red antique Marble (rocco antico of the Italians). This beautiful marble is of a deep blood-red colour, here and there with white veins, and if closely examined is found to be sprinkled over with minute white dots, as if it were fired with sand. Of this kind is the Egyptian Antinous in the museum at Paris. But the most esteemed variety of rocco antico is that of a very deep red, without any veins, such as it is seen in the two antique chairs, and in the bull of an Indian Bacchus, in the same museum. The white points, which are never wanting in the true red antique marble, distinguishes it from others of the same colour, such as the giotte, &c. It is not known from whence the ancients obtained this marble; the conjecture is that it was brought from Egypt. There is in the Criminale palace at Venice, a colossal statue of Marcus Agrippa in rocco antico, which was formerly preferred in the Pantheon in Rome.

Green antique Marble (verde antico of the Italians.) This may be considered as a kind of breccia, the paste of which is a mixture of talc and linoleum, and the dark green fragments are owing to serpentine more or less pure. The verde antico of the best quality is that of which the paste is of a grafts-green, and the blackish spots are of that variety of serpentine which is called noble serpentine. This marble is much esteemed in commerce, but large pieces of a fine quality are seldom seen. There are four fine columns of it in the Napoleon Museum; but much more beautiful ones are preferred at Parma. It was known to the ancients under the name of marmor Spartanum or Laedernominum. This verde antico, properly so called, must not be confounded with the
Marbles known by the names of *verde de mer*, or *verd d'Egypte*. The real *verde antico* is a breccia, and is never mingled with red spots, while those just mentioned are veined marbles mixed with a dull red subfulness, which gives them a brownish hue.

*Red spotted green antique Marble.*—Its ground is very dark green, here and there marked with small red and black spots. It also contains fragments of entrochi changed into white marble. The quarries of this marble are lost, and it is found only in small pieces, which are made into tablets, &c.

*Lock Marble* (Moubre povres of the French lapidaries). This is likewise a mixture of lime-tarne and a talcofe subsance of a light green, flaved with a blackish-green, and related to serpentine. Its texture is filamentose, and as it were ligeious; its fragments are splinter. When polished it exhibits long green veins. Like all other talcofe marbles it soon decomposes in the open air. There is a table of it in the hotel de la Monnere at Paris. Its quarries are lost to us.

*Marmo verde pagliaccio* of the It¢ians. This marble, which is of a yellowish-green colour, is only found in the ruins of ancient Rome.

*Marbre petit antique* of the French lapidaries. It is traversed by white and grey veins, the two colours being dis- posed in unseparated threads; the tablets made of this marble are irregularly lined with their whole length, and has a very fine effect. It is much esteemed, and only made use of for inlaying ornamental furniture. Its quarries are unknown.

*Blue antique Marble.*—This belongs to the variegated marbles. It is of a reddish-white colour, with flake blue spots representing feltoons. It is very scarce, and only seen in small tablets. The quarries of this marble are lost.

*Cerchia Marble.*—Of a deep red, with very numerous grey and white veins, from the colour and disposition of which its name is derived. It is much esteemed in commerce, and is said to be found in Africa.

*Yellow antique Marble* (Giallo antico of the Italians.) Of this we have three varieties: the first has more or less the colour of the yolk of an egg, and is nearly of an uniform tint; the other is marked with black or deep yellow rings, and the last is merely a paler coloured variety of the first. These different marbles, for which the Siena marble is a good sub- stitute, are found only in small detached pieces, and in antique inlaid work. It is in this manner that the two tables of lazzuli in the Napoleon Museum are surrouded by a border made of the deep yellow variety.

*Red and white antique Marbles.*—These marbles, to which separate names have been given, are not sufficiently distinct from each other to require separate articles. The following are from Ferber's letters: red and white marble, called *Porta santa forls*, because it was employed for ornamenting the door of St. Peter's church at Rome.—*Sene fonto*, or *Aricchio*, the spots of which resemble fishs, is made use of for several holy buildings. —*Pavonazzu*; white with red spots resembling ribbons.—*Marmo celio di pavone*; red, white, and rather yellowish. Ferber mentions a number of other red and white antique marbles, such as the Serpenteolu, Refiu annulato, Purichielo, Vendurino, Fiorupo, Cotonefu, &c. which are only found among the ruins of the ancient monuments in Rome.

Marble called *Grand Antique*. This variety, which is a breccia, containing some shells, consists of large fragments of a black marble, united by veins or lines of thinning white. This superb marble, the quarries of which are lost, is sometimes found in detached pieces and wrought. There are four columns of it in the museum at Paris. A leaf valuable va- riety is that in which the spots, instead of being an intense black, are of a grey colour.

*Antique Cipolin Marble.*—Cipolin is a name given to all such marbles as have greenish zones caused by green talc; their fracture is granular and fibrous, and shows here and there plates of talc. They are never seen to contain marine bodies. The ancients have made frequent use of the Cipolin. It takes a fine polish, but the red-like veins always remain, and are that part of the marble which first decomposes when exposed to the open air. There are modern Cipolinos as fine as that used by the ancients.

*Purple antique breccia Marble* (Brièche d'Alep or d'Alet of the French lapidaries). This should not be confounded with the African breccia. There is perhaps no marble, the colour and spots of which are so variable as that of the violet breccia. The following are the chief varieties. The first is that from which the name of the marble is derived; it has a purplish-brown base, in which are imbedded large angular fragments of a light purple colour, and others of a white colour. This first variety can be employed only in large works, on account of the size of its spots, which are sometimes a foot in diameter. There is a beautiful table of it in the Musee Napoleon. The second variety is as it were the miniature of the first; it exhibits the same spots, but within a much narrower compass, so that it may be used for less gigantic works than those for which the other is employed. The third variety is known in commerce by the name of rofe-coloured marble (marbre rote); in this the spots, instead of being white and light purple, have a very pleasing rofe colour. It is scarce and never seen in large pieces. The fourth, which is the most beautiful, appears, at first view, to be perfectly distinct from the others, but it is nevertheless a mere variety of the purple breccia; its ground is of a yellowish-green colour, and the spots, which are of various sizes, are white, green, purplish, and yellow mottled with red; these various spots are traversed by slant lines of a greyish-white colour. This fourth variety is very scarce; there are, however, two tablets of it at Paris, one at M. Faujas, the other in the possession of M. Dedé. From one of the names by which this precious marble is known, we see that the neighbourhood of Aleppo in Syria is supposed to be the place where it is found; but this is erroneous, for Bronzierti informs us that the name is derived from a place called Alet, near Aix, in France.

*African breccia Marble*, (called *antique African breccia.*) Its ground is black, variegated with large fragments of a greyish-white, of a deep-red, or of purplish wine colour; but these latter are always smaller than the former. This is one of the most beautiful marbles existing, and has a superb effect when accompanied by gilt ornaments. Though rather less vivid in its colours than the preceding violet breccia, it is yet, upon the whole, more beautiful. Whether Africa is the part of the world where it is found, as its name implies, is not certain. The pedestal of Venus leaving the bath, and a large column, both in the Napoleon Museum, are of this marble.

*Rofe-coloured antique breccia Marble*—The base of this small breccia is light red, and variegated with small rofe-red spots, and other rofe-coloured spots of a deep black colour; there are some other middle-sized spots of a beautiful white; the whole producing a very pleasing mixture. This marble, of which the locality is entirely unknown, is very scarce, and only small tablets are seen of it in collections.

*Yellow antique Marble Breccia.*—Two varieties may be united under this name: the one known in Italy by the name of Giallo brecciate, which is of a light yellow colour, ornamented.
ornamented with much deeper coloured spots; the other, called Breccia dorata, presents yellow spots separated by red intervals, which contain small white spots. Both are found only in small pieces among the ruins of ancient Rome.

The Arlequin breccia, or Breccia tratagnoza of the Italians. The ground of this antique breccia, which, on account of the roundness of its spots, approaches to the pudding-bone marbles, is of a pale yellow, and contains a number of small fragments of marble of all colours, which has procured it its name. There are two columns of it in the Napoleon Museum.

Red and white breccia Marble (Breccia pavonazzu of the Italians.) Its base is white, the fragments are red. According to Ferber, the interior of the Museo Clementino is ornamented with this marble, the quarries of which are lost.

Breccia di Porta Santa, so called from the use that has been made of it for adorning the door of St. Peter's church in Rome. It is a mixture of unequal, white, blue, red, and grey spots.

Marbre brèche vierge antique of the French lapidaries. This small antique breccia, of a chocolate-brown colour, is spotted with a multitude of minute angular fragments of white marble, besides which it contains some small red spots. It is so scarce that only one tomb is known to exit of it in Rome. Small tablets of it are sold at a very high price.

Peach blossom Marble (Marmo for of Perse of the Italians.) This antique marble is to be referred to the breccias, of which it has all the characters. It exhibits large purplish spots, united by a white cement. A column made of it is preserved in the Napoleon Museum. Several other marbles pass under the name for of Perse, that have no resemblance to the one here described, which is very scarce. Brand suspects that it is nothing but a variety of the purple breccia.

Yellow lumachella Marble, called also lumachelle Caffranche. Its base is of a very deep brown colour, and contains a great number of shells, forming a sort of well-defined small circles of a very lively orange-yellow. This beautiful marble is very scarce, and occurs only in small tablets. It is often called lumachellas of Atrachan, and supposed to be found in the neighbourhood of that city; but this is erroneous. D'Argenville and others affirm that small pieces of it are dug up among the ruins of ancient Rome.

Black and white antique lumachella Marble, (called pane di morto, the funeral pall.) Its base is of the deepest black, sprinkled with white shells, like flowers, from an inch to eighteen lines in length, and distributed rather regularly all over its surface. This shell-marble, the locality of which is unknown, ranks among the finest of its kind, on account of the beauty of its colour, the neatness and distinctness of its spots, and the exquisite polish it takes. It is, moreover, very scarce, a circumstance which much enhances its value.

D. Modern Marbles.

British Marbles.

Great Britain is by no means poor in fine varieties of marble, as has been intimated by some writers on this subject; though, on the other hand, it must be confessed that those are equally wide of the truth who imagine that its marmoric treasures will ever rival those of Italy, Spain, or France. There can be no doubt, however, that the number of British marbles we are at present acquainted with, will be considerably augmented when accurate research shall have been extended to those parts of the united kingdom, that are most likely to furnish this interesting subject of economical mineralogy.

English Marbles.

Black marble is found in Derbyshire, at Ashford, Matlock, and Monfaldale. Black and white marble in the north part of Devonshire; the varieties from Bridgetow, South Tweton, and Drewsteignton, are some black, others inclining to blueish-black. Some of the Chudley marble, and those of Staverton and Berry Pomeroy, have a black ground, with large veins of calcareous spar traversing it in all directions; alo red, lilac-coloured, and greenish veins are seen in it. Black with white veins occurs at Buckfastleigh, and black with yellow and white veins at Bickington, near Ashburton, in the same county. Intense black marble, with distant white spots, is found also in Somersetshire.

The variegated marbles of Devonshire are generally reddish, brownish, and greyish, variously veined with white and yellow, and the colours are often intimately blended. At Waddon there is a quarry of dunni marble veined with green; there is another at Cheriton. The marbles from Torbay and Babacombe display a great variety in the mixture of their colours, so much so that one and the same block often exhibits samples very distinct from one another both in tint and delineations.

The Plymouth marble is principally of two sorts; one ash colour, shaded with black veins; the other blackish-grey and white shaded, in concentric stripes intermixed with irregular red spots.

The cliffs near Marychurch exhibit marble not only of great extent, but of superior beauty, as well as other in Devonshire; being for the most part either of a dove-coloured ground with reddish-purple and yellow veins, or of a black ground mottled with purplish globules. In a valley below the cliff, about 400 yards wide, there are loose unconnected rocks of this marble, owing their situation probably to the falling down of the ground into the sea; for there are very large rocks even on the beach. The huge fragments of rock scattered over the valley, by which we can defend to the sea, give it a grotesque appearance, and have been whimsically called a petrified congregation; and the pleasantry of this fancy has been heightened by a rock, supposing to be about forty tons, in a very erect position, which has been, ludicrously enough, entitled "the parson." Polwhele's Devon.

The green marble of Anglesea is not unlike the verde antico; its colours are greenish-black, leek-green, and sometimes dull purplish, irregularly blended with white; but they are not always seen together in the same piece. The white part is limonite; the green shades are owing to magnetite flours, which is also sifted in narrow veins. This is an elegant marble, but apt to be imperfected by small cracks; nor is it susceptible of a high polish in those places where there are abutting veins. The quarry is situated on the lands of Monachty, in the parish of Lilan-Fair-Yngbornwy, and is found again in the isle of Skerries, off this parish.

There are several fine varieties of marble in Derbyshire, particularly such as are composed of petrifications. The largest quantity of the mottled grey marble is got in the neighbourhood of Moneynall. It may be distinguished into two kinds; the ground of the one is light grey, and that of the other has a slight bluish cast. The former is rendered extremely beautiful, by the number of purple veins which
which spread upon its polished surface in elegant and irregular branches. But the chief ornament of the mottled grey marble is the number of entochoi with which it abounds. The longitudinal and transverse fications of them produce an almost incredible variety in its figure. The purple veined marble is got at Ricklowdale near Monevath; that with the blueish ground at the village itself. There is another variety at a small distance from hence, at a place called Highlow; it is known by the name of Birdeye marble (Filkington). The marble of Purbreck, in Dorsetshire, is composed of fragments of shells, united by a compact limestone, partly of a yellow colour, and mingled with a greenish mottled earth, and black and yellowish particles of bitumen.

A shell marble, which is far from being beautiful, but which in former times has been much employed for architectural purposes, is the Pitworth marble, from a place of that name in Suffolk. It is thus described by Woodward: "The ground grey, with a cast of green. 'Tis very thick set in all parts of it with shells, chiefly turbinated. Some of them seem to be of that fort of river shell that Dr. Light (Hist. Coch. Angl. p. 133) calls "echele maximia, faja f. nigricans, faffista." Several of the shells are filled with a white spar, which varies and adds to the beauty of the stone. That spar was call in the shell before this was repolished in the mafs of marble, as is demonstrable from a view of this and other like marbles. This is of about the hardness of the white Gneisoe marble. The flender round scapi of the pillars of the abbey church in Westminster, and of the Temple church, are of this fort of marble. So likewise are those of the cathedral church of Salisbury. Some perfons that are less skilful in these matters, fancy theses fcap that occur in most of the larger Gothic buildings of England are artificial, and will have it that they are a kind of fuil marble, call in cylindric moulds. Any one who shall compare the grain of the marble of those pillars, the spars and the shells in it, with those of this marble got in Suffolk, will soon discover how little ground there is for this opinion, and yet it has prevailed very generally. Camden has entertained the fame notion of those vast ftones of Stonehenge; but is fully refuted by Inigo Jones. Stonehenge reforoed, p. 337." 

Scottish Marbles.

Scotland abounds in marbles, but only a few of them are generally known. A particularly fine variety of white marble is found, in immense beds, at Aiftent in Sutherland, out of which blocks of any size may be cut. The best fort is seen in the bed of the river, about a mile or two south of the church.

Mr. Williams, in his Natural History of the Mineral Kingdom, points out several other places where he has seen excellent varieties of marble. An exquisite faime marble of a pure white occurs near Blairgowrie in Perthshire, not far from the high road, towards the north; it may be easily raised in blocks and slabs perfectly free of blemishes, and in every respect fit to be employed in statuary and ornamental architecture.

Another white marble, composed of fine thinning broad grains, like spangles, may be seen in the duke of Gordon's lands, in the forest of Glenavon; but the situation is remote and difficult of access.

A beautiful ash-grey marble, of a fine uniform grain, and sufceptible of a fine polish, prevails itself in Lochaber, on the north side of the ferry of Ballachylibh. It is finely sprinkled throughout with grains of bright pyrites, and also contains disseminated lead ore of a fine texture, which to the eye appears to be rich in silver. This marble is capable of being raised in blocks of any size.

A black variety flowered with white, is found in the farm of Blairmachyldach, about three miles south of Fort William, in the bed of a river. It is of a clove green, but not very hard; the flowering in it is light and beautiful, like fine needlework, or rather resembling the frolly fretwork on glass windows in a winter morning; and diffused through all parts of the mafs.

A dark brown variety beautifully variegated with white, is mentioned by Dr. Meck, as being found in the parish of Cambuslang, in the county of Lanark. Of this marble, which takes very a good polish, there are several slabs in the palace of Hamilton; a chimney-piece in the college library of Glasgow; and three pair of fols, &c. in Mr. Dundas's house at Duddingston. The stratum, which has been lithovert seen, is from fix to twelve inches thick, and extends over a considerable part of the parish.

Also the red and white marble of Boyne; and the white with long veins of a different tint from Dunnefs, are mentioned by authors.

Professor Jamieson describes some varieties of marble found in the island of Skye. A white marble veined with ash-grey; it is very heavy, and by exposure to the air it washes down into a powder. An ash-grey variety, variegated by beautiful lemon-yellow stripes which traverse it in different directions, and which seem to be owing to an intimate combination of chlorite, or hornblende, with the marble. A variety of a pure white colour, with a slight admixture of blue-grey, in which alone it differs from the fine marble of Carrara.

But one of the most beautiful varieties is that from the hill of Belephetrich in Tirie, one of the Weften islands of Scotland. It is now generally known by the name of Tirie marble. Its colour is pale blood-red, light flint-red, and reddish-white; these colours are often seen in one and the same piece; the darker shades generally as spots and waved tirs. What renders this marble particularly curious is the hornblende, and the other green fubstance which it contains, and part of which appears to belong to that species of the hornblende family, which is now generally called fahlite; the lighter coloured particles have been considered as calcite. It is mixed in different proportions with the marble, so as to produce pale blackish-green, dark apargania-green, and a colour approaching to leck-green. Also particles of calcareous spar are seen intermixed with this fubstance; as also small rounded quartz particles of a bright red colour, and some mica in plates. Some of its varieties have the appearance of granite.

Besides this, the professor Jamieson mentions a white marble of the same kind, found with the one just mentioned; its colour is white, or very light blue; it contains scales of mica and crytals of hornblende, which latter, when minutely diffused, give the marble a green or yellowish-green colour, and when very intimately combined with the mafs, form beautiful yellowish-green spots.

Another intereting variety of compact marble, is that of Iona, described by count Bourron. It is of a fine dull white, and has at first light the appearance of pure compact feldspar. It is an intimate mixture of tremolite and pure compact carbonat of lime; sometimes with yellowish or greenish-yellow spots, owing to a less intimate admixture of a fleastic fubstance. It occurs in magnesian rocks, sometimes alternating with clayey and flaty fl electorate or magnefan flate.

A dark coloured shell marble occurs in the limestone quarries of the parish of Cummeraees in the county of Dumfries,
Dumfries, and large blocks of it (according to the anonymous describer of that parish) have been worked up for chimneys and hearths, some of which have been sent to London. The shells and other petrified bodies with which it is mixed, greatly add to its variety and beauty, as the whole receives a very fine polish.

IRISH MARBLES.

Ireland also has its valuable marbles, and quarries of them are wrought in various parts. The variety best known in England is the Kilkenny marble, with black ground, more or less varied with white marks produced by petrifactions. This marble contains a great variety of impressions of madreporae, of bivalve and turbinate shells: mytilites, turbinites, pelecypites, tellinellae, tubiporites, nautites, and ammonites may be distinguished. The spar which occupies the place of the shells, sometimes assumes a greenish-yellow colour; in some places there are spots, though rarely, that reflect iridescent colours; and sometimes a yellow spar is also exhibited in the marble. A kind of flaw sometimes appears in the stone, which, from its irregularly indented figure, is styled by the workmen a skull, as it resembles the futures of a cranium.

The quarry of this marble, of which Mr. Tighe has given a full account, is called the black quarry: it is situated in the limestone district of Kilkenny, half a mile south of the town, near the right bank of the river Nore. The flata of marble, each of which is known by its particular appellation, succeeded in this order:

```
Feet. Inches
Rock bed, about 4 0
Thin bed 4
Silver bed, from 1 6 to 2 feet.
Bad bed 2 0
Halfmoon bed 2 6
Bottom bed 3 0
Lower thin bed 1 6
Black bed 1 8
Griddle bed 2 0
```

The halfmoon and the bottom bed are reckoned among the best; the former is so called from the number of impressions of bivalve shells which it contains; the figures of the spaces they occupied, now filled with white spar, being more or less luted: the black bed and the silver bed are both esteemed. The marble which approaches nearest to black is most valued at Kilkenny. The white marks on the polished stone, it is said, appear more strongly, or increase, by long exposure to the air.

This marble, from experiments mentioned by Mr. Tighe, may be considered as consisting of 97 per cent. of calc, two per cent. carbon, and one per cent. magnesia and iron, of which the former is in the largest proportion.

Some coarse work of Kilkenny marble is finished at the quarry; a few of the blocks are split in the town by hand saws, where a little of the polished work is also done, and tomb-stones are cut, which are raised from a different quarry. But the principal work is done at the marble mill, which is on the left bank of the river, near two miles from Kilkenny.

The importation of the marble into England and Scotland has been hitherto prevented by a duty of two shillings the cubic foot; what is exported, therefore, is in the rude block. Tighe's Survey. The quantity exported is about fifty tons annually. The marble sent to Dublin is conveyed on cars as far as Leith-lin bridge, where it is embarked on the Barrow; that which is exported is usually sent to Waterford, and goes by land, at least as far as Dunmow. The blocks exported are contiguously chiefly to Liverpool and Glasgow. Wakefield's Ireland.

Black marble, exceedingly fine, has been raised at Cray-leath, in the county of Down. It is susceptible of a very high polish, and, if well chosen, is free from those large white spots which are supposed to disfigure some of the Kilkenny marble. Dubourdieu's Survey.

In the county of Waterford different kinds of marble are discovered, as at Tureen, a fine variegated sort, composed of chocolate colour, white, yellow, and blue, blended into various shades and figures, which takes a good polish. A black marble, without any mixture of white, has been found near Kilcrump, in the parish of Whitechurch, of the same county; as also a grey marble beautifully clouded with white, spotted like some kinds of thagreen, and susceptible of a good polish.

At Loughngler, in the county of Tipperary, a fine purple marble is found, which, when polished, looks exceedingly beautiful. Smith.

There are several fine variegated marbles in the county of Cork; Smith describes one with purplish ground, and white veins and spots, found at Churchtown; a blue and white variegated marble, from the same place, which, and a black variety, like that of Kilkenny, the chancel of the parish church is floored; several fine ash-coloured varieties of marble, as that of Castle Hyde, &c.

The county of Kerry affords several variegated marbles, such as that found near Tralee, not unlike the Kilkenny marble, except that the white spots are much larger, and the colour of the mass is not so deep a black, but inclining more to the blue: it takes a fine polish, and may be raised in blocks large enough for tables, chimney-pieces, &c. Marble of various colours is found in the same county, in the islands near Dunkerron, in the river Kenmare. Some is black and white, others are purple and white, intermixed with yellow spots, and some beautiful specimens have been seen of a purple colour veined with dark green, resembling the veins in bloodstone. Sir William Petty had several quarries opened in these islands in his time, in order to carry on a marble manufactory; but they are now worked chiefly for the making of lime.

FRENCH MARBLES.

Brard has given a very complete account of the numerous varieties of marble found in France, of which the following is an abstract:

Department of the Arrièse: the black marble of Moulis, said to have been known to the ancients. Purple breccia marble, from Seix, similar to the Italian purple breccia. There are several more fine varieties of marble found in this department, especially in the mountains called Du Cos.

Department of the Aude: the variety called marbre de Languedoc, or de Sainte Beane; it is of a fiery red, with white and grey zones, formed by madreporae. The eight columns which adorn the new triumphal arch, in the Caroussel at Paris, are of this marble, which was formerly only employed for the decoration of the royal palaces. The quarries are at Sainte Beane. The neighbourhood of Narbonne furnishes several valuable marbles, such as that improperly called marbre de Languedoc, which is white with blue-grey; a black marble of an intense black colour, with white veins; a purple marble with yellow spots, &c. This department is particularly rich in marbles.
Department of the Mouths of the Rhone: among the beautiful varieties of marble with which this department abounds are, the breccia marble of Marcella, called breche de Membris; it is reddish, and contains small white, grey, and brown fragments; a marble mixed of white, red, and yellow, known in the country by the name of marbre de Sainte Deune, but very different from the marble of the department of the Aude, to which this name properly belongs.

Department of Calais: a marble of a dirty red, with large, grey, or white veins, composed of madrepores, called marbre de Cam, from the place where it is quarried; tables made of it are very commonly seen in the cafes and houses, &c. of Paris.

Department of the Côte d'Or: besides several spotted and breccia marbles, there are found in this department two varieties of lumachella, the one a reddish-yellow, the other a grey colour, both of which are known in commerce under the name of lumachelles de Bourgogne.

Department of the Herault: one of the most esteemed French varieties of marble is that called griotte. Its colour is a deep brown, with blood-red oval spots, produced by shells. This marble has obtained its name from its brownish colour, being similar to that of a variety of cherries, likewise called griotte; but it also sometimes contains large white veins, which are situated in a transverse direction to the other spots and which, as destroying the harmony of the other tints, are considered as a defect. The lapidaries dignify the variety which is destitute of these white veins with the epithet Italian; but the fact is, that both varieties occur in the department of the Herault, and that neither of them is found in Italy. Some of the ornaments of the triumphal arch of the Caroufle are made of griotte; which is now much employed in the decoration of public monuments, and of splendid furniture. It is sold at about 200 francs the cubic foot. Several other varieties of marble are found in the same department, and used at Montpellier and in other neighbouring places.

Department of the Iferre: a light grey marble, with fragments of a lively rofe-red of different shades, and with spots of a chocolate-brown colour, from Tenlin in Dauphiné. This fine marble takes a good polish.

Department of Jemappes: the madrepore marble of Mons, called petit gris, or petit grand, by lapidaries; its colour is blackish-grey, dotted with grey-coloured fragments of madrepores. There are many more varieties of marble in this department, but most of them not employed in commerce.

Department of Maine and Loire: a grey and white marble veined with red, improperly called peach-blossom marble.—Grey, with white veins, known by the name of marble of Angers.

Department of Montblanc: a shining white marble, with grey veins, at Pons-de-la-Bride; being mixed with vegetable earth it has the property of giving out sparks with the red; it is also much harder and more solid than the common marbles, and its specific gravity is greater. The Romans have employed it for the construction of several of their monuments. A breccia marble, called breche de Tarentaise; it consists of a purple base, with small fragments of white, yellow, and sometimes blackish marbles. This marble, which is found at La Villette, above Moutier, is much esteemed, both on account of its fine colour, and the superior polish it takes. Also, a yellow breccia marble, not unlike some antique varieties, it found in this department.

Department of the North: a white and reddish-brown marble, with white, all-grey, and blue veins, called marbre de Rance, from the place in Havre, where it is found. It is esteemed on account of its beauty, and as an article of commerce. The black marble of Barbancourt, with white veins, the grey variety with black spots, and white and aurora red veins from Clermont, the breccia marbles of Dinant, and Efroing-la-Rouillie, are also among the most valuable varieties found in the department.

Department of the Oarth: the grey and white variety with blood-red spots, called marbre de Hon, is well known. It comes from the neighbourhood of Lige, and is made use of for tables, chimney-pieces, vases, &c.

Department of the Strics of Calais: a yellowish-brown marble, with white, grey, and yellowish-red veins, has been lately discovered at Boulogne, and employed for the construction of the column placed there in commemoration of the victories of the French emperor, whence it has obtained the name of marbre Napoleon. Its structure is lamellar in some places, and compact in others. It takes a good polish, and, what adds much to its value, it may be procured in very large blocks, which, though solid, are of very moderate weight: the cubic foot weighing about 150 pounds. There are several other varieties of marble furnished by this department, such as the brocatolet of Boulogne, the marbles of Stavelot, Lige, &c.

Department of the Pyrenees: the marble of Bayonne in the Lower Pyrenees, (called there marbre pierre, on account of its whiteness) is rather fine-grained than Carrara marble. It is used in these parts for purposes of sculpture, but has the defect of turning yellow and spotted in a short space of time. More generally known is the marble of Campan in the High Pyrenees; this is a mixture of limestone and a talcose substance, which latter forms the entangled veins observable on its surface. There are three varieties of Campan, which, however, are often united in the same piece; the first, called green Campan, is of a very pale sea-green colour, and exhibits on its surface lines of a much deeper green, and forming a kind of network; the second, called Iabel Campan, is of a delicate rofe colour, and, like the first, furnished with undulated veins of green tale; the third variety, the red Campan, is of a deep red colour, with veins of a still deeper red, and in some measure resembles some parts of the groutte. In order to form a correct idea of the Campan marble, properly speaking, we must imagine that these three varieties are united, fo as to form large stripes of from a few inches to two, three, or even six feet wide, which produce a very grand and pleasing effect when viewed in large masses. Where, therefore, the Campan marble can be employed in the large way, it may be looked upon as the most beautiful and splendid of all marbles. It should not, however, be exposed to the weather, since, by so doing, the talcose substance exfoliates, and leaves hollow places, which render its surface uneven and rough; but it answers extremely well in the interior of buildings, for chimney-pieces, slabs for tables, &c. There are immense quarries of this valuable marble at Campan, near Bagnère, in the High Pyrenees. The marble of Sarencolin, in the High Pyrenees (in the ci-devant Gascony) exhibits on its surface large straight zones and angular spots of a yellow or blood-red colour, so that at first view it bears some resemblance to the marble called Sicilian. This is commonly known by the name of Sarencolin or Sarencolin; that of superior beauty has become scarce, and it is even said that the quarry which yielded the most perfect is entirely exhausted. The marble vulgarly called breche Caroline appears to be nothing but a modification of the Sarencolin. The variety of marble called marbre d'Autin, has a white ground, and exhibits at its surface fire-red veins, which
which sometimes produce very pleasing appearances. It is found at Verey, in the High Pyrenees. According to M. de Cambray it derives its name from the Celtic words an tin (of fire) or fire marble. In the High Pyrenees a most beautiful breccia is likewise found, the mass of which is of a light orange colour, containing small fragments of a brilliant whiteness. It takes an excellent polish, and may be manufactured into vases, tablets, &c. The breccia, called breche des Pyrenees, is likewise held in great esteem; its base is brownish-red, and exhibits black, grey, and red middle-fixed spots. It admits of a good polish. Besides those here enumerated, a number of other marbles are met with in the Pyrenees, than which no chain of mountains is richer in fine varieties.

Department of the Sambre and Meuse: the colour of the marble of Dinan is a fine black, but perhaps inferior in point of intensity to that of the antique black marble. It is used in sculpture: the arabesques in relief which ornament the church of St. Vaurain at Mons, are made of it. There are two other black marbles found in this department, viz. that of Theux and that of Namur; the former, which is sprinkled with grey dots, is wrought with facility, and takes a very good polish, but emits a slightly sulphureous odour when rubbed or struck with a hard body; the latter, which often inclines to greyish-black, and is traversed by grey veins, is exported to Holland in square flakes, and constitutes a valuable article of commerce. All these black marbles are in great request for the flooring of churches, for tomb-stones, &c. The grey marble of Saint Anne is sprinkled with white spots, the remains of madrepores, has been much used at Paris for tops of commodes, chimney-pieces, tables, &c.; but ever since the introduction of the unsightly marble from Jemmapes, called petit granit, it has greatly funk in estimation. The breccia marble of Vaulfort, between Dinan and Givet, also known by the name of breche de Dourlaix, has a reddish base with black, grey, and white spots; the pillars in the church of Saint Roque are covered with large flakes of this marble, which is susceptible of a good polish.

Specimens of the preceding varieties, and of the following Batavian marbles, are in the lar of the rotunda before the library of the Central School (ci-devant palace of the governors of the Netherlands) at Bruxelles; marble of Agimon, near Namur; brownish-red mixed with grey, traversed by thick white veins.—Of Avennes-le-Selgic near Valenciennes; a white flat gray marble, easily to be wrought, and becoming harder when exposed to the air.—Of Bourtombe; pale blue and reddish, with large white clouds.—Of Bray, near Rocele, dep. of Jemmapes; deep grey, mixed with white.—Of Clermont, near Valcourt, Sambre and Meuse; pale grey, with large white spots.—Of Deigne, pale grey, shaded with deep grey, and marked with fome white spots.—Of Dourlais; a calcareous breccia with reddish-grey base, incrusted with grey fragments of different shades and sizes.—Of Etrece, near Namur; a mixture of bluish-grey and pale grey, with whitish veins.—Of Franchimont near Florenne, Sambre and Meuse; pale red and pale blue, with white veins.—Of Fiery-le-petit, between Mons and Namur; white, with yellow and grey granular spots.—Of Gerfontaine, pale red shaded with blue, and traversed by large white veins.—Of Goghne near Florenne, Sambre and Meuse; pale reddish-grey, waved with red in equal portions.—Of Grosshov; dark grey, shaded with pale grey, with small white veins.—Of Hure, near Charleroy; pale blue and pale red, in clouds, with large white spots.—Of Lorraine; bluish-grey, a little veined with grey and white.—Of Limburg; brown, with white granular spots, appearing like small belemnites.—Of Mouchine; greyish and white blended, with natural figures.—Of Ourdin near Valenciennes; a white marble for statues and architectural ornaments.—Of Pegagnes; blueish-grey, with large white spots.—Of Rancon; near Beaumont, dep. of Jemmapes; reddish with various veins; used for chimney-pieces.—Of St. Renier, near Luxemburg; red, with brown, green, and blue veins, being one of the most beautiful marbles in Europe. It sometimes contains Muly and other figures.—Of Reilly; red and grey in large clouds, with white veins and spots.—Of Royale; grey shaded, with white veins.—Of Roy-Soine, Sambre and Meuse; pale grey, with white zigzag figures.—Of Solfe; greyish-blue, with many white veins. Another variety from the same place, of a blueish-grey base, with difluminated small white shells.—Of Somme; grey shaded, with some white veins; with natural figures.—Of Strœe, near Thonin, Jemmapes; grey veined, with white spots.—Of Thillée, near Thuin; dark grey, with white veins, and fragments of shells.—Of Vaulart; pale blue, shaded pale red, with white figures.—Of Zoude-Bart; dark grey with small clouds, mixed with grey and white.

Department of the Lower Seine: several varieties of yellow marbles, streaked with darker yellow, and exhibiting black dendrites, are found at St. Etienne, near Rouen; they are capable of a good polish, and M. Tory has invented an economical mode of polishing them.

Department of the Seine and Marne: an elegant marble called Chateau-London, of a very pale yellow, containing small inconspicuous shells and white transflucid veins, has but lately been discovered in this department. The beautiful bridge of Namours is constructed of it.

Department of the Var: the highly esteemed marble called Portor, on account of the brilliant yellow veins in its deep black ground; the most beautiful variety comes from St. Maximin.

Department of the Vôges: an excellent quarry exists near Framont, in the mountain called the Mathikopp, in which the marbles are diposed in horizontal beds; their principal colours are white, penetrated by red or black, and grey.

Department of the Po: a white flatuary marble, of a finer grey than that of Carrara, is found at Ponté, near Turin; of this marble are constructed the mausoleums of the kings of Sardina in the vaults of the church de la Supergue, near Turin.—Verde di Sufa is a green and white marble, resembling the verde antico; it is found at Sorza, in Piemont.—Marmo di Giffoni, called fo from the place near Turin where it is found, is light grey spotted by shells which are easily detached from the mass; beautiful columns have been made of it.

The territory of Genoa furnishes several beautiful varieties of marble, the most remarkable of which is the polvere de Genoa, called alto also in French vert d'Egypte and vert de mer. This marble is a mixture of granular limomite, with a talcose and serpentine substance dispersed in veins; but sometimes these latter substances constitute by far the greater part of the whole, while the white granular limomite appears only here and there in veins and patches. It is sometimes mixed with a reddish substance. This marble was formerly much employed in Italy, France, and England for chimney-pieces, &c.; but owing to its fombre appearance is come into disuse.

Corinica possesse, among other varieties, a good flatuari marble of a fine and cloie grain, and pure milky whitish, quarried at Orsone; it is comparable to that of Carrara.—Alto a grey marble (bardiglio), a cipolin, and
and some other varieties occur in Corfica. The island of Elba has immense quarries of a white marble with blackish-green veins.

Among the innumerable varieties of Italian Marbles the following deserve more particular notice.

The perego di Pistoia is a white marble found at Padua; it is used for architectural purposes, but is inferior in quality to those of Carrara and Genoa.—The white marble of St. Julian, at Pisa, is of a finer grain than that of Carrara, but takes no good polish; the cathedral and the celebrated tower of Pisa are constructed of this marble.—The Biancone marble is white with a light tinge of grey; it is quarried at St. Gregorio, Magione, &c. and chiefly employed for altars and tombs. Near Mergozzo the white marble with grey veins is found, with which the cathedral of Milan is built.—A white marble sprinkled with little spots and dotes of blood red, occurs at Lune, on the coast of Tuscany.—Another white variety variegated with red and yellow spots and veins, is found in different parts of the Venetian territory.

The black marble of Bergamo is called paragone (derived from the black colour of touchstone); it is the most pure and intense tint, and susceptible of a fine polish.—The black marble of Como, in the Milanese, is also greatly esteemed on account of the intensity of its colour. Near the lake of Como and at Valerano, there are, likewise, quarries of excellent black marble, which has been employed in the cathedral of Siena.

The perego of Malo is a black marble sprinkled with dots, which gives it the appearance of being covered with diut; there are beautiful flabs of it on the walls of the famous chappel of San Lorenzo.—A most beautiful white marble with black spots from the Lago Maggiore, which has been employed for decorating the interior of many churches in the Milanese.

The Margorare marble, found in several parts of the Milanese, is blueish veined with brown. Part of the dome of the cathedral of Milan is built of this marble.

The green marble of Florence owes its colour to a copious admixture of flasite. Another green marble, called verde di Prado, is found near the little town of Prado, in Tuscany; it is marked with spots of a deeper green than the red, and passing even into blackish-blue.

The beautiful Siena marble, or brocatello di Siena, has a yellow colour resembling the yolk of an egg, and disposed in large irregular spots, surrounded with veins of blueish-red, passing sometimes into purple. It is by no means uncommon in this country. At Montecarlo, two leagues from Siena, another yellow marble is found, which is traversed by black and purplish-black veins. This is frequently employed throughout Italy.—The marble of Breccia is yellow with white spots.

The mandello of the Italians is a light red marble, with yellowish-white spots, found at Lugazzano, in the Veronese. Another variety, bearing the name, occurs at Profa. They are both employed for columns and various other works.—The red marble of Verona is of a red, rather inclining to yellow, or hyacinth; that of a brighter red, and which contains some ammonites, is highly esteemed, and the tomb of Peruzzi, at Arquato, recently engraved by Panjas, is of this variety; the other variety, of a dull red, has been employed by the Romans, as may be seen, for instance, in the valley of the theatre of Verona, which is entirely built with it. Another marble is found near Verona, which Panjas calls effusa marble, because he fupposes the large white spots in the reddish and greenish pale to be owing to the remains of bones, of which they fill retain the figure. Very fine columns have been made of this marble.

Another Italian shell-marble is the occhio di pavone, the shells of which form large orbicular spots, red, white, and blueish. According to Da Colfa, the peacock's eye is of a bright cinnamon colour, with spots and veins of milk-white spar; many of the spots, forming circles about the size of a flaxence, are filled with a red ground, and from an imaginative resemblance have conferred the name. (P. 213.)—A madrepore marble, known under the name of Pietra felata, much employed in Italy, is entirely composed of star madrepores, converted into a grey and white substance, and is susceptible of an excellent polish.

Among the Italian breccia marbles are: the violet, called in France breche d'Italie, the ground of which is reddish-brown, veined white; it is a beautiful marble, but requires much care, since it becomes soon spotted by coming into contact with greasy substances. The village of Breccianco, in the Veronese, furnishes a splendid breccia marble, composed of yellow, fleck-grey and rose-coloured spots. That of Bergamo consists of black and grey fragments, in a greenish cement.

Florence marble, also called ruin marble, is a calcareous marble; which see.

Sicily abounds in marbles. Baron Dorch, in his Sicilian mineralogy, describes upwards of a hundred varieties, of which the following appear to be the most important. The principal and most valuable marble of Sicily is that frequently called Sicle, or Sicile antique, and by English flintcutters Sicilian Jasper; it is red, with large stripes like ribbons, white, red, and sometimes green, which here and there revolve, forming petty acute angles. At Bifalima a milk-white and an apple-green variety occur; both take a fine polish. Trapani presents a red marble with deeper red spots, and another with green spots: at the same place is found the variety called bigia bianca, being grey with white spots. another spotted with several colours; and one (called pito bigio), formed by the union of small red and yellow grains or spots. That of Calcedonio is yellow spotted with red.—Taormina furnishes several varieties: red with black spots; red with white veins, and deeper red spots; greenhish mixed with bright brown spots; purplish, with particular reflections. The marble of Santa Maria del Bisco is of a deep black with yellow veins, not unlike that called Portar. At Termun we find a greenish marble with white veins and red dots. Near Sciacca they quarry a bright green marble, varied with deeper green and yellow shades.

Among the Sicilian breccia marbles are those of Gallo, the one of a light grey colour, presenting elegant rose-coloured spots of several shades; and the other also gay, veined yellow, and exhibiting on its surface white translucent veins. The breccia marble of Monte Alano is light grey, with round and rose-coloured spots. That of Taormina has a deep red ground, and presents at its surface yellow and greyish-white spots.

**Spanish Marbles.**

Spain rivals Italy in the abundance and beauty of its marble. The vicinity of Valencia, Cadiz, Burgos, Granada, Molina, Carthagena, offer a great number of them. A mountain entirely composed of beautiful marbles exists at the distance of three leagues from San Felice; the Tagus takes its course partly through hills of marble that constitute its bed, and the Carpathian mountains are equally provided
provided with them. Hence it is that the monuments of antiquity in Spain, those of the middle ages, and of modern times, are profusely decorated with indigenous marbles. The vault of the beautiful theatre of Toledo is supported by 350 marble columns. The moleque of Cordova, erected by caliph Abdoulrahaman III., is ornamented with 1,200 columns, most of which are of Spanish marble: among the ruins of ancient Merida (Augufta Emerita), which was built 25 years before Christ, fragments of the most valuable marbles are still discovered; and finally, the church of the Elerciad, and the palace itself, are decorated with the most beautiful marbles, and the fame may be said of the principal churches of Madrid.

The milk-white marble of Cordova is very fit for sculpture; it has a fine grain and takes a good polish. Near Filabres, three leagues from Almeria, in Grenada, there is a mountain of about a league in circumference, and 2000 feet in height, which is entirely composed of the purest white marble, capable of the finest polish. The rocks which surround the town of Molina, in New Castile, are composed of a white marble, which has been employed in the palace of the Alhambra, at Grenada. The white fahne marble of Grenada is slightly tinged with red. Also the white marble of Badajoz has rather a reddish tint, but its grain is finer and closer than that of the preceding. A white variety with large grey spots, at La Mancha, in New Castile. A greyish marble is quarried at Toledo, and one, grey with white veins and spots, at Elvira.

The black marble of La Mancha is of a very intense colour, and susceptible of a high polish. Another of the same colour is found near Segovia, and a deep black variety with grey dots at Moron. Bifca furnishes a black marble veined with white, and another of greyish-black colour with yellow veins: this latter is often called Spanih Portor, but it is much inferior in beauty to that from St. Maximin, in the department of the Var.

A beautiful deep red variety, with shining white and bright red spots and veins, called red Sruville marble — Flesh-coloured, veined with white, from Santiago; and an entire mountain of this kind near Antiquera. — A dull red marble, with black papillary veins, found in Megueru, in Valencia, which is much employed in Spain for tables. — Near Molina there is an entire hill of a red, yellow, and white marble, with granular and brilliant fracture, like sugar. — The mountains of Guipuscoa furnish a red marble veined with grey, and closely resembling that of Sarancolin: Patra even conjectures that it may be of the same bed. At Cordegana, in Andalucia, a fawn-coloured variety powdered with grey.

The violet marble, spotted with bright yellow, from Tortosa, is much admired on account of its fine colours and the polish it takes. — A marble of a dull violet colour, like wine-lees, with orange-yellow angular spots, is found near Valencia; it is not susceptible of a high polish. — A green marble, resembling the verde antico, prevails itself at Grenada.

Near Morvedra there is a hill of black marble, veined with white, which, towards the summit, gradually passes into a yellowish-blue and reddish breccia. — A beautiful breccia marble is found at Kidi, in Arragon; it consists of angular fragments of a black marble imbedded in a reddish-yellow base. — The breccia of Old Castile is of a bright red, dotted with yellow and black, and includes mafhined fragments of a pale yellow, brick-red, deep brown, and blackish-grey; it is much employed at Paris.

One of the most celebrated Spanish marbles (which may be regarded as a shell-marble), is the brocatello; its chief colour is claret-red, variegated with numerous small spots, and points of yellowish-yellow, yellowish-grey, and a transfused white. All the greyish spots in this marble, when closely examined, prove to be fragments of shells, but the irregular yellow and red spots are not owing to remains of organic bodies. The name of brocatello is given to all those marbles that resemble gold cloth and embroidered silk. Of the same kind.

Portuguese Marbles.

Portugal appears to be poor in marbles; there are, however, several varieties mentioned by authors; such as that of Villa-vicosa, in Alentejo, spotted with grey, and (as Bowles has it) resembling the marble of Mount Atlas. The chain of mountains of Arrabeda, in Estremadura, likewise furnishes some esteemed marbles. — The marble of Troncaio is pale yellow, with greyish veins, and contains also remains of marine bodies.

The church of Alfara is built with marble of Cintra, a village on a mountain seven leagues distant from Lisbon.

Swiss Marbles.

The marbles of Switzerland, at least those which are objects of commerce, are not numerous; nor is there great variety of colours among those few that are found in its mountainous regions.

At Roche, near Aigle, in the canton (now department) of Leman, is a quarry of a marble veined with red, white, grey and black; it is wrought on the spot, and is almost the only one used at Geneva, and all over the Pays de Vaud; polished slabs of it are sent as far as Lyons. It often presents peccatines and madreporites, which have assumed the name and grain of marble, so that the shells seldom or never appear in their original form.

The localities of some other marbles, which we know to be Swiss, are not indicated by any writer on the mineralogy of Switzerland. There was formerly a marble mill at Bern, from which the finest varieties found in Switzerland were sent into France, Germany, and England; but this we suppose does no longer exist.

German Marbles.

The marbles of Germany are very numerous, and many of them far more beautiful than those foreign kinds which its wealthier inhabitants are so eager to obtain. A great number of them are even left unnoticed in the writings of topographical authors of that extensive country.

Austria, so rich in mineral treasures, excels also in the number and variety of its marbles. The most esteemed of those of Lower Austria are the marbles of Schottwien, of Liifenfeld, of Seitenlatten, and of the Kammerguth. That of Liisenfeld is of an intense black colour.

Those of Stiria (of Lambricht, Rothstetten, Zell, Maria-trost, &c.) are of the first quality. Carinthia has some fine white marbles, and also possesses the most beautiful of all known shell-marbles, viz. that of Bleyberg, called fire-marble, or opalescent lunachellas. The colour of the marble itself is not particularly iridescent; it is brownish-grey, shaded with a darker tint, which latter belongs to the fragments of shells of which the mafis are chiefly composed. But what distinguishes this variety of shell-marble from all others, are the opalescent fragments of a species of nautilus, here and there disseminated in its mafs; the tints which they reflect are red, green, and blue, of considerable intensity. This most esteemed of all varieties of lunachellas is seldom seen in large pieces. The greatest
greatest variety of boxes and other articles made of it, exists in the collections of Vienna.

In Carniola are found, among others, a flesh-coloured and grey marble, veined with white and blue; nearly the same as that called by the Italian Marmo breccia antica gebrata.—A yellow and dark red variety, with thrum-like veins; the same with that improperly called Diaforo di Sicilia a veno.—A pudding-stone marble, with pale red base, including grey and whitish rounded pieces; the same as the Marmo breccia catinata of the Italians.—A flesh-red marble, traversed by some calcareous spar, and called by the neighbouring Italians Palmine di Porta Santa; this is the most common variety of marble in those parts.—A black marble occurring in beautiful perpendicular strata; it is used for architectural purposes.—A white marble, not unlike that of Carrara, but mixed with dirty spots; nor can it be quarried in large blocks. Hakcut mentions several white varieties in other parts of Carniola, equalling and even surpassing the Carrara marble in whiteness and delicacy of structure.

Of Bohemian marbles, the finest white variety is that of the circle of Königgrätz; and among the variegated we have those of Czeftin, Koltef, and Sternberg, in the circle of Kuranz. But till finer are those in the circle of Berou: thus we have at Teltin a brown-red, at Hermanns- mieder a light blue, at St. Juan a red and yellow, and red and white variety; the marble of Kofors is black, with imbedded petrfactions, blemmites, entomolithus paradoxus, &c. Allo Karlstein and Dobritzchowitz of the same circle furnish fine varieties of marble. That of St. Juan only is found in small pieces; all the others occur in considerable beds.

Moravia, though less rich in marbles than Bohemia, still furnishes some very valuable kinds in those of Holkenitz, in the circle of Bürn, and of Niklafburg (which latter is a beautiful lunachella); not to mention several others, the quarries of which are not wrought.

In Franconia we have the rich quarries of Hoff, which, among others, yield a fine black marble, a curious brown-marble of red spots, a sea-green, blueish, and several kinds of red marble. The marbles of Bayern present a great diversity of colour and delineation, and are of a fine close grain. There is a manufactory of various articles in these marbles, at the house of correction, in the capital of the principality.

The Hartz mountains in Lower Saxony produce some good marbles. Those of Blankenburg have been described and praised, on account of the pleasing colours they exhibit; there are some of a beautiful black, with straight and oblique white stripes; others of the same colour, and with green and white spots; others with red spots; grey varieties, with white, brown, and red spots; and numerous red marbles, variegated with white, brown, greenish, and other colours. Several of these with a black, grey, and brown ground, contain medusporae and corallines. There were marble mills at Blankenburg, but there is very little employment for them at present.

At Langenstein, near Halberfladt, they quarry a very fine marble, another of a light green colour, and two white ones, with large brownish-red and yellow spots, of a fine appearance.

Norwegian Marbles.

Several of them are mentioned by Pontoppidan in his History of Norway, but it is dubious whether the worthy writer has been correctly informed in this particular. Indeed, according to Mr. Neergard, there is only one quarry in Norway, viz. that of Gillebeck, seven leagues distant from Christiana; but as the marble which it furnishes is saturated with a great quantity of pyrites, it generally becomes decomposed in a few years. The great church of Frederick, at Copenhagen, which is unfinished, is built with this marble. Neergard has often seen some pretty tablets of it, which contained garnets and actinote.

Swedish Marbles.

Only a few of these are mentioned by authors, such as that found in the province of Jemland, which is black and white, and also of an unmixed black; that of Kolmorden, in the province of East Gothland, composed of white granular limelime and serpentine. Neergard has given us an account of the quarry of Fagernech, situated between the two little towns of Norkoping and Nykoping, and about thirty leagues from Stockholm. It belongs, at present, to Mr. Eberlein, and to baron Unger, who purchased it from count Gymlenberg for only 220,000 francs, on account of its bad condition. This marble, which is white, with veins of green slate, the fracture brilliant, began to be wrought about 150 years ago, in the reign of queen Christina. The space where it is found is about 2000 fathoms in length, but its breadth is inconceivable. They make of it tombstones, slabs for tables, vases for butter, salt cellars, and mortars; and the sale of these different articles amounts annually to about 20,000 francs. There are magazines of it at Stockholm, at Gottenburg, at Carlerona, and at Abo. The manufactory employs about twenty workmen, who receive each two livres ten sous daily; and its position is fine and well adapted for working, as it is near the Baltic sea.

In the parish of Pargos, near Abo, in Finland, a very fine white marble is said to occur.

Russian and Siberian Marbles.

The vast Russian empire may naturally be supposed to abound in marble quarries; they are found in the Finnic and Thuringian mountain, on the Caucasus, in the Ural, the Altai, the Saanic, the Krafonarian, and the Auric mountains; in the northernmost parts of Siberia, on the sea of Ochotzk, at the Peninsular bay, on Tchutschenoif, Kamththaka, the Kurile and Akutan islands. The following varieties are enumerated in Georgii’s ‘Beschreibung des Russifchen Reichs’:—white fimal marble in the Oronk mountains, near the lake Gifh, where there is a quarry near Tifdowa; also on Novaga Semia. A greyish variety, with needles of flour, in the Onega islands; and another of the same colour, with green spots, on the banks of the Onega. A greyish-white fimal marble, containing much tremolite in fiscular and radiating circular crystals, in the quarry of Tifdowa. White fimal marble is found in various parts of the Ural and Altai mountains, in the Kircgefe Steppe, in Nertchinske, &c. &c. Pearl-grey, glittering, granular lime-stone on the U and Tagil of the Tobol; in the Siberian marble quarries. Blue-grey granular marble, with copper green, on the banks of the Lower Tcheilowaja. Grey-clouded marble, near the Perguba of the Onega; in the marble quarries of Cathericburg, &c. Brown granular marble on the banks of the Irith, near Jempalat; near Tifchinffe, in Nertchinske. Black fimal marble, at Kexholm; a variety of the same colour, but considerable hard- nefs, in the vale of Alufhta, in Tauris. A blackish-green variety, resembling parchment, on the banks of the Tifful twaja, at Severkoi Sawod, and in the Gubernifcian Ural. A light green variety in Dauria, at Kicchat; and another of the same colour, with dark green spots, on Jana, an island.
Island of the lake Ladoga. Reddish sable marble at Olonez. Dark red marble in Klimezkoi, one of the Onega islands, also in the Ural of Catherineburg. A variety of a light red colour, on the Argun of Dauria. Red sable marble, with brown stripes, near the Ul of Tobol, at Ataguz, where it is quarried in large blocks. Yellow sable marble in the northern Ural, in the bay of Casia, near the Isf of Tobol, on the banks of the Irth, at Jamuhewa. A greyish-yellow variety, with denticbia, near the lake Ilmen. Dark and light red sable marble, with white veins, in the Oneloefi quarries. Blackish-brown, with white veins, on the banks of the Onega. White marble, with black veins, on the banks of the Donetz, at Bachmut. A grey variety, with white veins, on the 1k, at Wofenfenkow. Greyish, with red veins, on the Tura, at Turinikow Sawod. Red, with white veins, also dark green striped marble, in the Ural of Catherineburg, &c. White marble, with veins of white calcareous spar, and short-like spots, at Catherineburg. Blackish-grey marble, with veins of quartz, near the Lektowska, in Kolyvan, and the Kookkata of the Upper Irth. A blackish-blue variety, with white veins of spar, at Northinikow Sawod. Black sable marble, with brown stripes, at Tiwdeva, in Olonez. Marble, with stripes of various colours, in the mountains of Kolyvan, the Ural, and Kurgoffe mountains. Marble, with dots of various colours, in Onoloefi, near the Ul of Tobol, &c. Spotted and famed marble of various colours in Tiwdeva, on the banks of the Ladoga, in various parts of the Ural, &c. Black marble, with yellow spots, at Northink. Clouded uni-coloured and variegated marble, mostly with grey for its bafe, in the quarries of Finland and Catherineburg. This is quarried in very large blocks: it is very durable, and therefore employed for the construction of balconies, &c. in the imperial palaces. Scaly marble, of a white colour, mixed with red, in Finland, on the banks of the lake Gifti, in the Ural. The same, of a grey colour, mixed with red, having dark spots, on an island of the lake Lifsha, &c. A blue variety, mixed with red, on the northern banks of the lake Ladoga. Parti-coloured marble, a mixture of greeniib, blackish, and white, at Kiitscha, in the mountains of Dauria, &c.

Patrin, who, during a residence of eight years examined the mineral treasures of those regions, has given the following account of the Siberian marbles. The Ural mountains furnish the finest and most variegated marbles. The greater part is taken from the neighbourhood of Kateringenburg, where they are wrought, and from thence transported into Russia, and particularly to Peterburg. The late empress caused an immense palace to be built there for Orlof her favourite, which is entirely coated with these fine marbles, both inside and out. This empress built the church of Isaac with the same marbles, on a vault space, near the statue of Peter the Great. This church was not finished in 1757. Patrin saw there columns of very large dimensions, which seemed to be of a single block, of a white and blueish marble in large veins. Only this kind of marble was used in that church. The palace of Orlof has many varieties, which are distributed in compartments. Patrin found no white flatmari marble in the Ural mountains; but in that part of the Altai mountains which is traversed by the river Irth, lie in two places sav enormous rocks of marble, perfectly white and pure, from which large blocks might be lewn. The only use made of it is to convert it into lime for the service of the fortresses situated along the Irth.

Asia is probably very rich in marbles, but they are little known.

Shaw makes mention of a red marble with dendritic delineations from mount Sinai.

Of Syrian marbles we have no other account but that given in Ruffel's Natural History of Aleppo. They have at that city an inferior kind of yellow marble, which takes a tolerable polish, and is used for the ornamental parts of buildings, and for paving the court-yard. But a variety of other marbles is brought from parts more distant. From Damascen they receive a red marble; whence also and from Kilhis, a coarse black fort; and from Antioch they procure various ancient fragments. The common Aleppo-marble is brought to resemble the Damascen red by rubbing it with oil, and letting it stand some hours in an oven moderately heated.

Some Persian marbles are mentioned by Chardin, particularly a translucent white one. Mr. Morier, in his interesting "Journey through Persia," just published, mentions the latter under the name of marble of Tabriz. The tomb of Haltz, the celebrated Persian poet, is constructed with this beautiful substance; and the maiment of the principal room of the Hailten, near Shiraz, is likewise of Tabriz marble: one of the largest slabs is nine feet in length and five feet in breadth. Its colours are described, by this author, as a combination of light greens, with here and there veins of red and sometimes blue; he adds that it is not procured near the city of Tabriz, or taken from a quarry, but that it is paid to be rather a petrifaction found in large quantities, and in immense blocks, on the borders of the lake Shabee, near the town of Meraugheh. We should take this substance to be a variety of calcareous alabaster, were not the size of the pieces above-mentioned against this supposition.

The marbles of Hindoootee are unknown to us, and the fame may be paid of those of Siam and China: we are told that in the latter the streets of some towns are paved with marbles of all colours, and most public buildings, bridges, and monuments are constructed of it. Mention is made by authors of a quarry of white marble in the neighbourhood of Pekin. Liboublere speaks of a quarry of a beautifully white marble near the capital of Siam.

Some of the antique African marbles have been mentioned in their proper place. A blue-marble variety (according to Brongniart) is still found at Sifiti in Mauritania; it is called turchiefa, or marbre bleu turquin, on account of its colour, which Tondi has found to be owing to the amphirole by which the marble is penetrated.

America.

There are many curious varieties of marble in North America. The chief quarries in the territories of the United States are at Stockbridge and Lunenburg, Massachusetts; in Vermont and Pennsylvania; in New York, and in Virginia: some of which are said to equal the finest kinds from Europe. At Marble town, near Hadfun river, are quarries of fine black marble, spotted with white flecks. Marble of various qualities, (as professor Hall informs us,) has been found in many places on the west side of the green mountains in Vermont. A few years since a valuable quarry was discovered in Middleburg, a town situated on Otter Creek, eleven miles above Vergennes. The quarry forms one bank of the creek for several rods, and extends back into the side of a hill to a distance at present unknown. The stone lies in irregular strata, varying considerably in thickness, but all more or less inclined to the north-west. The marble is of different colours in different parts of
of the bed. On one side it is a pure white, and of a quality little, if at all, inferior to Italian white marble; but this seems to constitute but a small portion of the whole mass. The colour that predominates through most parts of the quarry is a grey of different intensities. The marble of both kinds is solid, compact, free from veins of quartz, and susceptible of an excellent polish. A mill of peculiar construction has been erected for the purpose of sawing the stone into slabs. It contains sixty-five faws, which are kept almost constantly in operation. During the years 1809 and 1810 these faws cut out 20,000 feet of slabs, and the sales of marble tables, sideboards, tomb-stones, &c. in the same period, amounted to about 11,000 dollars.

Part of the marbles of South America will probably be illustrated in Von Humboldt's travels in those interesting regions. Those of Chili, described in Molina's work on the natural history of that part of South America, are of various kinds. The varieties of a single colour hitherto discovered are, white statuary marbles, black, greenish, yellow, and grey. Two mountains, the one in the Cordelera of Copiapo, and the other in the marbles of Mauco, entirely confit of marbles in zones of several colours; but in such strata as surround the mountains, from their base to the summit, with a symmetry that seems an artifice of nature. The variegated marbles are the grey with white, yellow, and blue veins; green, speckled with black; and yellow with black, brown, and green irregular spots. This latter, the quarry of which is at San-Ternando, the capital of the province of Cochabamba, is in great esteem, because it is easily wrought, and hardens in the air. All the marbles of Chili are generally of a good quality, and all take a good polish. Persons who have had occasion to examine the Llacer Anderes, have assured Molina that these mountains abound in marbles of different qualities, and nearly of all colours. In the plains near the city of Coquimbo a white field marble has been found, somewhat granular, three or four feet under the vegetable earth. The shells in it are more or less entire. The bed of this marble extends in length and breadth more than three miles; its thickness, generally about two feet, varies, and depends on the number of the beds, which are sometimes five, sometimes eight. These beds are almost always divided by very thin layers of sand. This stone increases in hardness in proportion to its depth; the first beds only present a coarse friable stone, of no use but to make lime; the following, although compact, easily yield to the iron instruments used to cut it, and raise it from the quarry; but in building acquire a sufficient hardness to resist any impression of the air or water. Molina, p. 77.

Marbles. Artificial. The flavo, wherever they make statuary, busts, bas-reliefs, &c., and other ornaments of architecture, ought to be marble powdered, mixed in a certain proportion with plaster; the whole well sifted, worked up with water, and used like common plaster. See Stucco.

There is also a kind of artificial marble made of the flaky felinites, or a transparent flint, rendering marble, which becomes very hard, receives a tolerable polish, and may deceive a good eye. This kind of felinites resembles Musscoyite.

There is another sort of artificial marble, formed by corrodive tincture, which penetrating into white marble to the depth of a line or more, imitate the various colours of other dearer marbles.

There is also a preparation of brimstone in imitation of marble.

To do this, you must provide yourself with a flat and smooth piece of marble; on this make a border or wall, to encompass either a square or oval table, which may be done either with wax or clay. Then having provided several sorts of colours, as white-lead, vermilion, lake, orpiment, mallicot, smalt, Prussian blue, &c. melt on a flow fire some brimstone, in several glazed pipkins; put one particular sort of colour into each, and stir it well together; then having before oiled the marble all over within the wall, with one colour quickly drop spots upon it of larger and less size; after this, take another colour and do as before; and so on, till the stone is covered with spots of all the colours you design to use. When this is done, you are next to consider what colour the mafa or ground of your table is to be; if of a grey colour, then take fine sifted ashes, and mix it up with melted brimstone; or if red, with English red ochre; if white, with white-lead; if black, with lamp or ivory black. Your brimstone for the ground must be pretty hot, that the coloured drops on the stone may unite and incorporate with it. When the ground is poured even all over, you are next, if judged necessary, to put a thin washcoat upon it: this must be done whilst the brimstone is hot, making also the board hot, which ought to be thoroughly dry, in order to cause the brimstone to stick the better to it. When the whole is cold, take it up, and polish it with a cloth and oil, and it will look very beautiful.

Smith's Laboratory, p. 248.

Marble. Colouring of. The colouring of marbles is a nice art, and in order to succeed in it, the pieces of marble, on which the experiments are tried, must be well polished, and clear from the least spot or vein. The harder the marble is, the better it will bear the heat necessary in the operation; therefore alabaster, and the common soft white marble, are very improper to perform these operations upon.

Heat is always necessary for the opening of the pores of the marble, so as to render it fit to receive the colours; but the marble must never be made red-hot, for then the texture of the marble itself is injured, and the colours are burnt, and lose their beauty. Too small a degree of heat is as bad as too great: for, in this case, though the marble receives the colour, it will not be fixed in it, nor strike deep enough. Some colours will strike, even cold; but they are never so well sink in as when a just degree of heat is used. The proper degree is that which, without making the marble red, will make the liquor boil upon its surface. The menustra used to strike in the colours must be varied according to the nature of the colour to be used. A lixivium made with horse's or dog's urine, with four parts quick-lime, and one part pot-ash, is excellent for some colours; common ley of wood-ashes does very well for others; for fume, spirit of wine is best; and finally, for others, only liquoris, or common white wine.

The colours which have been found to succeed best with the peculiar menustra are these: flax-blue dissolved in fix times the quantity of spirit of wine, or of the universal lixivium; and that colour which the painters call litmus, dissolved in common ley of wood-ashes. An extract of saffron, and that colour made of buckthorn berries, and called by the painters sap-green, both succeed, well dissolved in urine and quick-lime, and tolerably well in spirit of wine. Vermilion, and a fine powder of cochineal, succeed also very well in the same liquors. Dragon's blood succeeds very well in spirit of wine, as also a tincture of logwood in the same spirit. Alkani-root gives a fine colour, but the only menstrem to be used for this is oil of turpentine; for neither
neither spirit of wine, nor any lixivium, will do with it. There is another kind of 
fungus draco, called dragon's blood in tears, which, mixed with urine alone, gives a very
Beside these mixtures of colours and menstruums, there are some colours which are to be had on dry and unmixed. These are dragon's blood of the purest kind, for a red; gamboge for a yellow; green wax for a green; common bright brown, pitch, and turpentine, for a brown colour. The marble for these experiments must be made considerably hot, and then the colours are to be rubbed on dry in the lump. Some of these colours, when once given, remain immutable; others are easily changed or destroyed. Thus the red colour given by dragon's blood, or by a decoction of logwood, will be wholly taken away by oil of tartar, and the polish of the marble not hurt by it.

A fine gold colour is given in the following manner: take crude sal ammoniac, vitriol, and verdigris, of each equal quantities; white vitriol succeeds bift, and all must be thoroughly mixed in fine powder.

The fining of marble to all the degrees of red, or yellow, by folutions of gamboge, or gamboge, may be done by reducing these gums to powder, and grinding them with the spirit of wine, in a glafs mortar; but for smaller attempts, no method is so good as the mixing of a little of either of these powders with spirit of wine, in a filver spoon, and holding it over burning charcoal. By this means a fine tinture will be extracted, and with a pencil dipped in this, the finest traces may be made on the marble, while cold, which, on the heating of it afterwards, either on hand, or in a baker's oven, will all sink very deep, and remain perfectly distinct in the stone. It is very easy to make the ground-colour of the marble red or yellow by this means, and leave white veins in it. This is to be done by covering the places where the whiteness is to remain with white paint, or even with two or three doubles only of paper, either of which will prevent the colour from penetrating in that part. All the degrees of red are to be given to marble by means of this gum alone; a light tinture of it, without the affixture of heat to the marble, gives only a pale flesh-colour; but the stronger tintures give it yet deeper. To this the affinity of heat adds yet greatly; and finally, the addition of a little pitch to the tinture gives it a tendency to blackness, or any degree of deep red that is desired.

A blue colour may be given also to marble by dissolving turpentine in a liquid of wine and urine, or in the volatile spirit of urine; but this has always a tendency to purple, whether made by the one or the other of these ways. A better blue, and used in an easier manner, is furnished by the Canary turpentine, a subtility well known among the dyers. This needs only to be dissolved in water, and drawn on the place with a pencil: this generates very deep into the marble, and the colour may be increased by drawing the pencil, wetted aforehand, several times over the same lines. This colour is subject to spread and diffuse itself irregularly; but it may be kept in regular bounds, by circulating its lines with beds of wax, or any other such subtility.

It is to be observed, that this colour should always be laid on cold, and no heat given even afterwards to the marble; and one great advantage of this colour is, that it is therefore easily added to marbles already stained with any other colours, and it is a very beautiful tinge, and lasts a long time.

Mem. Acad. Par. 1732.

This art has in several people's hands been a very lucrative secret, though there is scarcely any thing in it that has not at one time or other been published.

Kircher has the honour of being one of the first who published anything practicable about it. This author meeting on some cabinets suppose to be natural, but having figures too nice and particular to be suppose to be nature's making, and these not only on the surface, but sunk through the whole body of the stones, was at the pains of finding out the artist who did the business; and on his refusing to part with the secret on any terms, this author, with Alber, Gunten, a Saxon, endeavoured to find it out; in which they succeeded at length very well. Their method is this: take aqua fortis and aqua regia of each one ounce, sal-ammoniac one ounce, spirit of wine two drachms, about twenty-six grains of gold, and two drachms of pure silver; let the silver be calcined and put into a phial, and pour upon it the aqua fortis; let this stand some time, then evaporate it, and the remainder will first appear of a blue, and afterwards a black colour; then put the gold into another phial, pour the aqua regia upon it, and when it is dissolved, evaporate it, and the remainder will first appear of a blue, and afterwards of a black colour; then put the spirit of wine upon the sal-ammoniac, and let it be evaporated in the same manner. All the remainders, and many others made in the same manner from other metals dissolved in their proper acid menstruums, are to be kept separate and used with a pencil on the marble. These will penetrate without the least affixture of heat; and the figure being traced with a pencil on the marble, the several parts are to be touched over with the proper colours, and this renewed daily till the colours have penetrated to the desired depth into the stone. After this the maps may be cut into thin plates, and every one of them will have the figure exactly represented on both surfaces, the colours never spreading. The nioest method of applying these, or the other tinging substances, to marble that is to be wrought into any ornamental works, and where the back is not exposed to view, is to apply the colours behind, and renew them so often till the figure is sufficiently seen through the surface on the front, though it does not quite extend to it. This is the method that of all others brings the stone to a nearer resemblance of natural veins of this kind. The same author gives another method to colour marble by vitriol, bitumen, &c. forming a design of what you like upon paper, and laying the said design between two pieces of polished marble; then closing all the interstices with wax, you bury them for a month or two in a damp place. On taking them up, you will find that the design you painted on the paper has penetrated the marbles, and formed exactly the same design on them. Kircher's Mund. Sibcri. lib. viii. § 1. cap. 9.

Wallerius, in his Mineralogy, vol. ii. p. 128. recommends the last method of Kircher; and the first method is copied in the Phil. Trans. N. 7.

The art was practised by Mr. Bird, a fome-cutter at Oxford, before the year 1666; but his method is not recorded. Mr. Robert Chambers, of Minchinhampton, in Gloucestershire, discovered and practised a method of colouring marble, which he kept a secret. Mr. Da Costa has published an account of experiments made on several pieces of marble stained by this artifi. Phil. Trans. vol. lii. art. 5. p. 35. &c.

Spots or oil stains on the whole body of the stone, so that they cannot be taken out. See Staining of Stones.

Marble, Polishing of. The art of cutting and polishing marble was, of course, known to the ancients; whole mode of proceeding appears to have been nearly the same with that employed at present; except, perhaps, that they were unacquainted with those superior mechanical means which now greatly facilitate the labour, and diminish the expense of the articles thus produced. There are many celebrated manu-
factories of this kind generally called marble mills, on the continent, and also in Great Britain; but as the principle on which they proceed is nearly the same in all, it will suffice in this place to give the description of one or two of the latter. The following description, together with some preliminary observations, communicated by a person practically acquainted with this subject, relates to the manufacture of Messrs. Brown and Mawe at Derby.

An essential part of the art of polishing marble is the choice of substances by which the prominent parts are to be removed. The first substance should be the sharpest sand, so as to cut as fast as possible, and this is to be used till the surface becomes perfectly flat. After this the surface is rubbed with a finer sand, and frequently with a third. The next substance after the finest sand is emery of different degrees of fineness. This is followed by the red powder called tripoli, which owes its cutting quality to the oxide of iron it contains. Common iron-ore powdered and levigated answers the purpose very well. This last substance gives a tolerably fine polish. This, however, is not deemed sufficient. The last polish is given with putty. After the first procecss, which merely takes away the inequalities of the surface, the sand employed for preparing it for the emery should be chosen of uniform quality. If it abounds with some particles harder than the rest, the surface will be liable to be scratched so deep as not to be removed by the emery. In order to get the sand of uniform quality, it should be levigated and washed. The hard particles, being generally of a different specific gravity to the rest, may be separated by this means. A separate method will be found much superior to that of fitting. The substance by which the sand is rubbed upon the marble is generally an iron plate, especially for the first processes. A plate of an alloy of lead and tin is better for the succeeding processes, with the fine sand and emery. The rubbers used for the polishing, or last processes, consists of coarse linen cloths, such as hop bagging, wedged tight into an iron frame. In all these processes, a constant supply of small quantities of water is absolutely necessary. The faying of marble is performed on the same principles as the first processes of polishing. The faw is of soft iron, and is continually supplied with water and the sharpest sand. The faying, as well as the polishing of small pieces, is performed by hand. The large articles, such as chimney-pieces and large faws, are manufactured by means of machinery working by water or steam. We shall next give a description of this branch of manufacture in the large way, as carried on by Brown and Mawe at Derby, and in London, N° 149 Strand, who have justly attained great celebrity as workers of fpar and marble into different ornaments.

Fig. 1. Plate XXIII. Miscellaneous, is a side view of a mill for faying and polishing faws of marble; fig. 2., being a ground plan of the same, and marked with corresponding letters. A B C is a frame of wood, suspended by the upright frames of wood, D E F G, from the beams H H H H, so as to be capable of oscillatory motion. Motion is given to this frame by the rod I communicating with the crank O K, which is turned by water or steam.

This frame, being put in motion, gives motion to the faw frames L L M M, and to the polishing arms N P Q, which work on the pivot P, and are pushed backwards and forwards by the connecting iron rods a n. The faws are iron plates shaped like a common faw, and fastened into oblong rings by means of pins. These rings are put upon the cresps bars E E, b b, and the faws are stretched tight by the screws s s and C R R S S, are four upright posts constituting a frame, in which are placed the blocks of marble to be fayed into faws, which, at the same time, grate the frame of the faw. At each end of this frame there are a number of upright figure bars of iron i i, between which the faws pass which bars, act as conductors. The poles R R, can be removed to a greater distance, fo as to make the frame longer for receiving different sized blocks. The part T, to which the faw is attached on the movable frame, slides upon the upright post A C. It is suspended by a rope, which goes over a pulley c, and is counterbalanced by the weight W. By this means the faw may be made to proceed upon its work with any degree of force. It will be evident that the movable frame, from its pendulous motion, does not move in a straight line, but a curve. The sliding part T, therefore, serves to induce a rectilinear motion of the faw. The upright bars of iron i i, and C, are of a fize equal to or less than the thinnest faws, so that the faws may be placed at different distances, according to the thickness of the faws. In order to alter the faws for this purpose, nothing more is necessary than to loosen the cresps s s, &c. and shift the oblong rings which contain the faws.

The faws of marble to be polished are laid upon the carriage b, so as to correspond with the rubber Q, which passes over it in the direction of its length. In order to extend the rubber to the other parts of the faw, the carriage, b, has a lateral motion, by means of four grooved wheels running upon the iron guides let into the beams e e. The endless screw e, in the main shaft, turns the wheel r. This gives motion to the lever o o, fig. 2, by means of the crank g. The lever communicates with the crank k, and turns the wheel i i, more or less of a revolution, according to the length of this crank, which can be altered at pleasure by shifting the temporary pin e. By this latter motion the wheel, k, works the ratch e, and gives the lateral motion to the carriage. By this means the whole of the surface is exposed to the action of the rubber. Round articles of fpar, gypsums, and marble, are turned in the lathe with pointed instruments of hardened steel. The pieces to be turned are attached to a wooden cheek by means of cement. The gypsum is very soft, and turns with great facility. The hard fpar and marble require the tool to be very hard, while the part to be turned requires a constant supply of water, which drops from a vellum above. Above the articles are turned into the given fhape, they are drefled with sand and emery, and afterwards polished with tripoli and putty.

Small specimens for collections of marbles are generally polished upon a hp, which runs in a lathe. Thefe laps, however, ought to run with the axis perpendicular to the horizon, the face of the lap being truly flat and horizontal. The lap used for the first processes should be of iron; the last faw is made of an alloy of lead and tin; and the third, which is for polishing, should be of iron with pitch. By means of some auxiliary machinery, a number of pieces might be polished in this way at once, which would save much manual labour. Small pieces of marble may also be polished on the large machine, by cementing them with plaster upon the surface of a large faw. By being placed on the fame level, the large rubber sweeps them all at once.

The marble mill in the neighbourhood of Kilkenney, in Ireland, mentioned under the article Irish marbles, seems at present to be in a bad state of repair, and is little used. One of the principal objectors to the mill was an Alderman Collins, grandfather of the present proprietor, which is remarkable for the simplicity of its structure, and for the powers it exerts. One wheel, ten feet diameter, with twelve floats or ladles, gives motion, by a crank at one end of its axis, to a frame containing twelve faws, which do the work of about twenty men. By a
crank at the other end, it moves a frame of five polishers, which do the work of about ten men. At this end Mr. Collis has lately fitted a frame beneath the polishers, with eight faws, to the motion of which he has found the power of the machine fully equal. This mill may be fairly said to do the conifant work of forty-two men daily. During the night the mill stopped, a conifant attention being required to supply the faws with hand, and to attend the polishers. The faws are made of soft iron, and fall about a week; they are constantly supplied with water and land; the latter is taken out of the bed of the Nore, and wafted till nothing remains, but very fine and pure fliceeous particles. A faw cuts ten inches in a day, and twelve when the water is strong; it would require two men to do the fame with a hand faw. The marble taken from the mill is firft polished with a cow-flone, that is, a brown hand-flone imported from Chefters, and which takes its name from being used in chimney coyes. It is afterwards polished by a bow-flone, which is a piece of smooth nodule of the argillacious iron ore, found in the hills between Kilkeney and Freifhead. It receives the last polish in the mill with rags and putty. By means of this mill, the marble is so eafily worked as to be sold at a very moderate price.

A great improvement in cutting marble and other flones, but particularly columns by machinery, was invented in Ireland by the late Mr. George Wright, bart., who procured a patent for it. By this a number of hollow columns can be cut from a folid block, each decaeeing in fize, fo that nothing of the flone is left, except what is converted into dust by the faw.

Marble Harbou, in Geography, a bay in the Mergui Archipelago, on the E. coast of Sullivans island. N. lat. 10° 38'.

Marble Island, a small island of the Mergui Archipelago, at the entrance of Marble harbour.—Also, an island in Hudson's bay. N. lat. 62° 35'. W. long. 91° 30'.

Marbled, something veined, or clouded, reembling marble. Marbled paper is a paper flained with various clouds and flades, reembling, in fome meafeure, the diverse veins of marbles; the method of making which, fee under Paper.

Marbled China-ware, a name given by many to a fpecies of porcelain or China-ware, which feems to be full of cemented flaws. It is called by the Chinese, who are very fond of it, tsou-techi.

It is generally plain white, fometimes blue, and has exactly the appearance of a piece of China which had been first broken, and then had all the pieces cemented in their places again, and covered with the original varnish. The manner of preparing it is eafy, and might be imitated with us. Instead of the common varnish of the china-ware, which is made of what they call oil of flone and oil of fern mixed together, they cover this with a fimple thing made only of a fort of coafte agates, calcedine to a white powder, and faeparated from the grofer parts by means of water, after long grinding in mortars. When the powder has been thus prepared, it is left moist, or in form of a fort of cream, with the last water that is fufted to remain in it, and this is ufed as the varnish. Our crytal would serve full as well as the coafte agates, and the method of preparation is perfectly eafy. Observe, fur les Coats, de l'Afie.

The occasion of the singular appearance of this fort of porcelain is, that the varnish never spreads evenly, but runs into ridges and veins. These often run naturally into a fort of mofaic-work, which can fearcely be taken for the effeet of chance. If the marbled China be defcribed blue, they ftill give it a general coat of this colour, by dipping the veifel into a blue varnish; and when this is thoroughly dry, they add another coat of this agate-oil.

Marblehead, in Geography, a port of entry, and poilt-town of America, in Essex county, Maffachufetts, containing one epifcopal, and two congreational churches, and 5211 inhabitants. The harbour lies in front of the town S.E. extending from S.W. to N.E., about a mile and a half in length, and half a mile broad. A battery and citadel were erected here in 1795, for the defence of the place, by order of Congrefs. The bank-fhirley employs the principal attention of the inhabitants, and more of this buifeen is done here than in any other poift in the lade. The trade of the year 1794 amounted to 16,052 dollars. Marblehead was incorporated in 1649, and lies 3 miles S.E. of Salem, and 10 N.E. of Boflon. N. lat. 42° 30'. W. long. 69° 49'.

Marbles, Playing, are mostly imported from Holland, where it is faid they are made by breaking the flone ala-7ftcr, or other fubftance, into pieces, or chips of a fiut-able fize; these are put into an iron mill which turns by wa-ter: there are feveral partitions with raps within, cut flat-ways, not with teeth, which turn confantly round with great fwiifeifs; the ftriction againft the raps makes them round, and as they are formed they fall out of different holes, into which fize or chance throws them. They are brought from Nuremberg to Rotterdam, down the Rhine, and from thence difperfed over Europe.

Marbletown, in Geography, a township in Ulter county, New York, on the W. fide of Hudfon river, N.W. of Pultz, adjoining. It contains 2847 inhabitants.

Marbling, the art or act of painting or difpofing colours in fuch a manner, that they may repreffent marble. Thus we marble books, paper, wood, &c. See Paper, and Colouring, &c. of Bone.

Marling of Books, among Binders, denotes the sprink-ling over the cover of a book firt with ink, and afterwards with weak aquaforis. See Book-binding.

They also marble books on the edges; but, in this marbling, there is no black used, but, in lieu thereof, red, blue, &c.

Marble, in Geography, a town of France, in the department of the Eure; 12 miles N. of Conches.

Marbo, a town of France, in the department of the Ain; 8 miles N. of Bourg-en-Bresse.

Marburg, a town of the duchy of Stiria, feated on the Drave, which had formerly counts of its own; 31 miles S. of Graz. N. lat. 46° 40'. E. long. 15° 37'.

Marburg, or Marburg, a town and capital of Upper Heffel, on the W. fide of the Lahm, defended by a fittle, in which the landgraves of Heffel formerly refided. This town has an university, founded in 1527 by the landgrafe Philip the Magnanmous, also an academy for claffical literature, and three Profeftant churches. About the beginning of the thirteenth century, this place was raifed from a village to a town.

In 1561 and 1319 it was wholly defroyed by fire. In 1759 it was garrifoned by French troops, who were foon after obliged to surrender themselves prifoners of war; 36 miles N. of Francfort-on-the-Maine. N. lat. 50° 48'. E. long. 8° 48'.

Marc, in Biography. See Marcians.

Marca, Peter d'e, a celebrated French prelate, was born at Gaft, in the principality of Bearn, in the year 1594. Having laid a good foundation in claffical learning and polite literature, he went through a course of philofophy under the Jefuits at Toulouse: after this he studied the law, and at the age of twenty-two was nominated by Lewis XIII. counfellor in
in the foreign council of Pau, in which, though he was the only Catholic in that court, he conducted himself with so much prudence, that he maintained perfect harmony with all his coadjutors, and was successful in bringing back several of the reformed into the bosom of the Catholic church. In the midst of other important engagements, he devoted much of his time to the study of theology and ecclesiastical antiquities. In 1650 he was called to the council of France, and was brounished with the rank and dignity of councillor of state. In this important year he published his "History of Bear", which tended greatly to confirm the reputation that he had already acquired for learning and abilities. About this time M. Herissant published an artful defence of the Papal pretensions over the Gallican church, in the form of a satire on the policy of cardinal Richelieu, which, it pretended, aimed at the separation between the churches of Rome and France, similar to the schism produced by Henry VIII. in England; and the erection of a patriarchate in France in the person of the cardinal. To counteract the effects of this work, Richelieu employed the pen of M. de Marea, who, in 1651, published a piece entitled "De Concordia Sacreroci et Imperi, five, de Libertatis Ecclesiae Gallicae." This was a very learned, and generally esteemed excellent, vindication of the rights and liberties of the French church and state, and it was received with great approbation by those Catholics, who, though steadily attached to the doctrines of the church of Rome, refuted the tyranny and injustice of its aspiring pontiffs: but in the court of Rome it failed to Paris, and was his- tory of which he soon felt the effects. The king appointed him to a bishopric, which the cardinals, by certain manoeuvres, prevented him from entering upon, till he had retraced or explained away every sentiment that had given offence at Rome, and by declaring his unreserved submission of what he had written, or might in future write, to the foreign judgment of the holy apostolic see. Having by this servile conduct appeased the resentment of the papal court, he was ordained priest, and immediately afterwards consecrated bishop. This was in the year 1648, and in 1652, as a reward for other services, he was nominated archbishop of Toulouse; but, by a new opposition from the court of Rome, he was not translated till the year 1655. In 1658 he was made a minister of state, and followed the king to Lyons, after which he was appointed to preside over the states of Narbonne, upon the death of the archbishop. After Cardi al Mazarin had concluded a peace, he was sent to Rouffillon for the purpose of determining, with the commissioners of the king of Spain, the precise limits between France and Spain, according to the boundary line of the ancient geographers. Upon the death of the cardinal, in 1661, Marea was selected as one of the persons to preside over ecclesiastical affairs, and in the following year he was, in consequence of the resignation of cardinal de Retz, nominated to that dignity, but he did not live to enjoy, or even to take possession of this high office. He died about the sixty-eighth year of his age: he was a man of profound erudition, of a fine understanding, and of an extraordinary genius for business. He was a great politician, a good lawyer, a learned divine, and an able orator. He never eruped to make his principles give way, if by so doing he could promote his own interests. A few months before his death he dictated to his secretary "A Treatise on the Infalibility of the Pope," with the express view of recommending himself to a cardinal's hat. The last edition of his celebrated work "De Concordia" was published after his death, in 1703, in which the concessions with which he had purchased the papal bull to obtain the prelacy, were, by his order, directed to be omitted, and the work given in its original state. He was the author of several other pieces, among which were "Marea Hispanica," containing a curious and valuable geographical and historical description of Catalonia, Rouffillon, and the neighbouring countries; "An Account of what passed in the Ambassadors of the Bishops in 1653;" "Theological Treatises;" and two volumes of "Opposites." Moreri.

MARCANTHUS, in Botany, is a genus of Loureiro's, so called by an accountable, though we presume accidental, mistake for Macranthus, since the derivation of its name being erroneously from μακρον, long, (which he erroneously writes μαρκονος) and ανθη, a flower; the genus being very remarkable for the great length of its flowers. Loureir. Cochinch. 460.

Gen. Ch. Cal. Perianth inferior, tubular, coloured, downy, permanent, cloven into four, acute segments, the two lateral ones shorter. Cor. papilionaceous, very long, almost closed. Standard ovate, emarginate, connivent, longer than the calyx. Wings oblong, creft, three as long as the standard. Keel longer than the wings, with an acute, ascending point. Stam. Filaments ten, fimple and nine-cleft, all linear-rotate, acuminate and straight, four of them three times as thick as the rest; anthers of the thicker ones ovate, incumbent; of the others oblong and upright. Pilj. Germin superior, oblong, cylindrical; ftyle thread-shaped, hairy all over, the length of the filaments; stigma obtuse, roughish. Peric. Legume straight, nearly cylindrical, thick, pointed. Seeds numerous, nearly ovate.

Eff. Ch. Keel and wings very long. Legume thick, somewhat cylindrical.

1. M. koekenhenfex. Loureir. Dau meo, of the natives.—A native of cultivated ground in Cochinchina.—The stem is herbaceous, long, round, twining, branched. Leaves ternate, ovate-hoimold, hairy. Stipulas thread-shaped. Flowers white, with a calyx of the same colour, on many-flowered, axillary flaks. Legume cleft, although neither well tailed nor furibulous.

MARCAPATA, in Geography, a town of Peru, in the jurisdiction of Quilincachi.

MARCARIA, a town of Italy, in the department of the Mincio, on the Oglio; 14 miles S.W. of Mantua.

MARCAI, three small islands in the Pacific ocean, near the coast of Peru. S. lat. 11° 30'.

MARCASTE, in Mineralogy, Arfetiafl Pyrites of Kirwan, See Arsenic.

MARCAI, in Geography, a town of France, in the department of the Vienne; 7 miles S. of Poitiers.

MARCEL, St., a town of France, in the department of the Ardèche; 24 miles S. of Privas.—Also, a town of France, in the department of the Mouths of the Rhône; 5 miles E. of Marcellies.—Also, a town of New Navarre; 150 miles S.W. of Cafa Grande.

MARCELLIANISM, in Ecclesiastical History, the doctrines and opinions of the Marcellians, a feft of ancient heretics, towards the commencement of the third century, so called from Marcellus of Ancyra, their leader, who was accused of reviving the errors of Sabellius.

It is generally supposed that Marcellus, bishop of Ancyra, in Galatia, was present at a council of Ancyra in 314, as bishop of that city. He was also at the council of Nice in 325, where he signified himself against the Arians; and it is concluded, from the testimony of Epphanus, that he died in 372, when he had been bishop almost 60 years, and had lived almost or quite a century. Socrates says, that in opposing Aurelius, against whom and other Arians he wrote a book.
a book in the year 1534 or 35, Marcellus went into the other extreme, and embraced the opinion of Paul of Samo- fata, who says, that Jesus Christ is a mere man. He was deposed by an affent of bishops at Constantinople, in 335, but restored by the synod at Sardica in 347. His book, which was a large work, and the only one he had published, was answered by Eufebius of Cæsarea, from whose quotations and arguments, as well as from Marcellus's letter and confession of faith, delivered to Julius, bishop of Rome, about the year 341, which is preferred by Ewipianus, that he received the same scriptures with other Chriftians, and paid them a like repect. Socrates and Sozomen feem to have fuppofed, that he adopted the opinion of Paul of Samo- fata; but Eufebius continually charges him with Sabellan- ifm. Theodoret says, that he denied a trinity of perfons. However, there have been formerly, as well as lately, different apprehenfions concerning the real sentiments of Marcellus; but, according to Dr. Lardner, there is sufficient reafon to think, that he was a Sabellian or Unitarian. Montefuon is of opinion, that not long before his death, about the year 372, he fent a deputation to Athanasius, with a confeffion of his faith, completely orthodox; but this story, as Dr. Lardner thinks, is not well supported. If the doctrine of Marcellus be afceribed to him, it will appear, says Mo- thefin, that he confidered the Son and Holy Ghost as two emanations from the divine nature, which, after performing their repective offices, were to return again into the fulblance of the Father; and every one will receive, at firft fight, how incompatible this opinionis with the belief of three dif- tinct perfons in the Godhead. Lardner's Works, vol. iv. Of the Confecration of the Church. vol. i.

MARCELLIN, St., in Geography, a town of France, and principal place of a district, in the department of the Ile; 30 miles S.E. of Vienne. The place contains 3047, and the canton 14,579 inhabitants, on a territory of 2490 kilometres, in 16 communes.—Alfo, a town of France, in the department of the Rhone and Loire; 9 miles S.S.E. of Montbrifon.

MARCELLINO, a town of Naples, in Calabria Citra; five miles E. of Scalea. MARCELLINUS, Ambianus, in Biography. See Ambianus Marcellinus.

Marcellinus, pope, a native of Rome, succeeded to the see of that city in the year 296. He was accufed by the Donatifa of having afpolitified under the Dioclelian perfecufion; of having given up the scriptures to be burnt by the Pagans; and of offering incenfe even to the gods. It should, however, be obferved, that the innocence of Marcellinus was defended, and his conduct justified by St. Augustine and Theodoret, who affirm that he acquired great glory during the perfecufion. He prefided over the Roman church fomething more than eight years, and died in the year 304. Moreti.

Marcellinus, count of Illyria under the emperor Juf- timius, drew up a chronicle, commencing at the point in which Jerome finifhes, and carrying it down to the year 534. It is much applauded by Caflidorus, who fays that the count also compos'd a very minute defcription of Constantinople and Jerufalem. The chronicle has been feveral times printed, firft by Schoonhovius, in the fiextufenth century: then by Joseph Scalger, and still more correctly by father Sirmond. Moreti.

MARCELLO, Benedetto, a Venetian nobleman, de- fended from one of the most illufrious families of that re- public; he had cultivated music fo ferioufly and fuccefsfully as a dilettante in the art, under the guidence of the celebrated Venetian maefiro di capella, Gafparini, that no contemporary profeflor was more reverenced for mufical fcienee, or half fo much prized for his abilities as a compofitor, as Mar- cello. This accomplifhed nobleman, besides his musical pro- ductions, confifting of psalms, operas, madrigals, songs, and cantatas, was frequently his own poet, and fometimes assumed the character of lyic bard for other musicians. It is probable that Marcello had received fome difguft in his early attempts at dramatic music; for, in 1720, he published a fu- rious satire upon compofers, finging-mafters, and fingers in general, under the title of "Teatro alla Moda," or "An easy and certain Method of confoping and performing Italian Operas in the modern Manner." But his great musical work, to which the late Mr. Avison's encomiums and Mr. Garth's publication to English words, have given celebrity in our own country, was firft printed at Venice in eight volumes folio, under the following title: "Elocuo poetic-armonico. Para- frasi sopra i primi 50 Salmi, Policia di Girolamo Acanfeo Giuffini, Musica di Benedetto Marcelllo, Patrizi Veneti, 1724."

There is a long and learned preface to the firft volume, in order to give weight and authority to the au- thor's plan and style of compofition. But besides the great display of mufical reading, fagacity, and superior views to any of his predecessors, letters are prefixed to each volume from the author's friends and admirers, in the fame encomi- tic strain as the recommendatory verbs, with which almoft every book was ushered into the world during the feventeenth century. But not dazzled by thefe, or the hyperbolical praises of Algarotti or Avison, we have confecutionally ex- amined the whole eight volumes of the Italian edition, and find, though there is considerable merit in the work, that the author has been over-praised: as the subjects of many of his fugues and airs are not only common and old-fashioned at prent, but were far from new at the time thefe psalms were compofed. But Marcello was a Venetian nobleman, as Venodi was a Neapolitan prince; both did honour to music by cultivating it; but both expected and received a greater return in fame, than the legal interefct of the art would al- low. Marcello was a disciple of Gafparini, and died in 1741.

We found firll subsifting at Venice, a society for the per- formance of Marcello's compositions exclusively, and we were invited to one of its meetings. Several of Marcello's psalms were here very well fung by the Abate Martini and fome other dilettanti, among whom one had a very good bafe voice, and between the psalms, finge Marcello's famous cantatas, called Caflandria, where this compofitor has entirely fudied the music to the poetry, by changing the time or style of his movement at every new idea which occurs in the words; this may, perhaps, fiew a compofitor to be a very fenfible man, but at the fame time it muft discover him to be of a very phlegmatic turn, and wholly free from the enthuifiafim of a creative mufical genius. And, indeed, fine melody has been allied to grace and fance, mufical disjointed thoughts on various fubjects would be but ill received by the public. One of thefe gentlemen performers was old enough very well to remember Benedetto Marcello, and favoured us with fe- veral anecdotes concerning him and his family which ftill subsifted, and the head of it then was ambaffador from the rale to the Porte.

Marcello was not only his own poet in dramas which he fett to mufic, but fometimes turnd words to other mufical compofitors. He was author of a drama called "Arato in Sparta," which was fet by Ruggieri, and performed at Ve- nice in 1724; and in 1725 he produced both the words and the mufic of an oratorio, called "Giselda." He let the
"Pylche" of Caffini, about the same time. In 1718, he published sonnets of his own writing, without music; and in 1725 he both wrote and set a serenata, which was performed at the imperial court of Vienna.

To some of his madrigals and cantatas, of which we prefer the compofition to that of many of his psalms, we were told at Venice that he was his own poet.

But we have lately been favoured with a complete score of an oratorio by Marcello, of which we had never before heard of the existence. Its title, which is somewhat long, and its subject singular for an oratorio, is the following:

"Il Trionfo della Poesia, e della Musica, in which celebrated the a Morte, la Efsaltazione, e l'Incoronazione, di Maria sempre Vergine assisto in cielo, Oratorio fagro a 6 voci 1733. Musica e Poesia di Benedetto Marcello." The interlocutors are Poetry, Mufic, Painting, Sculpture, and choruses of Poets, Liberal Arts, and Old Musicians.

But these perfections are not fo wide from sacred subjects as Alexander's Feast, and Semele, which are indeed sacred subjects of Paganism. And though the subject of this drama may be too playful, and the airs too gay for an oratorio, yet it is amusing to see how a great man may amuse himself in trying to amuse others. The airs are much superior to those of the noble author's psalms, and more ingenuous and accompanied.

The oratorio, which begins with a spirited movement, ends with an admirable fugue in double counterpoint, instead of an air. There are ingenious airs and duets in echo, in the first part, and the coro finale is an alla-breve fugue on the hexachords.

In the second part there are many curious airs, duets, and chorusses, well accompanied; and all in clear and good counterpoint, though it is called an oratorio, the movements are as gay and cheerful as any secular music of the same period. It must be owned that the chorusses and accompaniments of Handel's oratoires have made the English faintidious about sacred music. But Marcello's music was admired for Italian grace and smoothness, and Handel for German force and vigour.

Marcello, St., in Geography, a town of France, in the department of the Dora; 5 miles S.E. of Aosta.

Marcellus, surnamed Empiricus, the Empirics, in Biography, was a native of Bourdeaux, and held an appointment under the emperors Theodosius and Arcadius. He died in the reign of Theodosius, the younger, who ascended the throne of the eastern empire in the year 408. It does not appear that Marcellus pursued the study of medicine as a profession, but took it up as an amateur, without acquiring any profound skill in it. He compiled from authors, both ancient and contemporary, and especially from Scribonius Largus, whom he copies literally without acknowledgment, and also from popular report, a collection of medicines and receipts for all the diseases of the body; in which, however, his superstition is more conspicuous than his judgment. Nevertheless his work has been preferred, and printed under the title of "De Medicamentis empirici physicis et rationalibus Liber a Jano Cornario verus," Balil, 1556, &c. and was included among the "Medici Artis Principes," collected by Henry Stephen. Marcellus dedicated this compilation to his children, in an epistle which is preferred, with a view of teaching them the means of relieving their diseases by simple remedies; but at the same time he counsels them not to neglect the more compound ones when necessary, and to confit the most expert physicians before they employ them. Eloy Diét. Hilt.

Marcellus Donatus, a physician of the sixteenth century, quitted the practice of his profession, and became secretary to the duke of Mantua. He is known as the author of a compilation of medical cases and observations, collected from the Greek, Arabian, and later writers, who had preceded him. This work was first published at Mantua, in 1536, quarto, and afterwards at Venice, 1588, and 1597, in six books, with the title of "De Historiis Medicis Mirabilis Lib. VI." Horius afterwards republished it at Frankfort, in octavo, in 1613, with a seventh book, on diseases reputed magical, and on extraordinary abstinence. Marcellus was also author of a tract, "De Virolis et Morbilis." printed at Mantua in 1569, quarto, and 1597, octavo, with another tract, "De Rudicé purgante, quam vocant Mekoskan." Eloy, loc. cit.

Marcellus, Marcus Claudius, a celebrated Roman general, descended from a plebeian, but an ancient and cornful family, entered early into the military service of his country, and obtained many honorable rewards for his valour and heroism. He was elected consul with Cn. Cornelius Scipio in the year 222 B.C. They were, immediately after their election, obliged to take the field against the enemies of the republic; and Marcellus was singled out by Viridomarus, king of the Gaetani, for single combat. The confid foold his enemy, and confederated his spoils to Jupiter Feretrius, which being reckoned propitious to his designs, he made all the more evident, and gained a complete victory. On the account of this success, a triumph was decreed to Marcellus, of which the noblest ornaments were the opine spoils, that is, those taken from a plain king. The greatness of this distinction may be inferred from the lines which are referred to him in Virgil's prospective view of the Trojan prophecy:

"Afpice ut insignis spoillis Marcellus opinis
Increditur, victorisque supereminent omnes.

Eneid vi.

In the second Carthagian war, Marcellus was appointed prator of Sicily, and had got ready a fleet for that service, when the event of the fatal battle of Cannes induced the senate to send him to take command of those who survived that disaster. He threw himself into Nola, which was threatened by Hannibal with a siege, and gave that commander a considerable check, which revived the courage of the Romans, and saved the place. In the year B.C. 215, Marcellus was again unanimously chosen confid, but a fortune-favoured happening at the time of assembly, it was thought the election was displeasing to the gods, and the confi was accepted by the office, though prefixed to it by the people. Fabius Maximus was elected in his stead, and Marcellus was continued in a proconsular command over the troops at Nola. After this he was chosen confid in connection with Fabius Maximus, and thus it was said, Rome was defended at the same time by her sword and her shield, which were the epithets applied to these two great commanders. Marcellus was now called to active exertions in Sicily, in which island the Carthagian interest was very prevalent; he invaded Syracuse, the capital, then one of the richest and strongest cities in this part of the world. He first propofed terms of accommodation, which being rejected, he laid siege to the city by land and by sea, taking command of the Roman fleet upon himself, while the praetor Appius commanded the land forces. This siege was rendered very remarkable by the various mechanical contrivances of the great Archimedes for its defence. By their means, the suffocating attempts of the Romans were defeated with great loss; and Marcellus, converting the siege into a blockade, led the greater part of his troops against the revolted cities of Sicily, many of which he reduced to obedience.
diocese. After his confiture was expired, he was continued as proconfil in the chief command in Sicily, and bent every effort to the finishing a siege upon which the eyes of all parties were attentively fixed. Marcellus determined on making an assault upon Syracuse, and fixed on the ensuing festival of Diana for this purpose, in which it was imagined the garrison would probably be buried in wine and sleep. At the appointed time a choice band of troops scaled the walls without discovery, and certain quarters of the city were taken without reffistance Marcellus, surveying from an eminence the vast and opulent city which was about to suffer all the miseries of a capture, is said to have shed tears, because he could not persuade the inhabitants to save themselves from plunder by a timely surrender. They were deaf to remonstrances, and Marcellus had to sustain a furious attack from the Carthaginians without, and the Syracuscans within, which he repulsed with vast loss to the assailants. A plague which broke out in Syracuse added to the calamities of that unfortunate city; it ravaged likewise the Carthaginian camp to such a degree as to break it up after carrying off the commander. It was not, however, till the end of three years, that Syracuse was taken by assault, when it was impossible to save the inhabitants from the effects of a fack: the houses were pillaged, and many citizens were put to the sword, among whom was Archimedes, whose fate was particularly afflicting to Marcellus, and who was slain while he was calmly working a mathematical problem. The Roman commander, as soon as he was able, put an end to the atrocities of his soldiers, and displayed much personal clemency and humanity to the vanquished, but he carried away all the public monuments of art which decorated Syracuse for the ornament of Rome. Marcellus continued some time longer in Sicily, but his last action ended in a confiderable victory obtained over the combined forces of Hanno and Epicydes, after which he returned to Rome with great glory. In the year 210 B.C. he was again chosen consul, when he was accufed by the Syracuscans with cruelty and a violation of treaty. He was, however, after the expiations, acquitted of the charges, and his subsequent behaviour would have done honour to any man; he raised up the Syracusan deputies, who had been his auxiliers, and had fallen at his feet to implore forgiveness, allured them not only of his pardon, but of his future protection, and obtained of the senate that the people of Syracuse should be reinstated in their liberties, and confidered as the allies of Rome. They, unwilling to be behind in reft for his manly virtues, exprefied their gratitude to him by a decree, that when he or any one of his family should visit Sicily, the people should walk in procession before him, crowned with garlands, and celebrate the day with public facrifices; and that thenceforth the whole island should be under the peculiar patronage of the Marcelli. After this Marcellus was a second time called upon to oppose Hannibal. He displayed as usual his great military talents in his operations against this general, but was not sufficiently vigilant against the fnares of his adversary. He imprudently separated himself from his camp, and was killed in ambush in the 60th year of his age, and in his fifth confiture in the month of May. When the body of this great commander was brought to Hannibal, he revered it a confiderable time in thoughtfu1 flence; and caufed it to be buried, or, as others fay, to be burned on a funeral pile, and then fent the ashes enclosed in a silver urn, and crowned with laurel, to his fon. Plutarch.

Marcellus I., pope, a native of Rome, became a prefbyter under Marcellinus, and was his fuccelfor in the bishopric of that city in the year 308, after the fee had been vacant for more than three years and a half. The particulars relating to this pope are not given on fufficient authority. It is faid, in his epitaph, written by pope Damasus, that his firmnefs in maintaining the discipline of the church, and in obliging thofe who had fallen during the times of perfecution to give proof of the genuinenefs of their repentance, excited againft him the general hatred, which was not confined to private difputes and divisions, but ended in public tumults, bloodshed, and murders. He adds, that Marcellus was fent into banifhment, and died in the second year of his pontificate, in the year 310. The church of Rome has given him a place in her list of martyrs, but in the moft ancient martyrlogies he has only the title of confessor. Morel. Bower.

Marcellus II., pope, a native of Fano, in the Marche of Ancona, was fon to the receiver-general of the revenues of the holy fee. He was educated at Sienna, and honourably diftinguifhed himfelf in literary pursuits. He afterwards went to Rome under the pontificate of pope Paul III., who appointed him his principal Secretary. He accompa"
acknowledges, left evil-minded persons should accuse him of enriching his works with forged decorations." Linnaeus says, Crit. Bot. 79, that a relation of Marcgravia has accented Pilo of deriving all his information from the papers of the former, after his death. He is reported, moreover, to have been himself the servant of the man he attempts, in that respect, to debate. It seems that Marcgravia was of a good family, ulefs his surname (de Lieblad) merely, as Haller supposes, indicates the place of his birth. Pilo became a physician at Amsterdams (See Pisonia hereafter in its proper place.) Linn. Gen. 290. Schreb. 347. Willd. Sp. Pl. v. 2. 1127. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 3. 284. Juff. 244. Plum. Gen. 7. t. 29. Linnarck Illnhr. t. 4:47. -Chlis and order, Polyandria Monogynia. Nat. Ord. Pataunaceae. Linn. Capparidice, Juff.

Gen. Ch. Cal. Perianth inferior, permanent, of fix imbricated, rounded, broad, concave leaves; the two outer moll largest. Cor. of one petal, vertical, ovate, somewhat conical, undivided, covering the organs of impregnation like a cap, at length separating all round at the base, deciduous. Filaments numerous, awl-shaped, short, spreading, deciduous; anthers large, ovate-oblong, erect.

Pil. German superior, ovate; style none; stigma capitate, permanent. Peric. Berry globose, coriaceous, of many cells, and many imperfect valves. Seeds numerous, small, oblong, lodged in soft pulp.

1. M. umbellata. Climbing Marcgravia. Linn. Sp. Pl. 719. Jacq. Amer. 136. t. 96. (M. fennica; Browne Jam. 244. t. 26. Plum. IC. t. 173. f. 1.)-Native of woods in South America and the West Indies. Browne says, it is frequent in Jamaica. The stem is at first flender and weak, climbing up the trunks of large trees, by means of fibres like those of ivy, and furnished with alternate heart-shaped, emarginate, entire leaves, on very short footstalks. When it reaches the summit, it "lays its trunk," says Browne, "more commodiously on some of the larger branches of the tree; then it begins to strengthen, and calls many flender, dependent, and subordinated branches from the upper parts. But as it increases at the top, the stem grows thicker, separates from the supporter, throws off its own useless leaves and roots (fibres), and appears a strong withy shrub, whose trunk is frequently no less than four or five inches in diameter." The pendulous branches are a foot or two in length, roundish, large, bearing numerous, alternate, elliptic-oblong, pointed, entire, smooth, somewhat flaky leaves, on short footstalks, spreading in two directions, each about three inches long, furnished with a strong rib, and several small transverse veins. Sympus non, except a little intrafoliaceous gland, just above the infection of each footstalk. Umbel terminal, pendulous, solitary, simple, of about a dozen flow,ers, on widely spreading downward flasks, swelling upwards, above an inch long. The flowers appear to be turned downwards. Their corolla, while it remains, gives them the appearance of small acorns, being about one-third of an inch long, and might easily be mistaken for a footstalk. Of its colour there is no mention. The fruit is the size of a moderate gooseberry, with a thick rind, which is but imperfectly disposed to split into valves. The internal partitions originate from it, and are narrow and thin. The pulp and seeds are said to be of a vivid scarlet. We presume, from the natural affinities of this plant, that it is of a poisonous quality. Its greatest peculiarity consists in four, five, or more appendages to the umbel, placed in the centre, each on a stalk half the length of the flower-stalk. These are above an inch long, tubular, obtuse, and clefted at the extremity, but furnished with a dilated lip at their orifice where the flower is inserted. Being, from the position of the umbel, pendulous, Browne says they catch the water that trickles down the branch in rainy weather; but their use has not been fully explained. Linnæus supposed them neturaries. If such, they may serve to tempt insects or humming-birds to frequent the flowers, and affil impregnation, as in numberless other cases.

Wahl now Wildenow has adopted another species, M. coriacea, from Vahl's Etaglez. Of this magnificent plant we have been favoured by Mr. T. F. Forster with a fine specimen from Guiana. It has the habit of M. umbellata, but more elliptical, obtuse, coriaceous, shining, and almost veined, leaves. The umbel, like all the other parts, is much larger. The supposed neturaries, or pouches, grow, without any stalks, on the lower part of each flower-stalk, and are shorter and more inflated than those of the former. This plant has certainly all the habit of the genus in question, but neither the corolla, nor the valves of the fruits. It is, therefore, difficult to say whether it is a typical species, or a variety. Wildenow supposes there is nothing peculiar in the corolla, which is totally different, consisting of five separate concave petals, so that it proves to belong to Schreber's genus Actium, the Narra cea of Aublet; which differs in that respect only from Marcgravia, having exactly the same form of pouches, though they have been called bracteas, because the inflorescence in Aublet's plant is racemose. Marcgravia, therefore, differs from Actium exactly as Swartz's Calyttrantes differs from Myrtus, and no further; for the difference in their inflorescence, which might have been thought of some moment, is done away by this new species, which is in that respect a Marcgravia, though in generic character an Actium. See Actium and Calyttrantes.

MARCH, MARTius, in Chronology, the third month of the year, according to the common way of computing.

Among the Romans, March was the first month; and, in some ecclesiastical computations, that order is still preferred; as particularly in reckoning the number of years from the incarnation of our Saviour, which is done from the 25th of March.

In England, (before the alteration of the style,) March, properly speaking, was the first month in order, the new year commencing from the 25th; though, in compliance to the customs of our neighbours, we usually ranked it as the third; but, in this respect, we spoke one way, and wrote another.

Till the year 1564, the French reckoned the beginning of their year from Easter; so that there were two months of March in one year, one of which they called March before Easter, and the other March after Easter; and, when Easter fell within the month of March, the beginning of the month was in one year, and the end in another.

It was Romulus who divided the year into months: to the first of which he gave the name of his supposèd father Mars. Ovid, however, observes, that the people of Italy had the month of March before Romulus's time; but that they placed it very differently, some making it the third, some the fourth, some the fifth, and others the tenth month of the year.

In this month it was that the Romans sacrificed to Anna Perenna; that they began their comitia; that they adjudged their public farms and leaves; that the milkmaids served the flaves and servants at table, as the maids did in the Saturnalia; and that the Veiiachs renewed the sacred fire.

The month of March was always under the protection of Minerva, and always cons:isted of thirty-one days. The ancients
sients held it an unhappy month for marriage, as well as the month of May.

March, in Geography, a market-town in the parish of Doddington, hundred of Witchford, Isle of Ely, Cambridgehire, England, is situated 26 miles dialist from Cambridge, 15 from Ely, and 8 from London, nearly midway between Chatteries and Wisbech, on the banks of the river Nene: from which circumstance it has the advantages of a considerable trade. The population, as returned to parliament in the year 1801, was 2514, occupying 555 houses. The chapel is a spacious edifice, with a spire, erected about the year 1313. A market is held on Fridays, and three fairs annually. Many Roman remains have been discovered in this vicinity. When the road was making from March to Wisbech, in the year 1730, three urns were dug up, full of burnt bones and ashes; and also a pot, containing 160 Roman denarii, of all the emperors from Vespasian to Antoninus Pius, but chiefly of the latter. Various other coins have been found, and an altar 21 inches high. Beauties of England and Wales, vol. ii.

March, in Military Language, is in general the motion of a body of men from one place to another.

The best of the drum, upon particular occasions, is likewise called the march; which explains itself. It is likewise a word of command, when a battalion is to alter its disposition.

Neither musick nor drums are now used to regulate the march, which is in three measures. 1. Ordinary time, in which 75 paces are taken in a minute. 2. Quick time, in which there are 108 steps in a minute. 3. The quickest time, or wheeling march, which is at the rate of 120 steps of 30 inches each, or 300 feet in the minute. This last is used only for wheeling. For a more particular account of the subject of this article, see Battalions.

As many accidents may happen in the march of an army from defiles, marshes, woods, and the like, it is the prudence of a general to order his march accordingly, and to take care that the columns of his army have a free communication one with the other. The march of an army is composed of an advance guard, the main body, and the rear guard, and is sometimes in two, four, six, or eight columns, according as the ground will allow.

The order of march of the troops must be so disposed, that each should arrive at their rendezvous, if possible, on the same day. The quarter-master-general, or his deputy, with an able engineer, should sufficiently reconnoitre the country, so as to obtain a perfect knowledge both of that and of the enemy, before he forms his routes. Before a march, the army generally receives several days' bread. The quarter-masters, camp-colour men, and pioneers, parade according to orders, and march immediately after, commanded by the quarter-master-general, or his deputy. They are to clear the roads, level the ways, make preparations for the march of the army, &c. The "general," for instance, beats at two, the "assembly" at three, and the army commence their march in 30 minutes after. Upon beating the "general," the village and general officer's guards, quarter and rear-guards, join their respective corps, and the army pack up their baggage. Upon the "assembly," the tents are to be struck, and tent, with the baggage, to the place appointed. The companies draw up in their several files, and the rolls are called. At the time appointed, the drummers are to beat a march, and fifers play at the head of the line; upon which the companies march out from their several files, form battalions as they advance to the head of the line, and then halt. The several battalions will be formed into columns by the adjutant-general, and the order of march, &c. to be given to the general officers who lead the columns. The cavalry generally march by regiments or squadrons. The heavy artillery always keep the great roads, in the centre of the columns, escorted by a strong party of infantry and cavalry. The field-pieces move with the columns. Each battalion generally marches with 60 rounds of powder and ball, and three good rounds; one of which is to be fixed in the cock of his fire-lock. The routes must be so formed, that no column may cross one another on the march. See Battalion.

March, in Music, a military air played by martial instruments to regulate and mark the steps of the field-drill, to which the drums usually beat time. There are military pieces for field instruments on the parade, which are called marches, though the regiment or corps is stationary.

In Persia, according to Chardin, when a building is to be pulled down, the ground to be levelled, or any work to be performed that requires dispatch, and the united efforts of a multitude, all the inhabitants of a district are assembled, who work to the sound of instruments, and the business is done with more zeal and promptitude than it would be in silence.

Marshall Saxe, in his Reverses, shews, that the effect of drums is not confined to a mere uleleos noise; but as the pulsations are more or less rapid, they naturally inform the soldier to accelerate or retard his pace. It may also be said, that the melody or movement of marches should have different characters, according to the occasion, upon which they are played; and this is implied by the name. It gives to certain beatings of the drum, as the general, the retreat, the charge, &c.; but all the advantages of such signals have not been taken that might be. The measures that are beaten or played, have hitherto been confined to one style, to suit the common beat of the drum. And there are many airs that are denominated marches which fullit that object very imperfectly. The French troops (said Rouffeau, in 1768,) having few military instruments for the infantry, except fifes and drums, have likewise very few marches, and these, in general, ill composed; but how admirable are those in the German troops. It is only the infantry and light horse that have particular marches. The kettle-drums of the cavalry have no regular march; the trumpets have only a single note sometimes, and never more than a tenuare or sourifur. The march, pace, or movement, in music, is used figuratively by the French in speaking of the succession of sounds in melody, which follow each other in a certain order; as the base and treble proceed by contrary motion, the base moves in quavers, the treble in semiquavers, &c. For the agreement between the musical air and the military steps, Rouffeau has given the first part of the march of the Monfquitaire of the king of France at the time when his Diction de Mus. was printed, which we have copied in our musical plates. It was found by English travellers, four or five years after Rouffeau's Dict. was published, that the French military music in Flanders was very much improved by the adoption of the instruments and style of music used in the bands of the Walloon and German regiments in the Austrian Netherlands. German Musical Tour, vol. i.

In the Supplement to the first edition of the Encyclopédie, it is truly said, that a march should be always composed in common time, with an odd crotchet or quaver at the beginning; and that it is almost impossible to march in cadence to a movement in triple time, unless it is composed in such a manner that the cadence is felt at the end of every two bars; that is to say, unless the composer has written an air in common time, as if it were in triple.

The ars, or up part of the bar, naturally marks the lifting up of the foot in marching; on which account the air usually begins with an odd note.

Of
Of the marches and military music of our ancestors, we may form some judgment by the remains of our venerable composer, William Bird, transcribed in the Virginal book of lady Nevil, which is still preferred, and in the possession of Dr. Burney. This book, curiously written in 1591, contains no less than forty-two pieces by the admirable Bird; among which are the following military movements, set for the Virginal by that venerable composer, and very neatly copied on fine paper.

We shall give the motto, or subject, of some of these pieces, on one of the music plates.

The copyist of this curious MS. having terminated his labour, has made the following record of his achievement.

fine: finished and ended the seventh of September in the year of our Lord God, 1591, and in the 330 year of the reign of our sovereign lady Elizabeth by the grace of God queen of England.

MARCHAND, AUSIAS, in Biography, the best known of the Limosin poets, was born in Valencia, of Catalan parents, and flourished about the middle of the 15th century. He was educated in the duke of Gandias household, and married a woman of noble family, but, like Petrarch, whose example he followed, he fell in love with another man's wife, and spent his time in writing verses upon her in the Provençal style. Could the Catalans have shaken off the yoke of Aragon, against which they struggled, their dialect would have become a cultivated tongue, and Ausias March would have been the father of its poetry. As it is, his reputation is very great, considering the obsolelce language in which he wrote. His poems have been frequently printed: the earliest edition is that of Valencia, in 1539. The Valladolid edition of 1555 contains a copious glossary, with observations on the grammar and pronunciation of the language. Gen. Biog.

MARCHAND, Prosper, born towards the close of the 17th century, was brought up in the book-selling trade at Paris, and acquired a great knowledge of books and literary anecdotes. His attachment to the Protestant religion, and his connection with Bernard, the continuator of the "Novelles de la République des Lettres," induced him to remove to Holland, where he acted some time as a bookseller, till at length he entirely devoted himself to literature. His studies led him chiefly to bibliography and French history, and on these topics he was occasionally consulted by persons from all parts of Europe. He took an active and leading part in the "Journal Litteraire," and he furnished other literary journals with curious extracts, which he had collected by his extensive course of reading. He died at an advanced age in 1756, and left his library and manuscripts to the university of Leyden. He had published, in 1740,
MARCHANTIA.

Obst. Some species bear, besides the flowers, little cups, toothed at their edges, full of grains which prove to be buds, gemme. Linnæus, trusting to Dillenius, mistaken these for the female fructification, and the real female flowers for male ones, the seeds being supposed the pollen. The true male flowers, ascertained by Hedwig, were, in the species in which they were observed, thought a mere variation of form.

Female, Calyx pelete, flowering underneath. Capsules deflexed, opening at the top by several revolute valves. Stalks attached to the flowers.

This genus is next akin to JUNGERMANIA (see that article), with which it very much agrees in habit, especially with those species that have no item separate from the leaves, and grow like them in damp umbraegeous places. The herbage however is, on the whole, of larger dimensions than in JUNGERMANIA, and the fructification more elaborate, or at least better defined, as well as essentially distinct in characters.

Five species are described as natives of Britain, and LINNÆUS has two besides, and we add an eighth from SCOPOLI, his friend.

1. M. polymorpha. Star-headed Marchantia. Linn. Sp. Pl. 1603. Bulliard, t. 291. HUDF. n. 1. Engl. Bot. t. 210. (M. Linnæus marginatus, calyce plano; Schmid. IC. 38. t. 9. Marchantia 1—5; Mich. Gen. 2. t. 1. Lichen fontanus major, fluellatus æque, ac umbellatus, et caulifiophorus; Dill. Mufc. 532. t. 76. f. 6. L. domésticus minor, fluellatus æque, &c.; ibid. 527. t. 77. f. 7.)—Calyx of the female flowers cloven into about ten narrow segments. Very common in damp places, about springs, wells, and shady courts, throughout Europe, varying much in RACES, in proportion to the moiture of its situation; being often a most troublesome weed in gardens, over-running pots that are obliged to be kept moist, as well as beds of alpine or American plants. It flowers about Midsummer, and is perennial. Few plants are endowed with such ample and pertinacious powers of propagation. The fronds spread horizontally, creeping close to the earth, alone, or wall, by means of dense, fibrous, soft, and silky radicles of a shining brown. They are several inches in extent, bluntly lobed, of a dark shining green, fringed with scales, and more or less reticulated; less reticulated and fringed in DILLENIUS'S t. 77. f. 7., though SCHMIDEL observes that it is hardly possible to draw a line between these two varieties, or supfed species. The latter seems to grow in drier situations than the former. The upper surface of the leaf or frond is fluted with several pale cups, toothed at their edges, half filled with green lenticular buds, as mentioned above. By these the plant is copiously increased, in lea moils places, where it does not really flower. The proper flowrers grow from marginal clfts, on erect simple stalks; flouer to three inches high, thoé of the female tall, and on a separate plant. The common calyx of the latter is deeply cut into eight or ten deep, linear, radiant, obtuse segmets, from the under side of which, towards their base, the flowers are produced. The seeds are yellow, and the spiral filament to which they are attached, have an apparent spontaneous motion, which lowerer arises merely from their elasticity, and exquisite susceptibility of moiture.

2. M. elata. Goose-foot Marchantia. Linn. Sp. Pl. 1603. (Lichen anapodocarpus; Plum. Fl. 142. t. 142. Dill. Mufc. 531. t. 77. f. 8.)—Calyx of the female flowers halved, palmate, with four obtuse segmets.—Newt of the Wett Indies, on moist rocks. The segmets of the frond are oblong, flutated or wavy at the edge. Fruct-fflks nearly terminal. Common calyx of the female flowers remarkable for being cut away on one side, all its four segmets being directed the other way, like the fingers of a hand, or toes of a web-footed bird. We have from JAMIES, gathered by Browne, what seems to answer to Plumer's figure and description, which DILLENIUS has copied; we have also the fame from DR. SWARTZ. In both specimes the upper side of the frond is besprinkled with fine pellicled dots or grains. Mr. Dr. kent excels these specimes a different species from the original one of Plumer.

3. M. crassulata. Cross-headed Marchantia. Linn. Sp. Pl. 1603. (L. crassulatus, Dill. Mufc. n. 2. (L. crassulatus, flowerer, Dill. Mufc. Ul. crassulatus; Dill. Mufc. 514. t. 75. f. 1.—Lunaria vulgaris; Mich. Gen. 4. t. 4.)—Calyx of the female flowers in four deep, cross-like, tubular segmets. Native of shady damp places in Italy, France, and England, fructifying in July. The fronds are smaller than in M. polymorpha, and dilated outwards. Flower-flks each from a toothed cup on the disk of the leaf. Common calyx of the female flowers at first conical, but soon becoming deeply divided into four spreading, cruciform, tubular segmets, from whose extremities the capsules and seeds are protruded. DILLENIUS has a remark unworthy of so great a philosopher, that "the flowers are rarely produced, but the seeds very frequently." Surely, as no seeds can come without flowers, this might have led him to discover that what he took for seeds were really buds!

4. M. tenella. Slender Marchantia. Linn. Sp. Pl. 1603. (Lichen pilatus varius, capitulis umbilicatis; Dill. Mufc. 519. t. 75. f. 2.)—Calyx of the female flowers hemisperical with a little point; its margin radiated.—Gathered by GROVONIUS in Virginia. The frond of this delicate species spreads circular, but is not altogether much above an inch broad. The fronds are nearly terminal, very slender, above an inch high. Calyx very convex, crowned with a minute blunt point, and fringed with numerous segmets that bear the capsules.

5. M. hemisphérica. Hemispherical Marchantia. Linn. Sp. Pl. 1603. HUDF. n. 2. Engl. Bot. t. 503. Schmid. IC. t. 34. (Lichen pilatus varus, foliis crenatis; Dill. Mufc. 519. t. 75. f. 2. Hepatica media, capitulo hemisphaerico; Mich. Gen. 3. t. 2. f. 2.)—Calyx of the female flowers hemispherical, cloven into about five oval segmets. Stalks naked at the base.—Native of Europe, about the banks of rivers and ditches, or the moist crevices of rocks, sometimes in expoded situations, flowering in the early spring. The fronds are lobed, forming broad patches; their upper surface granulated, of a fine green, often purplish at the edges. Stalks not above an inch high. Calyx convex, rounded, without any terminal point; the margin in five, or more, oval segmets. Capsules and seeds black. By a strange oversight, a barren specimeen of this species was decribed as a new genus by FORSTER, under the name of Altónia, see his Geogr. t. 74.; and adopted by the younger LINNÆUS, by that of Rupinia; see his Suppl. 69. and 145.

6. M. triandra. Three-celled Marchantia. Scoe. Carn. ed. 2. 554. t. 63. Web. Goett. 163. (M. tenella; THUMB. Prod. 175.)—Calyx of the female flowers hemispherical, undivided, of three or four cells.—Found by SCOPOLI in Carniola, by WEBER in HERYNIA, and by THUMBERG at the Cape of Good Hope; for the original specimeen of the tenella of the last-mentioned author prove to be this plant. We have others from Siberia, which appear the fame, but their condition is not sufficiently good for us absolutely to decide. This is a small specimeen, whose fronds are at most but an inch long. Stalks half an inch high, or thereabouts, purplish. Calyx convex, granulated, without a point; its margin

Vol. XXII.
M A R

margin wavy, not cut or lobed. Cells three or four, very prominent underneath, furnished with long, taper, bristle-like appendages. The specific name alludes to the old Linnanean idea of the female being the male flowers.

7. M. androgyna. Monococcus Marchantia. Linn. Sp. Pl. 1605. Dickf. H. Sicc. fæce. 4. 21. Crypt. fæce. 4. 17. With. 886. (Lichen pilleus angustifolius dichotomus ; Dill. Mucf. 320. t. 75. f. 3.) Hepatica minor angulifolia, capillata humifragi. (Mich. Gen. 3. t. 2 f. 3.)—Calyx of the female flowers hemispherical, half four-ribbed of four cells.—Native of Italy, France, Switzerland, and Scotland. This is much larger than the last. *Frondes* two inches or more in length, various in breadth, smooth. *Stalks* one and a half or two inches high. *Calyx* very convex, smooth, its margin in four blunt lobes, beneath which the *cells* are very prominent. Linnaneus mistook his Siberian specimen above mentioned, which we judge to be *triandra*, for the true *androgyna*, and therefore erred in his specific character of this latter. We conceive Scopoli's *M. quadrata*, Carn. ed. 2. 355. t. 63, to be no other than the real *androgyna*.

8. M. conica. Conic Marchantia. Linn. Sp. Pl. 1604. Hudf. n. 4. Engl. Bot. t. 504. Schmid. t. 31. (Lichen vulgaris major, pilleus et verrucossus; Dill. Mucf. 516. t. 75. f. 1.) Hepatica vulgaris major, vel officiarum Italiae; Mich. Gen. 3. t. 2 f. 1.)—Calyx of the female flowers ovate, pointed, with five marginal notches. Male flowers in sessile warts.—Common in damp sandy places in Britain and other parts of Europe, but the female fructification is rare. The *frondes* are broad, reticulated, bluntly lobed, highly aromatic and fragrant, giving their perfume to the air, especially after rain, like many *Jurgenmannia*. *Stalks* from clfts between the lobes, two inches high, white and tender. *Calyxes* conical, with four small marginal lobes. *Capsules* and seeds black. On separate plants from these are found hemispherical sessile warts, such as *M. androgyna* appears to bear on the same plant with the capsules, and which Hedwig believes to be the male flowers. We presume, however, that what are represented on a portion of a frond in *Engl. Bot.* are not thcse, but gemmiparous cups, like those of *M. polyphora*, by which the plant is usually propagated. S.

MARCHAUX, in Geography, a town of France, in the department of the Doubs, and chief place of a canton, in the district of Besançon. The place contains 382, and the canton 8894 inhabitants, on a territory of 220,000, in 36 communes.

MARCHÉ, OLIVER DE LA, in Biography, son of a gentleman of Burgundy; entered, in early life, into the service of Philip the Good, duke of Burgundy, by whom he was highly valued. After this Charles the Bold raised him to the posts of marshal of the household and captain of his guards, and knighted him at the battle of Montlhéri, in 1465. He was with that prince at the fatal battle of Nancy, and was made prisoner. We find him next, first master of the household to Maximilian of Austria, and afterwards to his son the archduke Philip, by whom he was sent on an embassy to the court of France after the death of Lewis XI. He died at Brüffels in 1501, leaving behind him "Memoirs or Chronicles," relating to the two dukes of Burgundy; these were published at Lyons in 1562, and again at Brüffels in 1616. He also wrote "Le Paremout et le Triomphe des Dames d'Honneur:" "Traité sur les Duels et Gages de Bataille," and other pieces. Moret.

MARCHÉ, LA, in Geography, was before the Revolution a province of France, bounded on the N. by Berri, on the E. by Auvergne, on the S. by Limousin, and on the W. by Poitou; lying between 43° 45' and 40° 35' N. lat., and between 6° 45' and 2° 31' E. long.; being from N. to S. 10 leagues, and 20 from W. to E. Its rivers are the Tonin, the Great Creuse, the Gartempe, and the Vienne. This province was formerly under the dominion of the Romans, Visigoths, and Franks. Under the reign of these powers it was governed by counts, and was constituted by Philip the Handicome. Francis I. annexed it to the crown A.D. 1541. Some tracts of this province are tolerably fertile, yielding grain and fruits, and others are covered with excellent pasturage. The soil is composed of sandy and friable loams, some on granite, and others on a calcareous bottom. The chief towns in Upper Marche, on the eastern division, are Gueret, Almou, Aigurande, Aubusson, Felletin, Bourganeuf, Grandmont, and Benevent; and those in Lower Marche are Bollac and Dorat. This province now principally constitutes the department of the Creuse, and part of that of Vienne.

MARCHÉ, a town of France, and principal place of a district, in the department of the Sambre and Meuse, situated on the Marchette, in the road from Paris to Lige. The place contains 1257, and the canton 6382 inhabitants, on a territory of 250,000, in 25 communes. The parish church is a handsome structure; 20 miles S.E. of Namur.

MARCHÉC, LA, a town of France, in the department of the Yonne, and chief place of a canton, in the district of Neufchâteau, situated near the source of the Meuse; 27 miles W.N.W. of Luxemburg. The place contains 1554, and the canton 13628 inhabitants, on a territory of 335,000, in 26 communes. N. lat. 48° 4'. E. long. 5° 22'.

MARCHÉ, LA, a small territory of Switzerland, in the canton of Schaffausen, situated S. of the lake of Zurich.

MARCHÉ, LA, a town of February, in the department of the Loir and Cher, and chief place of a canton, in the district of Blois; 15 miles N. of Blois. The place contains 421, and the canton 8340 inhabitants, on a territory of 260,000, in 18 communes.

MARCHÉS, or LORDS MARCHÉS, in our Old Writers, noblemen that lived on the marches of Wales, or Scotland. They were times past, according to Camden, held their laws, and power of life and death, &c. like petty kings. But such powers were abolished by the flat; 27 Hen. VIII. cap. 27, and 1 Edw. VI. cap. 10.

MARCHÉS, MARCHIS, from the German, march, i.e. *luene*, or from the French *marque*, *signum*, being the notorious distinction between two territories, are the limits between England and Wales, or Scotland; which last are divided into west and middle marches. (4 Hen. V. cap. 7. 22 Edw. IV. cap. 8. 24 Hen. VII. cap. 9.) And there was formerly a court, called the court of the marches of Wales, where pleas of debt or damages, not above the value of 50£ were tried and determined; and if the council of the marches held plea for debts above that sum, &c. a prohibition might be awarded.

MARCHÉS, LEI, in Geography, a town of France, in the department of Mont Blanc; four miles W. of Montmelian.

MARCHÉS, LUCA, in Biography, one of the greatest vocal performers which Italy has produced on the opera stage since the first establishment of the musical drama, ar-
rived in England in April, 1788. This finger, whole talents have been the subject of praise and admiration in every great theatre of Europe, where musical dramas are performed in the Italian language. It first appeared at Rome in 1774, in a female character, the usual introduction of a young and promising finger, with a soprano voice and beautiful person. In 1775, he performed the second man's part at Milan with Paccherotti, and at Venice with Millico; but the same year he was advanced to the principal character at Treviso. In 1776 and 1777, he was first man at Munich and Padua; and in 1778, he had worked his way to the great theatre of San Carlo at Naples, which is the criterion and poet of honour of an opera finger. He continued here two seasons, and has since performed with increasing celebrity at Pisa, Genoa, Florence, Milan, Turin, Petersburg, Rome, and Vienna.

The "Ginio Sabino" of Sarti, was the first opera in which Marchetti performed on our stage. The elegant and beautiful music of this drama did not please so much here as it ought, and had done in other parts of Europe. Several of the songs, indeed, had been previously sung here at concerts, and did not appear new. Marchetti's style of singing is not only elegant and refined to an uncommon degree, but often grand and full of dignity, particularly in his recitative and occasional low notes. His variety of embellishments and facility of running extempore divisions are truly marvellous. Many of his graces are new, elegant, and of his own invention; and he must have studied with intense application to enable himself to execute the divisions, and running phrases from the bottom of his compass to the top, even in a rapid series of half notes. But besides his vocal powers, his performance on the stage is extremely embellished by the beauty of his person, and grace and propriety of his gestures. We expected a great finger, but that does not always include a fine actor.

As Marchetti was the last of three great fingers who appeared on our stage at the latter end of the eighteenth century, and as each had his exclusive admirers, it would be difficult to draw a fluided parallel between them to the satisfaction of all parties; comparative praises, as well as censure, would be thought invidious. But as we have received great pleasure from the talents of each of these exquisite performers, and never expect to find abilities exactly similar in different fingers, we are always thankful for the good we find, and endeavours to hear the right with candour.

In discriminating the several excellencies of these great performers, we should without hesitation say, that Paccherotti's voice was naturally sweet and touching; that he had a fine, exquisitely theft, great fancy, and a divine expression in pathetic songs. That Rubinielli's voice was full, majestic, and musical; and besides the accuracy of his intonations, that he was preeminent and judicious in his graces. And that Marchetti's voice was elegant and flexible; that he was grand in recitative, and unbound in fancy and embellishments.

All seem to have studied their art with great diligence during youth, and to read music as easily as their native language.

As actors: Paccherotti esteemed in earnest on the stage, and consequently interested the spectator. Rubinielli had great dignity in his deportment, though he discovered but little sensibility by his gestures or tone of voice. Marchetti, with an elegant figure and pleasing countenance, is at once graceful and intelligent in his demeanour and action.

Marchetti has continued to support his character of a great and refined finger, ever since he quitted England fifteen years ago, and we believe still continues to exercise his talents on the stage.

When the French first invaded the Milanese, during the revolution, report says that he was treated by the military with favage indignity, for declining to obey a peremptory order to sing to the Gallic general's lady; to which he felt a repugnance from gratitude to the Austrian government, under which he had frequently refided, and been not only honourably but kindly treated. On his not instantly obeying the ungracious order that was sent him, he was seized by a party of soldiers, who, to deface his personal charms, deprived him of one eye-brow, and of half his fine head of hair.

MARCHESINA, in Geography, a town of Italy, in the department of the Montagna; 10 miles S.W. of Lecco.

MARCHESVAN, in Chronology, the eighth month of the Jewish ecclesiastical year, answering to part of our October and November.

MARCHET, or MARCHETTA, a pecuniary fine, anciently paid by the tenant to his lord, for the marriage of one of the tenant's daughters.

This custom obtained, with some difference, throughout all England and Wales, as also in Scotland; and it still continues to obtain in some places. According to the custom of the Manor of Dinover in Carmarthenshire, every tenant, at the marriage of his daughter, pays ten shillings to the lord, which, in the British language, is called gower-merched, i.e., maid's fee. See Ambery.

In Scotland and the north parts of England, the custom was, for the lord to lie the first night with the bride of his tenant; but this usage was abrogated by King Malcolm III. at the instigation of his queen; and, instead thereof, a mark was paid by the bridegroom to the lord: whence it is called marchettu muleris. See Borough-English.

MARCHETTI, I.A., in Biography, a finger from Bolonia, engaged for the Pantheon in 1774. She had a powerful, brilliant, and sweet-toned voice, with which she might have become a finger of the first class, if want of health had not prevented her from that persevering practice, which is so necessary to the vanquishing of vocal difficulties. Besides singing at the Pantheon during her residence in England, she performed the second woman's part in Sacchi's opera of "Nietti" and "Perico."

MARCHETTI, Peter de, a physician, was professor of anatomy at Padua, his native place, where he continued to teach that art from 1652 until 1659, when he was allowed to resign his chair to his son Anthony. In the year 1661, he also obtained the appointment to the first professorship of surgery, the duties of which he fulfilled at the same time with those of his anatomical chair. His lectures in these departments of the profession obtained for him the honour of knighthood of the order of St. Mark. At the age of 80 years, he retired altogether from the university; and, after having enjoyed a short period of repose, he died in April 1673. He left the following works: "Anatomia," in 4to. Venice 1654. "Syllloge Observationum Medico-chirurgicarum rariorum," Padua 1664, which was afterwards several times reprinted, and was translated into German. It contained fifty-three cates of some interest, and three tracts on ulcers, on fistula of the urethra, and on impura ventosa.

His two sons, DOMINIC and ANTHONY DE MARCHETTI, were likewise both professors in their native university of Padua. The former was author of a good compendium of anatomy, according to the judgment of Haller, which passed

Marchetti, Alexander, a poet and mathematician, was born at Pontormo, in the Florentine territory, in the year 1632. Being deprived at a very early period of his father, he was intended for a mercantile life; but it being then discovered that he had decidedly a literary turn, he was placed with a professor of the civil law. This proved as little adapted to his taste as trade; and he was sent by the kindness of Leopold, cardinal de Medicici, to the university at Pisa, where he pursued his favourite studies in belles lettres, in conjunction with philosophy and mathematics, in the latter of which he enjoyed the particular instructions of Borelli. He took a doctor's degree in 1659, and became professor of logic in that university, and also taught the elements of geometry to a private class under Borelli. In 1669 he published a mathematical work, entitled "Resiftentia Solidorum;" and in a short time after, another with the more general title, "Exercitationes Mechanica." By the former he gained a high reputation; but the latter did not at all answer the expectations which he had raised by the other. About the same period he accomplished his translation of Lucretius, "De Rerum Natura," into Italian blank verse, which has contributed more to establish his fame than all his other pieces. It has been said that it surpasses almost every other classical version in modern language, in dignity, elegance, and clearness. Marchetti was devious of dedicating this performance to Cosimo III., great duke of Tuscany; but the pique of that prince was so much shocked by the impious dogmata of the Epicurean philosophy, that he not only refused the dedication, but prohibited the publication of the work in his dominions; and it was not printed till after the author's death, by Paul Rolli, in the year 1717. It has since been frequently reprinted, and is allowed a place among standard works of the kind. He died in the year 1714, in his eighty-third year. In his youth he had translated the first five books of the Aeneid, and likewise the odes of Anacreon. He had also composed several original poems, especially of the lyric kind, which were reckoned to poëtes great merit. These and other pieces have been printed in collections of Italian poetry. Marchetti had a very high opinion of his own talents as a mathematician and philospher; but he was, at the same time, humble and easy, and ready to do good offices to any person. He had been in habits of correspondence with many literary characters of distinguished eminence.

Marchetto da Padova, an intelligent writer on music in the thirteenth century, of whose works we found two inedited MSS., preferred in the Vatican library, No. 5322. The first is entitled "Lucidarium Artis Musice plane," beginning, "Cum inquit," &c.; and the second, "Pomerium Artis Musice Menurabilis: quatuor sunt Cantae," &c. The Lucidarium is frequently mentioned by Franchinus, Pietro Aaron, and other old musical writers of Italy.

There was a copy of this last-mentioned tract in the Ambrobian library at Milan, in 1770, D. 5, in folio, where it is said to have been begun at Celena, and finished at Verona, 1274: "Lucidarium in Arte Musice plane, inchoatum Celena, perfectumque Verone," 1274. The copy of his works in the Vatican was dedicated to Charles, king of Sicily, about the year 1283: "Marchettus Pudamni qui fum opus Kardlo Regi Siciliae dedicavit circa annum 1283."

We obtained large extracts from this MS., as it contained the most early mention that we had met with of the dissonant, or accidental sharp, or chromatic counterpoint, discords, and the proportions of such concords and discords as are used by the moderns in practical harmony. His examples of counterpoint, in the MS. whence our extracts were made, like those of Franco, are written upon only one flaut of four, five, fix, or more lines, according to the distance of the intervals, with two clefs, one for the lute, and one for the tenor or upper part, with this peculiarity of notation, that the notes of the upper part are written in red ink, and the lower in black.

This MS. contains many curious attempts at infant harmony. Marchetto is the first who speaks of discords and their resolution; and lays it down as a rule, that no two sevenths, or fourths, used as discords, should succeed each other; and that after a discord, the part which has offended the ear should make it amends by becoming a concord, while the other sounds still: indeed he never mentions the preparation of discords.

Marchetto Cara, an Italian finger, mentioned with Bidon, another contemporary vocal performer, with great eloquence, by Calliglione, in his "Cortegiano," written about the beginning of the sixteenth century. What kind of secular music the Italians cultivated, before the general use of counterpoint was established, we know not; but we find in the Lives of their first Painters, that many of them had been brought up to music, as a profession. Leonarto da Vinci was a great performer on several instruments, and invented a new species of lyre, in the shape of a horse's skull. (Da Tefchio di Cavallo. Vafari, Vite di Pitt.) Italy had likewise, at this time, fingers with great talents for execution and expression; for Calliglione, speaking of the variety and power of contralt in the arts, observes, that "influences of dissimilar things producing similar effects that are equally pleasing and meritorious may be given in them all; particularly music, in which the movement is sometimes grave and majestic, and sometimes gay and animated, yet equally delightful to the hearer. Thus, in singing, what can be more different than the performance of Bidon and Marchetto Cara? The one artificial, rapid, nervous, vehement, and impassioned, elevates and inflames the soul of every hearer; while the other, more gentle, pathetic, and impassioned, soothes and calms, and affects by a sorrowful and tender sweetness, which penetrates the heart, and affords it the most exquisite pleasure of a different kind." This description the late Mr. Galliard (Translation of Toft, p. 170) has thought applicable to the different powers of the two great female fingers, Faustina and Cuzzoni, the superiority of whose abilities was so disputable when they performed on the fame stage in England, 1727, that the patrons and friends of the one became invertebrate enemies to those of the other.

Great natural powers will sometimes astonish and charm without much allusion from art; and so late as the year 1547, Pietro Aaron (Lucidario in Musica, fol. 31.) gives a list of such extraordinary performers as were able to sing by book, cantori a libri; by which we may suppose that the art was new and uncommon. And according to Tartini, (Trattato di Musica, p. 17.) "The old Italian fongs being only made for a single voice, were simple in the highest degree; partaking of the nature of recitare, but largo; as the gondoliers at Venice still sing the flanars of Tasso." "None were confined to regular bars; and the key was determined by the kind and compass of voice that was to sing them."

However, during the sixteenth century, when the works
of Palestiniæ appeared, the Italians may with justice be said to have given instructions to the rest of Europe in counterpoint, as, ever since operas were established, they have done in singing.

MARCHI, FRANCIS, a famous military engineer, who flourished in the sixteenth century, was a native of Bologna. He is chiefly known by a book, entitled "De L'Architectura Militaria," which was published in 1599, in folio. This, which contains 161 figures, is an extremely scarce book; a circumstance which has been attributed, by some Italian writers, to the suppression of most of its copies by certain French terriers, who passed off his inventions for their own. It was probably a work of vast labour, as it was begun in the year 1546, and was not completed till after the death of the author. It is said to contain the germ of several contrivances, which have since been adopted. The Italian writers maintain, that in it is to be found the origin of Vauban's method of fortification; but the French admit only a trailing resemblance between the two authors.

MARCHIENNES, in Geography, a town of France, in the department of the North, and chief place of a canton, in the district of Douay; 7 miles E. N.E. of Douay. The place contains 3,109, and the canton 34,903 inhabitants, on a territory of 1124 kilometres, in 16 communes.

MARCHING, in Military Language. See March and Battation.

Marching Regiments, a denomination given to those corps who had not any permanent quarters, but were liable to be sent not only from one extremity of Great Britain to another, but to the most distant of her possessions abroad. Although the term "marching" is improperly confounded with those of "line" and "regular," it was originally meant to convey the notion of something more than a mere liability to be ordered upon any service; for by marching the regular troops from one town to another, the inhabitants, who from time immemorial have been jealous of a standing army, lost their antipathy to real folders by the occasional absence of regular troops. At present, the guards, militia, and fencibles, may be considered more or less as marching regiments. The marines and volunteer corps have stationary quarters.

MARCHIONIS PULVIS, in the Materia Medica, a term used for a certain compound powder, prescribed in the Leyden Dispensatory, and greatly recommended by many as an antispasmodic and absorbent.

The ingredients are: 1. Pliny-root, half an ounce, wood of mullein of the oak, rafings of ivory, elk's hoof, hops, the teeth of the unicorn, or, in its stead, the antlers of the stag's horn, red and white coral, and pearls, each a dram. These are all to be rubbed into a powder, with twenty leaves of pure gold, and given half a dram twice a day.

MARIAC, in Geography, a town of France, in the department of the Gers, and chief place of a canton, in the district of Mirande; 10 miles W. of Mirande. The place contains 1,479, and the canton 8,028 inhabitants, on a territory of 1173 kilometres, in 22 communes. N. lat. 43° 31'. E. long. 0° 14'.

MARCIANO, a town of Etruria; 30 miles E. of Florence.

MARCIANISI, a town of Naples, in Lavora; 10 miles N. of Naples.

MARCIANUS, in Biography, emperor of the East, was born of obscure parents about the year 391. His father served in the Roman army, into which he himself entered as a private soldier. Owing to fickleness, he quitted the station in 431; and upon the return of his health, he repaired to Constantinople, and enrolled himself among the troops commanded by Ardaburius, and his son Apar. By his talents and good conduct he was raised to the post of secretary, in which quality he attended Apar into Africa in 431. He was then taken prisoner by Genneric, who, after a time, to liberate him upon a promise never more to serve against the Vandals. He soon attained the rank of tribune and senator; and on the death of Theodosius the younger, in 450, he was associated in the empire with his father. Attila was, at this time, threatening both empires. He had already sent an insolent message to the court of Constantinople, demanding the annual tribute which had been extorted from the weakness of Theodosius. The newly crowned emperor was not to be so treated; he boldly replied, "that he had gold for his friends, but had prepared steel for his enemies." This determined spirit was probably the reason that Attila turned his arms against the western empire, rather than the eastern. By the death of Pulcheria, he became sole poilefr of the throne. He executed with the most pious fidelity her last wills, by which the left a vast property to the church and the poor. After the death of Attila, several tribes of barbarians deserted the banners of his sons, and obtained permission from Marcianus to settle in Thrace and Illyrium; which countries had been almost depopulated by the incursions of the Huns. He died, much regretted, in the year 457, after a reign of about six years and a half. His piety and zeal in defence of orthodoxy were highly applauded by ecclesiastical writers: his rigorous edicts against heretics, and his kindness to recalling those who had been exiled on account of tenets which he espoused, gave him a high rank, and the title of saint in the Greek church; and he is entitled to general praise for his having bestowed his promotions only on persons of known abilities and uncommon character, whence the departments of the state were at all times filled with credit. 

MARCIANO, in Geography, a town of Naples, in Lavora; 9 miles N.E. of Naples.

MARCIANY, a town of France, in the department of the Saone loir, and chief place of a canton, in the district of Charolles; 12 miles S.W. of Charolles. The place contains 2,414, and the canton 10,403 inhabitants, on a territory of 200 kilometres, in 12 communes. N. lat. 46° 17'. E. long. 4° 7'.

MARCILLOT, a town of France, in the department of the Allier, and chief place of a canton, in the district of Moutchon. The place contains 1,414, and the canton 10,002 inhabitants, on a territory of 235 kilometres, in 16 communes.

MARCILLY LA HAYE, a town of France, in the department of the Aube, and chief place of a canton, in the district of Nogent-sur-Seine. The place contains 4,88, and the canton 6,49 inhabitants, on a territory of 400 kilometres, in 24 communes.

MARCIONITES, or MARCIONISTS, Marcionita, in Ecclesiastical History, a very ancient popular sect of heretics, who, in the time of St. Epiphanius, were spread over Italy, Egypt, Palestine, Syria, Arabia, Peruia, and other countries: they were thus denominated from their author Marcion.

Marcion was of Pontus, the son of a bishop, and at first made profession of the monastic life; but he was excommunicated by his own father, who would never admit him again into the communion of the church, not even on his repentance. The cause of his father's displeasure is told by Epiphanius to have been a criminal connexion with a young woman;
Marcionites.

Marcion, according to Theodoret, maintained the existence of four principles, or unbegotten substances, as his expression is: one the good God, and unknown, whom he also calls the father of our Lord Jesus Christ; and the Creator, called by him just, and sometimes evil; and, besides these, Matter, and the evil one that governs it. Some, as Epiphanius and Cyril of Jerusalem, attribute to Marcion and his followers the doctrine of three principles; Augustine says, that he held two principles; and Tertullian often affirms, that Marcion believed two gods, though not both equal. Dr. Lardner apprehends, that Marcion believed in only two eternals; the Supreme God the Father, who was good, and Matter; for, according to him, the Creator was from the Father; and the Devil, somehow or other, sprang out of Matter, which he thought to be his own country. He appealed to ancient doctors, says Mothecombe, the Marcionites held the existence of two principles; the one perfectly good, and the other perfectly evil; between these they imagined an intermediate kind of deity of a mixed nature, who was the creator of this inferior world, and the god and legislator of the Jewish nation, who wages perpetual war with the evil principle; and both the one and the other aspire to the place of the Supreme Being, and ambitiously attempt to subject their authority all the inhabitants of the world. The Jews are the subjects of that powerful genius who formed this globe: the other nations, who worshipped a variety of gods, were supposed to be under the empire of the evil principle. These two conflicting powers exercise oppressions upon rational and immortal souls; and, therefore, the supreme God the Father, who had also a world of his own making, but better than this, immortal and invisible, in order to deliver them from bondage, sent to the Jews a being most like unto himself, even his son Jesus Christ, clothed with a certain shadowy resemblance of body, that he might be visible to mortal eyes; whose mission was to destroy the empire of the evil principle, and of the author of this world, and to bring back wandering souls to God. This celestial messenger was attacked by the prince of darkness, and by the god of the Jews, but without effect; since, having a body only in appearance, he was thereby rendered incapable of suffering. Those who follow the directions of this celestial conductor, mortify the body by fasting and sufferings, and renounce the precepts of the God of the Jews, and of the prince of darkness, shall, after death, ascend to the mansions of felicity and perfection. The rule of manners which Marcion preferred to his followers was excessively aulterious, containing an express prohibition of wedlock, wine, flesh, and all the external comforts of life. See Marcianians.

Marcion denied the real birth, incarnation, and passion of Jesus Christ, and held them to be all apparent only. He denied the resurrection of the body; and allowed none to be baptized but those who preferred their continence; but these, he granted, might be baptized three times. In many things he followed the sentiments of the heretic Cerdon, and rejected the law and the prophets. He pretended the gospel had been corrupted by false prophets, and allowed none of the evangelists but St. Luke, whom also he altered in many places, as well as the Epistles of St. Paul, a great many things in which he threw out. In his own copy of St. Luke, he threw out the two first chapters entirely. He says that Marcionites are neither more nor less thanl, as above stated, two gods, one good, the other evil: but, as at other times they represent them, calling one good, the other a judge, or fevere: this must be their meaning. Jerom says, that Marcion taught Jesus to be the son of the good God, that is, not of the same God spoken of in the prophets, who is there represented as cruel, righteous, just, a judge, and the like. To the fame purpose is the representation of Clement of Alexandria, upon whose testimony we may rely. The Marcionites say, that nature, or the world, is evil, because it is made of matter, which is evil in itself; and that the world was made by the Creator, who is just. They are, therefore, spoken of as having but low thoughts of this world on account of its being very imperfect, and not worthy of the Supreme Deity; and yet, as Tertullian says, they respected the Creator. The Marcionites seem to have been led into their erroneous notion of dividing the Deity from respect to his attributes. For they thought, if a good God had made the world, he would have excluded it from all truth and misery, and that all men could have been both holy and happy. Their reasonings upon that point are given by Tertullian, as well as some other arguments, deduced from the law, and other parts of the Old Testament, to prove the being from whom that was derived, different from the supreme or good God. Although, in some instances, they seem to blame justice, denominating it severity, and representing it as inconsistent with the character of goodness in God; and for this reason referring to themselves another God, different from the Creator, a God of unmixed goodness; yet they allowed there would be a future judgment. But then the Creator was to be the judge, whose justice they represented to be so strict as to approach near to severity. It seems also to appear from the testimony of Tertullian, and some other evidence, that the Marcionites did not allow the freedom of human actions, but were believers in a kind of necessity. They thought that the virtuous would be put into possession of eternal happiness after their departure out of this world, and that the place of their enjoyment would be where the presence of the good God was, and where Christ their favour should also reside; but they did not allow that the body would be a partaker of this happiness, or at least they denied the resurrection of the same body; for which reason they are censured by Tertullian. According to the account given by Epiphanius,
Marcionites.

Epiphanius, if we may depend upon it, Marcion taught the transmigration of souls from one body to the other; but this is contradicted by a passage in Clemens Alexandrinus, which implies that this was not the opinion of the Marcionites. According to Irenæus, Marcion taught that when Christ descended into hell, He delivered many wicked people, but left there the particulars, and many other good men of the Old Testament. Upon this statement Beausobre has made many pertinent and just observations.

Marcion was so far from believing that our Saviour was born of a virgin, that he did not allow He was born at all. He thought the Son of God assumed the exterior form of a man, and appeared as a man; and that, without being born, or gradually growing up to the full stature of a man, He shewed himself at once in Galilee, as a man grown. His gospel of St. Luke, it is thought, began with these words, "In the 15th year of Tiberius, God descended into Capernaum, a city of Galilee." And the Marcionites also supposed that at the first moment of his appearance in this world, He was completely fitted for entering on his great work, and that he immediately assumed the character of a Saviour. Although Marcion acknowledged Jesus to be Christ, He denied His being the Chrilt foretold by the Jewish prophets. The deliverer promised to the Jewish nation was not, as He pretended, the Son of God; nor did the oracles of the Old Testament agree to Jesus Christ. Marcion, says Tertullian, was a believer in two Christs, one who appeared in the time of Tiberius, for the salvation of all nations; and another the restorer of the Jewish flace, who is yet to come. Marcion allowed the truth of our Saviour's miracles, and thought them a sufficient foundation for believing in him. His doctrine concerning our Saviour was, that, from love to the human race, and for their fake He descended into this world, and submitted to great humiliations. Although, as his followers did not acknowledge him to have had real flesh, it may be supposed that they did not allow him to have really suffered, yet they believed that He was betrayed by the Jews, at the inclination of their God the Creator, and that He did and was buried. They even said that the death of the Messiah was necessary for the salvation of man, though they did not suppose it to be an exemplary sacrifice. They must, likewise, have believed our Lord's resurrection. From various testimonies, and from the arguments alleged by Tertullian, it appears that the Marcionites believed the whole history of our Saviour's appearance in a human form, and of his death on the cross. They also believed that He was crucified between two malefactors; they moreover allowed the truth of the miraculous earthquake and darkness at the time of his crucifixion. They acknowledged his having twelve apostles, and that one of them was a traitor. They also admitted the reality of the appearance of Moses and Elias on the mount, and of that voice from heaven which said, "This is my beloved Son, hear him."

Their manners, as we have already said, were strictly virtuous. Tertullian hints, that none were admitted by them to baptism and the eucharist, the obligation of which institutions they allowed, unless they had taken an oath against having any children, as if they meant it against the Creator; and Clement supposes that they abstained from marriage, that they might not people the world of the Creator, and that they offered themselves voluntarily to mary-removal out of hatred to the Creator. On the sabbath, or seventh day, they failed, because it had been a day of rest to the Creator, or God of the Jews, whom they defied. They permitted women to baptize, and they repeated baptism several times upon the same person, if he happened to commit any sin after this rite had been administered to him; and at the eucharist they used only water in the cup. They had among them churches for the flaunted performance of public worship.

The Old Testament was altogether set aside by Marcion, under the notion that it proceeded from the Creator, who, in his estimation, was delirious of good-nefs, and the author of all that is fin and misery which subsisted in the world; and his followers agreed, that the law and the gospel could not come from the same being, because there are, in their opinion, several things contained in the former inconsistent with many in the latter. They objected to the appointment of sacrificers, and to the distinction of meats into clean and unclean; and they were displeased with the order given to the Jews, to spoil the Egyptians. Tertullian says, that they allowed such and so many objections against the law and the prophets, that they seemed more like the objections of Heathens than of persons who embraced Chriftianity, through ever so heretical in their notions. Their aversion to the Old Testament was so great, that on this account they mutilated many passages in the New, even in those books which they admitted; rejecting all which related to the law and the prophets, or which were quoted from them, as plainly foretelling the coming of Jesus Christ, and which spoke of his Father as the Creator of the world. Considering this Creator, or God of the Jews, as of a character very different from the good God or Father of our Lord Jesus Christ, they afferted that Christ came to destroy the law given by him, because it was opposite to the gospel.

Marcion received but eleven books of the New Testament, and those were strangely curtailed and altered. He divided them into two parts, calling the one the Gospel, and the other the Apollonicon. The former contained only one of the four gospels, viz. that of St. Luke, and this was mutilated and altered, and interpolated in a great variety of places. Not allowing it to be called the gospel of St. Luke, he retrenched the first and second chapters entirely, and began his gospel at the first verse of the third chapter, and this verse he read in a different manner from our copies, as we have already observed. He rejected the genealogy and baptism of our Saviour; and it, therefore, seems not unlikely that he connccted that part of the first and second verses of the third chapter which he retained, with the 31st verse of the fourth chapter. He also rejected the history of the Temptation, because he would not attribute too much of human weaknesses to our Saviour; and the other story contained in the fourth chapter of Christ's going into the synagogue, at Nazareth, and reading out of the prophet Elias, was also rejected. This they expounded with the whole that follows it to the end of the 59th verse. But it would be tedious to enumerate all the alterations, or omissions, or interpolations, which Marcion and his followers made in the gospel of St. Luke. They are recited from Epiphanius by Dr. Lardner. We may observe, however, that a sufficient number of passages remain even in the copies of the Marcionites, to establish the reality of the flesh and blood of Christ, and to prove that the God of the Jews was His Father, and a being of compound goodnes. Marcion rejected the Acts of the Apostles from his canon of the New Testament; his Apollonicon consisting of ten of the epistles of St. Paul. The reason why he rejected this book is very obvious, according to Tertullian, because from it we can plainly shew, that the God of the Christians, and the Creator, or God of the Jews, were the same being; and that Christ was sent by him, and by no other. The ten epistles of St. Paul, admitted by Marcion, are much altered. Those which he receives, in a very mutilated
M A R

writings, and to compare copies together, and on this account to speak
of whole books, and particular passages, very frequently in their works; which
had enabled us of later ages to authenticate those books, and to come at
the genuine reading of many texts, in a better manner than we could
otherwise have done." Lardner's Works, vol. ix.

M A R C O I N G , a town of France, in the department of
the Nord, and chief place of a canton, in the district of
Cambray. The place contains 1175, and the canton 14,977
inhabitants, on a territory of 2122, in 20 communes.

M A R C O S I A N S , or C O L A R B I A N S , an ancient fect in
the church, making a branch of the Valentinians.

St. Irenæus speaks at large of the leader of this fect,
Marcus, who, it seems, was reputed a great magician. Mar-
fart computes that Marc appeared about the year 160.

Besides, on the authority of Eusebius, who undermoded
Irenæus to say that Marc appeared about the fame time with
Valentinus, speaks of him at the year 127. Many learned
moderns are of opinion, that Marc belonged to the Valen-
tian school, and they formed this opinion on the testimo-
nies of Irenæus and Tertullian. Nevertheless, Rhenford
and Beaufobre say, that the Marcianians were Jews, or juda-
izing Christians; and Grabe likewise owns that they were
of Jewish extràc. Irenæus leads us to imaging that Marc,
who was an Atiad, had come into Gaul, and made many
converts there. Nevertheless, learned moderns think that
they were only disciples of Marc, who came into that
country where Irenæus resided, of whom, in one place, he
makes particular mention. Irenæus represents him as ex-
ceedingly skilful in all magical arts, by means of which he had
great successes. Tertullian and Theoretus concur in calling
Marc a magician. Irenæus, after giving an account of the
magical arts of Marc, adds, that he had, probably, an
afflicting demon, by which he himself appears to prophesy,
and which enabled others, especially women, to prophesy
likewise; this practice favoured his seduction of many fe-
males, both in body and mind, which gained him much
wealth. He is also said to have made use of philters and
love-potions, in order to gain the affections of women,
and his disciples are charged with doing the same. Dr.
Lard-
ner, with his usual candour and impartiality, juggled some
doubtless to the justice of these accusations, with his rea-
sons for questioning their truth.

The Marcianians are said to have placed a great deal of
mythology in the letters of the alphabet, and thought that
they were very useful in finding out the truth. They
are charged unjustly with holding two principles, and as if they
were Docetes, and denied the resurrection of the dead; for
which there is no sufficient evidence. They perverted in
the practice of baptism and the eucharist. As to their opinion
concerning Jesus Christ, they seem to have had a notion of
the great dignity and excellence of his person, or his ineff-
able generation and, according to them, he was born of
Mary, a virgin, and the word was in him. When he came
to the water, the supreme power descended upon him; and
he had in him all fulness; for in him was the word, the
father, truth, the church, and life. They said that the
Chrift, or the Spirit, came down upon the man Jesus. He
made known the Father, and destroyed death, and called
himself the Son of Man; for it was the good pleasure of the
Father of all that he should satisfy ignorance and destroy
death: and the acknowledgment of him is the overthrow
of ignorance. From the account of Irenæus, we may infer
that the Marcianians believed the facts recorded in the
gospels, and that they received most, or all the scriptures of
the Old and New Testament. Irenæus also says, that they
had an innumerable multitude of apocryphal and spurious
writings, which they had forged: and that they made use
of that fiction concerning the child Jesus, that when his
father bade him say, alpha, the Lord did so: but when
the father called him to say beta, he answered, "Do you
fist tell me what is alpha, and then will I tell you what
beta is?" As this story concerning alpha and beta is found
in the gospel of the infancy of Jesus Christ, fill in being,
some are of opinion, that this gospel was composed by the

M A R C O T T I Z I , in Geography, a town of Selavonia; 20
miles N.E. of Kralovavelka.

M A R C O U F , S t . , two rocky islands in the English
Channel, near the coast of France, about nine miles S.E.
of La Hogue. The surface of each island, which is 18
or 20 feet above the surface of the sea at high water, com-
prises about an acre. They were taken possession of in
1795.
1795, by Sir Sidney Smith; and, in the following year, block-houses, with detachments of marines, invalids, and 12 artillery men, were ordered out by government. In the year 1798, the French dispatched a very numerous body of troops on board 52 gun-vessels, in order to attack these fortresses; but after having made several attacks, they were compelled to retreat to La Hogue, with the loss of 1,100 killed, drowned, and wounded; but on the side of the British only one killed, and two wounded. N. lat. 49° 31'. W. long. 1° 41'.

MARCOUSIS, a town of France, in the department of the Seine and Oise; 15 miles S. of Paris.

MARCUS HOOK, in Geography, a place of America, in Chester county, Pennsylvania, on the W. side of Delaware river; 20 miles below Philadelphia, containing about 30 families. Here are two rows of piers, or long wharfs, for defending vessels from the driving of ice in winter.

MARCAZA, a town of Aulphian Poland; 16 miles S. of Halicz.

MARDEN BLANC, St., a town of France, in the department of the Ille and Vilaine; seven miles W. of Fougeres.

MARD, St., or St. Medard, a town of France, in the department of the Forez; 35 miles W. of Luxemburg.

MARD, St. Mery, St., a town of France, in the department of the Marne; 12 miles S. of St. Menehould.

MARDS ON OTHE, a town of France, in the department of the Aube; 15 miles S.W. of Troyes.

MARDAC, in the Materia Medica of the Ancients, a name given by some to litharge. The Arabian writers have sometimes called it by this name, and sometimes by that of mardefengi. Many of their commentators have thought that they meant two different substances by these two names; but it does not appear to be truly the case, the two words standing, in different writers, for the same thing. Avicenna has given us a chapter on mardus, in which he has translated the chapter of Dioecodires on litharge: and Serapion has given us a chapter on the mardefengi, in which he has given us an account of the same substance, under the terms that Galen uses for the description of litharge, and even quotes him for the account.

MARDAYTES, in Ecclesiastical History. See MAROTITES.

MARDICK, in Geography, a small town, or rather village, of France, in the department of the North, situated near the coast of the English Channel; three miles S.W. of Dunkirk. This place was once famous for its canal, constructed after the peace of Utrecht, by order of Louis XIV. This canal, 3338 toises and two feet in length, commenced at the canal of Bergues, near Dunkirk, and extended with a breadth of between 25 and 30 toises, no less than 1,000 toises from E. to W. in length, and then widened from S. to N., and at the distance of 300 toises farther it had a sluice with two basins in it, one of which was 44 feet broad, for the reception of large vessels, and the other 26 feet broad, for the accommodation of those that were small. It afterwards extended still farther to the main sea. Many of the works constructed in this canal were destroyed in consequence of a treaty with England in the year 1717, and no others were to be erected on that coast within six miles of Dunkirk and Mardick.

MARDJE, a town of Egypt, situated on a spot abounding with palm trees; six miles N.E. of Cairo.

MARDIKERS, or TOPASSES, a breed of Dutch, Por.

Vol. XXII.

tuguefe, Indians, and other natives, incorporated with the Dutch, at Batavia, probably deriving their name from Mardick, or Marikha, the subject of the above article. As the Dutch adventurers formed the leading party when Batavia was taken possession of, the natives attached the appellation to all persons of European descent or connection.

MARDIN. See MARRIN.

MARE, NICHOLAS DE LA, in Biography, was born about the year 1641, and was, in after life, a commissioner of the Chatellet during the space of forty years. In consideration of his great zeal in the king's service, he was made steward of the houholders of the count of Vermandois, and after the death of that prince, he had a pension for his life. He was employed in various important commissions relative to the revenue, and made several journeys to the provinces on public occasions, in which he acquitted himself to general satisfaction. He died in 1723, and was author of a work of high merit, entitled "Traité de la Police," 3 vols. folio, 1705—19. This contains a detailed account of the establishment of the police in France; the functions and prerogatives of its magistrates, its regulations, &c. A fourth volume was added in 1738, by M. le Clerc de Brillet. Morei.

MARE, PHILIBERT DE LA, a literary character, and counsellor of the parliament of Dijon, who flourished in the 17th century. He was author of several works in the Latin language, taking that of De Thou as an example, which were well received by the public. The chief of these is entitled "Commentarius de Bello Burgundico apud Sequanos," containing a relation of the war of 1670. In a second edition by his son Philip, in 1659, is given a catalogue of writers on the history of Burgundy. M. Mare compiled a number of biographical sketches, chiefly of literary characters, and he left in MS. Memoirs of the public transactions from the year 1673, to his death, Morei.

MARE, in Rural Economy, the female of the horfe kind of animal. Mares intended for the purpose of breeding, should be selected with great care and attention, so as to be as free as possible from faults or imperfections in their forms, and be well limed in their kind to the purposes for which they are designed. The practice of making use of such mares as may happen to be on the farm should never be adopted, as it is prejudicial to the raising of good horse flesh. The particular directions regarding the kinds of horses to be bred, are these: if for the manage, or pads, the mares should have their heads well set on, and their breasts broad; their legs not too long, their eyes bright and sparkling, and bodies large enough, that the foal may have room to lie in their belly. They should be of a good and gentle disposition, and their motions easy and graceful; the more good qualities the mares have, the better, in general, the colts will prove.

If the owner would breed for racing, or for hunting, the mares must be chosen lighter, with short backs and long sides; their legs must be longer, and the breast not too broad; and such should always be chosen as have good blood in their veins. If the speed and wind of any particular mare have been tried, and found good, there is the more certainty of a good colt from her: but she should be in full health and vigour at the time, and not above seven years old, or eight at the utmost. The younger the breeders are, the better, in general, the colts will be.

Mares may be put to the horse when three years old, but it is a better practice to defer it a year longer, where it can be done with convenience. Some advise mares to be kept in
the horse some time before they are put to the horse, but this seems of little inconvenience when they are in proper health.

The best season for putting mares to the horses is in the spring, about April or May, in order that the foals may be dropped sufficiently early, which is of convenience in their rearing afterwards.

The length of time that they usually go with foal is about eleven months, which is a circumstance that should be kept in the mind of the breeder, though there are often considerable deviations. Mares should always be kept well while in foal, in order to have a nice healthy offspring.

The custom of performing much work with the mares while in foal is improper, as being attended with danger, as well as liable to check the growth of the foals: when this is practised with farm mares, they should only be gently wrought, and that with great care and attention. See Horse.

Mare, in Geography, a small island near the W. coast of Scotland. N. lat. 56° 14'. W. long. 5° 45'.

M. Reb, a river of Africa, which rises in Abyssinia, about sixty miles N.E. of Axum, and joins the Teccæzè, in the country of Nubia, 100 miles before its junction with the Nile.

Mareb, a town of Arabia, in the province of Yemen, and capital of the district of Bellad es Scharèf. Its sheriff possesses this town with some adjacent villages. The town consists of only about 300 poor houses; situated 16 leagues N.E. of Sana. It was known to the ancients by the name of "Mariaba," as the capital of the Sabæans; and in its vicinity are ruins, pretended to be the remains of the palace of queen Balkis. The Sabæans had a famous reservoir for water, called by the Arabs "Sitte Mareb," which was a narrow valley between two ranges of hills, and a day's journey in length. Six or seven small rivers meet in that valley, some of which contain fish, and their waters flow through the year; but others are dry, except in the rainy season. For confining the waters in this season, the entrance into the valley was shut up by a high and thick wall, and as outlets through which the water thus collected might be conveyed, in the time of drought, for watering the neighbouring fields, three large flood-gates were formed in the wall, one above another. The wall was 50 feet high, and built of large hewn stones. Its ruins are still visible. The tradition that the city of Mareb was destroyed by a deluge, occasioned by the sudden burbling of the wall, is fabulous. This accident, however, proved fatal to the city, by rendering the neighbouring fields waste and barren, so that it was thus left without the means of subsistence. The prince who formerly reigned over Mariaba was a powerful prince; but Mareb is now the abode of a poor sheriff, who is hardly able to withstand the encroachments of feeble neighbours. Niebuhr.

Mareca, in Ornithology, the name of a Brazilian species of duck, much valued there at table. It is of the shape of our duck; its head is grey, but has a beautiful red spot on each side, at the infection of the beak, and a whitenees in the lower part under the eyes; its breast and belly are of the colour of fresh-cut oak, variegated with black spots; its legs and feet are black; its tail grey; and its wings elegantly variegated with grey and brown; but they have in the middle a large mixture of that glossy green, which we see in the necks of our drakes. There is, besides this, another species of the mareca, which is of a dusky olive-coloured brown on the back, white on the throat, and grey on the breast and belly, and very remarkable for the fine bright red colour of its feet. See Duck.

Marechal. See Marshal.

Marechaux, Cape, in Geography, a cape which forms the north-east side of the bay of Jacmel in St. Domingo. N. lat. 18° 18'.

Marechites, a denomination of Indians, who inhabit the banks of the river St. John, and around Panamaquddy bay, in North America. To this class of Indians belong about 140 fighting men.

Mareckan, one of the southern Kurile islands, in the North Pacific ocean, about 30 miles long, called by the Russians "Chimoscis." N. lat. 47° 5'. E. long. 152° 50'.

Maregorian, one of the Molucca islands, about 15 miles long and 5 broad. S. lat. 0° 36'. E. long. 127° 18'.

Mareillac, a town of France, in the department of Aveyron, and chief place of a canton, in the district of Rodes. The place contains 1216, and the canton 10,453 inhabitants, on a territory of 2523 kilometres, in 18 communes.

Marella, a town of Hindooftan, in the Carnatic; 21 miles S.S.W. of Ongole.

Maremme, Is, a district of the Sienna, in Etruria, divided into a demana di quà, and Maremna di là; the former on the eafe, the latter on the west side of the river Ombrone; both bounded by the sea on the south. The soil is fertile, but the air is reckoned unhealthy.

Marena, in Ichthyology. See Salmo marandu.

Marengo, in Geography, one of the six departments into which Piedmont was divided, after it was united to the French republic, Aug. 26, 1802: it is composed of Montferrat, Alexandria, Tortoneze, and Launelline, and is bounded on the north by a part of Italy and the department of the Sefia, on the east by Parma, on the south by Genoa, and on the west by the departments of the Tamaro and Doire. This department lies in N. lat. 44° 50', and contains 181 square leagues, and 231,954 inhabitants. It is divided into five circles or districts, viz. Caffè, Cail, containing 108,926 inhabitants; Alexandria, 76,081; Voghere, 67,293; Bobbio, 31,288; and Tortone, 48,366. This department, lying between the Po and the Ligurian republic, is hilly, but fertile, yielding all sorts of grain, fruits, wine, and excellent pastures. There are iron mines in the vicinity of Serravalle. This department derives its name from that of a village, four miles east of Alexandria, which was rendered famous by a severe and sanguinary battle fought there June 14th, 1800, that terminated in subduing Piedmont and Lombardy to the dominion of the French. This battle was commenced by the Austrians, who compelled the centre of the French army, though ably supported, to fall back. The Austrians advanced upon Marengo with a movement that produced dreadful carnage, and gaining fresh reinforcements, they took possession of the village; part of the centre of the French having given way, and fled in disorder from the field of battle. The right wing, thus infuriated, was attacked by two lines of infantry, which marched against it with a formidable artillery; and the retreat of the centre obliged it, after vigorous resistance, to follow the same movement. Nothing could save the French army, in these desperate circumstances, but the body of reserve under general Dufaux, which was not yet ready for action; Buonaparte, in order to gain time, having recurred to its movement. The retreat of the French was made under the fire of 80 pieces of artillery; and though the carnage
carnage was horrible, they kept their ranks, and infantly replaced those who fell with fresh troops. Victory now seem'd to declare in favour of the Austrians, whose numerous and excellent cavalry covered the plain, supported by several squadrons of light artillery, and threatened to turn the army. At this critical moment, the grenadiers of the confular guard marched to support the right, which was the only column that had held firm. They advanced, and like a wall of granite, as they were called at the time, sullied three successive charges. At the fame instant, Monnier's division, which formed part of the corps de reserve, was ordered to attack the battalions which protected the Austrian cavalry, part of which was pursuing the centre and left of the French. On the plain of St. Juliano, the reserve under Defaix was drawn up in two lines, supported on the right and left by the artillery under Marmont, and by the cavalry under Kellerman. Behind this corps the fugitives of the centre and left formed; and the presence of Buonaparte, who flew from rank to rank, reanimated the soldiers, and at four in the afternoon, the battle which had raged for seven hours was about to recommence. The Austrians, apprehending themselves sure of victory, after having routed two-thirds of the French army, and ready to surround the remainder, had not taken any account of a division that had not yet attacked. They had therefore imprudently wasted their strength, and scattered their battalions in the ardour of pursuit. Buonaparte perceived the advantages which this ardour on the part of the enemy had given him. Defaix, at the head of his legion, rushed forward with impetuosity among the victorious battalions, charging them with the bayonet; the remainder of the division followed this movement, and the whole army, catching the enthusiasm, advanced at the pas-de-chargc. The Austrians, overwhelmed with astonishment at this sudden explosion, withdrew their artillery, and the infantry began to give way. At this critical moment Defaix fell; but the loss of this brave officer, instead of disconcerting, routed the ardour of the troops into a fury, in order to avenge his death; but the bayonet, which had driven back the first line of the Austrians, could not pierce the second. The refliaue of the Austrians slopping the French in their career, rendered the event of the day still doubtful; but its fate was decided by Gen. Kellerman, who, ordering a charge of cavalry, threw the Austrians into disorder, and made a whole division prisoners, to the number of 6000 men, among whom were several generals, and almost all the officers of the staff. A third line of infantry yet remained as a corps de reserve, supported by the reti of the artillery, and the whole of the cavalry. Against this last division the right wing of the French advanced with the grenadiers of the consular guard, and part of the reserve under Baudet, and supported by the artillery under the command of Marmont. The Austrian line still maintained its ground; but the French cavalry under Murat, having charged the Austrian cavalry, this latter gave way precipitately, and was completely routed; so that night fearcely put a stop to the pursuit and carnage. The French boof of having wounded, killed, and taken prisoners, 15,000 men; the victory on their part, it must be acknowledged, was signal, but their loss was probably equal to that of the army with which they contendcd. Many traits of heroism were exhibited on occasion of this battle, and many consequences resulted from it which will render it memorable in the page of history.

MARENNE, a town of France, in the department of the Stura; 4 miles N.E. of Savigliano.

MARENNES, a town of France, and principal place

of a district, in the department of the Lower Charente, at the mouth of the Scudre; 9 miles S.S.W. of Rochefort. The place contains 4633, and the canton 9950 inhabitants, on a territory of 215 square kilometres, in fixed communes. The principal article of its trade is salt. N. lat. 45° 49'. W. long. 1° 1'.

MARENZIO, Luca, in Biography. an eminent and favourite Italian musical composer, who flourished during the latter end of the sixteenth century. This ingenious and fertile author, who distinguished himself chiefly as a madrigalist, was born at Concaglia, in the diocese of Brescia, and the scholar of Giovanni Contini, who was himself a voluminous composer: having, in 1565, published Cantic. 6 voices, Introitus et Hallelujah, 5 voices, for festivals: Hymnos, 4 voices; Threnos Hierennice, 4 voices, for Paschallon; and a Misere, in four parts.

The inclination of his disciple Marenzio leading him very early to the composition of madrigals, he cultivated that style more successfully than any of his predecessors, and the number he composed is prodigious. At Venice, between the years 1587 and 1601, were printed nine books of his madrigals, for five voices; the two last were posthumous. Besides these, this author composed fix books of madrigals, in six parts. Madrigals for three voices; another for five, and still another for fix voices, different from all the former. Canzonets for the lute. Motetti, a 4, & Sacros Cantiones, 5, 6, & 7 Vocibus modulandus. All these works were first printed at Venice; and afterwards at Antwerp, and many of them in London, to English words; see "Musica TranfAlanina," two books, and a collection of Italian madrigals, with English words, published in 1589, by Thomas Watton. Quadrio, t. ii. p. 324, gives a long list of his Villanelle, a 3 voic; and Draudius, p. 1614, of his motets, a 4, for all the festivals throughout the year. Ven. 1588. Et ejusd. Completorium & Antiphona, a 6, 1595.

Of the madrigal style he was called in Italy, il piu dolce Cigno; and the proud antagonist of Nanino, Sebastian Raval, the Spaniard, who was editor of some of his works, styles him a divino composter. He was some time maestro di capella to cardinal Luigi d'Este; and, according to Adami and others, carented and patronized by many princes and great personages, particularly the king of Poland and cardinal Cinthi, Aldobrandini, nephew to pope Clement VIII. Upon his return to Rome, after quitting Poland, he was admitted into the pope's chapel, and dying in that city, 1599, he was buried in the church of St. Lorenzo, in Lucerna. Adami Offerv. per ben regolar il Coro Pienif.

Our countryman, Pacham, in his Complete Gentlemen, speaks of his delicious aire and sweet invention in madrigals; and says, "that he excelled all other whatsoever, having published more sets than any author else, and hath not an ill song." Adding, that his first, second, and third parts of Thryria, Veggio dolce il mio ben, &c. are songs the Muses themselves might not have ashamed to have composed." To all this we can readily subscribe, and will not dispute his figure, or the colour of his hair, when he further tells us, that "he was a little black man," but where he afferts that "he was organist of the pope's chapel at Rome a good while," he lores all credence with us; as there never yet was an organ in the papal chapel; nor is it likely, however great his musical merit may have been, that the niece of any reigning pope could have been fent for to Poland, with so little ceremony, as he tells us, in the character of a lunetit and finger, in order to gratify the curiosity of
his Polish majesty, and the affection of Luca Marengio. Indeed, the whole account favours of hear-fay evidence and absurdity; and is so much the more incredible, as no other musical writers, who were eager to record every memorial they could procure concerning Luca Marengio, have ventured to relate these circumstances.

There are no madrigals so agreeable to the ear, or amusing to the eye, as those of this ingenious and fertile composer. The subjects of fugue, imitation, and attack, are traits of his art and winning melody; which, though they seem selected with the utmost care for the fake of the words they are to express, yet so artful are the texture and disposition of the parts, that the general harmony and effect of the whole are as complete and unembarrassed as if he had been writing in plain counterpart, without poetry or contrivance.

The first set of his madrigals for five voices, however, feems the most elaborate; the fugues and imitations here are more ingenious and frequent than in his other works. He has, indeed, in those of later date more melody; but as yet there was too little to compensate for the want of contrivance. Whoever takes the trouble to score and examine this set, will discover marks of real genius with respect to harmony and modulation, with many attempts at melody of a more graceful kind than is to be found in the works of his contemporaries; as we may reasonably conclude this to have been one of his early productions, of nearly the middle of the sixteenth century.

We have never met with more than one entire movement, in triple time, among all the works of this excellent composer; and that is in the eighth set for five voices, "La mia Clorice brunetta." In a collection of his madrigals for five voices, published at Antwerp, 1594, some of the movements are gay and spirited, and contain passages that continued in fashion more than a hundred years after publication, as appears by the use that Purcell and Handel have made of them; and indeed there are others which modern Italians have not disdained to adopt.

The words of his ninth book of five-part madrigals are all from the Canzoniere of Petrarcha, and of those the composition seems the most free and fanciful of all his works.

Though the madrigals of the sixteenth century appear now so grave as to be fearfully distinguishable from the music of the church, yet the matters of that period had very distinct and characteristic rules for composing in both styles. Pietro Pontio, who had himself produced many that were excellent, in giving instructions for composing madrigals, says, that "the subjects of fugue and imitation in them should be short, and the notes of a quicker kind, and more syncopated in church music; otherwise they would not be madrigals." The parts likewise should frequently move together; but the greatest care should be taken to express the sense of the words as exactly as musical imitation will allow, not only by quick and slow paffages, or notes ascending and descending occasionally, but by modulation, which, when the sentiment of the poet implies harsfness, cruelty, pain, sorrow, or even joy, pleasurc, or the like, will assist the expression more than single notes." Here he refers to the fourth madrigal of Orlando di Lasso (book i) for an example of the happy expression of words. Though composers were now very timid in the use of flats, sharps, and transposed keys, yet licences were taken in madrigals which were inadmissible in musica capella. In the eighth madrigal of Luca Marengio's ninth book, a 5, Solo c'enefa, a bold and curious composition, the upper part ascends from the key-note G to A, the ninth above by a series of fifteen semitones, and then descends from A to D by the fame intervals. The answer to subjects proposed in madrigals were more imitations than regular replies, according to the strict laws of fugue; yet, with respect to the melody of the short paffages or musical sentences which were used, and the harmony with which they are accompanied, great pains seem to have been taken in polishing both. Indeed, as this was the chief muse of the chamber, where it is probable the critics and lovers of music attended, for neither public concerts nor operas had as yet existed, there can be no doubt but that every refinement was bellowed on this species of composition, which the ideas of musical perfection could then suggest.

MAREOTTI, in Geography, a lake of Egypt, 8. of Alexandria, which is become almost dry, though occasionally, as it is said, moistened by inlets from the sea. This lake, says Savor, whose banks were covered with papyrus and date-trees, is no longer in existence, because the Turks have neglected to preserve the canals which conveyed the waters of the Nile. Belor, who travelled in Egypt some years after the conquest of the Ottomans, affirms us, that in his time lake Mareotis was only at half a league's distance from the walls of Alexandria, and that it was surrounded by forests of palm-trees. "At the moment of my writing, (says the famous traveller,) it is entirely occupied by the sands of Lybia. These deplorable changes must be attributed to the destructive government of the Turks." See ALEXANDRIA.

MAREISO, a town of Ithra; four miles S. of Capo d'Itria.

MARETIMO, an island of the Mediterranean, near the W. coast of Sicily, about 22 miles in circumference, containing a chateau and some farms, 15 miles W. of Trapani. N. lat. 38 4'. E. long. 12 15'. In this island, as well as Favoyanna, both belonging to the king of Naples, he used to banish his state-prisoners.

MARETS, ROLAND DES, in Biography, a native of Paris, was born in 1594: he pleaded some time as an advocate at the French bar, till, disgusted with the contents of the profession, he retired to a life of literary repose, and died in 1653. He was celebrated for an excellent skill in criticism, and for his knowledge in the Latin tongue. He wrote a number of Latin letters on literary topics, which were published after his death by M. de Launois, under the title of "Roland Marei Epitoihorum philologicaeum. Lib. ii." Moreri.

Bayle.

MARETS DE ST. SOLIN, JOHN DES, brother of the preceding, a man of letters of a singular character, was born at Paris in 1595. He very early distinguished himself by the liveliness of his parts, and was in great favour with cardinal Richelieu, whom he used to affix in his literary productions. In recompence for his labours he had conferred on him the polls of comptroller-general of the war extraordinaries, and secretary-general of the marine of the Levant. He was one of the first members of the French Academy, and made himself known by a variety of compositions in poetry and romance. He was likewise a writer, and his most popular piece is the comedy of "Les Vifonnaires." He led a very licentious life, but in old age he became a devotee and fanatic, and was a bitter enemy of the Jansenists, whom he attacked in writings full of extravagance. He applied the prophecies in the book of Revelations to Lewis XIV., who, according to his account of the matter, was at the head of 144,000 men to destroy hereby and Mahometanism, and bring the whole world to the pre-fusion of the true faith. He died in 1676, at the age of eighty-one.

Bayle.

MAREUIL, in Geography, a town of France, in the department
department of the Dordogne, and chief place of a canton, in the district of Montmorin; 21 miles N.W. of Perigueux. The place contains 754, and the canton 9320 inhabitants, on a territory of 210 kilometres, in 18 communes.—Allô, a town of France, in the department of the Vendée, and chief place of a canton, in the district of Fontenay-le-Comte; five miles N. of Luçon. The place contains 240, and the canton 4239 inhabitants, on a territory of 160 kilometres, in 17 communes.

MARGA, MARLE. See MARLE.

MARGA, St., in Geography, a small island of Hungary, in the Danube; 10 miles S. of Buda.

MARGAB, or MAGUS, a river of Persia, which rises about 30 miles E. from Herat, and loses itself in the earth near Badam.

MARGAMARGA, a river of Chili, which runs into the Pacific ocean, S. lat. 33°.

MARGAM, a town of Japan, in the island of Xicaco; 8 miles N. of Ovith.

MARGARET, in Biography, queen of Denmark, Norway, and Sweden, daughter of Waldemar 111., king of Denmark, was born in 1354; she was married, while very young, to Haquin, king of Norway, and son of Magnus, king of Sweden. At her father's death, in 1375, she was a widow, and her son Olau, then only nine years of age, was chosen king of Denmark and Norway, she being appointed the regent. In 1387, Olau died, leaving the male line of the three northern crowns extinct. Margaret was unanimously elected to the crown of Denmark, and afterwards to that of Norway. The States urged her to enter into the matrimonial connection a second time, in order to prevent any disputes with regard to the succession of the crown, but she declined the proposal, and nominated for her succesor apparent, the nearest of blood of the royal family, viz. Henry of Pomerania, from that time called Eric. Henry, duke of Mecklenburg, brother to Albert, king of Sweden, declared himself a competitor with Margaret, and engaged Albert in his cause. Preparations for war were made on both sides; a decisive battle was fought, in which Albert was defeated and made prisoner, and Margaret was presented with the crown of Sweden. In 1395 she was solemnly crowned queen of the three northern kingdoms. She cauied Eric to be confirmed and acknowledged as her successor, procured a redemption of the crown land alienated by Albert in Sweden, and adopted a number of prudent regulations for the confirmation of her authority, and the healing of animosities. She was particularly attentive to the administration of justice in her dominions, and to the enforcement of the laws upon all ranks of her subjects. She protected and encouraged commerce, by providing for the security and good treatment of foreign merchants resorting to her ports, and employed the most vigorous means of suppressing piracy. In 1397 was concluded the famous union of Calmar, by which the three northern kingdoms were declared to be indissolubly united under one head, who should be chosen successively by each of the three, and then confirmed at an assembly of the whole, and should spend his time equally between them, applying the revenue of each to its own expenditure. Other regulations also were enacted for the maintenance of the equal rights and privileges of the three kingdoms, and the prevention of disputes. Notwithstanding, however, all the care that was taken on the subject, this treaty proved the fruitful source of wars and dissensions for several centuries. An attempt was soon after made to recover the title of Gothland from the Teutonic knights. There were likewise disputes with the house of Holstein, which had been suffered to gain possession of Sleswick, and these continued, with little interruption, during the remainder of the reign. Margaret, by the courage of her administration, retained her full authority at home, and made herself felt abroad. She was left friendly to her Swedifh subjects than to those of Denmark, on which account the nobles of Sweden, in a body, presented a remonstrance on the violations of their rights, to which she hautily and imprudently replied, that "they might guard them with so much vigilance as the would keep the fortresses of the kingdom." She died in 1412, after a reign, including the regency, of thirty-six years. From the extent of her dominion, the policy of her administration, and perhaps from a fulpicion of irregularity in her morals, she obtained the title of the "Semiramis of the North." That she possessed the qualities of industry, activity, readiness, and resolution, there can be no doubt; and it is said she had a natural eloquence fitted to impress a public assembly. Univer. Hist.

MARGARET of Anjou, celebrated in the history of England, was the daughter of René, titular king of Sicily, Naples, and Jerusalem, defended from the court of Anjou, brother of Charles V. of France. Brought up in a court without power or rule, her natural strength of mind was not enfeebled by early indulgence; and she became distinguished as the most accomplished young princess of her time, when she was fixed upon by cardinal Beaufort and his friends as wife of Henry VI. of England. Upon her marriage she threw herself into the hands of that party which had been the means of her elevation, and to her disgrace it has been charged upon her that she was actually privy to the murder of Humphrey, duke of Gloucester. The reign of Henry VI., at this time, was disquieted by rancorous and contending factions, and in 1454, while the national discontents were rising to a crisis, Margaret was delivered of a son, and she was, almost immediately upon her recovery, called upon to exert herself in refitting the Yorkists, who had gained the victory of St. Alban's. Henry was made prisoner, but his comfort was not dispirited; he raised troops, and supported the royal cause with so much spirit, that he was able to restore her husband to a nominal sovereignty, and effect a favourable compromise. In 1459, the war was renewed, when Henry fell again into the power of his enemies, and the queen, with her infant, was glad to escape frith to Durham, and then into Scotland, whence returning to the north of England, she engaged the nobles and great men who lived in that part in her cause, and soon by their means collected a powerful army. With this she met the duke of York at Wakefield in the month of December 1460, and gave him a total defeat. The duke was slain, and his head by the express command of the queen, was cut off, and placed on the gates of the city of York, being first crowned, in derision, with a paper diadem. After this she was again victorious in several actions, and in 1461 recovered the person of the king. In every instance she displayed a singular and revengeful disposition towards those who fell into her hands, and against whom she bore any ill-will. The approach of Edward with a superior force obliged her again to retreat to the north, and that prince was elevated to the throne by the people of London, an event which seemed to give a fatal blow to the hopes of the house of Lancaster. In the month of March, the most bloody of all these battles was fought at Towton, in Yorkshire, in which the Lancastrians were totally defeated, and Margaret and Henry made a halting retreat into Scotland. After this they went over to France, to seek that assistance from the French which she had vainly solicited from her nearer neighbours the Scotch. For this purpose
pose he proposed to deliver Calais to the French king on the event of Henry's being restored to the crown, and on this condition she obtained two thousand men at arms, with which she was allowed to land in Scotland. Here she was joined by others in her own interest, and proceeded to Hexham, in Northumberland, where she was met by a force under lord Montacute, who routed and totally dispersed her troops. Margaret with her son fled into a forest, where she was deferred by a band of robbers, who stripped her of her jewels, and treated her perfin with great indignity. Fortunately she escaped while her plunderers were quarrelling about the booty, and penetrating into the depth of the forest, she wandered about till she was exhausted with fatigue and terror. 'At length, seeing a man approach with a drawn sword, she summoned resolution enough to go out to meet him, saying, 'here friend, I commit to you the fon of your king, for that protection which I am unable to afford him.'" The man, though a robber, was disarmed of every ill intention by the confidence which was repose in him, and devoted himself to their service. After concealing them some time in the woods, and providing for their support, he conducted them to safety in the sea-coast, whence they took an opportunity of escaping into Flanders. She lived several years in retirement, while her husband continued a prisoner in the Tower of London. At length, in 1470, she was encouraged to join the earl of Warwick, who had commenced a rebellion against Edward, who routed and totally dispersed her troops, which obliged the king to quit his country, and take refuge in Flanders. Margaret, with the view of forwarding his efforts, landed at Weymouth with a small body of French troops, and on that day, the 14th of April 1471, the battle fought at Barnet put an end to the life of Warwick and the hopes of the confederacy. Margaret, relying still on her good fortune, once more encountered the victorious Edward at Tewkesbury, where she suffered a total defeat, and was with her son taken prisoner; the latter was slain in cold blood by the men of his conquerors. Margaret was brought into the Tower of London, in which her husband about that time perished; she was afterwards ransomed by Lewis XII., and returned into France, where she died in 1482. She underwent many changes of fortune, and suffered a larger portion of calamities, than can scarcely be paralleled in the history of crowned females. Her great talents and unflinued spirit excited general admiration, while her sagacity and ferocious disposition, and the preference which he was inclined at all times to give to her native country, rendered her an object of reverence to the greater part of the English nation. Shakespeare, whose historical plays are the echo of popular opinion, describes her in very dark colours, and as insinuate of all the tenderness and modesty of her sex. Hume's Hist. of England.

Margaret of Foix, queen of Navarre, sister to F rence L, king of France, was born at Angoulême in the year 1492. She married the duke of Alençon in 1509, and became widowed in 1525. When her brother was prisoner in Spain, and extremely ill through the treatment to which he was exposed, the paid him a visit, and restored him to health by her kind offices; in return for which he promoted her marriage with Henry d'Albret, king of Navarre, upon very advantageous conditions. As soon as he was seated on the throne of this small kingdom, she united with her husband in every effort to make it flourish, by encouraging agriculture and the useful arts, improving the administration of justice, and promoting knowledge and civilization. She was herself of an equable turn of mind, and in contemplating the principles of the reformers, it was supposed she had become a convert to their opinions; at any rate she afforded protection to several divines who were persecuted for their opinions, and even interceded with her brother in favour of the reformed in his territories. She was fond of the bible, of which she got a rude translation in the French language, and from this she extracted parts which she formed into stanzas that were reprinted in her court. She wrote a work intitled "Le Miroir de l'Amé pecherelle," which was printed in 1532, and which incurred the cenfure of the Sorbonne. On account of her attachment to the new opinions, she underwent some ill treatment from her husband, who would probably have been more severe with her had not her brother interpolated to stop his hand. His affection for her continued even after he himself had become a violent persecutor of the reformed in his own kingdom; but it must be observed that she never threw off the exterior profession of the Catholic religion, and became more affiduous in her complicity with its ceremonies as he advanced in years, and is even supposed finally to have returned to the faith in which he had been educated. "It will appear remarkable," says one of her biographers, "that a lady so much addicted to licentious and pious contemplations, and certainly of unsuspected virtue, should have composed a set of tales as licentious as those of Boccacio; but such contradictions were not uncommon at a time when the general manners were gross, and decorum was little observed." This work was entitled "L'Heptameron, ou Journées de la Reyne de Navarre." It was written while she was young, and was not printed till after her decease, which happened in 1519, leaving only one child, Joan d'Albret, queen of Navarre, and mother to Henry IV. The style of the L'Heptameron, &c. was lively and simple, and the colors well invented. It has been very frequently reprinted. A collection of her poems and other pieces was published in 1537, by her valet-de-chamber, John de la Haye, with the title of "Marguerites de la Marguerite des Peres." Univer. Hist Bayle.

MARGARET, St in Geography, a river of Canada, which runs into the Jageray, N. lat. 48° 20'. W. long. 69° 36'.

MARGARET'S Bay, St., a port on the S coast of Nova Scotia, between Prospect harbour and Mahon bay; from which last it is separated by a promontory, on which is the high land of Apodagogus. - Alto, a bay in the English Channel, on the E. coast of Kent; five miles N. E. of Dover.

MARGARET'S Island, islands in the North Pacific ocean, discovered by Capt. Magee, in the ship Margaret of Bolton, on its voyage from Kamtchatka in 1782. N. lat. 24° 40'. E. long. 131° 12'.

MARGARET'S, St., Island, near the S coast of Wales; three miles W. of Tenby.

MARGARICARUS, in Botany, so called, as it appears, from μαργαρίτης, a pearl, and καρυτης, fruit, because of its white round drupa. Vahl indeed, and the authors he quotes, write it Margsyricarctus, which may surely be corrected without offence. Vahl. Enum. v. 1. 307. Flats and order, Diandria Monogynia. Nat. Ord. Senticos, Linn. Raphace, sect. 3. Songusfarbe, Juff.

Gen. Ch. Cal Poranthus inferior, in four or five deep, ovate, equal segments. Cor. Petals four or five, ovate, smaller than the segments of the calyx; sometimes wanting. Stam. Filaments two, sometimes three, thread-shaped, longer than the calyx; anthers roundish, in two deeply divided lobes. Pyl. German inferior, ovate, compressed; stye thread-shaped, the length of the stamina; stigma petalate. Pyc. Drupa roundish, somewhat fleshy, umbilicated, of one cell. Seed. Nut quadrangular, of one cell.

Obf. The flowers are said to be sometimes dioecious, in which
which cafe the males, at least, are furnished with petals. Vahl characterizes the genus as delitute of a corolla. The permanent leaves of the calyx have, by some perfoms, been taken for leaf-like styles or stigmas.

Eff. Ch. Calyx in four or five deep segments, superior. Petals smaller than the calyx. Stigma peltate. Drupa with one seed.

1. M. fistulosa. Britly Pearl-berry. Fl. Peruv v. 1. 28. t. 8. f. d. Tabh. (Aemetrum pinnatum; Lamarck Dict. v. 1. 567; Ancilium barbatum; Lamarck Illutr. v. 1. 77.)—Native of Brazil, Peru, and the dry hills of Chili. This specimen was gathered by Commerfon at Monte Vidos, in sandy ground. The flum is hrubby, round, smooth, with a deciduous scaly bark, and numerous scattered leafy branches, clothed with the permanent, rigid, brittle-like spines, dilated at their base. Leaves opposte, crowded, pinnate, near an inch long, of three or four pairs, with an odd one, of equal, linear, pointed, entire, revolute leaflets, smooth, except some deciduous hairs at the point. Flowers axillar, nearly sessile, small. We find flumen and pistil in the same flower, the former being permanent till the frut is ripe, as is also the style, which is curved, tipped with its white peltate stigma.

MARGARITA, Francesca, de l’Epine, in Biography, an Italian finger, born in Tuscany, who came to England at the beginning of the last century with a German musician of the name of Geere, seems to have been one of the first female Italian fingers who appeared on our stage, before any attempt had been made at an Italian opera. June 1, 1793, in the theatrical advertisement for Lincolns-Inn-Fields, when the “Rival Queens” was promised, it is said that “Signora Francesca Margarita de l’Epine would sing, being positively the last time of her singing on the stage during her stay in England.” She continued, however, singing more last and positively last times during that whole month, and never quitted England, but remained here to the end of her life. In most of the first attempts at opera in England, she performed a capital part, till the year 1798, when, retiring from the stage, she married Dr. Pepusch.

In 1794, Signora Margarita sings, for the first time, at Drury-lane. At her second appearance there was a disturbance in the theatre while she was singing, which, from the natural and uncommon effects of rival malice, was suspected to have been created by the emissaries of Mrs. Tofts; an idea the more difficult to eradicate, as the principal agent had happened to live with that lady as a servant. But as the law of retaliation is frequently profcribed on the like occasions by the injured party, it was thought necessary, a few days after, to infest the following paragraph and letter in the Daily Courant, Feb. 8, 1704: “Ann Barwick having occasioned a disturbance at the theatre-royal Drury-lane, on Saturday night last, the fifth of February, and being thereupon taken into custody, Mrs. Tofts, in vindication of her innocence, sent a letter to Mr. Rich, master of the said theatre, which is as follows: Sir, I was very much surprised when I was informed that Ann Barwick, who was lately my servant, had committed a rude deed last night at the playhouse, by throwing of oranges, and hissing when Mrs. l’Epine, the Italian gentlewoman, sang. I hope no one can think that it was in the leaf with my pretty, as I assure you it was not. I shew such practices; and I hope you will cause her to be prosecuted, that she may be punished as the deferves. I am, sir, your humble servant, Katharine Tofts.—To Christopher Rich, esq. at the theatre-royal, Feb. 6, 1704.”

The rivalry of Mrs. Tofts, the favourite English finger, at the beginning of the last century, and the Margarita, and the zeal of their several friends, gave rise to the first musical feud which we heard of in this country. According to Hughes, author of the Siege of Damascus, their abilities were disputed by the first people in the kingdom.

“Music has learn’d the discords of the flute, And concerts jar with Whig and Tory hate. Here Somerset and Devonshire attend The British Tofts, and every note commend; To native merit just, and pleasure to We’re Roman arts, from Roman bondage free. There fam’d l’Epine does equal skill employ, While lifting peers crowd to th’ eclat joy: Bedford to hear her song his dice forfakes, And Nottingham is raptur’d when she flakles. Lul’d flatesmen melt away their drowsy cares Of England’s safety, in Italian airs. Who would not send each year blank paftes o’er, Rather than keep such strangers from our shore.”

From the connection between the Margarita and Greber, with whom she arrived in England, she became distinguished by the title of Greber’s Peg. When she quitted Greber, she commenced another connection with Daniel earl of Nottingham, to which Rowe alludes in an imitation of an ode of Horace, “Ne fit ancilla tibi amor puderi.”

“Did not base Greber’s Peg inflame The sober earl of Nottingham, Of sober fire defend’d? That careless of his soul and fame, To play-houses he nightly came, And left church undefended.”

The earl had written against Whilton on the doctrine of the Trinity. An epigram, written by the earl of Halifax, is extant on the same subject.

On Orpheus and Signora Francesca Margarita.

“Hail, tuneful pair! I say by what wonderous charms, One ‘scar’d from hell, and one from Greber’s arms? When the soft Thracian touch’d the trembling strings, The winds were hush’d, and curl’d their airy wings; And when the tawny Tuscany rais’d her strain, Rook fuels the tails, and darts it on the main. Treaties unfish’d in the office steep, And Shovel yawns for orders on the deep, Thus equal charms and equal conquests claim, To him high woods and bending timber came, To her shrub-hedges, and tall Nottingham.”

The applause of the public, and admiration of individual partisans, were pretty equally bestowed on the two Sirens of the time, Mrs. Tofts and the Margarita.

The vocal merit of the Margarita must have been very considerable to have kept her so long in favour as a finger on the English stage, where, till she was employed at the opera, the same either in musical entertainments, or between the acts, almost every night. Besides being outlandish, she was so swarthy and ill favoured, that her husband, Dr. Pepusch, used to call her Hecate, a name to which the answered with as much good humour as if he had called her Helen. But with such a total absence of personal charms, our galleries would have made her fongs very short, had they not been executed in such a manner as to silence theatrical shrieks, and command applause.

Dean Swift, who was no respecter of persons, particularly musical,
MARGARITA, or Margaréta, in Geography, an island in the Caribbean sea, near the coast of Terra Firma, discovered by Columbus about the year 1498. It now forms one of the provinces belonging to the royal audience of Caracas, established in 1786; the other provinces being Venezuela, Maracaibo, Cumaná, Varinas, and Guiana. The governor of Caracas represents the monarch throughout those provinces; all the military departments being completely subject to his orders, though on great occasions he consults a "Junta de Guerra," or council of war, composed of the chief officers. Governors, however, are delegated for each province, who are appointed for five years, with a lawyer as an afferior. The island possesses but few attractions; the forest is scant and produces only cotton. It has, however, a small garrison, consisting of one company of regular troops, four of white militia, one of artillery, one of cavalry, and four infantry companies of people of colour. One of the discoveries of Terra Firma, a pearl-fishery, which was the principal source of the riches of the country, and of the revenues of the king, was carried on between the islands of Cabagua (which see) and Margarita, at the expense of the lives of a great number of Spaniards and Indians who perished in the buccaneers. The island is, perhaps, defensible as a military and commercial station; because, as it is separated from Terra Firma by a distance of only eight leagues, and to windward of all her provinces, it might become under a system of free commerce the general entrepot of Cumana, Barcelona, Caracas, Guayra, and all the cities of the interior. This island also serves to form the channel, that separates it from Terra Firma, sometimes called "the Straits of Margarita." This channel is not navigable for the whole eight leagues of its width. The island of Coche, situated in the middle, leaves the navvator, a very narrow passage two leagues from Margarita, through which he must indefatigably pavy. Every vessel coming from windward, or from Europe to Cumana, to Barcelona, and even to Guayra, is obliged to run down the S. side of Margarita. If this island were in the power of the enemies of Spain, all the commerce with Europe, all intercourse with the neighbouring islands would be so much the more easily intercepted, as they, which endeavoured to avoid the channel, would be taken by pirates, when Margarita would serve as an arsenal. Besides, an enterprising enemy would find in the situation of Margarita means of easily diverting expeditions against any part of Terra Firma which he might wish to invade. Through the whole coast of this island there are but three ports; the first and principal is "Pampatar" to the E.S.E.; the second, called "Pueblo de la Mar," is one league seaward of the preceding; and the third is on the N. side, and therefore called "Pueblo del Norte" the village of the North. The capital city is "Assumption," built almost in the centre of the island. The whole population of the island is 14,000 persons, consisting of 5,000 whites, 2,000 Indians, and 6,500 slaves and freed persons. The principal riches of the inhabitants are derived from the pearl-fisheries established in the island of Coche, in the middle of the channel. These fisheries are carried on by the Indians of the island, who also take a number of turtles and an immense quantity of fish, which they sell, and sell throughout the continent and neighbouring islands. They fabricate, from Margarita those hammocks of cotton, whose web is so much finer than the hammocks manufactured in any other place. They also make very fine cotton flockings, which are sold at a very dear rate. This island has also to many parrots and curious birds, that no vessel leaves the ports of Margarita without having a small cargo of them on board. The poultry raised here becomes a resource for the poor, who sell their fowls and turkeys to the foreign islands. N. lat. 10° 56'. W. long. from Paris between 66 and 67°.

Margarita. (a rabbinical term), a white speck on the eye. See LEUCOMA.

Margaritae. See PEARLS.

Gen. Ch. Male. Cal. Perianth inferior, of one leaf, four-cleft, furcate, permanent. Cor. Petals four, rounded, inserted into the calyx. Stam. Filaments eight, bristle-flanged, spreading, rather long, inserted into the receptacle; anthers roundish, small. Pfl. Germen superior, roundish; side-bristle-flanged, the length of the stamens; stigma obtuse. Female, on a distinct plant. Cal. Perianth as in the male, permanent. Cor. as in the male? Pfl. Germen superior, globose; styles four or five, thread-shaped; stigmas simple, permanent. Peric. Berry globular, crowned with spreading, short styles. Seeds ovate, compressed on the inner side, inclosed in a tunic of four or five lobes and as many cells, which is cartilaginous and highly polished.

Female, Calyx and Corolla like the male. Styles four or five. Berry four or five-needled, inclosed in a cartilaginous tunic.

1. M. nobilis. Linn. Suppl. 428. Syll. Veg. ed. 14. 890. (Euonymus margaritifera pentacoccos americana; Plin. Phyt. t. 176. f. 4.) - Linnaeus had several specimens of this plant, at different periods of its growth, sent by Dalberg from Surinam. - The stem is shrubby. What Linnaeus conceives to be the male has opposite, oval, large, veined, entire leaves, on footstalks. Panicles formed by compound clusters of small flowers. In the Female, the branches and leaves are alternate. Stalks single-flowered.

The
The kernel of the berry four or five-grained, remarkably thinning and pearl-coloured. There seems to be great reason for supposing that under these two sexes of *Margaritaria*, very different plants are described, though sent to Linnaeus as different sexes of the same species. At the end of his account of *M. nobilis*, as described in the Supplementum Plantarum, he appears somewhat to doubt whether their union be correct.

**Margaretina**, in Geography, a town of European Turkey, in Albania; 34 miles W. of Arta.

**Margaretina** are glass ornaments, made at Venice of small glass tubes of different colours, which are blown at Murano, and which the women of the lower classes wear about their arms and necks. This larger sort are used for making rosaries. This work is performed with great dispatch, the artisan taking a whole handful of these tubes at once, and breaking them off one after another with an iron tool. These short cylinders are mixed with a kind of ashes, and put over the fire in an iron pan; and when the two ends begin to melt, by fusing them about with an iron wire, they are brought to a round figure; but care is taken not to leave them too long over the fire, lest the hole through which they are to be fngured, should be entirely closed by the melting of the glass. There are several streets at Francesco di Vigna, entirely inhabited by people whose sole occupation is to make and fusing these margaritini.

**Margate**, in Geography, a market-town in the jurisdiction of the liberties of Dover, and county of Kent, England, is situated on the sea-coast, at the northern extremity of the Isle of Thanet, 16 miles distant from Canterbury, and 72 N.E. of London. Though now one of the most fashionable and best frequented watering-places in the kingdom, it has only obtained its principal celebrity within the last fifty years, before which it was a small fishing-town, irregularly built, and the houses generally old and low. Its antiquity, however, is much more considerable; it has been a member of the port and town of Dover from a remote period; in Leland's time there was a pier "here for shyppes, but now decayed." When the survey of maritime places in Kent was made in the eighth year of Queen Elizabeth's reign, the number of houses in "Margate was 168; boats and other vessels, fifteen of various burthens, from one ton to eighteen; the persons belonging to these vessels, occupied in carrying grain and fish, sixty." Where the pier is now built, there was anciently a small creek, which probably gave origin to the town, from the shelter it afforded to fishing-vessels and other craft. The land on each side of the creek was progressively washed away by the sea; and the inhabitants were obliged to construct a pier to prevent the town from being overpowered, and to defend that part of it which lies next the water. This pier was at first very small, and extended but a little way from the land; but the encroachments of the sea rendered it necessary to enlarge it. In Queen Elizabeth's time it was maintained by certain rates paid on corn and other merchandise, which were either shipped or landed here: but, through the neglect of the persons employed, these rates were neither duly collected nor applied, and the pier went gradually to decay. By an act of parliament, (11 Geo. I.) these payments, and the application of them, were enforced, and the pier maintained till the year 1787; when another act was obtained, under which the pier has been re-built with stone, and extended so as to enlarge the harbour, and form a more complete security for shipping. To provide security to this harbour, and construct a pier in a permanent manner, have frequently been but unsuccessfully attempted: it is confidently expected that these important ends will be at length accomplished under the able and scientific direction of John Rennie, esq., engineer.

The improvement of the harbour, and the great refort of company to this coast, have occasioned a considerable increase in the number of fishing and other craft belonging to this port; so that the town is not only supplied with fish for its own consumption, but great quantities are continually sent to the metropolis. The whole number of packets, sloops, boats, &c. which now belong to Margate, is about seven. Among the articles imported, are coals from Newcastle and Sunderland, and deals, hemp, tin, iron, &c. from Memel and Riga.

Margate is a large and scattered place; it is built on irregular ground; part of it being very elevated, while the other part is situated in a bottom, close to the sea-shore. The houses are principally of brick, and many of them are large and commodious. The general recommendation given by medical men to sea-air and sea-bathing, and also the fashionable propensity of spending some portion of the year at a watering-place, have been the grand causes of the extension and progressive improvements of the town. As the number of visitors increased, the buildings for their accommodation were rapidly augmented, the landholders rightly judging that the speculation would be successful. Two hand-f tome squares have been formed; various new streets and ranges of houses have been raised, and scarcely a year passes without some additions being made. The amufement as well as the accommodation of the visitors have been provided for by the erection of hotels, lodging-houses, &c. At the south corner of Cecil-square are the assembly rooms, which form a spacious building of the Ionic order, with Venetian windows, entablature, and cornice; on the ground-floor are a billiard-room and a coffee-room, several dining-parlours, and a piazza supported by a range of duplicated Doric columns. On the first-floor are the tea, card, and ball-rooms; the latter is a very elegant apartment, eighty-seven feet in length, and forty-three in breadth: five large elegant glass chandeliers are suspended from the ceiling. Near the east corner of Hawley-square is the theatre-royal, a spacious structure, erected in the year 1787, at the expense of 4000l. The exterior is plain; but the interior is highly ornamented: the time of acting is restricted to the featon. Other sources of amufement are found in several hand-fome and respectable libraries.

The bathing-rooms are situated on the western side of the High-street, near the harbour. The bathing-place is a level sandy shore, extending under the cliffs for several miles, and forming, at proper times of tide, a pleasant walk. But the most fashionable promenade is the pier, which, being finifhed by a parapet built over, is perfectly safe, and is the general refort of the company.

Margate was anciently a chapelry to Minster, but was made parochial in the year 1290. The church, a spacious edifice, stands on an elevated spot at the south-east side of the town; it consists of a nave, chancel, and aisles, with a square tower at the north-west angle. The nave is divided from the aisles by eight arches, springing from octagonal and round columns; the latter have ornamented capitals in the Norman style. The monuments and brasses within the walls are numerous, and several of them are of considerable antiquity. Beside the church, here are four places of religious worship: one for Baptists, one for Roman Catholics, a third for the followers of Mr. Wesley, and the fourth, called Zion-chapel, on the establishment of the late countess of Huntington. The principal charitable institutions are a general sea-bathing infirmary, established in 1792; Draper's hospital, or alms-houses for widows, erected in 1769, pursuant to the will of Michael Youakley, a Quaker; and a charity...
M. A. R.

M. A. R.

charity-school, built in 1787, for forty boys and forty girls.

There appears to have been a market kept here in the time of Charles I., of which a monthly return was made to Dover; but this was soon discontinued. Well-upholstered market stalls are now held on Wednesdays and Saturdays, under a consent made in the year 1727 to Francis Cobb and John Baker, then wardens of the pier, and their successors. Under the population act of 1809, the number of inhabitants of this parish was 4766, occupying 1115 houses: whereby it appears that the population has been nearly doubled since Lewis wrote his History of the Isle of Thanet, in 1723. A Picture of Margate, &c. 12mo. 1819. Hailes's History of Kent, 12 vols. 8vo. Brayley's Beauties of England, &c. vol. viii. 8vo. 1807.

About a mile distant from Margate is situated Dandelion, so named from the original possessor, Dent de Lyon, who came to England with William the Conqueror. There still remain four towers, and a fine antique gate-house, of the original building, composed of alternate layers of brick and flint. On a Meghan the armorial bearing and name of the founder may still be seen. Here is a fine garden and bowling-green, whence there is a beautiful and extensive view of Margate roads, the sea, and shipping. In this garden are public breakfasts, with music and games, and given twice a week during the season. They are under the regulation of the master of the ceremonies, and constitute one of the most agreeable and rational amusements of this place.

The country round Margate is very fertile, and peculiarly healthy. The probable reasons of the salubrity of the Isle of Thanet are detailed in the preface to Dr. Buchan's "Treatise on Sea-Bathing," which will be found an useful companion to all persons resorting to the sea-coast on account of their health.

MARGEN, in the Mularia Medica, a name used by some of the later Greek writers to express red coral. It is founded on an error, however; the word margen being made from the Arabian margian, which does not signify coral, but a purple seaweed, or fucus, used in dying. See MARCIA.

MARGENFELT, in Geography, a town of Prussia, in the province of Oderland; 11 miles S. of Oderrod.

MARGENGAW, a town of Prussia, in the province of Pomorcia; six miles N. of Marienburg.

MARGENSCHITZ, in Natural History, a name given by the German botanists to a sort of indurated marl, which, while in the strata, is nearly of the hardness of flint; but when laid on the surface of the earth, and exposed to the wind and rain, soon disintegrates, and reduces the pores of the ground, enriching the soil to a very great degree.

We have the same sort of flinty marl in some parts of England, only that our's is less hard, and yet takes more time to break and disintegrate in the air. They are both most proper for lands of a loose loamy nature, and keep them in heart a long time.

MARGGRABOWA, in Geography, a town of Prussia, in the Lithuanian department; 80 miles S.E. of Königsberg. N. lat. 53 52'. E. long. 22' 47'.

MARGGRAF, ANDREW STIGMANN, in Biography, a celebrated chemist, was born at Berlin in the year 1769, where his father was apothecary to the court, and fellow of the college of medicine. Thus situated from his early years, his attention was naturally turned to the pursuits of chemistry and pharmacy, for which he imbibed a taste, which he afterwards cultivated with great industry under the celebrated professor Neumann, during a period of five years, and subsequentially under professor Spicelmann, at Strasburg. In 1773, he went to the university of Halle, where he became a pupil of Hoffmann in the study of medicine, and continued his chemical pursuits under the direction of Juncker, to which last science he ultimately devoted his sole attention. For the purpose of obtaining practical information on the subject of mineralogy, he returned to Freyberg, in Saxony, in 1741, where Dr. Hennckel was then in high reputation in that department of natural history; and he practiced the art of assaying under Suhrnich. In the following year he visited the Hartz mines, and then returned to Berlin, where, by a close and incessant application to his chemical labours, he so materially injured his health, that it was never afterwards vigorous. He passed the remainder of his life in his native city, notwithstanding an offer of the place of ducal apothecary to the duke of Brunswick, with a department in the mines, which was made to him in 1737 by that prince, but which he did not deem sufficiently advantageous to induce him to leave Berlin. In 1738, he was received into the Society of Sciences, and furnished some memoirs for the "Miscellanea Berolinensia," and when this society was re-organized in 1744, as the Royal Academy of Sciences and Delles Lettres, he was placed in the class of experimental philosophy, of which he was chosen director in 1747. He had also the high gratification of being entrusted with the laboratory of the academy in 1754, in which he almost lived, absorbed in the study or practice of his favourite art. He was, nevertheless, a man of great amenity of temper and considerate conviviality, when mixing in the society of his friends. He had been for some years liable to spasmodic affections, and, in 1774, was attacked with apoplexy, which left a paralysis behind it. He continued, however, to attend the meetings of the academy till the autumn of 1776; after which his mental and bodily powers gradually declined, and he died in August, 1782.

Marggraf was held in considerable estimation as a chemist throughout Europe, and had the honour of being elected a member of several learned bodies. All the writings which he produced were published in the Memoirs of the Literary Society of Berlin, before and after its renovation; but they have been collected and published both in German and French. They contain the details of a great number of processes and analyses, described in clear and simple language. Some of the most important of his discoveries relate to phosphorus, which he distilled in 1776, and to the high extraction of zinc from zinc oxide; to the fixed and volatile alkalies; to man- ganese, the Bolognian stone, platina, and the acid of sugar. In short, he is entitled to rank among the most accurate experimentalists, who contributed to the advancement of the science of chemistry, before the recent luminous improvements which it has gained. Gen. Biog. See also his Elloge in the Mem. de l'Acad. Roy. de Berlin.

MARG-GRAVE. See MARCIA.

MARGIAN, in Botany, a name given by some of the ancient writers, particularly the Arabian physicians, to the plant called by others argimin, or argimen. This is descripted to be a purple-leaved plant. Some have supposed that cochineal was meant by this word, but that is an error. Others have some from what nearer, in supposing it to be the name of coral, but as the ancients have laid that it was used in dying, it could not be coral; and indeed there is no other plant that it can mean, but that it was used by the Greeks in dying, and called fucus porphyrius, or the purple-dying leaved-plant.

MARGIANA, in Ancient Geography, a country of Asia, along the river Margus, from which it derives its name. According to Ptolemy, it lay Hyrcania on the W., on the N. Oxus, on the E. Batium, and on the S. Aras. The people who inhabited it were the Dercida, the Massagetae, the Taphoni, the Parni, and the Dax. Its towns were Aryan,
Ariaca, Sinia, Aratha, Argadjar, Jafanon, Rhea, Antiochis, Guriano, and Nicca. Pliny gives us a very favourable notion of the situation and fertility of this country. It now forms a part of Khorasan, which Lee.

MARGIANI, in Geography, a town of Persia, in the province of Comis; 25 miles N. of Biltan.

MARGIDUNUM, in Ancient Geography, a place of Great Britain, situated, according to the sixth Iter of Antonine, between Verometum (near Willoughby) and Ad Pontum (near Southwell.) Dr. Stukeley places it at Bridgeford, but Mr. Horace, and some other antiquaries, fix it near East Bridgeford.

MARGILAN, in Geography, a town of Turkestan, at the union of a river of the same name with the Sirr; eight miles S. of Tashkund.

MARGOT, a river and height of America, situated on the E. side of the Mississippi. The course of the river is westerly, and it is said to be navigable for bateaux for a number of miles. The ground below its junction with the Mississippi, in N. lat. 57° 28', affords a commanding, airy, pleasant, and extensive situation for settlements; the soil is remarkably fertile.

MARGOT PORT, a maritime village on the N. side of the island of St. Domingo, in N. lat. 19° 48', nine leagues W. of cape Francois.

MARGOZZA, a town of Italy, giving name to a lake near it, called N.W. of Milan.

MARGUARSTEIN, a town of Bavaria, on the Acha; 25 miles W. of Salzburg.

MARGERITAS, isles of; islands in the Mediterranean, near Ivisa, one of which is large and near Pic Nono, which advances into the sea, in the form of a cone, covered with trees.

MARGUERITE, St., an island in the Mediterranean, near the coast of France, nine miles from Antibes. N. lat. 45° 31'. E. long. 7° 7'.

MARGUERITE, a river of America, which runs into lake Michigan, N. lat. 44° 24'. W. long. 85° 34'.

MARGUERITES, a town of France, in the department of the Gard, and chief place of a canton, in the district of Nimes; four miles N.E. of Nimes. The place contains 2057, and the canton 6359 inhabitants, on a territory of 173,7265 kilometres, in eight communies.

MARIJA, Ave. See Ave Maria.

MARIA THEREZA, in Biography, empress of Germany, and queen of Hungary, daughter of the emperor Charles VI. was born at Vienna in 1717, and married Frances of Lorraine, grand duke of Tuscany, in the year 1736. At the death of her father in 1740, she remained sole heiress of the dominions of the house of Austria, which had been allured to her by the Pragmatic sanction, guarantied by almost all the powers of Europe. The hope of depoiling an unprotected female was, however, too great a temptation to be overcome by mere treaties, and claims were made on all sides to part or the whole of the inheritance. She, moreover, took quiet possession of it, and ingratiated herself with all her subjects. The storm first broke upon Silezia, which Frederic II. of Prussia seized. He soon secured to himself the possession of this rich province by a victory, and his success induced the court of France, in conjunction with the Elector of Bavaria, to enter into the war. Unable to contend effectually with the combined forces, Maria Therese hastily retired to Prewburg, where, allying the states of the kingdom, she appeared with her infant son in her arms, and made such an animating and affecting address, that the nobles all drew their sabres, and solemnly swore they would die in defence of the rights of their sovereign.

A powerful army was raised, which marched to Vienna, and secured it from attack, so that the enemy could only boast of the capture of Prague, and of having been the means of crowning the elector of Bavaria king of Bohemia. He was, shortly after this, by the influence of the French, elected emperor of Germany. England felt an interest in behalf of the queen, and joined her as an ally, while individuals of almost every rank opened their purses in aid of her cause. She prudently detached from the confederacy the king of Prussia, by offering to him Silezia, and the contrived likewise by other confessions to detach the king of Poland, elector of Saxony, from the number of her enemies. Without attempting to detail the occurrences of this war, which involved most of the powers of Europe, we may observe, that Maria Thereza displayed, through the whole of the contest, a degree of firmness and vigour, which would have done honour to any sovereign; that she was crowned queen of Bohemia at Prague, in 1743; that she placed the imperial crown upon the head of her husband in 1745; and that by the peace of Aix-la-Chapelle, in 1748, she was confirmed in the possession of all her dominions, excepting Silezia, which remained in the hands of the king of Prussia. On the restoration of peace, the empress queen, the title by which she was usually known, turned her attention to the improvement of her dominions, by encouraging commerce and the useful arts. New ports were opened, and new sources of trade explored; canals were formed and manufactyes established; schools and public libraries were founded, and a college for the sciences was instituted at Vienna. This and a multitude of other acts bore witness to the zeal and intelligence with which this sovereign and her ministers pursued the great objects of public good.

People are always grateful for the beneficial acts of their governors, and it was impossible for love and generation to be carried farther than those which were inspired by a sovereign, who, to female beauty and gentleness, added masculine dignity and excellence. The court of Vienna could not brook the loss of Silezia, and, in revenge, it infuriated a confederacy against Frederic, with the view of depriving him of his conquests, and perhaps of depoiling him of a part of his hereditary dominions. For this purpose an alliance was formed of the empress-queen, the emperors of Russia, and the king of Poland as elector of Saxony; Frederic discovered their plan and thwarted it. Soon after this the house of Austria joined France in an attack upon the king of Prussia, who was able to make a treaty with England. Frederic struck the first blow and carried his arms into Bohemia, which was the commencement of what is generally called the seven years' war. The junction of Ruffia with his other enemies brought Frederic to the brink of ruin. He was, however, saved by his own great and almost unparalleled efforts, and the treaty of 1763 confirmed him in the possession of Silezia, and restored Germany to its former political state. The only advantage gained by the empress-queen, was the election of her son Joseph to the succession of the empire as king of the Romans. In 1765, she lost her husband, the emperor Frederic, with whom she had lived in confidant and affectionate union thirty years. So strong was her attachment to the memory, as it had been to the person of her husband, that she ever after wore mourning, and paid frequent visits to his tomb. In 1772, a plan was laid for the first dismemberment of Poland, to which it was said to have been impossible. In 1775, the conference of Maria Therese could be obtained. Her son Joseph, fixed on the object, and knowing her failings, addressed to her the argument of religion, which subdued her ferupe, that were unquestionably founded in rectitude, and ought not to
to have been subverted. From this period she did not interefere much in the management of public affairs, though she did not hesitate to check the innovations of her foes, especially those which went to the abolition of convents, and other changes in the church establishment. She died at Vienna, in the autumn of the year 1780, at the age of sixty-three, comfounding herself in her last moments with the purity of her intentions in all her conduct, and with the idea of having merited the honourable title of the “mother of her people.” She left a numerous progeny, of whom one son Joseph II. was emperor; another the grand-duke of Tuscany; one daughter queen of France, another of Naples; “happy” says Dr. Aikin “that she could not look into the awful secrets of futurity.” A warm attachment to the duties of her religion was a prominent feature in her character; in some instances, perhaps, her zeal approached the borders of bigotry and intolerance; it must, however, be allowed, that her conduct in general displayed all the salutary influence of religious principles, and that as a wife, a mother, and a sovereign, she has had few equals upon the throne. Hist. of France. Gen. Biol. London 1790.

Maria, in Ancient Geography, a town of Italy, in Venetia; situated on the Padus, towards the S.E., and very near Hadria.

Maria, in Geography, a river of America, which runs into the Mississipi. N. lat. 37°37'. W. long. 90°33'.—Alfo, a town of South America, in the province of Carthagena; 32 miles W. of Carthagena.—Alfo, a river of Honduras, which runs into the bay, N. lat. 15°40'. W. long. 87°15'.

Maria Bay, a bay on the N. coast of Tongatapoo; seven miles W. of Observatory Point.

Maria, S. a town of Transilvania; 12 miles S.E. of Hunyad.—Alfo, a town of Naples, in Lavora; 37 miles N. of Naples.—Alfo, a town of Iberia; four miles N. of Monfalcone.—Alfo, a town with a convent of Hungary; six miles N. of Rosenburg.—Alfo, one of the Tremiti islands, now called “St. Nicola.”—Alfo, a sea-port of the Liguria Republic, in the gulf of Spezzia; four miles S. of Spezzia. N. lat. 44°6'. E. long. 9°42'.—Alfo, a small island near the coast of Chili. S. lat. 37°10'.—Alfo, a town of Brazil, in the government of Maranhao; eight miles N.E. of St. Felipe.—Alfo, a town of Mexico, in the province of Mechoacan; 23 miles S. of St. Louis de Potosi.—Alfo, a town on the W. coast of the island of Mindanao. N. lat. 9°33'. E. long. 122°18'.—Alfo, a small island in the Grecian Archipelago, near the N.E. coast of Paros.—Alfo, a town of New Mexico; 40 miles S. of Santa Fe.—Alfo, a town of New Navarre; 210 miles S.E. of Cafa Grande.

Maria della Alizza, a town of Naples, in the province of Otranto; four miles E. of Gallipoli.

Maria di Camarana, S. a town of Sicily, in the valley of Noto, at the mouth of a river on the S. coast; the remains of a city called “Camarana;” 28 miles S.E. of Alicete.

Maria del Alto, a town of Naples, in Otranto; two miles S.S.W. of Nardo.

Maria Apezafono, S. a town of Naples, in Capitanata; three miles S. of Monte St. Angelo.

Maria di Dileti, S. a town of Naples, in Otranto; 15 miles S.E. of Moteera.

Maria della Gratia, a town of Italy, in the department of the Mincio; five miles W. of Mantua.

Maria la Carta, S., a small island in the N. Pacific ocean. N. lat. 27°50'. W. long. 149°.

Maria della Gratia, a town of Naples, in Calabria Citra; six miles N. of Scalea.

Maria dell' Isola, a town of Naples, in the province of Bari; three miles N. of Convento.

Maria di Leuca, S., a town of Naples, in Otranto, on the sea-coast near cape Leuca; the see of a bishop; 18 miles S. of Otranto.

Maria Palomba, S., a town of Naples, in Otranto; five miles E.N.E. of Matera.

Maria della Serra, S., a town of Naples, in Calabria Ultra; 11 miles N. of Nicaltaf.

Maria de Iagua, S., a town of Paraguay; 220 miles E. of Afflumption.

Maria de Iguande, S., a town of South America, in Popayan; eight miles N.W. of Barbarao.

Maria de Monte, S., a town of Italy; three miles E. of Friuli.

Maria de Matamba, S., a town of Africa, capital of Matamba. S. lat. 9°35'. E. long. 18°34'.

Maria de Daro, S., a town of South America, and capital of the province of Daroan, on a river which runs into the bay of Panama. N. lat. 8°41'. W. long. 78°.

Maria del Gracia, a town of Etruria; 31 miles E. of Florence.

Maria Creek, a river of the western territory of America, which runs into the Wabash, N. lat. 38°48'. W. long. 88°.

Maria Van Diemen, Cape, the N.W. point of New Zealand. S. lat. 34°30'. W. long. 187°18'.

Maria Zeall, a town of the duchy of Storia; 12 miles N. of Pruck.

Maria's Islands, a cluster of islands, near the south part of New Holland, somewhat N.E. of Tannan's Head. S. lat. 43°15'. E. long. 147°46' to 148°10'.

Maria, Santa, Cape, the N. cape at the mouth of La Plata river, in South America; 9 leagues from the bay of Maldenado, and 20 from Montevedio, a bay fo called from a mountain which overlooks it.

Maria Therésa, Order of, in Heraldry, a military order, which was instituted by the empress queen on the 18th of June, 1757, and composed of two classes. viz. Grand Crosses and Knights. To these the emperor Joseph II. in the year 1765 added an intermediate class, under the appellation of Commanders. The number of knights is not fixed, and the emperor is grand master. The badge of the order is a cres of gold, enamelled white, edged with gold; on the centre are the arms of Austria, viz. gules, a fesse argent enorced with the word spectidini on the reverse is a cypher of the letters M. L. F. in gold, on an enamelled green ground. The badge is worn pendent to a striped crimson and white ribbon.

MARIAGALANTE, in Geography. See Mariagalannte.

MARIAGERS, a sea-port town of Denmark, in north Jutland, situated on a gulf which communicates with the Cattegat, called “Marragerfjord.” Its principal trade consists in flax and linen; 22 miles E.N.E. of Viborg. N. lat. 56°1'. E. long. 9°53'.

MARIALVA, a town of Portugal, in the province of Beira; 16 miles N.E. of Puehel.

MARIAM, a town of Abyssinia; 100 miles E.S.E. of Gondar. N. lat. 11°2'. E. long. 33°34'.

MARIAME, in Ancient Geography, an episcopal town of Phcenicia, the sovereignty of which was confirmed by Alexander the Great to Garadolatrus, king of Arad.

MARIAN, of MARIANNE, Islands, in Geography. See LADRONKE.
MARIANA, Juan de, in Biography, a celebrated historian, was born at Talavera in 1536. He was an illegitimate child of Juan Martinez de Mariana, afterwards canon and dean of the collegiate in that town. He received an excellent introductory education, and was sent at a proper age to Alcala, an university of considerable reputation. Soon after this Ignatius Loyola sent missionaries to Catalonia to establish his order there, and Mariana, who was only in his seventeenth year, joined them. At the age of twenty-four he was appointed to the professorship of theology at the great college lately established at Rome. Here he lectured four years, and had among others the famous Bellarmine as one of his pupils. From Rome he went to Sicily to open a course of theology which the company had begun there. After a residence of two years in that island, he was sent to Paris in the same capacity, where for five years he publicly expounded Aquinas, and the degree of doctor was, on account of his great learning, conferred upon him. Not having his health at Paris, he obtained permission to resign his chair and retire to Toledo, where he was elected to various high offices in the church, and was employed by the archbishop in forming a catalogue of prohibited books, and the Index Expurgatorius, which was published in 1584. About this time he bore a part in the edition of St. Tho'dore's works, and incurred some suspicion by the freedom with which he expounded the canons of Arias Montanus. Mariana had longpired to be the historian of his own country, and in the little leisure which his superiors left him, he followed the indications of his genius. "Nature," says his biographer, "had designed him for something better than to expound Thomas Aquinas, and to emaculate books for the inquisition. The result of his labours appeared in 1592, in a work under the title of "Historie de Rebus Hispanic Libri xx." It was afterwards extended to thirty books: the most complete edition is that of Mentz. The history comes down to the end of Fernando's reign, the author being fearful of coming nearer to his own times, left he should give offence by speaking the truth. The work is in high estimation, and it is said that they who read the history of Spain for entertainment will always read it in Mariana; he is the historical classic of his country. In 1599 he published his treatise "De Rege et Regis Institutione," which was burnt by order of the parliament of Paris. He was author of many other works, the titles of several of which are enumerated in the "General Biography," some of them, viz. "De Morte et Immortalitate," and "De Monete Mutatio," exposed him to persecution, imprisonment, and to such evils that even to a man, whom the higher powers, whether justly or unjustly, chose to frustrate Mariana had, however, a mind not to be borne down by the weight of authority, and could in that privacy and retirement into which he was driven, give up all his powers in the pursuit of science and literature. His last publication confounded Schola upon the Old and New Testament, with an elegant version of the Proverbs, Ecclesiastes, and Solomon's Song. He died at Toledo on the 16th of February, 1623. "The Jesuits," says Mr. Southey, "have often maintained the rights of the people for the fake of their own order: this was not Mariana's case: his views were of a wider range; he thought of mankind, not of the company." 

MARIANA, in Ancient Geography, a town and Roman colony of Corica, established by Marius: it was episcopal, and its ruins now bear its name. It is now the see of a bishop; 16 miles S. of Batica.

MARIANA, in Geography, a town of Italy, in the Veronese; 8 miles N.N.W. of Verona.—Alfo, a town of Italy, in the department of the Mincio; 15 miles S.W. of Mantua.

MARIANDYNI, in Ancient Geography, a people of Asia, in Bithynia, or extending from Bithynia to Phaphagonia, on the banks of the Gulf of Sangarius. Herodotus (1. i. 28.) reckons them among the nations subdued by Croesus.

MARIANKA, in Geography, a town of Poland, in Volhynia; 44 miles N.N.W. of Rytomiers.

MARIANNA, the name given to a district of America, granted by the Plymouth council to Capt. John Maton in 1621. It extended from the river Naumkeag, now Salem, round Cape Ann to Merrimack river, and from the sea to the heads of these rivers, with the islands lying within three miles of the coast.

MARIANO, a town of Italy, in the department of the Olena; 12 miles N. of Milan.

MARIANOPOLI, or MARIUPOLE, a sea-port town of Russia, on the borders of the sea of Azof, between the rivers Myus and Calmius. This town, as well as Kerchion or Chechin, and Catharinopolis, together with the numerous villages, which have risen to some degree of importance in a country formerly inhabited only by lawless banditti, or traversed by roving hordes, are filled with Russians, with Tartar's reclaimed from their wandering life, and with numerous colonists, particularly Greeks and Armenians, who migrated from the adjacent provinces of the Turkish empire.

MARIANOU, a town of Poland, in the palatinate of Bracaw: 48 miles W. of Bracaw.

MARIAQUACO, a town of Brazil, on the river of the Amazons; 36 miles W. of Pauixis.

MARIAS ISLANDS, three islands in the North Pacific ocean, occupying a space of about 42 miles. The most northern, which is the largest of the group, is about 13 miles long in a S.E. by E. and N.W. by W. direction, the direction in which the islands lie from one another, and about 9 miles broad. It is highest towards the S., and gradually descends, terminating in a long low point at its N.W. extremity. Its shores are composed, particularly on the S.W. side, of steep white rocky cliffs, which kind of superficiality forms its principal component part. Notwithstanding a low kind of shrub, with which it is partially covered, it presents but a dreary and unproductive scene. Its S.E. extremity terminates凹, after a descent from the summit of the island, in a low projecting point, with rocks lying from it, as on the opposite extremity. On either side is a small bay, that on the E. side being bounded by a beach, composed alternately of rocks and land, and affording, by Capt. Vancouver's findings in its vicinity, good anchorages, and protected against the general prevailing winds. Between this island and the second of the group, called by Dampier "Prince George's island," is a passage about 6 miles wide, with findings of 20 to 30 fathoms, and sandy bottom. The S.W. side of this latter island is bounded by detached rocks, some of which depend from the centre of the island and terminate at the water side, in a fine sandy beach. This island abounds more with vegetable productions than the other, but it did not seem to afford any streams of fresh water. In size and direction Prince George's island is next to the former, being about 24 miles in circuit; and the third, or southernmost, is about nine miles in compass. The most valuable production of Prince George's island is lignum vitae, which it yields in great abundance, besides some plants of the orange and lemon kind, and other thorny plants, which reach nearly to the edge of the water. Of birds this
iland has great variety, such as hawks, green parrots with yellow heads, parakeets, pigeons, and doves, and small birds of beautiful plumage; but no quadrupeds were seen. On the shores great numbers of fish were observed, and among them some very bold and daring sharks. A few frakes and guanacos were seen, but no traces of human visitors were perceived; though on some shore drift wood was found, which appeared to have been wrought with European tools. Capt. Vancouver's anchoring place lay in N. lat. 23° 28'. E. long. 253° 54'.

MARIASTAIN, an old town of Aurlia; 14 miles S.S.W. of Steyr.

MARICA, in Botany, an old name for something of the Iris kind. Ambrotifus thinks it a corruption of Naronica, which was derived from the Naro, a Dalmatian river, about whose banks the best Iris or Orris roots were plentifully produced. The name is retained by Schreber for the Cipura of Aublet. Mr. Gawler, now Ker, who has referred to this same genus some additional species, separated from Iris, Morea, and Sisyrinchium, properly follows Schreber in the name; but enquires, in Curt. Mag. p. 646, why Cipura was rejected. We preume that as Aublet has given no explanation of its meaning, and nothing is to be gathered from any part of his description, Schreber judged it at any rate, a hybrid, if not a barbarous, name, and he was too critical a scholar, as well as too faithful a Linnearian, to admit such in general. He would justify his own barbarous and uncoth. B Rumely, for what Jussieu has properly called Aialus, we will not venture to guess. See Bambusa, Nastus and 

Gen. Ch. Cal. Spalthas of one or two valves, single-flowered, cinoled in a common involution of two valves. Cor. superior, regular, in fix deep spreading segments, united into a tube; the three inner alternate ones smaller. 

Stam. Filaments three, distinct, inserted into the mouth of the tube, very short; anthers oblong, erect, longer than the filaments. 

Pfd. Germen inferior, oblong, obtusely angular; style simple, triangular, its angles opposite to the stamens; stigmas three, longer than the style, variously shaped, more or less conicering a triangular figure. Peric. 

Capsule oblong, slightly triangular, coroseous, of three cells and three valves, as if pecked at the top. Seeds numerous in two rows, roundish, somewhat angular. 

Eff. Ch. Corolla superior, in six deep segments; the three inner ones smaller. Stamens opposite to the three angles of the style.

Obif. Mr. Ker now includes in this genus some species with united filaments, which we agree with our late friend Mr. Dryander (in Atit. Hort. Kew.) in referring to Sisyrinchium; a measure justified, if we mistake not, by the habit of their flowers.

1. M. Northiana. Broad-lemmed Marica. Ker in Curt. Mag. t. 654. (Morea Northiana; Andr. Repof. t. 255. M. vaginata; Redout. Liliac. t. 56.)—Stalk (word-shaped, winged—Native of the Brazilis. It was first known here in the collection of the Hon. Mrs. North, at Farnham castle, who procured it in 1789. The plant is now frequent in hot-houses, flowering in spring and summer, being much admired for the beauty of its short-lived petals, whose bases are all elegantly mottled with yellow and deep brownish orange, while the limb of the larger ones is white, of the smaller blue. The roos is tuberous, with many fibres, and perennial. 

Leaves radical, sword-shaped, dark green, coarsely ribbed, two or three feet high. Flower-stalk much resembling the leaves, about as tall, though rather narrower, oblique, bearing several succicent fragrant flowers, about two inches in diameter, from a lateral sheath near the top, sometimes viviparous.

2. M. martineinfis. Yellow Martinico Marica. (Iris martineinfis; Linn. Sp. Pl. 58. Jaqc. Amer. t. 7. Willd. Sp. Pl. v. 1. 238. Curt. Mag. t. 416. Redout. Liliac. t. 172.)—Stalk round. Leaves linear, flat—Jaccquin found this species in moist meadows among the hills of Martinico, flowering in November and December. Mr. Alexander Anderson sent it from St. Lucia to Kew in 1782. It blooms in the flowe with us about May or June, and is perennial; but bearing only small flowers, of an uniform yellow, is not particularly esteemed. The late Mr. Curtis has justly remarked its ill agreement with the character of an Iris, and its generic affinity to the foregoing. The leaves, however, are narrower, flat, and fingle-ribbed. 

Stalk slender, round, 12 or 18 inches long, one or two concave dillent braenices. Flowers few, succicent, very transient, modest, about an inch wide. It ripens seeds abundantly, which M. Northiana does not.

3. M. paludofa. Dwarf Marica. Willd. Sp. Pl. v. 1. 246. Curt. Mag. t. 646. (Cipura paludofa; Aubl. Guian. 38. t. 13.)—Leaves lanceolate, tapering at each end, plated. Stalk round. Inner segments of the corolla erect, concave, half the length of the outer. Native of moist meadows, called sannallas, at the foot of the mountains in Guiana. Mr. A. Anderson sent it from St. Lucia to Kew in 1792. The plant is perennial, flowering in the flowe from June to August. Its leaves are about a foot high, deep green, lanceolate, tapering much at each end. Strongly plaited on each side the middle. 

Flower-stalk radical, very short, simple, bearing a small tuft of succicent, short-lived, white flowers, accompanied by a few sheathing scales, and surmounted by a long leafy basite equal to the leaves. The three inner segments of the corolla are erect and convoluted, but half the length of the rear, concave, a little recurved at their summits, and tipped with green, so that the whole flower recalls the idea of a Snowdrop.

4. M. plecata. Small-flowered Marica. Ker in Curt. Mag. t. 655. (Morea plecata; Willd. Sp. Pl. v. 1. 243. Swartz. Ind. Occ. 82. M. palmsifolia; Jaqc. Ic. Rar. t. 227. Sisyrinchium palmsifolium; Cavan. Diff. 348. t. 19. f. 1. Bermudiana palmis folio, radice bulbosa; Plum. Ic. 35. t. 46. f. 2.)—Leaves elliptic-lanceolate, with numerous ribs and plaited. Stalk round. Segments of the corolla all nearly equal in length.—Native of Cayenne and the West Indies. Miller is said, in Hort. Kew. ed. t. 3. v. 3. 309; to have cultivated it at Chelsea, in 1759. Linnæus had specimens, which he confounded with his true Sisyrinchium palmsifolium, which has a winged stalk, and a dense corymbose tuft of many flowers. We have it not in any of our gardens. M. plecata is a tender flowe plant, with much broader and more elliptical leaves, whose ribs and plaits are much more numerous than M. paludofa. The 

stalk, moreover, is almost as tall as the leaves, and the bractea proportionately smaller. The flowers are small and white, distinguished by all their segments being nearly of equal length, and obvate, though the three innermost are rather the narrowest. They have little beauty to attract general admiration or care. 

Mr. Ker comprehends under this genus of Marica, besides the above, the Sisyrinchium palmsifolium, Linn. Mant. 122.

Willd.
MARIENGAUL, a town of Saxony, in the circle of Erzgebirge, which has in its vicinity mines of silver, coal, iron, vitriol and sulphur. It has a manufacture of fine lace, and a medicinal bath; 34 miles S.W. of Dresden. N. lat. 50° 36'. E. long. 13° 0'.

MARIENBURG, a town of Prussia, in the government of Pommern; 28 miles S. of Vering.—Alto, a town of Transylvania, called also Foldmar; six miles N. of Cronstadt. N. lat. 46° 2'. E. long. 45° 14'. — Alto, a town of Prussia, denominated also Mallorg, which is the capital of a prefecture situated on the Vistula. It was formerly the chief place belonging to the Teutonic knights. It was once again taken by the Swedes; 24 miles S.E. of Dantzic, N. lat. 54° 3'. E. long. 18° 55'. — Alto, a town of the bishopric of Hildesheim; five miles S.E. of Hildesheim.

MARIENFELD, a town of Germany, in the bishopric of Münster; 11 miles E. of Warendorf.

MARIENGAL, a town and lake of Russia, in the government of Polotsk; 40 miles N.E. of Rezina.

MARIENHAVEN, a town of East Friesland; nine miles N. of Emden.

MARIENSTERN, a town of Upper Lusatia; nine miles W. of Budinien.

MARIENWALDE, a town of Brandenburg, in the New Mark; six miles N.W. of Woldenberg.

MARIENWERDER, a town of Prussia, in the province of Oberland, situated on the small river called the Leibe, not far from the Vistula. This town, which was first built in the year 1223 on a weir, or small island, called "Quidzin," but soon after rebuilt in its present situation, was occupied by some grand masters of the Teutonic order. The cathedral, erected in the 13th century, is the largest church in the kingdom of Prussia, and seems by its strong brent-work to have been intended for a fortress. The palace is a spacious edifice, constructed in the Gothic style, and is surrounded by a pleasant country of varied surface. The inhabitants of this town carry on a considerable trade with their neighbours. It has been often damaged by inundations, fire, and war. The famous league formed against the knights of the Teutonic order was concluded here in 1440; 35 miles S. of Dantzic. N. lat. 53° 43'. E. long. 18° 42'.

MARIENS, a town of Hindoostan, in Malwa; 12 miles E. of Scorgne.

MARIEBOE, a town of Denmark, in the island of Lolland, situated near a lake abounding in fish; 12 miles E. of Naeow. N. lat. 54° 51'. E. long. 11° 32'.

MARIEFRED, a town of Sweden, in the province of Sudermanland, on a bay of the Mazal lake; 25 miles W. of Stockholm.

MARIE-GALANTE, an island in the West Indies, discovered by Columbus in the year 1493, of a circular figure and about 42 miles in circumference. It was first settled by the French in 1647; and has since been taken by the Dutch and by the English, but restored to the French by the English in 1763. This island affords a considerable quantity of tobacco; and contains many grottos in which are found large crabs, and also several rivers as well as ponds of fresh water. It is flat on the western shore, and the soil is fit for cultivation. At the time of its last reduction by the English the annual manufacture of sugar amounted to 1000 hogsheads. N. lat. 16°. W. long. 61° 6'.

MARIENBERG, a town of Saxony, in the circle of Erzgebirge, which has in its vicinity mines of silver, coal, iron, vitriol and sulphur. It has a manufacture of fine lace, and a medicinal bath; 34 miles S.W. of Dresden. N. lat. 50° 36'. E. long. 13° 0'.

MARIENZELL, a town with a convent in the archdiocese of Austria; the convent has a celebrated image of the Virgin; six miles W.S.W. of Baden.

MARIES, St., Lt. a town of France, in the department of the Mouths of the Rhone, on an island formed by the divided stream of the Rhone, near the sea; 16 miles S. of Arles. N. lat. 43° 27'. E. long. 5° 31'.

MARIES, Three, three desert islands in the Pacific ocean, near the west coast of Mexico; the largest of which is about 21 miles in circumference. They abound in bares, guannes, pigeons, &c., and the coasts with turtles and fish. N. lat. 21° 30'.

MARIESTADT, a town of Sweden, in Wett Gotha-land, built by Charles IX. on the rivulet Tidia, where it falls into the Wemmer Lake. The houses are mohly built of wood, and painted of a red colour; 80 miles N.E. of Gothenburg. N. lat. 58° 27'. E. long. 13° 38'.

MARIETTA, a town of America, in the state of Ohio and county of Washington, situated at the confluence of the Muskingum and the Ohio. It is laid out, on a delightful plain formed by the banks of the two rivers, into 1000 house-lots, with 92 feet in front by 180 feet in the rear, with suitable open squares, referred for use, ornament and pleasure. Its streets intersect one another at right angles. It derives its name from Marie Antoniette, the late queen of France, and was settled in April 1788, and incorporated in 1800. In 1803 it contained 550 inhabitants and 41 dwelling-houses, besides eight merchants' stores, 19 buildings occupied by public officers and mechanics, three rope walks, a saw, a court-house, and an academy used as a place of worship. This town is rapidly increasing in population, wealth, and elegance. Its situation is delightful; it is environed by high hills, some of which are covered with trees, and others afford excellent stone for building. The vales and lower grounds are extensive and very fertile. Within the limits of the town are nine ancient forts, on the bank of the Muskingum, which have furnished the curiosities and subjects of diligent investigation. N. lat. 39° 25'. W. long. 81° 30'.

MARIGNANO, a town of Italy, in the department of the Olena; 11 miles S.E. of Milan.

MARIGNIA, in Botany, a name given by Commerson to a sort of baldur roen tree, of the Mauritius, which Jullien reduces to Bursera, though it has five petals and ten flaments, with a coriaceous, not pulpy, fruit. See Bur- sera.

MARIGNY, in Geography, a town of France, in the department of the Channel, and chief place of a canton, in the district of St. Lô; six miles W. of St. Lô. The place contains 1260, and the canton 7018 inhabitants, on a territory of 102½ kilometres, in 12 communes.—Alfo, a town of France, in the department of the Indre and Loire; 15 miles S.W. of Chiron.—Alfo, a town of France, in the department of Mont Blanc; 20 miles S.S.E. of Geneva.

MARIGONON, a town situated on the W. coast of the island of Lucon. N. lat. 13° 8'. E. long. 123° 20'.

MARIOT, a town of the island of Martinico; nine miles N.W. of Cul de Sac de la Trinite.

MARIJABAG, a town on the E. coast of Mindanao; N. lat. 8° 48'. E. long. 126° 12'.

MARIKINA, in Zoology, the name given by Buffon to the Simia Rostalia; which bee.

MARILA, in Botany, Swartz. Prod. 84. Schreb. 829. Mart. Mill. Diæt. v. 3. This genus, consisting of a single species only, M. racemosa, a Weit Indian shrub, was adopted by Swartz from the manuscripts of Solander. The name seems taken from μαρια, live embers or sparks; but we cannot tell whether it alludes to the "elegantly transparent" dots and lines in the foliage, or to the sparkling yellow pelicle and fringe which is said to accompany the seeds. We are most inclined to suppose the former; but the matter is of little importance, as this genus is reduced by Dr. Swartz himself, in his Fl. Ind. Occid. 165, to the Bonnetia of Schreber, which is Aublet's Mahura palustris. We think it not advisable to change the specific name of this lafo, to the far left eligible one of meridionalis, though the other species is likewise found in wet situations.

BONNETIA being omitted in its proper place, we subjoin its characters. This genus was fo called by Schreber, in honour of the celebrated Charles Bonnet of Geneva, who died in 1793, aged 73, and who has distinguished himself by various physiological and speculative works in natural history. His enquiries concerning the use of leaves entitle him to botanical commemoration, though he was not adept in the practical or systematic departments of the science. Schreb. 365. Wild. Sp. Pl. v. 2. 1215. Mart. Mill. Diæt. v. 1. Swartz Ind. Occ. 963. (Marila, as above. Mahura, fee that article.) Class and order, Polyandra Monogynia. Nat. Ord. Columnifera, Swartz; uncertain, Jew.

Gen. Ch. Cal. Persiant inferior, of five oblong, concave, rather unequal leaves. Cor. Petals five, ovate, obtuse, concave, longer than the calyx, two of them rather larger and more spreading than the rest. Stam. Filaments very numerous, inserted into the receptacle, shorter than the corolla, thread-shaped, a little dilated upwards; anthers oblong. Pfl. Germen superior, oblong; style thicker, incurved, the length of the germen; stigma obtuse, somewhat capital. Peric. Capsule oblong, columnar, of three or four cells, and three or four acute valves, whose indented margins are inserted into the angles of the central column. Seeds very numerous, imbricated, minute, oblong, each enveloped in a fringed coloured membranous tunic. Eif. Ch. Calyx of five leaves. Petals five. Capsule superior, of three or four valves, and as many cells. Seeds numerous, imbricated, each in a membranous coloured tunic.

2. B. racemosa. Swartz Ind. Occ. 965. (Marila race- moso; Prod. 84).—Leaves opposite. Clusters axillary.—Native of the banks of rivers in the West Indies. A tall shrub, with many stems. Leaves eight or ten inches long, lanceolate, acute, finely veined, and full of pellicent dots and lines, which are beautifully conficuous when seen against the light. Poofiheels half an inch long. Stipulae none. Flowers greenish-white, in simple axillary clusters, half as long as the leaves. Petals very short-lived. Cap- sula an inch long.

MARILHOSIA, in Geography, a town of Portugal, in the province of Alentejo; 78 miles E.N.E. of Mourao.

MARIM, a river of Brazil, which discharges itself into the Atlantic, S. lat. 2° 25'. W. long. 44° 46'.

MARIKATA, a town of Arabia, in the province of Oman; 90 miles S.W. of Mafkat.

MARIN FABRICIUS, in Biography, a French compofer, who fet the songs of Ronard, Bal, Janier, and Despertes, in
in four parts, which were printed and published at Paris in 1578, by Adrian le Roy.

MARIN, Monseur, ci-devant comte, a great dilettante musician, and a performer on the Pedal-harp, in the most singular and masterly style, perhaps, at which any other performer on that instrument ever arrived. His modulation, passiges, and strokes of genius in the music which he plays, whether written or extempore, seem the effusions of a bard inspired;

"Who with a master's hand and prophet's fire,
Strikes the majestic concords of his lyre."

The whole of his performance is unlike any other music but the voluntaries of a great organist. It can only therefore be truly enjoyed by masters and deep musicians. It may surpize, but cannot delight the public. It is not so amiable, or indeed so fit, for a female to attempt as the exquisite performance of madame Krumpholtz. But it shews the extent of the instrument's powers, as well as the performer's abilities, greatly to surpases whatever was heard before, or thought possible for genius and diligence to attain.

M. Marin, we believe, was the first who accompanied his eleves on the same instrument, after the manner of a duet on one piano-forte, by standing behind them and picking out notes in both parts of the claveir as are unoccupied by the principal performer. This expedient was not put in practice for want of abilities to accompany them on any other instrument; as, if he was not superior to all other performers on the harp, he would be called an exquisite player on the violin, upon which instrument, though many may exceed him in execution, there are very few that are equal to him in expression. Almost every year produces a musical phenomenon of some kind or other; and M. Marin was certainly the phenomenon of his time among harpists wherever he went.

MARIN, in Geography, a small island of Russia, in the Baltic; 72 miles N. of Kemnou.—Also, a town of the island of Cyprus, on the S. coast; four miles S. of Lernica.

MARINDUGERA, or Marinique, one of the Philippine islands, near the S. coast of Luzon, about 60 miles in circumference; 30 miles N.E. of Mindoro. N. lat. 13° 29'; E. long. 115° 51'.

MARINE CHAOS, is a contrivance of Mr. Irwin, for facilitating the necessary observations, in order to determine the longitude at sea. It is said that Mr. Irwin, on a trial of this machine, found the longitude within twenty-three miles, or about one-third of a degree. See Longitude.

MARINE CLOTHING ROOM, in a Ship, an apartment built in the after platform on the larboard side, to receive the clothing used by the marines.

MARINE INSURANCE. See Marine Insurances.

MARINE LAW. See Law.

MARINE REMAINS, a term used by many authors to express the shells of sea-fishes, and parts of crullaceous a and other sea-animals, found in digging at great depths in the earth, or on the tops of high mountains. Their being lodged in these places, is an evident and unquestionable proof of the sea's having once been there, since it must have covered those places where it has left its productions. It has been a favourite system with many, and particularly with the late Dr. Woodward, that all these marine bodies were brought to the places where they now lie, by the waters of the universal deluge; which, as we are informed by holy writers, covered the whole surface of the globe, and even the highest mountains. (See Deluge.) But though this is a very ready expedient to account for many of the natural phenomena, yet there are evident proofs that it cannot have been the cause of all that is attributed to it; and there must necessarily have been some other cause of many of these remains having been placed where we now find them. Neither does the opinion of some particular authors, that partial inundations of different places have left these marine bodies behind them at the reeds of the waters, seem sufficient to account for the multitude of these remains, many of which we find thrown upon places inaccessible to such floods.

Moro, de Cruillaceis in Montb. deprehens.

Signior Moro has attempted to account for these phenomena on a new plan of reasoning. He observes that it is the best basis of argument to begin from facts; and that if we can certainly find how some part of these animal remains come to be deposited at such great distances from their natural residence, we may very rationally conclude, that by the same means, be they what they will, all the rest were also brought thither. He adds, that the earth, once the bottom of the sea, or the level surface of a plain, may be, and frequently has been, in the memory of man, raised up into a mountain by subterraneous fires, earthquakes, and volcanoes. He mentions the famous finding of the new island raised out of the bottom of the sea near St. Michael, in the year 1737, which became of a circumference not less than six miles, and of the new mountain raised near Ponzelli in 1538.

These, and many other like facts, prove that the origin of mountains and islands may have been such, and that the matter they consist of may have been the same with that which was once the bottom of the sea; and that the marine bodies found in these mountains, were such as were living, or remaining of living fishes at the time when the island or mountain were raised above the surface of the water which before covered it.

This is no new opinion; but this author has fet it in a new and much stronger light than ever it had appeared in before, by the instances and examples he has brought in proof of it. Some have been fond of believing that the bodies we call marine remains, were never indeed any parts of living animals, but that they are merely latus nature formed in the places where they are found; but Fabius Columba proved this to be an error, shewing that the shark's teeth, or glio-petrae of the island of Malta, when calcined by a strong fire, yielded a film the same with those from animal bodies, and by no means of the same nature with those produced from calcined bones.

That changes of parts of the bottom of the sea into dry land, have often been made, is proved not only from the late known instances, but from the testimonies of Strabo, Pliny, and other writers of credit; and nothing is more obvious to reason, than that in the sudden rife of such parts of the bottom of the sea, all its contents, all the shells, and other hard parts of fishes lying there, would be carried up with it.

As some mountains and some islands must have certainly been produced in this manner, it is not impossible but that all of them may have been so; and there is no more than this required to account clearly and evidently for all the vast profusion of marine bodies at land as we find them, without having recourse to the improbable means of the universal deluge, which, for many plain reasons, cannot have been the cause; or to the effects of particular inundations, which must have been wholly incapable of lodging many of them there. The lodgment of shells in the fields, strata of mountains, is better accounted for by this system of Signior Moro than any other; and if it be asked why some mountains afford them in great plenty,
plenty, and others not at all, it will be not difficult to answer, by oberving, that among the mountains of the more known parts of the world, some confift of mere solid rock, and others of various slates of earthy and other matter; that the flail of these may be suppos'd primary or natural mountains, and the other secondary or accidental ones; and that these marine remains are always wanting in the former, and usually are found in the latter, which is a fact greatly favourable to this system.

There are many difficulties attending the accounts of all authors of the formation of the earth, and the lodging of these bodies in it; nor is this last system without difficulty. The caues here assigned a to the origin of mountains and islands, doubts, have been so in regard to some, but scarcely to all; and the bodies here treated of are so numerous, in some particular places, that fearely any account can solve the difficulty of their being collected together in so strange a manner. See Adventitious Fossils, and Theory of the Earth.

MARINE SALT. See SALT.

MARINE SURVEYOR. See the name of a machine contrived by Mr. H. de Saumarez, for measuring the way of a ship in the sea. This machine is in the form of the letter Y, and is made of iron or any other metal. At each end of the lines which constitute the angle or upper part of that letter, are two pallets, not much unlike the figure of the log; one of which falls in the fame proportion as the other rises. The falling or pendent pallet meeting a reflance from the water, as the ship moves, has, by that means, a circular motion under water, which is faster or slower, according as the vessel moves. This motion is communicated to a dial within the ship, by means of a rope fastened to the tail of the Y, and carried to the cîl. The motion being thus communicated to the dial, which is a bell in it, it strikes exactly the number of geometrical places, miles, or leagues, which the ship has run. Thus the ship's distance is attained; and the forces of tides and currents may also be discovered by this instrument; which, however, has been very little used. See a large account of it in the Abr. Phil. Trans. vol. vi. p. 444, &c.

MARINES, in Geography, a town of France, in the department of the Seine and Oise, and chief place of a canton, in the district of Pontoise; seven miles N.W. of Pontoise. The place contains 12,32, and the canton 13,814 inhabitants, on a territory of 295,000, in 39 commun.

MARINES, or Marine Forces, a body of troops employed in the sea-service, under the direction of the lords of the admiralty. Thofe marines compose certain regiments trained to the different modes of sea-fighting, and made useful also in some of those maneuvers of a ship, where a great number of hands is required. The precise time when this institution first took place, is, like many other parts of military history, involved in obscurity. The oldest corps of this kind, which Grofe has been able to discover, was the third regiment of infantry in the lift of the army for the year 1682. It then contained 12 companies, without grenadiers. The men were clothed in yellow coats, lined with red; their colours were red cloths, with rays of the sun shining from each of its angles. This was not the present third regiment, now distinguished by the name of the old buffs, which then stood the fourth on the lift. In the reign of king William III. there were several marine regiments. In the beginning of the reign of queen Anne fix regiments of marines were raised; these regiments have been very useful, more especially upon fitting out squadrons of ships for an immediate expedition; for as they are constantly quartered, when not at sea, as near the principal ports as possible, viz. Plymouth, Portsmouth, and Chatham, they were very easily put on board such ships as had most occasion for them; for they were under the immediate direction of the admiralty; and rules and instructions for their better government were settled by his majesty in council, July 1, 1702. In the war preceding the peace of 1748 there were 10 regiments of marines, which were disbanded about the year 1749; they were under the direction of the lords of the admiralty, and when abore were quartered in the neighbourhood of the docks and sea-ports. In 1755 a number of companies of marines were raised, under the direction of the secretary of war; they were afterwards formed into three divisions, and stationed at the towns of Plymouth, Portsmouth, and Chatham; and at each of these places have now convenient barracks. These companies, A. D. 1741, being 130 in number, were, from the time of their establishment, put under the immediate direction of the lords of the admiralty. At the peace many of them were reduced; and in 1770 there remained only 70 companies; but in the year 1782, they were increased to 150. The marines are clothed and armed in the same manner as his majesty's other corps of infantry. Their uniform is scarlet, faced with white, white linings, wafcoats and breeches; they also wore caps, like those of the fuller regiments. Their pay is the same with that of the marching regiments of foot. There are annual acts for the better governing of his majesty's royal marine forces whilst on shore; which are much the same with those that respect the land-forces, only with some variations on account of their being subject to the jurisdiction of the admiralty. Thus, the lord high admiral, or three commissioners of the admiralty, are to form articles of war, and grant commissions for holding courts-martials. Notice of a defeter being apprehended is to be sent to the secretary of the admiralty. The billeting, and carriages, are to be in pursuance of orders from the admiralty.

MARINER, the same with seaman or sailor.

The mariners of a ship are accountable to the master; the master to the owners; and the owners to the merchant, for all damages by negligence, or otherwise. If a mariner be hired, and he defects the service before the voyage is ended, by the law marine, and by common law, he shall lose his wages; and if a ship is lost by tempest, &c. the mariners lose their wages, as well as the owners their freight; and thus is to oblige them to use their utmost endeavours to preserve the ship.

Perfounding mariners, and receiving their wages, and forg'd letters of attorney, &c. or falsely taking out letters of administration for the receipt of seaman's wages, is felony without benefit of clergy. See Forger, and Greenwich Hospital.

Concerning seamen in the merchant service, it is enacted by 2 Geo. II. c. 56, that no baller of a ship shall proceed on a voyage, without agreeing in writing with such mariner (apparrel excepted), to be signed by such master, for wages; and by 3 Geo. III. c. 39 the same is extended to seamen employed in the coasting trade, on pain of 5l. for each mariner, on conviction before one justice, by the oath of one witness, to be levied by distress. (See 56 Geo. III. c. 73.) If the mariner defect after he hath signed the agreement, he shall forfeit the wages due to him at the time of defecting; and on application from the master, owner, &c. commander of the ship, such justice may cause him to be apprehended; and if he shall refuse to proceed on the voyage, without sufficient reason to the satisfaction of the justice, the said justice shall commit him to the house of correction, for not exceeding 20 nor less than 14 days. (2 Geo. II. c. 36.)
MAR

For forfeitures to Greenwich Hospital, and privilege of admission, see that article. The matter of the ship shall pay the feamen’s wages, if demanded, in 30 days after the ship is entered in the colthing-book, or by the term of discharge, which shall fail happen, deducting out of such wages the aforesaid forfeiture; on pain of 20l. to such seaman, to be recovered in like manner as his wages. (2 Geo. ii. c. 36; 31 Geo. iii. c. 19, 45 Geo. iii. c. 31.) By 44 Geo. iii. c. 13, it is enacted that petty officers or seamen, arrested by sheriffs or other officers, shall be kept in custody after being entitled to a discharge from any process; and he conveyed to the commander-in-chief, or some commissioned officer, to serve on board his majesty’s fleet. And the sheriff, gaoler, or other officer, shall be paid by the treasurer of the navy, upon producing a certificate for conducting such seaman at the rate of 25. per mile. The transfer of such seaman shall be certified upon the back of the process. If any sheriff, &c. shall neglect so to convey such seaman, he shall be liable to an action of trespass at the suit of such petty officer, &c. or seaman. If any sheriff, &c. shall suffer any such seaman, &c. to escape, he shall be liable to the penalty of 100l. recoverable in any of the courts of record at Westminster, one moiety to the king, and the other to the party feizing. Any action by virtue of this act, shall be brought within three months after the suit; and if the plaintiff fail in such action, the defendant shall have treble costs. By 37 Geo. iii. c. 73, to prevent the defertion of seamen from merchant ships, every seaman who shall defect during the voyage, either out or home, from any British merchant ship, trading to or from his majesty’s colonies in the West Indies, shall, over and above all punishment, penalties, and forfeitures, to which he is now subject, forfeit all the wages he may be entitled to from the master or owner of the ship, on board of which he shall enter immediately after such defection. And every master or commander of any ship, who shall engage any such person, knowing him to have defected from any other ship, shall forfeit 100l. In the act above cited there are several other provisions and regulations relating to seamen in the merchant service. By 37 Geo. iii. c. 28. s. 25, petty officers, seamen, boatwain, gunners, &c. may all at a certain part of their monthly pay for the maintenance of wives and children, or mothers. And by 37 Geo. iii. c. 53, an increase of wages is made to such persons, and they are empowered to allow a part of such pay, to be calculated as nearly as may be equal one half of it. All petty officers, seamen, mariners, &c. who may be wounded in action with the enemy, shall receive their full wages until their wounds are healed; or until (being declared incurable) they shall receive a pension from the chief at Chatham, or be admitted into Greenwich hospital. (See also 46 Geo. iii. c. 127.) All allotments of wages are to be paid without deductions, on penalty of 20l.

Mariners wandering up and down, and who shall not settle themselves to work, or have not a testimonial under the hand of a justice, shewing where they lived, and whither to go, &c. or having such testimonial, if they exceed the time limited more than fourteen days, not being sick in their papple home, &c. are guilty of felony by 39 Eliz. cap. 17. This languishing law, though in practice deservedly antiquated, still remains a disgrace to our statute-book; yet attended with this mitigation, that the offender may be delivered, if any honest freeholder, or other person of sufficiency, in the town wherein he abides, is suffered in the fame for one year; unless licensed to depart by his employer, who, in such case, shall forfeit 10l. But if they cannot work, for want thereof, the two next justices, upon their complaint, shall take order that they may be provided of work; or otherwise may tax the whole hundred, till relief shall be had. (Stat. ubd.) And every parish may be charged for relieving mariners, as for maimed soldiers; and they shall be relieved by the treasurer of the county, &c. (43 Eliz. cap. 3.) The probate of the will, or letters of administration, of any common felder, or farmer, who shall be slain or die in the service, shall be exempted from the flamp duties; a certificate being produced from the captain under whom he served, at the time of his death, and oath made of the truth thereof, before the proper judge or officer, for which oath no fee shall be taken. 5 Will. c. 21.

In order to facilitate the returns of mariners and sailors, as well as soldiers, when discharged, to their respective places of legal settlement in England, and to prevent their being deemed rogues and vagabonds, and punished as vagrants, it is provided by the 43 Geo. iii. c. 61, that, carrying their discharge, within three days from its date, to the mayor or chief magistrate of the city, town, port, or corporate place nearest to, or within 15 miles from, the place of their discharge, they shall receive from such magistrate a certificate stating the place to which the persons to be discharged are defirous of going, being their home or legal place of settlement, together with the time to be fixed, not exceeding ten days for every 100 miles, and 20 in proportion, except for a reafore said cane to be taken. Such certificate and such person producing such discharge and such certificate, when lawfully demanded, and being in due route accordingly as to time and road, shall not, by reason of alighting relief, be deemed to be a rogue or vagabond; provided such discharge bear the true date, both as to the time when, and place where it was given; and shall express the sum or sums, if any, which were paid to such folder or sailor at such time and place. New certificates are to be affixed to the former in case of delay from accident or sickness. And all certificates or palfes granted as herebefore from the office of admiralty, or war-office, to discharged sailors, soldiers, or marines, or to the families of such, feering abroad, or lately deceased, to carry them to their respective homes, shall have the same effect and force to all intents and purposes whatsoever as the certificates herein permitted to be given by the magistrate as aforesaid; and the terms of the same may be extended, &c.

By the 22 Geo. ii. c. 44, all officers, mariners, and soldiers, who have been employed in his majesty’s service, and not deferted, may lay up and exercise such arms allotted to his service fit for in any town or place within Great Britain or Ireland, except Oxford and Cambridge, and if they shall be fixed thereupon they shall have double costs. By 31 Geo. ii. cap. 10, no seaman aboard his majesty’s ship can be arrested for any debt, unless the same be sworn to amount to at least 20l.

The method of ordering seamen in the royal fleet, and keeping up a regular discipline there, is directed by certain express rules, articles, and orders, first enacted by the authority of parliament, soon after the Restoration (15 Car. ii. fl. t. cap. 9.) but since new-modelled and altered, after the peace of Aix-la-Chapelle, (22 Geo. ii. cap. 23, amended by 19 Geo. iii. c. 17,) to remedy some defects, which were of fatal consequence in conducting the preceding war. In these articles of the navy, almost every possible offence is set down, and the punishment thereof annexed: in which respect the seamen have much the advantage over their brethren in the land-service; whose articles of war are not enacted by parliament, but framed from time to time to the pleasure of the crown. For these articles, see Navy.

Mariners’-Compass. See Compass.
MARING, in Geography, a town of Prussia, in the province of Ermland; 10 miles W.S.W. of Allenheim.

MARINGANDO, a town on the W. coast of Madagascar. S. lat. 13° 50'; E. long. 42° 30'.

MARGINES, a town of France, in the department of the Pay-de-Dôme, and chief place of a canton, in the district of Thiers; 14 miles N.W. of Clermont. The place contains 3030, and the canton 7560 inhabitants, on a territory of 82½ kilometres, in four communes.

MARINHA, Sr., a town of Portugal, in the province of Beira; 23 miles S.E. of Oporto.

MARINI, GIAMBATTISTA, in Biography, known generally by the name of Il Cavaliere Marini, an Italian poet, was born at Naples in 1560. His father was a counsellor of eminence, and was deprived of bringing up the young man to his own profession, but was unable to overcome the repugnance to legal studies, which an early attachment to poetry produced in him, as it has done in so many others. His father would not be appeased at the disappointment which he felt in the son's refusal to acquiesce in his wish, and expelled him from his house. For a short time he obtained an asylum with a parson of rank, till a juvenile misbehaviour caused him to be committed to prison. On recovering his liberty, he went to Rome, and was introduced to cardinal Peter Aldobrandini, with whom he lived some years, and whom he accompanied to Ravenna and Turin. At the last city he rendered himself conspicuous by his talents and learned warfare with several literary antagonists; of these, the one most noted was Gaspard Murtola, a Genoese, who, jealous of Marini's reputation, and of his having been honoured with knighthood, attacked him in sonnets and lampoons. Marini was not behind hand in taking his revenge, and was so fierce in his "Muroleide," that the enraged poet attempted to affliate him in the streets of Turin; he missed his rival, and wounded a favourite of the duke, who fled by his side. For this act Murtola would have been hanged, had not Marini interceded with the duke for his life. After this, Marini's enemies gained the advantage over him, and obtained an order for his imprisonment. Upon his liberation, he went to France in 1617, whether he had been invited by queen Margaret. Before he arrived, his patroness was dead, but he met with a kind friend in queen Mary of Medicis, who settled on him a liberal pension. In France, he published his most famous poem, the "Adone," first printed in 1623. He returned to Rome, and was elected president of the academy Degli Umoristi. He afterwards went to Naples, where he was favourably received by the viceroy, duke of Alva. He died in 1625, at the age of fifty-six. Defides his "Adone," of which there were many editions, he published, among many other things, "La Strage degli Innocenti;" "La Sampognas;" and a collection of "Letters." He had a lively imagination, and very fertile invention; but is not celebrated for a good style; and many of his pieces contain licentious passages, which, however, when he was near his end, he begged might be expunged in all future editions; but they were too much in the taste of the age for such a facsimile. Moreri.

MARÍN, in Geography, a town of Spain, in New Castile; 4 miles N.W. of Albacén.

MARÍNO, Sr., a small republic of Italy, near the coast of the Adriatic sea, between Romagna and Urbino, in N. lat. 43° 55'; the territory of which is confined to a mountain, with a diminutive tract at the foot of it. The number of inhabitants is estimated at between five and six thousand; and it has been their happy lot to enjoy freedom and tranquility for more than thirteen centuries with little interrupion. Surrounded by the dominions of the pope, they have claimed his protection. The founder of this inconsiderable state was St. Marino, a Dalmatian by birth, and a monk by trade. Having finished some repairs of Rimini, in the ninth century, he retired to this sequestered mountain, where he led the life of a hermit, and subjected himself to all the austeritys of religion. The princes of the country, it is said, observing his extraordinary sanctity, made him a prefect of the mountain; and a number of inhabitants resorting hither, he established the republic that has ever since been distinguished by his name. Their whole history is comprised in two purchases made of a neighbouring prince, one the castle of Pennueta in 1160, and another, called Cafala, in 1170, and in the assistance afforded to the pope, Pius II., about 290 years after against Malatetta, lord of Rimini. In return for this service he transferred to them four small castles, together with the village of Piagge. This was the epocha of its highest grandeur, but now it is reduced to its primary limits. In 1739, the miserable ambition of cardinal Alberoni, disappointed in considerable projects and embroiling larger states, was directed against this republic, and he subjected it to the fee of Rome; but on complaints of its council, the pope restored it to its former freedom and privileges. The government of this state consists of a council of 40 half-nobles and half commoners. On very important occasions a senate, or great council, is convened, to which every family has the privilege of deputing a representative. The principal officers are two captains, who are changed every half year; a commissary, who is a foreigner, and who tries civil and criminal causes; a doctor of laws, whose office is triennial; and a physician, who must be a foreigner, and who is chosen for three years to attend the sick, and to inspect the shops of apothecaries. In this republic are three castles, three convents, and five churches.

MARINO, Sr., the capital of the above described republic, which is an indifferently built town or rather a village, situated on a rugged hill of difficult ascent, formerly called "Mons Sacri," and well fortified, with only one avenue to it; 10 miles S.W. of Rimini, and as far from the sea cost, N. lat. 42° 50'; E. long. 12° 24'.—Alfo, a town of Naples in Bafilea; 9 miles S. of Turin.

MARINONI, JOHN JAMES, in Biography, a celebrated mathematician and astronomer, was born at Udina, in the Friuli, in 1676. He made a rapid progress in his education, outstript his contemporaries, and showed a decided turn for mathematical studies. In 1696, he repaired to the university of Vienna, and obtained the degree of doctor in philosophy. He was soon after this appointed by the emperor Leopold mathematician to the court; in which capacity he fortified the city so as completely to prevent the incursions of the rebels, and to put a stop likewise to the practice of smuggling, which at that time prevailed. After the death of the emperor, he was taken under the protection of his successor; and by his orders, in 1706, made a survey of the capital, and its environs, which was engraved, the same year, in four large sheets. In 1709, Marioni was appointed engineer of Lower Austria; in 1714 he invented an instrument for measuring superficies in an easy manner, and without the necessity of calculation. This instrument he called the planimeter balance, and he dedicated the work, in which its principles were explained and illustrated, to the emperor Charles VI., which, however, was never printed. In 1717, he formed a plan for the establishment of an academy designed to teach geometry and the military sciences, which, being approved by the emperor, was immediately carried into execution, and in the following year Marioni was appointed fol-
He was admitted a member of the French Academy of Sciences in 1666, and died in 1684. He was an excellent mathematician, and one of the earliest French philosophers who applied to experimental referbices. His principal works are "A Treatise on the Shock or Collision of Bodies;" "An Essay on Physics;" "A Treatise on the Pressure and Motion of Fluids;" "New Discoveries relating to Vision;" "A Treatise on Levelling;" "A Treatise on the Motion of Pendulums;" and "Experiments on Colours." He also communicated many curious and valuable papers to the academy, which were inserted in their Memoirs, from vol. i. to x. A collection of all his pieces was published at Leyden in 1717, in 2 vols. 4to.

MARIQUA, in Geography, a town of Brazil, on the Rio Negro; 156 miles W. of Fort Rio Negro.

MARJoram, in Botany and Gardening. See ORIGANUM.

MARJoram, in the Materia Medica. The sweet marjoram has been thought to be the Σανόξιον or Amaranthus of the ancients. It has been long cultivated in our gardens, and is in frequent use for culinary purposes. The leaves and tops have a pleasant smell, and a moderate, warm, aromatic bitter taste. They yield their virtues both to medicines, and to spirituous and spirituous liquors by infusion, and to water in distillation; affording a considerable quantity of essentif oil, amounting, according to Beaumé, to 15 ounces from 150 pounds of the recent plant. On being long kept this oil assumes a solid form. When carefully drawn it is of a pale yellow colour, and of a hot penetrating taste. This plant has been chiefly recommended in disorders of the head and nerves, in uterine obstructions and mucous discharges, proceeding from a laxity and debility of the solids, and a flaggish state of the juices, and in the humoral afflams and catarrhs of old people. The powder of the leaves, their distilled water, and the essentif oil properly diluted, are agreeable ethers, and accounted particularly useful in putaceous obstructions of the nostrils, and disorders of the olfactory organs. Its medicinal qualities agree with those of the wild marjoram; but being much more fragrant, it is deemed to be more cephalic, and better adapted to the complaint denominated nervous; it may, therefore, be employed with the same intentions as lavender. It is directed in the composition of the physic officinarius in the Pharmacopoeias, with a view to the agreeable odour which it diffuses to the aperarbeccia, rather than to its erine power, which is very considerable. In its recent state, it is said to have been successfully applied to firrhus tumors of the breast. Lewis and Woodward.

The leaves and flowery tops of the common wild marjoram, which grows on dry chalky hills and gravely grounds in several parts of England, and flowers in July and August, have an agreeable aromatic smell, and a pungent taste, approaching to that of the garden marjoram, and much resembling thyme; with which they appear to agree in medicinal virtue, being deemed emmenagogue, tonic, flemachic, &c; effects which can only be ascribed to the aromatic and stimulant powers which all the herbs of this natural order seem to poiffe in common. Infusions of them are sometimes drank as tea, in weaknesses of the flemach, disorders of the breast, for promoting peripitation of the fluid secretions; in general, they are sometimes used also in nervice and anti-rheumatic baths; and the powder of the dried herbs as an erine. Distilled with water, they yield a moderate quantity of a very acrid, penetrating, essentif oil, smellying strongly of the marjoram, but less agreeable than the herb itself; this oil is applied, on a little cotton, for easing the pains of carious teeth; and sometimes...
times dilated and rubbed on the nostrils, or snuffed up the nose, for attenuating and evacuating mucous humours. The country people use the tops of the plants to dye purple. Lewis and Woodville.

The history of Crete, which is a species of originuum, is a very warm aromatic, of an agreeable smell, and hot biting tafe: the leaves, which impart their virtues both to the body and rectified spirit, tinging the former of a yellowish, and the latter of a greenish colour, have been chiefly recommended as emmenagogue, alexipharmic, and vulnerary. When distilled with water, if the quantity of distany be large, there separates, says Neumann, a small portion of a yellowish effertent oil, of a highly pungent aromatic tafe and smell, and which conveys to the cold into the apparence of canthorp. This furt was much valued among the ancients, and applauded by their poets.

Thus Virgili describets it:

"Hie Venus, indigno nati concussa dolore, Ditamnum gemini Rexa carpit ab Ida.

Paburnius canem folis, at flore evarintem Purpureum: non illa feris incognita capris
Grama, cim tergo vulnerum visua facirp".

An. I. xii. 411.

It was esteemed a specific for wounds of arrows, which it drew out with wonderful ease, and according to them only grew in the island of Crete, and only in a little obscure corner of it, whence it obtained its name ditamnum Creticnus. It fills grows in that island. M. Tourneforri, who was in Crete, describets the place where it grows, and says it flourishes there almost all the year.

The is a perennial plant, and though a native of fliny grounds in Greece, and the island of Candy, bears the ordinary winters of our own climate. The flowers are generally supplied from Italy with the leaves tied up in bundles, which are often damaged or decayed, and yet not inferior to those of our own growth. Although rarely used at this day, this plant certainly poffefs, in a very considerable degree, the stimulant and aromatic qualities which charac-terize this class of plants. Lewis and Woodville.

MARIPUT, in Geography, a town of Egypt, on the W. coast of Birk Marious; 15 miles S.S.W. of Alexandria.

MARIPA, in Botany, a barbarous Carinian name, adopted by Juffieu from Aublet, but, according to his own principles, retained only till the genus is either better established, or entirely set aside. Aubl. Ghian. 230. Joff. 133. Lamark Illubr t. 110.—Clas and order, Pen- tandria Monogynia. Nat. Ord. Cenovus, Joff.

Gen. Ch. Cal Peruhius, of one leaf, in five deep, roundish, concave segments, folding over each other. Cor. of one petal, tubular; tube twice as long as the calyx, dilated at the base, as well as at the mouth; limb in five equal, roundish, crenate, spreading lobes. Stam. Filaments five, short, thread-shapet, inserted into the lower part of the tube, opposite to the segments of the limb; anthers vertical, oblong, clowen at the base of two cells, shorter than the limb. Pij. Germen superior, ovate; flaye thread-shapet, declining; longer than the corolla; stigma peltate, convex. Peric. Capflile of two cells. Seede two in each cell, erect, parallel, convex externally, angular on the inside.

1. M. feandos. Aubl. Guian, t. 91.—Found by Aublet in Guiana, on the banks of the river Sinemari, eight leagues from its mouth, flowering in November. The stem is twisting, somewhat woody, supporting itself, by means of tendrils, upon the neighbouring trees. Leaves alternate, forked, ovate, entire, pointed, smooth, firm and shining, six inches long at most. Panicles terminal, branched and forked, with a pair of small ovate bracteae at each subdivision. Flowers white, about the size of the common White Jasmine.

MARIPPI, in Geography, one of the smaller Philip- pine islands; 20 miles S.E. of Malubate.

MARIPONDY, a town of Hindooftan, in the Carnatic; 15 miles S.W. of Ongole.

MARIPONDY, a town of South America, in the vice-royalty of New Granada, and province of Santa Fe, formerly celebrated for the rich mines of gold in its vicinity; on the W. are those of the Bencarni, and San Juan de Cordova, bordering on thefe of Herri, Malpaso, Gusuino, and Puma; and on the E. the silver mines of St. Anna, Lojas, and Frias; the silver, however, being mingled with the purest gold, of but difficult separation. This city, which was formerly opulent, is reduced to 300 inhabitants, a decline owing to the failure of the mines, so that those who have been engaged in them are unacustomed to other branches of industry. Quefada, the conqueror of New Granada, died at Maripiqua in 1597, but his body has been removed to the cathedral of Santa Fe. This city is situate 80 miles S. of Santa Fe de Bogota. N. lat. 5 10°. W. long. 74° 6'.

MARIS, in Ichthyology, a name given by Charleton and some others to a fish called by the generality of both the ancient and modern writers, pantis, and by some loxom- nides, from its whitish colour, and its external resemblance to the fish called menis and mena; it is, like that fish, a species of the sparas; and is distinguished by having a black spot on each side, and the tail and belly-fins red. See Sparis Smaris.

MARISCA, in Surgery, an exsorosence near the anus, so named from its resemblance to a fig.

MARISCH, in Geography, a town of Moravia, in the circle of Posen; 12 miles N. of Freyberg.

MARISCUS, in Botany, a Latin word used by Pliny for some kind of bullrush, and supposed to be derived from mare, the sea, near which the plant naturally grows. Hal- ler adopted this name for the Schenius of Limmenus, because he thought the latter too near Schenius, and because it was merely the Greek synonym of Junecs. This last reason is faulty, and est strike by innumerable examples. Gartner however follows Halber; but they have not been imitated. As the Schenius Marisus of Limmenus is probably a good distinct genus, having only two stems, and a drupa containing one seed, see Eng. Bot. 1950, it is much to be wished that the name in question has been referred for that genus. It is, nevertheless, now otherwise appropriated, by Vahl and Brown, whose peculiarly great authority in this tribe induces us, without hesitation, to concur with them. Vahl Enum. v. 2. 372. Brown Prod. Nat. Hult. v. 1. 218.

Gen. Ch. Cal a glume of two unequal membranous valves, containing two or three florets. Cor a single glume, ribbed, that of the lower floret embracing the base of the upper. Stam. Filaments three; anthers linear. Pij Germen superior, angular; flaye three-cleft, deciduous; stigma simple. Seed trilgge, naked, triangular, without any bristles at its base. Eff. Ch. Calix of two valves, two or three-flowered. Glumes
Glumes of the corolla imbricated, ribbed. Style three-crested, deciduous. Seed triangular, without bristles at its base.

Obf. Mr. Brown remarks that this genus differs from Cyperus, with which it agrees in habit, only in the fewness of its florets. Professor Vahl describes its habit thus:

"Root throwing out feyons. Stem erect, acutely triangular, somewhat bulbous at the base, leafy in their lower part. Inflorescence, differing in breadth in different species, keeled, theathing and purple at the base, rarely with minute ferratures at the edges and keel. Involutecals leaves as the others. Spike in a terminal umbel, one upon each stalk, with a feyile spike in the centre. Spikelets alternate, rather dilated, cylindric, imbricated. Bractea solitary at the base of each spike, gradually tapering upwards. Glumes of the corolla filiate. Receptacle of the spikelets angular, toothed."—The same author adds, that he has separated the plants composing this genus from KYLLINGIA, (see that article and CYPERUS,) because their habit, as well as fructification, is different. The spikelets are round and awl-shaped, not ovate and compressed. The calyx does not contain a solitary floret, but at least two, for the most part three. The glumes of the corolla are disposed in a different manner, not being parallel, but one above the other, so that the lowestmost includes the lower half, or thereabout, of that above it, each glume being furnished with a ptilid, as may readily be perceived, even in dried specimens. While the lower glume is in full flower, the upper is convoluted, they having nothing in common but their receptacle. There are therefore as many florets as glumes. The style is always in three, not two, division. If there be three florets, the second is always raised on a partial stalk. A seed is found at the bottom of each glume. These plants seem more akin to Cyperus, and might, perhaps, without great impropriety, be referred to that genus, as their glumes are two-ranked, and the small number of florets constitutes the only difference. That the two lowermost scales of the spikelet are arren, and therefore considered as a calyx, is no objection, the fame being the case with many species of Cyperus. If however the present genus be allowed to remain, either on account of the fewness of its florets, or because Cyperus is already sufficiently extensive, the characters above given will distinguish it.

Vahl defines eleven species of Mariscus, to which four more are added by Mr. Brown's Prodromus.

1. M. capillaris. Vahl n. 1. (Schœnus capillaris; Swartz Ind. Occ. 186. Cyperus nanus; Willd. Sp. Pl. v. 1. 272, excluding Plukent's synonym.)—Spike oblong, crowded. Spikelets deflexed. Involutecals of two leaves. Stem and foliage almost capillary.—Native of the West Indies. From six to twelve inches high, very slender, resembling a small capitate Carex. The spikelets are three-flowered, oblong, taenio, strongly deflexed, crowded into a round head the size of a large pea.—Willdenow has this plant also at p. 268. See Vahl.

2. M. gracilis. Vahl n. 2.—Leaf solitary. Spike feyile, nearly globose. Involutecals of two feyile leaves.—Found by Richard in South America. Stem a foot high or more, very slender, clothed at the base with two sheaths, one of which only bears a narrow leaf, two or three inches long. Involutecals of three leaves, two of which are two or three inches in length, the third but half an inch. Spike scarcely larger than a coriander seed, yellow. Spikelets ovate, acute, triangular when in seed. Stamus but two. Richard.

3. M. abyphius. Vahl n. 3. (Juncus cyperoides, culmo compremo trieto, radice odorata tuberosa, capitulo rotundo compato; Slome. Jam. v. 1. 121. t. 51. f. 2.)—Leafless. Spike globose, feyile. Involutecals of a few broad leaves, shorter than the spike.—Native of sandy ground in the bay of Honduras. Slone. Root knotty, creeping, red, fragrant like the sweet Cyperus, much esteemed by the Indians for curing the cholic. Stems a foot high, or more, rather flout, triangular, and compressed, clothed at the base with several close sheaths, but defllute of leaves. Involutecals of three, four, or five spreading ovate leaves, shorter than the head or spike, which is twice as long as a pea, composed of very numerous little spikelets, whole glumes are dotted with purple. Stamen three.—Vahl had a specimen from Senegal, which he judged the same species, though twice as large as the American plant.

4. M. paniceus. Vahl n. 4. (Kyllingia panicea; Linn. Suppl. 107. Rothe. Gram. 15. t. 4. f. 1. Gartn. v. 1. 12. t. 2. f. 8. Mariscus biglumus.)—Spike cylindrical. Spikelets oblong, imbricated, accompanied by small fetaeous bracteas.—Native of Arabia Felix and of Tranquebar. A foot high, with numerous leaves, as tall as the stem, and a quarter of an inch broad. Involutecals of two long leaves, and two or three much smaller. Spike five or six, half an inch long, on spreading flats of various lengths. Spikelets numerous, spreading, somewhat imbricated, their glumes with a green keel and white edges. Spike three-ribbed, dotted with purple.

5. M. flavus. Vahl n. 5.—Spike cylindrical. Spikelets oblong, accompanied by fetaeous finely ferrated bracteas, of their own length.—Native of South America by Von Rohr and Richard. Akin to the last, but differing in its bracteas, as well as in its broader more serrated glumes. Vahl.

6. M. ovularis. Vahl n. 6. (Kyllingia ovularis; Michaux Bororeal. Amer. v. 1. 29. Schoenus umbellatus; Jacq. t. 1. Rar. t. 10. Scirpus echinatus; Linn. Sp. Pl. 74. Herb. Linn.)—Spike roundish-ovate. Spikelets spreading every way. Involutecals of many leaves.—Native of North America; whether of the East Indies also we cannot determine. It is akin to the two last, but distinguished by the very numerous involucral leaves, and globose spikes, composed of spikelets that spread in all directions, resembling the head of a Sparganium, as Plukent, who figures it in his t. 91. f. 4, well observes. Vahl has rightly brought together the above synonyms, as belonging to one species.

7. M. retrofractus. Vahl n. 7. Gartn. t. 2. f. 5 (Scirpus retrofractus; Linn. Sp. Pl. 74. Cyperi genus indig. e. c.; Pluk. Phyto. t. 415. f. 4.)—Spike oblong imbricated downward. Spikelets awl-shaped, reflexed. Involutecals of few leaves.—Native of Virginia. The whole plant has a glaucous hue. Its habit is not like the last, but the slender taper-pointed spikelets are all remarkably drooping, or bent downward, and not loosely imbricated.

9. M. alternifolius. Vahl n. 9.—Spike cylindrical, imbricated downward. Involutecals leaves, as well as the flower-flalks, alternate.—Native of Guinea. Stems a foot high or more, as thick as a piglione's quill, taller than the foliage. Involutecals of ten alternate crowded leaves, some of them as long as the stem, each accompanied by an axillary flower-flalk, half two inches long, invovled with a purpl
ple-dotted heath, hardly an inch in length. Spikelets half an inch long, green. Vahl.

10. M. cyperina. Vahl n. 10. (Kyllingia cyperina; Retz. Obf. fale. 6. 21.)—Spikelets cylindrical. Spikelets erect, accompanied by bracts shorter than themselves. Native of the East Indies and Guinea. Stems about 2 foot high. Leaves few, mostly taller than the stem. Involutum of six or few very long leaves. Spikelets few or seven, fiddle or stalked, an inch long, imbricated upwards. Spikelets awl-shaped, accompanied by bristle-shaped rough bracteas, about half their own length, or rather more. Glumes of the calyx longer than usual; those of the corolla twice as long as the calyx, deeply furrowed, with a green keel, and pale tawny edge.

11. M. clatus. Vahl n. 11. (Kyllingia incompleta; Willd. Sp. Pl. v. 1. 258. Jacq. Lc. Rar. t. 300.)—See Kyllingia, from whence this species should be removed hither, with the following character. —Spikelets cylindrical. Spikelets erect, with bracts about their own length.

To these we subjoin Mr. Brown's four species, which not having been seen, we could not otherwise arrange, for want of knowing their affinities.

15. M. conicus. Br. n. 4. —Spikelets large-flowered, pointed, Umbel simple. Spikelets conical, somewhat three-lobed. Involucrium and leaves rough.—From the same country.

MARISFELD, in Geography, a town of Germany, in the county of Henneberg; six miles E. of Meinungen.

MARITACACA, in Zoology, the name of a very remarkable American animal, more usually known by the name of the opoium.

MARITAGIUM, in Law, contradistinguished from Matrimoniwm, or right of marriage, denoted, in its feudal sense, the power which the lord, or guardian, in chivalry had of disposing of his infant ward in marriage. While the infant was in ward, the guardian had the power of tendering him or her a suitable match, without disparity of age, which, if the infant refused, they forfeited the value of the marriage, "valorem maritagii" to their guardian; that is, so much as a jury would allow, or any one would bind to give to the guardian for such an alliance; and if the infants married themselves without the guardian's consent, they forfeited double the value, "duplicem valorem maritagii." "I his, says judge Blackstone, seems to have been one of the greatest hardships of our ancient tenures.

MARITICO, in Geography, a river of South America, in the province of Carthagena, which runs into the Spanish Mar, N. lat. 8° 5'. W. long. 76° 42'.

MARITIME, of mare, sea, denotes any thing belonging to the sea.

MARITIME Causes and Court. See Court of Admiralty.

MARITIME Estate, is used in contradistinction to the civil and military estate, to express that part of his majesty's lay sub-

jects, that are occupied in naval or sea service. See Marines and Navy.

MARITUS, in the chemical jargon, a word used to express the sulphur of metals. The writers on the subject of the philosopher's stone usually express themselves in this enigmatical manner, calling sulphur the husband, and mercury the wife in all metals; which, as they are more or less perfectly combined, make the metal more or less pure, and approaching to perfection.

MARIVAUx, Peter CARLET DE CHAMBLY DE, in Biography, a dislinguished dramatical writer, was born at Paris in 1688. He enjoyed the advantages of a flight classical education only, but was regarded as a youth of parts, and the ambition of becoming an original writer was his ruling passion. One of his first attempts was a travelling of Homer, on the model of Scarron's Virgil, for the direct purpose of throwing ridicule on the father of ancient poetry. At the age of eighteen he produced, within a few days, in consequence of a wager, a comedy entitled "Le Fère Prudent." This was not acted in public; and it was not till he had attained to his thirty-second year that he ventured to present on the theatre his tragedy of "The Death of Hannibal." The reception of this piece was far from favourable, and he thenceforth confined himself to comedy, in which he struck out a new path. This was that of a delicate and refined sentiment in the development of passion and character, which, in general, succeeded very well with a people who pride themselves on a nice perception of all the shades and diversities in the human mind. He brought out the greatest number of his pieces on the Italian theatre, which is accounted less critical than the French theatre. He produced about thirty pieces, many of which are still occasionally represented on the stage, and are popular. Marivaux has obtained a greater reputation by his novels than by his dramas. The first novel which he composed was entitled "Pharamond, ou les nouvelles folies romanesques," a kind of imitation of Don Quixote: this is less esteemed, and, indeed, less known than his two others, "Marianne," and "Le Payfan Parvenu." The "Marianne" is reckoned the principal, and it is thought, by competent judges, that few works of the class rank higher. It displays an intimate acquaintance with the human heart, and presents many truly interesting situations; and many justly celebrated sentiments. The "Payfan Parvenu" is preferred by some as possessing more gaiety and variety, and a more direct moral purpose. Another work of this author deserving of notice is his "Spectateur Français," which abounds in acute remarks and lively portraits, and in wit and variety is reckoned to surpass all his other pieces. He published only two volumes for want of proper encouragement. When he had attained to his fifty-fifth year he obtained admission in the French academy. He died at the age of seventy-five, in the year 1763. He was mild, friendly, and philanthropical: full of sympathy towards the indigent and afflicted, towards whom he exercised a liberality often beyond the bounds of prudence. He was upright and indissoluble, careless of fortune, and contented to live in obscurity: he was sincerely attached to religion, as the great resource of the wretched, but without any affection of extraordinary devotion.

MARIVELAS, in Geography, one of the smaller Philippine islands, with a village, the houses of which were constructed of bamboo, and attended by a ladder. One of these houses, including the roof and frame, hardly weighed, according to Perouze, 200 lbs: but the habitation of the officiating clergyman was of stone. In the year 1780, the Moors from the islands S. of the Philippines, invaded this island,
island, burnt the village, destroyed the fort, the church, and the rector's house, and made slaves of all the Indians they could seize.

MARIOLAS Bay, a bay on the W. coast of the island of Luson, sheltered from all winds except those from S. to S.E.; with a clean bottom of sthff mud or clay, and sufficient depth of water for vessels of any size. It takes its name from that of the above-mentioned island. N. lat. 14° 32'. E. long. 126° 24'.

MARIUM, in Ancient Geography, a town on the isle of Cyprus, upon the southern coast, very near the sea, between Amathus to the W. and Citium to the N.E.

MARIUPOL, in Geography. See Mariopolis.

MARITZ, or MARISEA, in Ancient Geography, a river of European Turkey, which rises in a chain of mountains, called Balken (the ancient Hennas,) and flowing by Philopolis in a direction towards the E., and S. falls into the Aegean sea in the gulf of Eosos, after a course of 200 miles. This river was the ancient Hecur which fee.

MARIUS CAIUS, in Biography, a famous Roman commander and head of a party, was born of an obscure family in the district of Arpinum. In early youth he was distinguished by size and strength of body, and roughness of manners. Having entered into the army at the military age, he soon gave proofs of great valour, and by his conduct on various occasions, attracted the notice of his general, Scipio, who foretold his future greatness. In the consularship of Metellus and Cotta, in the year 119 B.C., he became a candidate for civil honours, and obtained the office of tribune of the people. In performing the duties of this office he obtained great reputation, and was regarded by the people as the most determined protector against patrician tyranny. He had many antagonists, and was unsuccessful in his application for the edictum; but in the next year, 118, he acquired the office of equestrian. In the following year he was appointed to the government of the farther Spain. In this station he conducted himself with great equity, and, by his vigour, cleared the province of the banditti which infested it. At the expiration of his office he returned to Rome, where his want of birth, of fortune, and eloquence, checked his farther advancement, and, for some years, he remained idle and undistinguished. At length, in the year 109 B.C., when the conful Metellus was sent into Africa to conduct the war against Jugurtha, he offered Marius the post of one of his lieutenants, which the latter gladly accepted. The field of ambition was now open before him, and he resolved to cultivate it by all the means in his power. He ingratiated himself with the soldiery by partaking of all their hardships and dangers, and he felt neither the principles of duty or gratitude operate upon him so as to restrain him from injuring his patron Metellus in the public estimation. His success in repelling Jugurtha, who had made an unexpected attack upon him, gave him such in the eyes of the army, and he did not fail to make invidious comparisons between his commander and himself. What he said was communicated by the soldiers to their friends at Rome; this prepared the way for those exertions in his favour upon which he relied for the attainment of his objects. Being determined to stand candidate for the consularship, he publicly asked leave of absence of Metellus for that purpose, who haughtily said to him, "It will be time enough for you to think of that honour when my son shall be old enough to be your colleague." After some time he was allowed to leave the army for Rome, and by his great activity and vaft exertions obtained the confultate by a great majority. This was in the year 107, and the next object of his ambition was to supplant Metellus in the command, for which purpose he did not scruple to make use of the basest means that a fercile mind could invent. He obtained his object, and on his arrival in Africa with the supreme command, Metellus declined an interview, and leaving his army to be delivered up by a lieutenant, embarked for Italy. Marius spent the summer in disciplining his new levies, and in watching the motions of the two kings, Jugurtha and Bocchus. At length his gloomy heart suggested to him that the city of Capia might afford him a fit object of enterprise: he suddenly marched and surrounded it, and having forced it to surrender, he cruelly put to death all the adult males, selling the other inhabitants for slaves, and then levelling the place with the ground. This unfortunale city was situated on the African desert, and its almost inlant destruction struck such terror into the heart of those, to which the knowledge of the fact could extend, that deputies came in from all sides making submission and offering him those supplies for his army which the country afforded. He next invaded Mulucha, a fortress situated upon a high and infalutated rock that had been deemed imprudable: after much time being spent, and various attempts to storm it had failed, he had given orders to abandon the enterprise, when a Ligurian soldier accidentally discovered an accessible part in a cleft of the rocks: by this they made themselves masters of the place, and found in it an immense quantity of treasure, so that the army were enabled to march back to the sea-coast laden with booty. On their return they were surprized by the united forces of the two kings, and brought into imminent danger, from which they were extricated by the skill and exertions of Marius, and his queller Sulla, who now began to distinguish himself. The Numidians, in repeated attacks, were repulsed with great slaughter, and the Roman army gained their winter-quarters in safety. In the following year overtures of peace were made by Bocchus, who agreed to part of the conditions, to betray Jugurtha into the hands of the Romans, which was effected by the management of Sulla. By this event the war was brought to a conclusion, with no less honour to Sulla than to Marius. Owing to some sudden and unexpected danger which threatened the city Marius returned, was a second time elected consular, and obtained a triumph in consequence of his successes, at which Jugurtha and his two sons were led chained before his chariot. The war against the Gauls and Cimbri was entrusted to him, and he continued in his career of successes: he was a strict disciplinarian, kept his soldiers in the most perfect obedience, and did himself honour by the equity with which he administered justice among them. An inference of this kind is mentioned, in which he not only pardoned, but rewarded a youthful soldier who had killed his nephew for an infamous attempt on his person. Thus preserving his reputation entire, and also on account of the services which he yielded his country, he was elected a third and a fourth time consul. When it was proposed to confer that high honour upon him a fifth time, he accepted it only as an obligation to free the republic from its remaining foes, and declared a triumph till his victory should be complete. In the mean time the Cimbri had poured into Italy such immense numbers of troops, that an universal panic and consternation were experienced, till Marius with his army made a junction with them, and he himself took the supreme command. A most bloody battle succeeded, and the Romans, by the superior skill of their generals, rendered the field of battle a scene of mere carnage. Almost the whole nation of the Cimbri, with their wives and children, fell in the action, or were made prisoners, while the loss of the Romans was...
Marius Leonard, a Dutch theologian, who flourished in the 17th century, was born at Goes, in Zeeland, but in what year is not known; nor have we any material facts relating to him till we find him created a doctor of divinity at Cologne. He was elected professor of theology in that university, and was afterwards chosen president of the Dutch college in that city. He was afterwards appointed vicar-general of the chapter of Haarlem, and pastor at Amsterdam. He died in the year 1628, leaving behind him a considerable character for talents and learning. He was profoundly skilled in the Greek and Hebrew languages, and in the knowledge of the sacred scriptures. He was the author of "Commentarius in Pentateuchum," which is regarded as a work of great merit: "Hierarchia Ecclesiastica Catholica afferita," intended as a refutation of the famous treatise of Mark Antony de Dominis "De Republica Ecclesiastica," and of a variety of controversial pieces in the Dutch language. Moreiri.

MARK, Pope, and a saint in the Roman calendar, probably a native of Rome, and successor to pope Sylvester in the year 336. There is nothing recorded of him or of his pontifical acts that can claim the attention of our readers. Some authors say that he occupied the papal chair between two and three years, but others, and those the most worthy of credit, state that he died within nine months of his election. Moreiri. Bower.

Mark, among Bowlers. See Bowling.
viewed and examined by the officers or magistrates charged with the inspection of that manufacture; or, lastly, to show that the duties imposed thereon have been regularly acquired.

Thus are cloths, leathers, cutlery-ware, paper, plate, weights, measures, &c. to be marked.

The mark on goods also is what ascertains the property or goodnenss thereof, &c.; and if one man shall use the mark of another, to the intent to do him damage, action upon the case lieth. A penalty is inflicted in this cafe, by the flat. 23 Eliz. cap. 8.

Mark is also a particular form or character, known only to the trader who pitches on it; whereby, being fixed to any commodity, he recollects the price it cost him.

These marks, otherwise called numeres, are taken according to the fancy of those who use them; but, ordinarily, they are chosen from among the letters of the alphabet, each having a relation to some particular number of figures. They are of so much use in trade, that the reader will not take it amiss, if we insert a little table to serve as a model for their construction:

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
<th>E</th>
<th>F</th>
<th>G</th>
<th>H</th>
<th>I</th>
<th>K</th>
<th>L</th>
<th>M</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>2</td>
<td>3</td>
<td>4</td>
<td>5</td>
<td>6</td>
<td>7</td>
<td>8</td>
<td>9</td>
<td>10</td>
<td>20</td>
</tr>
</tbody>
</table>

One example will give the whole use of this table. Suppose, e.g. I would put on a piece of stuff, that it cost 37s. 6d. per cll. I put an M for 20s., an L for 10s., an N for 7s., and a G for 6d. So that the several letters written after each other (observing always to separate shillings from pounds, and from pence, by points) will make this mark M.L.N.G. equal to 37s. 6d.

Note, the mark may be diversified infinitely, by adding other figures to the letters, in lieu of these.

Ordinarily some word of a proper number of letters, all different ones, is chosen, that no relation may be traced among the letters, which may be done in the table here given.

Mark, Marck, or Marco, also denotes a weight used in several states of Europe, and for several commodities, especially gold and silver in France; where it was introduced under Philip I about the year 1080.

The mark is divided into eight ounces, called the "poids de marc;" the ounce being subdivided into eight gros, 20 ceterins, 24 deniers, 40 maules, and 80 sols, or 576 grains. A French mark weighs 5094 Dutch ares, or 3778 English grains. Thus 60 oz. poids de marc are nearly equal to 59 oz. troy; or more accurately, 4608 French grains = 3778 English grains.

Diamonds are weighed by the ounce of 144 carats, each carat weighing four grains, poids de marc, or 3,750 English grains. The poids de marc was likewise, till the revolution, the legal weight for merchandise at Paris, and in most other parts of France; the livre or pound being divided into two marcs, or 16 ounces; and the ounce into eight gros, 24 deniers, or 576 grains; a quintal = 100 lb.; and a charge, three quintals; 100 lbs. poids de marc = 108 lb. avoirdupois. The apothecaries' weight in Paris was the common poids de marc, and the pound contained 16 ounces; but the ounce was divided into three ducles, four fachues, fix fextules, eight drachms, 24 scruples, or 576 grains. In other parts of France, the pound of apothecaries' weight was 12 ounces, and was therefore three quarters of the Paris apothecaries' pound.

At Amsterdam, the fineens of gold under the old system is expressed in carats and grains; the mark being divided into 24 carats, and the carat subdivided into 32 parts. The fineens of silver is expressed in deniers and grains. The mark fine being 12 deniers, the denier 24 grains. According to the new system, the fineens of gold and silver is expressed by supposing it to be divided into 1000 parts, called millimenes; thus 414 millimenes answer to a carat of gold, that is the 24th part, and 834 millimenes to a denier of silver, or the 12th part. (See Money.) Nineteen marks Dutch troy weight of fine gold answer to 164.4 ounces of standard gold in London; and 37 marks troy of fine gold in Amsterdam are equal to 2065 ducats of gold in Hamburg. The fineens of silver is expressed in pennyweights and grains; the mark being divided into 12 pennyweights, and the pennyweight into 24 grains. A mark of fine silver, in bars, is 20.25 florins 16 ducers current, more or less; a mark of English silver coin is worth 5 lb. 12 fl. current, more or less; a mark of French silver, about 10 darts. 21 gr. fine, is worth 23 fl. 8 fl., more or less. Wrought silver must be 104 darts, fine, and is flamed with two crossetts and a crown. Gold, silver, and coins, are weighed by the mark troy; a mark troy being divided into eight ounces, and the ounce into 20 engs., or 640 ares. This weight is the same in all parts of Holland; 10,000 ares equal to 7417 grains, English troy weight; hence, two marks, or a pound, Dutch troy weight = 15 ounces, 16 pennyweights, 11 grains, English troy weight, or 7595 grains; and 90 ares, Dutch troy, weigh 90 ounces, English troy; or 135 lbs. Dutch troy, 178 lbs. English troy weight. In weighing pearls and diamonds, the mark troy is divided into 1200 carats, so that one engel, or 32 ares, is then equal to 73 carats; these are subdivided into halves, 4ths, 6ths, 10ths, 32s, and 64ths parts. The troy weight contains 12 pennyweights, of 24 grains each, to the mark; and at the mint, one engel is divided into four eighths, eight tenths, or 16 ducers.

In the commercial weight, 1 lb. contains 2 marks, 16 ounces, 32 darts, or 128 darts, or weighs 10,280 ares, Dutch troy weight, or 7025 English grains.

At Cologne the pound is divided into 2 marks, 16 ounces, 32 darts, 128 cents, or 256 pences. This weight is the same as that with which gold and silver are weighed in Hamburg, particularly at the bank; and, by an edict of the emperor Charles V. of 1524, the Cologne mark was made the standard weight for coin all over the empire, and still continues the same. The Cologne mark must weigh 5628 English grains, 4400 French grains, 4352 Cologne fechen (a division used in Hamburg) or 4864 Dutch ares; and in the valuation of coins, it is divided into 65,556 parts, called richtpence, each Cologne pence containing 256 fuch parts; 480 marks Cologne weight = 451 ounces English troy; and 100 lbs. Cologne weight = 104 lbs. avoirdupois.

At Dantzic, the mark of fine gold is divided into 24 carats, and each carat into 12 grains; the mark of fine silver into 16 lots, each of 16 pences; wrought silver is from 12 lots to 12 pences, to 13 lots fine; a mark, gold and silver weights, is divided into 8 ounces, 16 lots, 24 schots, or carats, 64 quintals, or 256 pences, and weights 3574 Dutch ares, or 2045.7 English grains. Hence 30 oz. of Dantiz gold and silver weight = 23 oz. English troy nearly; or 45 marks of Dantiz = 23 lbs. troy.

At Geneva, the ounce of fine gold is reckoned at 24 carats, subdivided by some into 32, by others into 24 parts. The mark of fine silver is reckened at 12 deniers; and the
Mark.

The commercial weight of Leipzic is the standard weight all over Saxony.

At Milan, gold and silver are weighed by the mark of 8 ounces; the ounce being 24 denari, or 576 grani. The mark of Milan weighs 7 ounces 16 deniers 10 grani, French poids de mar, or 5629 English grani; hence 192 marks of Milan answer to 121 pounds English troy, or 128 ounces of Milan to 121 ounces English troy.

At Mantua, the weight for gold and silver is the same as in Milan; but the commercial weight of Mantua is about 2 per cent. lighter, or 100 pounds of Mantua = 45 5/5 pounds avoidiposi.

For further particulars, see the names of the several countries and principal towns in this dictionary; and for a fuller account, see Kelly's Universal Cambill., vol. i.

Mark is also used among us for a money of account; and, in some other countries, for a coin.

The English mark, formerly in circulation, is two-thirds of a pound roddling, or 121. 4d.; and Matthew Paris observes, it was of the same value as 1194.

Saxon, as many an inquisitor has supposed, called the mark mancus, or mancusa, and more; among them it was equivalent to thirty pence, i.e. to seven shillings and sixpence of our money. But Dr. Milles, dean of Exeter, has lately suggested that the mancus and mark were not the same.

Mr. Clarke observes, that the Danish silver mark was 20s., or one hundred Saxon pence; and that the gold mark was twelve times as much; whereas the French mark was 15s. ad. or one hundred and fifty pence: and he has shown, that the method of computing by the silver mark was introduced later into France, where it commenced between A.D. 1075 and 1093, than into England.

He discovers traces of it in England from the Danish kings till after the time of Henry II. The gold coin struck from Edward III. to Edward IV. were divisions of the mark, as half-marks, quarter-marks, and half-quarter-marks, at 6s. 8d., 5d., 2d. each; but from Edward IV., when our connections with France ceased, the old way of computing by the pound came again into fashion; but, as that by marks was jointly used, ducats, and angols, or half angels at 6s. 8d. and 3s. 4d. each, passed sometimes as parts of them. However, about 40 years afterwards, this regard to the marks in our coins was quite laid aside, and all the principal gold coins were struck in proportion to the pound roddling. Connection of the Roman, Saxon, and English Coins, &c. p. 357 &c.

The mark-lubs, or Lubec-mark, used at Hamburgh, is also a money of account, equal to 23 shillings Flemish, or 32 grotes; consequently the shilling or fol-lubs is 2 grotes or pence Flemish. The rix-dollars is 5 marks, 48 shillings, or 576 pences. The rix-dollar of exchange is 2 marks, 32 shillings, or 384 pences. The pound Flemish is 2 1/2 rix-dollars, 71 4/5 marks, 20 shillings Flemish, 120 mark-lubs, 240 grots Flemish, 720 dryings, or 1440 pences. Each mark is divided into sixteen folis lubs.

The commercial weight of Leipzic is the standard weight all over Saxony.

At Milan, gold and silver are weighed by the mark of 8 ounces; the ounce being 24 denari, or 576 grani. The mark of Milan weighs 7 ounces 16 deniers 10 grani, French poids de mar, or 5629 English grani; hence 192 marks of Milan answer to 121 pounds English troy, or 128 ounces of Milan to 121 ounces English troy.

At Mantua, the weight for gold and silver is the same as in Milan; but the commercial weight of Mantua is about 2 per cent. lighter, or 100 pounds of Mantua = 45 5/5 pounds avoidiposi.

For further particulars, see the names of the several countries and principal towns in this dictionary; and for a fuller account, see Kelly's Universal Cambill., vol. i.

Mark is also used among us for a money of account; and, in some other countries, for a coin.

The English mark, formerly in circulation, is two-thirds of a pound roddling, or 121. 4d.; and Matthew Paris observes, it was of the same value as 1194.

Saxon, as many an inquisitor has supposed, called the mark mancus, or mancusa, and more; among them it was equivalent to thirty pence, i.e. to seven shillings and sixpence of our money. But Dr. Milles, dean of Exeter, has lately suggested that the mancus and mark were not the same.

Mr. Clarke observes, that the Danish silver mark was 20s., or one hundred Saxon pence; and that the gold mark was twelve times as much; whereas the French mark was 15s. ad. or one hundred and fifty pence: and he has shown, that the method of computing by the silver mark was introduced later into France, where it commenced between A.D. 1075 and 1093, than into England. He discovers traces of it in England from the Danish kings till after the time of Henry II. The gold coin struck from Edward III. to Edward IV. were divisions of the mark, as half-marks, quarter-marks, and half-quarter-marks, at 6s. 8d., 3s. 4d., 2d. each; but from Edward IV., when our connections with France ceased, the old way of computing by the pound came again into fashion; but, as that by marks was jointly used, ducats, and angols, or half angels at 6s. 8d. and 3s. 4d. each, passed sometimes as parts of them. However, about 40 years afterwards, this regard to the marks in our coins was quite laid aside, and all the principal gold coins were struck in proportion to the pound roddling. Connection of the Roman, Saxon, and English Coins, &c. p. 357, &c.

The mark-lubs, or Lubec-mark, used at Hamburgh, is also a money of account, equal to 23 shillings Flemish, or 32 grotes; consequently the shilling or fol-lubs is 2 grotes or pence Flemish. The rix-dollars is 5 marks, 48 shillings, or 576 pences. The rix-dollar of exchange is 2 marks, 32 shillings, or 384 pences. The pound Flemish is 2 1/2 rix-dollars, 71 4/5 marks, 20 shillings Flemish, 120 mark-lubs, 240 grots Flemish, 720 dryings, or 1440 pences. Each mark is divided into sixteen folis lubs.

At Copenhagen, accounts are kept in rix-dollars of 6 marks, or 96 shillings Danik or Danifh; and this is the general way of keeping accounts throughout Denmark, except in the churches of Hulften and Steflwick, where they are kept in rix-dollars of 3 marks, or 48 shillings lubs; and at Elinfour on the Sound, where they are kept in rix-dollars of 4 orts, or 96 shillings Danifh. The bafe rix-dollar (flet-daler), an imaginary coin, is reckoned at 4 marks, or 64 shillings Danifh. A mark is divided into 16 shillings or shillinges; and a shilling into 2 fyrkes, 3 witten, or 12 pennings Danifh. The Danifh denominations of marks and shillinges
florins have only half the value of the same denomination in lbs or Hamburgh money: thus, 2 marks Dániish are worth 1 mark Hamburgh. & c. In coins, the effective rix-dollar, in which the bank of Altona keeps its accounts, is reckoned at 6 marks Dániish: in the Sundish specie, in which the tolls are paid by ships falling through the Sound, this coin is about 24 per cent. worse: or, more correctly, 472 rix-dollars Sundish specie = 459 rix-dollars specie: crown money is 1/3 of per cent. lower than specie: Dániish currency, in which the books of merchants and tradesmen are kept, which is 61 per cent. worse than crown money, and 22 1/4 per cent. worse than specie; and Holstein currency, in which accounts are kept in Holstein and Sle flwck, is 25 per cent. below specie. The coins of Denmark are, in gold, ducats specie, which, as well as Dutch ducats, are worth 14 marks 12 florins Dániish currency, more or less; current ducats coined since 1757, at 12 marks Dániish currency; Christian-d'ors, coined in Holstein since 1775, which are worth about 13 marks lbs, or 26 marks Dániish currency. In silver, the specie rix-dollars per 7 marks 6 florins Dániish currency, and are commonly reckoned at 6 marks 12 florins crown money, at the toll on the Sound; double, fingle, and half crowns, at 8, 4, and 3 marks crown money, or 8 marks 8 florins, 4 marks 4 florins, and 2 marks 2 florins current; double and fingle pieces called Ebreers or Julius Judex, at 28 and 14 florins; rykovars at 24 florins, and pieces of 15, 10, 8, 4, and 2 florins specie. In copper, pieces of 4 florins Dániish; fyrkes or 4 florins; and dreyrings or 1 florin. The new Holstein currency, coined since the year 1788, consists of specie florins, at 48 florins specie, or 60 florins Holstein currency; and pieces of 32, 16, 8, 4, and 2 florins specie, or 40, 20, 10, 5, and 2½ florins Holstein currency. In this money, the Cologne mark of fine silver is coined into 91 rix-dollars specie, or 11 ½ rix-dollars currency. Silver in bars is taken at the Dániish banks at the rate of 91 rix-dollars per mark fine, provided it is not under 13 lbs fine. Foreign gold coins in Denmark pass as follows: pistoles, Frederick's, and such like coins, for 12 marks 11 florins lbs; carolins for 15 marks 9 florins ditto; guineas for 15 marks 12 florins ditto; old French louis-d'or for 15 marks 7 florins ditto; pieces of an English piece, for 27 marks 2½ florins ditto; ducats for 7 marks 3 florins ditto, or double the value in marks and florins Dániish: 69 of the ducats specie, coined by the king of Denmark as duke of Holstein, being of the same weight and fineness as those of the empire, should weigh a Cologne mark, 23½ carats fine; 85½ ducats currency must contain a Cologne mark of fine gold, and they are little more than 21 carats fine. From a Cologne mark of fine silver, 62½ marks in crown, or 68 marks in silver currency should be coined; and by a royal edict of 1776, 91 rix-dollars specie are to contain a mark of fine silver, each piece weighing 537,698 ounces, Cologne weight, or 447.9 English grains, and being 14 lbs or 2½ lbs fine, so that it contains 391.9 English grains of fine silver. The rix-dollar Dániish currency, in current ducats or 12 markpieces, is equivalent to 28.48 German aces, or 21 ½ English grains of fine gold; and the rix-dollar, in silver currency, contains 429 aces, or 3118 grains of fine silver: the rix-dollars in crowns may be valued at 467 aces, or 3491 grains of fine silver, which is the proportion of gold to silver is at 15 to 1. See RIX-DOLLAR.

The pound, gold and silver weight, contains 2 marks, 16 ounces, or 32 lbs; the lord, four quarters, 16 1/4 chaldrons, or 272 chaldrons. This is called Cologne weight, but it is somewhat heavier, 608 marks of the Dániish weight being equal to 611 marks of the Cologne weight; so that 1 Dániish mark weighs 365½ English grains; 160 ounces Dániish silver weight are equivalent to 151½ English troy weight; and 245 marks, or 12 lbs. Dániish silver weight = 15 lbs. troy. The commercial weight is to the gold and silver weight as 15 to 16, and the pound has the same divisions; it weighs 7702 English grains; and 100 lbs of Copenhagen = 110 lbs.avoirdupois. Kelly's Universal Carnhill, vol. 1.

Mark, County of, in Geography, a principality of Germany, bounded on the N. by the county of Recklinghausen, and bishopric of Munster; on the E. by the duchy of Westphalia, on the S. by the duchy of Berg, and on the W. by the duchies of Berg and Cleves. The soil of this county is fertile; it has good meadows, and also arable land, which produces wheat, rye, barley, oats, buckwheat, peas, beans, rape, turnip seed, flax, and hemp, in such plenty as to supply neighbouring countries. It furnishes also all kinds of fruits and legumes. Its mountains yield coal, iron, lead, copper, and silver ores, and quarries of stone. It contains more than 20 towns; its inhabitants are partly Roman Catholics and partly Protestants, all of whom enjoy the free exercise of their religion. The manufactures of the country furnish commodities for exportation, and especially articles of wrought iron and steel. The ancient counts of Mark derived their origin from the counts of Altona; and this territory was transferred, after having been possessed by Adolphus V. count of Mark and of Cleve, together with Cleve, to the electoral house of Brandenburg. The capital is Hamm.

Mark Burgel, a town of Germany, in the principality of Cumbach; 13 miles N.W. of Anspach.

Mark Lenkarteim, a town of Germany, in the principality of Cumbach; 14 miles N. of Anspach.

Mark Manfrei, a town of Austria; 10 miles N. of St. Wolfgang.

Mark Maffaren, a town of Syria, in the pachalic of Aleppo, containing about 150 houses; it is generally the halting place for the caravans between Scanderoon and Aleppo.

Mark Oldendorf, a town of Westphalia, in the bishopric of Oldenburch; six miles W. of Eimbeck.

Mark Schellen, a town of Transylvania; four miles N. of Stoltenenberg.

Mark, St., a town of the island of Hispaniola, situated on a bay, on the W. coast, to which it gives name. The chief productions of the vicinity are sugar, indigo, coffee, and cotton; 48 miles from Port Paix. N. lat. 19° 18'. W. long. 72° 42'.—Alfo, a river of East Florida, which runs into Apalachee bay, a little below the town of St. Mark.

—Alfo, a sea-port town of East Florida, near the mouth of the river just mentioned. N. lat. 30° 16'. W. long. 84° 36'.

Mark, Gospel of St., in Biblical History, a canonical book of the New Testament, being one of the four gospels. The mark evangeMt is mentioned in i Pet. v. 13, and Dr. Lardner supposes, for reasons which he has adduced, that he was the same with John Mark, whose name occurs in the Acts and in some of St. Paul's epistles, and accordingly that he was the fellow labourer of Paul, and Barnabas, and Peter. He was the son of Mary, a pious woman at Jerusalem, and an early believer, at whose house the disciples used to meet, and to which Peter frequently returned. (Acts xii. 12.) The deliverance of Peter recorded in this passage happened in the year 44. At this time Mark, called in 2 Col.
Col. iv. 10. "fither’s son to Barnabas," went from Jeru-
alem to Antioch with Paul and Barnabas; and soon after, he
accompanied them to other countries as their minister (Acts,
xiii. 5.) ; but declining to attend them during their pro-
gress, he returned to Jerusalem, and kept up an Intercourse
with Peter and the other apostles. When Paul and Barna-
bas settled at Antioch, after the termination of their journey,
we find Mark with them, and disposed to attend them in
their journeys. At this time he went with Barnabas to Cy-
pus; and afterwards he accompanied Timothy to Rome, in
consequence of the particular request of the apostle Paul,
during his confinement in that city. (2 Tim iv. 11.) From
Rome he probably went to Asia, where he met with St. Peter,
with whom he returned to this city, and where he is sup-
posed to have written and published his gospel. Such are the
outlines of the history of this evangelist, furnished by the
New Testament. From Eusebius, Epiphanius, and Jeron we
learn, that Mark, after he had written his gospel, went
to Egypt, and founded a church at Alexandria, where,
according to the last of these ancient writers, he died in
the eighth year of Nero, and was buried. Some authors have
asserted, that he died a martyr; but this fact is not men-
tioned by Eusebius, or other more ancient writers; and the
expressions of Jeron seem to imply a natural death. Fabri-
cius, in his account of St. Mark, says nothing of his having
been a martyr. From various authorities cited by Dr. Lar-
der, it appears that the evangelist Mark was a companion
of Peter in the latter part of his life, and that he had great
advantages from that apostle’s preaching for composing a
gospel; and that he was well acquainted with Barnabas and
Paul, and other apostles and discipies, who had been eye-
witnesses of Jesus, besides Peter. Some have supposed,
that he was one of Chrift’s 70 disciple; but whether this
was the case or not, of which there is no decisive evidence,
he was an early believer, and an early disciple and companion
of the apostles, and intimately conversant with them, and thus,
as well as by hearing Peter preaching in Judea, and other
places, and lastly at Rome, he was well qualified for writing
a gospel.

St. Mark wrote his gospel at Rome, where he accompa-
nied St. Peter, in the year of Chrift 64 or 65. Many of the
most ancient writers assert, that St Mark was more than an
amænus or interpreter to St. Peter, who dictated this
gospel to him; others affirm that he wrote it after St. Pe-
ter’s death. It is probable that it was composed long before
Peter’s death, and that it was not published, or did not become
generally known, till after the death of Peter and Paul.
This gospel appears, from the accounts given of it by the
ancients, to contain the substance of Peter’s preaching:
and the gospel itself affords evidences of its being written
according to that apostle’s discourses, or according to infor-
mation and directions given by him to this evangelist. Many
circumstances tending to Peter’s honour, and recorded by
the other evangelists, are not mentioned in this gospel. (See
31, 32. John, xiii. 6. &c John, xviii. 10. compared with
Mark, xiv. 47. John, xxii. 7. John, xxi. 15. John, xvi. 18, 19.)
However, there are many things that occur in this gospel,
which are omitted by the other evangelists, see Mark, i. 13.
20. 29. 35. 36. 37. 45. ii. 2. iii. 5, 6. 17. 19. iv. 20—
29. 34. 36. 38. v. 1. 19. vi. 17. vii. 3, 5, 4. 21, 22, 31. 37.
viii. 22. 26. x. 46. 52. xi. 13. xii. 41. 44. xiii. 3, 4. xiv.
51, 52. xv. 21—24. xvi. 7; and this fact proves, that Mark
was not an epitomizer of Matthew, as some have supposed,
or of any other author, and that he was well acquainted
with the things of which he undertook to write a history. He
writes as an eye-witness, or as one who had full and authen-
tic information at the first hand. Hence Lardner justly con-
cludes, that St Mark’s gospel, though short, is a very
valuable and masterly performance. The learned have been
divided as to the language this gospel was wrote in, some
affirming it was composed in Greek, which is the more gen-
eral and probable opinion, others in Latin. Several of the an-
cient heretics received only the gospel of St Mark: others,
among the Catholics, rejected the twelve last verses; and
for explaining those twelve verses, and reconciling them to
other evangelists, he refers to Grotius and other com-

MARK, St. Canons of, a congregation of regular canons,
founded at Mantua, by Albert Spinola; a priest, towards
the end of the twelfth century.

Spinola made a rule for them, which was approved, cor-
rected and confirmed, by several succeeding popes. About
the year 1450 they were reformed, and followed only the
rule of St. Augustine.

This congregation, which at first consisted of eighteen or
twenty houses of men, and of some for women, situate in
Lombardy, and the state of Venice, having flourished for
the space of four hundred years, declined by little and little,
and was at length reduced to two convents; and in 1584, that
of St. Mark, at Mantua, which was the chief, was given,
by the consent of pope Gregory XIII. to the Camaldulans; and
to the congregation became extinct.

MARK, St. Knights of, an order of knighthood in the re-
public of Venice, under the protection of St. Mark the
Evangelist.

This order was instituted in the year 737, the reigning
doge being always grand master; it was always in great ef-
teem, being only conferred on those who had performed
signal services to the commonwealth. The badge of the
order is a medallion of gold richly chafed, with a winged
lion feant, the wings elevated, holding in its finifter paw a
sword erect, the dexter reposing upon a book; upon it
are these words, “PAX TIBI, MARCE, EVANGELISTA
MEUS;” on the reverse, the portrait of the reigning doge,
with the image of St. Mark, delivering a standard to him.
The medal is worn at the breast, pendant to a chain of
gold.

MARK, in Law, is the sign of the cross affixed by the
illiterate vulgar, to deeds, &c. when unable to write their names.
See Seal.

MARK, in the Manage. A horse marks, that is, he flies
his age by a black spot, called the bud or eye of a bean,
which appears, when he is five and a half, in the cavity of
the corner teeth, and is gone when the horse is eight years old.
After that age he ceases to mark, and is said to have raved.
See Age in Horsemanship, and Eye of a Bean.

MARK, in Rural Economy. See Land-mark.

MARK, Sea, in reference to Navigation, &c. See
Beacons.

MARK, Letters of. See LETTERS and MARQUE.

MARK-Statutes, are graduated flasses or polls to shew
the rise or fall of water in a river, canal, or riveror.

MARKAN, or MARKHAN, in Geography, a town of
Grand Bucharia; 70 miles N.W. of Balk.

MARKARYD, a town of Sweden, in the province of
Smaland; 50 miles S.W. of Wexio.

MARK-
MARKSFORD, or MARKSFORTH, a town of the duchy of Baden; nine miles N.E. of Contance. N. lat. 47° 45'.

MARKEN, a small island on the west side of the Zuider see, near the coast of Holland; two miles E. of Monke
dam.

MARKERSDORF, a town of Saxony, in the circle of Neultadt; six miles E. of Weyda.

MARKESDORF, a town of Bohemia, in the circle of Lettmeritz; four miles S. of Kamitz.

MARKET, a public place in a city or town, where provi
dions are exposed to sale.

The word is formed from the French, marché, which signifies the same.

Market is also used for a liberty or privilege, either by the king's grant, or by long and immemorial usage and pre
scription, which presupposes such a grant, whereby a town is enabled to keep a market.

If any person let up a fair or market so near mine that he does me a prejudice, it is a nuisance to the freehold which I have in any market or fair; but in order to its being a nuisance, it is necessary, 1. That my market or fair be the elder, otherwise the nuisance lies at my own door;
2. That the market be erected within the third part of 20 miles from mine. For sir Matthew Hale (on F. N. B. 184,) continues the dicta, or reasonable day's journey, mentioned by Bruton (1. 3. c. 16.) to be 20 miles; as it is usually understood, not only in our own law (2 Inlt. 507.), but also in the civil (Ff. 2. 11. 1.) from which we probably borrowed it. So that if the new market be not within seven miles of the old one, it is no nuisance; for it is held reasonale, that every man should have a market within one-third of a day's journey from his own part; that, the day being divided into three parts, he may spend one part in going, another in returning, and the third in transacting his necessary business there. If such market or fair be on the same day with mine, it is prima facie a nuisance to mine, and there needs no proof of it, but the law will intend it to be so; but if it be on any other day, it may be a nuis
ance; though whether it is fo or not, cannot be intended or presumed, but I must make proof of it to the jury.

Blackf. Com. book iii. See FAIR.

In former times, it was customary to have most fairs and markets kept on Sundays, and in the church-yard, so that matters of business and devotion were transacted all at the same place and time; which custom, though prohibited by several kings, particularly Ed. 1. Stat. 2. cap. 6. was yet held up till the reign of king Hen. VI. when it was effectually suppressed, 27 Hen. VI. cap. 5. In many places they are still kept in the church-yard.

In the country, things sold in the markets, are to be in the usual place appointed for the sale; and market ovet is only held on the special days, provided for particular times by charter or prescription; but in London every day, except Sunday, is market-day (Cro. Jac. 68.), and every shop is a market ovet, for such goods as are put there, to be sold by the trade of the owner (5 Rep. 83. 12 Mod. 521.); though if the sale be in a warehouse, and not publicly in the shop, the property is not altered. Sale upon a Sunday, though in a fair market, will not alter the properties of thing sold. If my goods are stolen from me, and sold, out of market ovet, my property is not altered, and I may take them wherever I find them.

Persons that dwell in the country, may not sell wares by retail in a market-town, except in open fairs; but country
men may sell goods in groves there. (1 and 2 P. and M. cap. 7.) All contracts for any thing vendible in fairs or markets ovet shall be binding, and sales alter the property, if made according to the following rules. 1. The sale is to be in a place that is open, so that any one who passeth by may see it, and be in a proper place for such goods. 2. It must be an actual sale, for a valuable con
sideration. 3. The buyer is not to know that the seller hath a wrongfull possession for the goods sold. 4. The sale must not be fraudulent, betwixt two, to bar a third person of his right. 5. There is to be a sale and a contract, by persons able to contract. 6. The contract must be originaly and wholly in the market ovet. 7. Tolls ought to be paid, where required by statute. The Mirror informs us (c. 1. § 31.), that tolls were established in order to tellify the making of contracts, for every private contract was discontenanted by law; inasmuch that our Saxon ancestors prohibited the sale of any thing above the value of 20 pence, unless in open market, and directed every bargain and sale to be contracted in the presence of credible witnessers. 8. The sale ought not to be in the night, but between sun and fun; though if the sale be made in the night, it may bind the parties. Sale of goods stolen in London, or within two miles thereof, to brokers, &c. alters not the property.

J. Jac. 1. cap. 21.

In market ovet, if the goods be the property of the king, such sale (though regular in all other respects) will in no case bind him; though it binds infants, feme covert, idiots, or lunatics, and men beyond sea or in prision; or if the goods be stolen from a common perfon, and then taken by the king's officer from the felon, and sold in open mar
ket; still is the owner has used due diligence in prosecuting the thief to conviction, he loses not his property in the goods. (Bacon's Ule of the Law. 158.) So likewise, if the buyer knoweth the property not to be in the seller, or there be any other fraud in the transaction; if he knoweth the seller to be an infant or feme covert not using trading for herself; if the sale be not originally and wholly made in the fair or market, or not at the usual hours (according to the rules above specified); the owner's property is not bound thereby. (2 Inlt. 713. 714.) If a man buys his own goods in a fair or market, the contract of sale shall not bind him, so that he shall render the price; unless the property had been previously altered by a former sale. (Park. § 93.)

And, notwithstanding any number of intervening sales, if the original vendor, who sold without having the property, comes again into possession of the goods, the original owner may take them, when found in his hands who was guilty of the first breach of justice. (2 Inlt. 713.) By which wife regulations, the common law has secured the right of the proprietor in personal chattels from being devoluted, so far as was consistent with that other necessary policy, that pur
chasers, bona fide, in a fair, open, and regular manner, should not be afterwards put to difficulties by reason of the previous knavery of the seller. But there is one species of personal chattels, in which the property is not easily altered by sale, without the express consent of the owner, and those are horses. (2 Inlt. 710.) For a purcaehler gains no property in a horse that has been stolen, unless it be bought in a fair or market ovet, according to the directions of the statutes 2 P. and M. c. 7, and 31 Eliz. c. 12. See Horse.

A piepowder court is incidental to a market, as well as a fair. (See Court.) Keeping a fair o market, otherwise than it is granted, as on two days, when only one is granted, or on any other day than that appointed, &c. is cause of forfeiture. And if a person erects stalls in a market, and does not leave room for the people to stand and sell their wares, so that they are thereby forced to hire such stalls, taking money for the use of them is extortion.
