Machinery.

Machinery for manufacturing Ships’ Blocks, in the royal dock-yard at Portsmouth. These machines are the invention of Mr. Isambard Brunel, esq.; they are the most ingenious and complete system of machinery for forming articles in wood, of any that this kingdom can produce, being not less creditable to the country as an exhibition of mechanical talent, than advantageous to the government in the economical supply of an article of such immense demand for the navy. The great celebrity these machines have obtained, and the valuable information their publication will convey to mechanics, has induced us to devote feven of our plates to their explanation, and will apologize for our entering into fo long an account of the manufacture of an article so trifling as a ship’s block; though even this should not be despised, when its importance in naval affairs is considered, and how often the safety of a vessel may be endangered by the failure of a single block, regulating any important action in a ship’s working. It is of great consequence that thefe, in common with every other part of a ship’s rigging, should be made in a most accurate and substantial manner.

The block machines are particularly worthy of notice, as performing most of the practical operations of carpentry with the utmost accuracy and dispatch, and will be found applicable to many other purposes besides the fabrication of ships’ blocks. Indeed, in the dock-yard all the small wooden articles required in the navy can, in some part or other, be executed by the machinery in the wood mill, as the building containing them is very properly called, and the largest timber is converted and sawn up into any scantling, by several curious circular and reciprocating saws adapted to various purposes. The succeeding operations, performed by the smaller machines, are boring, mortising, many very ingenious applications of turning for a variety of purposes, both in wood and iron, rivetting, drilling, broaching, burnishing iron pins, &c. as we shall describe at length. The different kinds of blocks used in the rigging of a ship are described in our article Block, and also the manner of constructing them by the old method which was then in practice, the machines in question having been erected since the printing of that article, or, at least, brought into use, or we should have described them in their proper place; but even here they are by no means misplaced, being the best examples of practical machinery, of any we could select from the numerous manufactures our country contains, being adapted to perform operations which are generally understood, but which have hitherto been executed by manual labour and dexterity only.

The blocks for the royal navy were for many years previous to 1807, when the machines were set to work, supplied, on contract, by Mr. Taylor, of Southampton, who employed a large mill, containing powerful sawing machines, for converting the timber into the proper scantling for the blocks, but left them to be formed by manual labour, as related in our article Block: the mill also gave motion to lathes of the common construction for making the finvres. Except what was done at this manufactory, and some few curious machines devised by general Sontham, the credit of bringing the block manufacture to its present perfection is due to Mr. Brunel, who has displayed as much judgment in the division of the operations by the several machines, as ingenuity in the contrivance of their parts, which are admirably well calculated to produce their intended effects. The greatest attention has been everywhere paid to that form of construction which would admit of the most perfect workmanship in the execution; in this, the ideas of the ingenious inventor have been ably seconded...
by Mr. Henry Maudslay, of Westminster-road, London, who made these machines with the most scrupulous attention to accuracy and durability, at the same time preferring an elegant proportion in their form, which is very agreeable to the eye. The framing of all these machines is made of cast iron, and many of those parts which are exposed to violent and rapid motion are made of hardened steel to avoid wearing}; and where this is impracticable, such parts are formed so that they can be readily renewed when worn out. A better proof of their durability cannot be desired, than the circumstance, that the machines have been now finished four years, and have been in continual work during that period, some of them being subject to very violent and rapid action; yet, among forty-three of them, nothing has happened to require any repairs of sufficient consequence to engage the attention of the maker or inventor; the trifling repairs of the cutting tools, &c. being made by the workmen on the spot, and of all such parts they have duplicates provided, by which any failure can be remedied in a few minutes. These circumstances we particularly recommend to the attention of manufacturers who have occasion to employ extensive sets of machinery; for this, when well constructed, though expensive in the erection, is cheaper in the end than imperfect works, which require constant repair, the expense of which is the least evil; as it generally happens that a machine will fail at that time when it is most wanted, in consequence of being then most worked; and the loss occasioned by the stoppage of great works, particularly where many people are employed, is too evident to require our notice. In the same manner, an attention to neatness, in the appearance of machinery, has its advantages, by inducing the workmen to be careful of the machines they work at, to prefer them from the slightest injury, and to keep them clean from dust, which, tripping as it may appear, is a very essential point in the perfection of those parts which are in rapid motion with friction against other parts, for dust getting between such surfaces grinds them away very fast, and in their most essential points.

Workmen and people employed about machines have no interest in their preservation, farther than to avoid such signs of violence and carelessnefs as may be immediately detected by their superiors; but by introducing an emulation among them, of having the nearest machines in the factory, and of keeping them in the best order, they may be induced to take as much care of them as if they were their own property. This fact is well known to some of the largest proprietors of cotton and woollen mills, though as much neglected by others. The machines contained in the wood mill at Portsmouth may be separated into four classes:

1. The sawing machine for converting the large timber into proper dimensions for the small machines to operate upon, consisting of the large machines for sawing up the elm trees from which the shells of the blocks are to be made, and the smaller sawing machines for cutting up the lignum vitae for the heaves. 2. Those machines which are employed in forming the heaves. 3. Those which form the iron pins for the blocks. And, 4. Those by which the shells of the blocks are manufactured. They are all situated in one large mill, which consists of two very tall buildings, or wings, having a smaller and lower one between them, lighted by sky-lights in its roof. The lower part of one of the wings is appropriated to the two steam engines, which actuate the whole, as also some immense chain pumps, which are occasionally employed in draining the dry dock. The mill has two engines of thirty horse power, one erected by Messrs. Boulton and Watt, and the other by Messrs. Murray and Wood of Leeds. Either of these can be applied indifferently to work the chain pumps, or for turning the wood mill, and their power is transmitted by a train of wheel-work to an horizontal shaft, extending along the centre of the middle building, very near its roof, and upon this are a number of wheels and drums, which, by endless ropes and slings, communicate motion to the various machines for making the block shells, which are situated on the ground, in the central building. They are seventeen in number: fourteen of this number constitute three complete sets for making blocks of different sizes following each other, from four inches in length to eighteen; the length in inches being the denomination of the size of ships' blocks. There is also a large machine for boring parts of those very large blocks which are called made blocks, and cannot wholly be made by the machines; it also cuts shot racks by tools for the purpose: and here are two machines for turning shot eyes, which are blocks without heaves, for attaching the ship's thongs to her sides.

The ground-floor of the wing opposite to that containing the steam engines, is appropriated to seven large sawing machines for cutting up the trees; and the floor over it contains three sawing machines for cutting up the trees of lignum vitae: also, the small machines for making the heaves, which are thirteen in number, and a small room, containing five machines, where the iron pins are turned and polished. In the upper parts of both wings of the mill are warehouses for containing the immense flock of finished blocks, which are always kept in store for armaments, and several workshops with common lathes, worked by the mill, for making and finishing various small articles of a ship's furniture. Many of them are, in part, made by some of the block machines, in addition to all those kinds of blocks which we have explained under Block. Some of these articles are dowels, for uniting ship's timber; trenails, mortising forks, serving millits, pump buckets, and many other trusses which it is unnecessary to particularize. At the top of the building is a large water cistern, kept always full by a pump belonging to the engine, and provided with pipes which conduct the water to every part of the works, and are in every room furnished with caw caps, at any of which an engine hose can be screwed on in the event of a fire, which is somewhat to be dreaded when they work by lamps in the winter time, as the great quantity of chips and saw dust, always lying about in every part of the mill, might be set on fire. To avoid this danger as much as possible, the lamps are included in glazes of a similar figure to a long cask, with a cap on the top, which has holes to allow the smoke to pass out, but so contrived, that it is impossible a spark should escape. Upon the roof-leads at the top of all, are racks for setting up the very large blocks to season by gradual exposure to the weather, or they would, if all at once subjected to the sun or rain, crack and split in all directions, so as to fall to pieces.

We shall commence our description of this ingenious mill by an enumeration of the several processes the blocks and their heaves are subjected to, beginning with the rough elm and lignum vitae trees, and tracing them through their various stages to the finished blocks with their heaves, and, in like manner, the pins for them.

The elm trees are first cut into short lengths, proper to form the various sizes of blocks, by two large sawing machines, one a reciprocating, and the other a circular saw. These lengths of the trees are next cut into squares, and ripped or split up into proper sizes by four facing benches, with
with circular faws, and one very large reciprocating faw, which is used for cutting up the pieces for very large blocks. These are the seven machines in the wing.

The cuttings, thus prepared for the blocks, are perforated in the three boring machines, with a hole through each, to contain the centre pin for the sheaves of the block, and as many other holes in a perpendicular direction to the former, as the number of sheaves it is to have, these holes being intended as the commencement of the several mortises to contain the sheaves.

The blocks are now mortised in the three mortising engines, which elongate the holes above-mentioned to their proper dimensions.

The angles of the blocks are now cut off by three circular facets, preparatory to reducing them to the elliptical figure they are to have.

The outside surfaces of the blocks are next formed to their true figure by the three floating engines, each of which forms every part of ten blocks together.

The facets, or grooves, are next formed round the block, to receive the rope or strap by which they are suspended: this is done by the two floating engines.

The blocks are now trimmed by hand labour, to smooth and polish them.

For making the sheaves, the first process is cutting pieces or flakes off the end of the trees of lignum vitae, of a proper thickness to form the sheaves: this is performed by three converting machines, one a reciprocating faw, and the other two circular faws.

These flakes are made circular, and the centres pierced in two rounding and centering machines, or trepan faws.

A hole is now excavated in the centre of each sheave, to inlay the coak or piece of bell metal which is fitted into the centre of each sheave, to form a socket for the centre pin.

The coaks, being put into their places, are rivetted fast by the two rivetting hammers.

In some kinds of sheaves, three small holes are drilled through each sheave, and also passing through the coak, by the drilling machine; and short wire pins, cut by the cutting faws, are put through these holes; then they are rivetted down at the same time with the rest of the coaks by the rivetting hammer. This method is not always adopted, the coaks being found to be firm enough without these pins or rivets.

The centre holes through the coaks are next broached out to a true cylinder in the three broaching engines.

The last process is turning the faces and edges of the sheaves to a flat surface, in the three facing lathes, which also form the groove round the edges of them, for the rope which accompanies them when in the block. This completes the machines for making the sheaves. The iron pins are forged by two smiths, in the usual manner of such articles, between two faws or tools, each having a hemispherical cavity formed in it, so that the two, when put together, form a cylinder. The heated iron being laid in one of these, the other is put over it, and beat with a hammer, by which means it forms the pin to a cylinder. The end of the pin is left square for a very short length. They are in this state turned smooth and true in the pin turning lathes, and afterwards polished and made perfect on the surface in the polishing machines.

Such blocks as are from four to seven inches in length, are generally fitted with wooden pins, which are turned in a simple lathe called a subject.

There are also two machines for making dead eyes, and a large apparatus or boring machine for making the largest sizes of blocks, of that denomination called马拉松 blocks, some of which are as much as four feet in length, and with four sheaves. They are of course made up of planks, and this machine is used for boring the holes of the numerous bolts which are used to unite these parts: it is also used occasionally to cut out flot racks. The whole of this list contains 43 machines.

We shall now proceed to a description of the several machines, beginning with the large sawing machines for elm trees, contained in the ground-floor of one of the wings of the mill. In the centre of this room is a vertical shaft turned by the machinery, having a capstan on the lower end of it, round which a rope is passed, to draw any log of timber into the mill from the yard, where the fume of elm is kept. The trees are by this means conducted to the first machine, which cuts them off across into proper lengths, to form such blocks as the tree seems best adapted for. Two machines are employed for this purpose, one a circular and the other a reciprocating faw: the latter we shall describe first.

The great cross-cutting saw.—The tree subjected to the action of this machine is placed on a long frame or bench raised a little from the floor, and at the end of it is erected a frame, composed of vertical posts and cross timbers, in the manner of a small and low door-way: through this frame the end of the tree is drawn by the capstan above-mentioned, its end projecting as much from the surface of the frame as is intended to be cut off; and it is fastened in the frame from rolling fayades, by a lever, which can be readily made to press upon it and hold it down. The faw itself is a straight blade, fixed into a wooden handle or pole at each end, to lengthen it: one of these handles is connected by a joint to the upper end of a lever, bent like an L, and having its centre beneath the floor; the horizontal arm of the lever is connected by a pin rod, with a crank on the end of a spindle near the ceiling of the room, the motion of which is regulated by a fly-wheel. By this means the faw has a reciprocating motion from right to left, nearly in a horizontal position, and exactly across the log it is to cut off, imitating in its motion the carpenter's hand faw, considering his arm as the arm of the bent or L lever. The teeth of the faw are of course on the lower side of the blade, and are shaped so as to cut in a drawing towards the lever. It rises and falls freely upon its joint at the end of the lever, and can only be lifted up by the handle, at the opposite end of the blade, to take it off its work, which it follows up, by its own weight. The machine being at rest, is prepared for work, by fixing the log in the frame as before mentioned, so that the surface of the frame interferes the log at the place where it is intended to be cross-cut. The faw, which was before lifted up by its handle, to be clear above the log, is now suffered to rest upon it, in the place where the cut is to be made; and to guide it at first setting in, the back of the faw is received in a faw kerf, made in the end of a piece of board, which is attached to the frame over the faw, but slides up and down in a groove to reach the faw at any height, according to the thickenss of the log lying beneath it. Being thus prepared, the machine is put in action by a rope or strap which turns the fly-wheel and its crank. This giving a vibration to the bent or L lever, causes the faw to reciprocate horizontally across the tree, until it cuts it through: it follows up its cut by its own weight alone, but the attendant can at any time lift up the faw from its work, though its motion continues, by means of a rope which suspends the handle of the faw when required. As the faw gets into the tree it quits the guide above-mentioned, which becomes the lefs necessary at the faw going deeper; a faw having no tendency to alter its first course, when cutting across the
MACHINERY.

The cross-cutting circular Saw.—This machine is for similar purposes, and stands close by the former. It is a circular saw, whose spindle is so mounted, as to move in any direction parallel to itself; the saw all the while continuing in the same plane and revolving rapidly upon its axis; the work that is presented to, and as it admits of being applied at first on one side, and then on another side of the tree, a few of moderate dimensions will be sufficient to divide larger trees, than could otherwise be done by it.

Plate 1. (Black-Machinery) contains two plans and two elevations of this machine. Fig. 1 is an elevation, shewing the tree A A (which is to be cut) lengthways. Fig. 2 is taken in the other direction, and therefore shews the tree endways. Fig. 3 is a plan, answering in its position to fig. 1, and shews the whole of the mechanism; but the plan (fig. 4) only contains the lower parts. The same letters of reference apply to all the figures. A A, as before mentioned, is the tree intended to be sawn across: it lies upon a framing of timber B, which may be considered as its bench or support. Across the end of this frame a strong timber, or ground-ill, C, is framed, and in this two uprights, R, S, are erected, which, with a cross beam at top, form the frame, which gives the means of confining the tree upon the bench B while it is cut. This is done by means of a lever D, one end of which is hitched beneath a bolt put in a hole in the pole S of the frame, to serve as a fulcrum, and the other end palies between the face of the pole R, and a piece of wood, a, fixed thereto, and the lever, being forced down upon the tree, is kept down by a bolt put through a hole in the piece a, and also into the poll. The other end of the lever is retained by a piece of wood similar to a, (see fig. 1,) fixed to the pole S; by this means the tree is held steadily whilst it is sawn. T is a roller, or capstan, to advance the tree forwards on the bench: it is turned round by means of the handspike E, which is fitted loosely upon the centre pin of it, and has a small clock engaging the teeth of a ratchet wheel b, fixed fast upon the gudgeon or centre pin. The handspike, being worked in the manner of a pump, turns the roller about a few teeth of the wheel at every stroke, and by a rope wound on the roller draws up the tree: d is a click which detains the teeth of the ratchet wheel, and prevents the roller running back, after being moved by the handspike. A framing of wood is placed beneath the tree at F, to form a continuation of the bench B, but leaving a space between it and the front of the beam C, for the saw to descend into when it divides the tree, when the frame, F, will support the piece cut off. A piece of wood is fastened down upon the frame F, at g; by means of a screw, it acts as a flop to the end of the tree, and measures out the quantity to be cut off from the end of it: it is of course adjustable, and may be fixed at any distance from the end of the bench B, according to the length intended to be cut off the end of the tree. We now come to describe the mechanism connected with the faw, which is shewn by G, fixed on the end of a spindle e, mounted in a frame consisting of two side-beams, H, H, connected by cross pieces, I, I, K, L, and strengthened by diagonal bolts or tyes, e; e: the top cross piece is formed of iron, as shewn in fig. 3; and its ends are jointed to the end of a frame M M, poised in the manner of the balance-beam of a draw-bridge, on a fulcrum supported by the fixed framing of the machine, consisting of two polls, N, N, extending from the floor to the ceiling, and connected by a cross beam O O. By this means, the spindle of the saw can be moved in any direction at pleasure, but always preserves its parallellism, ascending and descending by the inclination of the frame, M M, upon its fulcrum, and moving from right to left by the frame H, swinging upon the joints connecting and suspending it: from the former the saw receives its motion from the mill by a strap b, which encompases a pulley i, fig. 1 and 2, contained in an opening of the iron top, L, of the frame H; it is fastened on a short spindle, which is exactly in a line with the joints connecting the two frames, M M and H H; upon the same spindle is another pulley A, by which the strap, P P, passes, and is connected to a pulley b, fixed on the spindle of the jaw; m, m, fig. 1 and 2; two small wheels to guide the saw, and tighten it up, if necessary, when it stretches; the main strap, b, b, is guided over pulleys n, which, being near the centre of motion of the frame M, are not materially affected by the motion of the frame either to tighten or loosen the saw which passes round a large drum, turned by the mill. The attendant has government of the machine, to move the saw in different directions by two winch handles, V and W: the latter of these is on the end of an axis x, having two pinions upon it, which operate upon two racks at the end of wooden rods, Q, Q, fig. 1 and 2, which are connected with the end of the great frame, M M, at the frame joints which connect the two frames together: so that by turning this winch, W, in one direction, it elevates the saw, and in a contrary direction, depresses it, by inclining the frame, M, on its centre. In like manner, the handle, V, gives motion by a wheel and spindle to a similar pinion, which actuates by its pinions two rods, X, X, joined to the suspended frame H, and therefore moves the saw nearer or farther from the woodman who stands at the frame N N: the two frames, H and M, are greatly strengthened by the rods, Q, Q, and X, X, being connected with them; for as the pinions act equally upon the two rods, and thus move both sides of the frame alike, they preference them from twirling, which would cause the spindle of the saw to deviate from the parallellism; but to have this effect, it is necessary that the pinions should fit their racks accurately. For this purpose, the rods, Q and X, to which the racks are affixed, are supported behind by two rollers, y, y, applied to the back of each. These rollers are fixed in a triangular iron frame, the third angle of which is fitted upon the axis of the pinions; and by this means, the teeth of the racks and pinions are always kept in accurate contact, though the racks necessitarily alter their inclination at times, according to the position of the frames to which they are joined.

The operation of this very ingenious machine is almost evident from the description. The tree being fixed, the attendant takes the handles V and W, one in each hand; and by turning one or the other, directs the saw to platen to any side of the tree. At first he applies it, as in fig. 2, and it cuts half through the tree from that side, with very great rapidity; then he gradually raises it up by the handle W, and cuts into the log at the top side; but all the time the saw continues in the same plane; and at last brings it to the opposite side, and cutting through it there, the log is separated, even if it is nearly of the same diameter as the saw. The saw is now moved by its handles to be clear of the tree, the piece removed, and the tree advanced to cut another length. This machine is so expeditious and accurate in its performance as to take the lead of the other, except for such trees as are of a size too great for the circular saw. It has, since its first erection, received an addition of a rack and pinion to the frame R S, for holding the tree, which presses down the tree instead of the lever, and holds the wood in the manner of a vice or press: by this means, the saw can now
be used for sawing the pieces into squares, after they are cut off the tree; and for cutting them up to form different fixed blocks, or for sawing up any other timber. The next machine we shall describe is

The great reciprocating Saw, for cutting up trees lengthwise.—In this machine the faw works vertically: it has a horizontal carriage, on which the timber is fastened; this carriage is guided by a vertical frame with grooves, in which another frame slides up and down in the manner of a window-sash, and has the faw fretched in it. The faw-frame is moved up and down by means of a crank on an axis beneath the floor, which is turned by means of an endless rope. At every time the faw rises and falls, it turns a ratchet-wheel round, by means of a click, a few teeth; and this has on its axis a pinion, working a rack attached to the carriage of the tree, by which this means is advanced: at every stroke, the faw makes a proper quantity for another cut. The faw-frame is adapted to hold several faws parallel to each other, for sawing a tree into several boards at once, when required. Besides these machines, the wing contains four of

The circular saw breathes. These machines are used for cutting the wood full smaller, after the other machines. These machines are a bench, similar to a carpenter's, having a f spindle extending across it full beneath the boards, with a circular saw fixed upon it, which comes up through a crevice in the bench; and as it revolves, the workman applies a piece of wood to it, which it cuts with amazing rapidity. The wood is guided by a long wooden ruler, fixed on the bench, parallel to the plane of the faw. The wood is applied to this guide-ruler when cutting, and this regulates all the wood it cuts to the fame breadth; but the guide-ruler can be quickly adjusted to any distance from the faw, being attached to the bench by radius bars similar to a parallel ruler, so that it will always be parallel to the faw. We have been thus concise in describing these circular faws, and the great reciprocating faw, as they are the only machines in the mill which do not shew a completely original design, or which have any resemblance to other machinery. The reciprocating faw is such as is common on the continent and in America, and the circular faws have been long in use in this country. See saw-mill.

One of the sawing benches is much longer than the others, being continued the whole length of the house. It is used for sawing the edges of long planks to a straight line, after they have been cut up from the trees by the great reciprocating faw. It has a carriage for holding the plank, which is advanced towards the faw by a rack and pinion, which the workman turns with a winch in front of the bench; the plank is held in the carriage by its ends, each end being applied against a stop, similar to that which a carpenter's bench has for stopping a piece of wood, while it is planed; the other end of the plank is forced up to this stop by a screw, attached to the carriage, but in such a manner that it can readily be fixed at any part of its length, to hold planks of different lengths. The plank, when of great length, is kept down to bed firmly upon the carriage, while it is sawn by a roller, which presses upon it nearly near that part of the plank which is engaging the faw. This roller is pressed down on the plank by the weight of a long beam of wood set up on end, the roller being fitted in the end of it. This beam is fitted, in guides which permit it to rise and fall, to accommodate any inequalities in the thickness of the wood or plank which passes beneath it. This concludes our description of the machines in the wing on the ground-floor. The machines contained in the floor over the great sawing machines are devoted to converting or sawing up the tree of lignum vitae, for the sheaves, and the small machines for forming the sheaves. The first is

The reciprocating Saw, for converting the Lignum Vitæ.—This machine is somewhat similar to that first described for the elm tree, but made on a smaller scale and with more accuracy. The faw is fretched in a wooden frame, which is necessary, because, being for the hard wood, it is cut with a much finer tooth, and the blade is much thinner, so that it waives less wood in half-size than the former. The tree of lignum vitæ is placed horizontally, being held in a machine, which is, in fact, an enormous vice, though very different in appearance: it is opened and shut by two faws instead of one, as the common smiths' vice, and these faws are both moved at the same time by means of cog-wheels connecting them, so as to move the jaws of the vice parallel. This machine is used for cutting the ends of the tree into flakes of the proper thickness, to form those sheaves which the diameter of the tree is best adapted to make with the least waste. This vice which holds the tree is provided with a screw, which advances the whole together towards the faw a proper quantity at every time a sheave is cut off, to cut another of the intended thickness. For this purpose, the vice is stationed upon a carriage fitted upon proper fiders, so that it advances truly parallel, in order that the pieces it cuts off may have parallel sides. This machine is only used for converting the largest trees of lignum vitæ, which are drawn up to the floor on which these machines are situated by a crane worked by the mill, so as to occasion little more trouble than if they were upon the ground: the smaller trees are cut up in a very curious machine.

The circular saw, for converting the Lignum Vitæ.—This operates with a revolving faw, which is applied to the outside of the tree, which at the same time turns round to present every part of its circumference to the action of the faw. By this means the faw will cut a tree of nearly as great a diameter as itself, and make a very flat section. We have been compelled, from the number of our plates, to omit a drawing of this machine, and must, therefore, attempt a verbal description.

The f spindle of the circular saw is fitted in an iron frame, which moves in a fixed vertical axis, in the manner of a gate or door. The faw spindle being vertical, the faw itself is of course horizontal, and its centre describes the arc of a circle when turning upon its axis of motion, but continues in the same plane. It is turned, like the other machines, by an endless band, which is conducted over pulleys, on an axis concentric with the axis of motion for the faw-frame; by which means the band continues with the same degree of tension in all positions of the frame supporting it. The vertical axis of this faw-frame is supported between the points of centre screws belonging to an iron standard, which is attached to two vertical iron columns, extending from the floor to the ceiling of the room, and which constitutes the chief framing of the machine. The tree of lignum vitæ, being previously cut into lengths of two or two and a half feet, is fixed in a chuck or clam at the top of a vertical faw, which is fitted in a socket, in the middle of a cross-bar, sliding between the two vertical columns. This cross-bar has two iron rods extending up from it to another similar one, also sliding between the columns, these forming an iron frame which rises and falls at pleasure, in the manner of a faw frame, by means of a large screw, which is received into a nut, formed in the middle of the upper cross-bar of the frame. The lower end of the faw screw retails in a step in the middle of a fixed cross-bar extending across from one column to the other, and perforated with two holes for the
MACHINERY.

The Cranken or Trepus Saw.—See Plate II., figs. 1, 2, and 3. Fig. 1 is a horizontal section through the centre of the axis. Fig. 2 is an elevation of the whole; and fig. 3 an end view. A A is a cylindrical faw with teeth formed upon the end of it, in the manner of a surgeon's trephine, or the crown wheel of a watch. This faw is fixed upon a chuck B. (fig. 1.) which is fastened, by screwing to the pulley D, turned by an endless belt. This pulley and faw are fitted to flip round freely upon a fixed axis or tube E, supported by being fcrewed to a standard F, erected upon the iron frame K R, on which the whole machine is built. G is a standard, having a faw H through the top of it, and exactly in a line with the centre of the tube E. At the end of it is a cup L, which, when advanced by the fcrew, exactly meets the end of the fixed tube E, and between these two surfaces, or rings of surfaces, the piece of wood to be rounded is held, by screwing the fwear tight up. The wood is fhewn in a fection at I, fig. 1, within the faw. The faw slides backwards and forwards upon the fixed tube E, and can be thus prefented as it revolves against the piece of wood, to cut through it, and reduce its circumference to a perfect circle of the size of the interior diameter of the faw. The fixed tube E has a cylindrical fwear K fitted withinfide of it, which is turned round by a pulley I fixed in the middle of it, and turned round like the other by an endless ftrap or belt. This fwear has a drill fcrewed into the end of it, to perforate the centre hole in the fieve; and it can be moved endways to bring it up to its work in the fame manner as the other. Indeed, it is caufed to advance or retreat at the fame rate with it, by means of two connecting rods L, M, which passes through holes in the standard F, and are at their ends united by frews, to collars which are fitted upon fockets, formed in the central part of the pulleys D and L, so that the collars admit the pulleys to turn round freely, indepenfent of them; but when either pulley, with its fwear, is moved endways, it obliges the other to partake of the fame movement. The two collars are fhewn feparately at X and Y, and the standard F between them. The farther end of the fwear K is fupported by a collar in a fhandard M, also erected upon the frame R. The motion endways is given to the faw and drill by a lever N, fhewn between the frame R. The vertical arm n of this lever is forked at the upper end, as fewn feparately at Z, and has notchs cut in the extrinfly of each fork, to receive two pins projecting from the fides of a collar e, fhewn upon the end of the fwear K, which turns round freely in the collar, but commands the motion of the fwear endways. The lever N is raised up, and the fwear kept back by means of a spring O fixed to the frame of the machine, fo that when left to itelf, the faw and drill always retreat back as far as they can. In this fate the workman takes a piece of the lignum vitae, which is of an irregular figure, being the fhape of the fection of the tree. This he places against the end of the fixed tube E, and frews it fast by the fwear H. He now depresses the handle N, and thus advances the faw and drill, as they are turning all the time, againft the wood, which the former perforates in the centre, while the latter cuts off those parts which project beyond the circle, leaving the wood round on the edge and ready for the next operation, which is performed by

The Cooling Engine.—This machine prepares the tree for the reception of a bell-metal blur, or centre piece, called the coal, one of which is fitted into each fide of the fieve, to surrounder its centre pin, and avoid wearing. This piece of bell-metal, or coal, is fhewn in fig. 9 of the plate; it has a cylindrical part a, which passes through the centre hole of the
the flueave, and has a hole through it for the pin of the flueave. This, which is called its barrel, has at the end a shoulder, or flaunch, of the form of a cone, that is, a circle having three ears projecting from its circumference, which are buried into the wood, and thus keeps the coak from turning round in the flueave. This is shown at fig. 4 of the plate; r is a ring of the same size and form as the flaunch at the end of the coak; it is buried into the outer side of the flueave, but has a large hole through its centre to receive the part, b, of the other coak, which it comes through the centre of the flueave. This part being riveted down into the ring e, secures the two coaks together; but, in some kind of flueaves, there are further secured by means of a wire-pin put through the centre of each of the three ears, which is also riveted down. The first operation which is therefore performed on the flueave, after rounding and centering the wood for it, is cutting a hole, of a proper figure, for the reception of the brafs coak. The engine for performing this is described in the lower part of Plate B, of which fig. 4 is a front view of it; fig. 5, an elevation taken on one side; fig. 6, a plan of the top of the frame; and fig. 7, a plan of the lower part where the flueave is fixed. This is, in all the views, marked A: over this a small flipple, B, is situated; it is mounted in a frame C, C, and turned round with great velocity by an endless band passing round its pulley a, and conducted over the pulleys D, D, fig. 5, away to a drum, turned by the mill. The end of the flipple has a cutter screwed into it, such as is shown separately at X, formed out of one piece of steel, with three cutting edges, which cut out a circle of the size of each of the three ears projecting from the edge of the coak. The frame, C, C, of the flipple is fitted to slide up and down on two vertical rods, E, fixed in the framing; and the depth to which it falls is determined by a small screw b, fig. 5, on the point of which the frame rests. The flueave, A, is fixed to a chuck E, which has a very short axis, received into a socket in the middle of the lever G, attached to the frame by a centre-pin, a, at one end, and the other is used in the manner of a handle, to move the lever on its centre, and by this means remove the flueave away from the flipple, so as to give it any required eccentricity from the flipple; in which case, the cutter, X, will cut out a circular hole in the flueave, at any required distance of the centre thereof. The chuck, on which the flueave is fixed, has three arms, 1, 2, 3, fig. 7, projecting at equal distances from it; these are detained at pleasure by a detent f, which is forced towards it by a spring: the frame of the flipple, when raised to its greatest elevation, is suspended by a spring-catch H, and in this state the cutter is raised up out of the way. The workman now prepares the flueave for cooling, by fixing it on the chuck F. To explain the manner of doing this, see fig. 8, where N is a screw passing down through the centre of the axis and chuck, and has a screw cut on the lower end; and by means of a nut M, fig. 4 and 5, tapped upon it, the pin can be forcibly drawn down through the axis. The upper end of the pin is, as its figure shows, of a conical figure, and fills a hole through the centre of a fixed ring O, which is situated upon the face of the chuck, immediately over its centre. The external diameter of this ring fits the inside of the hole, through the centre of the flueave, which is by this means fixed to the chuck: but to hold it fast therewith, the ring is divided by a few into three segments, and a piece of watch-spring, P, being put round them, in a groove formed for its reception, keeps the three together, and always collapses them upon the central pin N; but on turning the nut, M, the pin is drawn down, and its conical head expands the three segments, so as to keep them fast in the inside of the flueave, and by this means fixes it fast. This contrivance of an expanding chuck, which will often into holes of different sizes, within certain limits, and always prefers its concentricity, is extremely ingenious, and is a very valuable tool for turning many small articles in the lathe. The workman thus fixes the flueave to its chuck, to perform which, with convenience, he pulls the end of the lever, G, to far forwards, that the axis comes as far as it can within the circular frame X, which supports the machine; but when the flueave is fixed he returns it, so as to come nearly concentric with the flipple. This point is determined by shooting a small bolt, q, q, fig. 4, beneath the lever, G, forwards, and then its end stops against the fixed point of an adjusting screw b. He now, by withdrawing the spring-catch H, sufferers the flipple to descend till it rests on the point of the drop-screw d. In this state, the end of the cutter is as much beneath the surface of the flueave as the thickness of the shoulder d, fig. 9, of the coak; but the cutter is within the centre hole, at least in part, though, in descending as it revolves, it cuts away the wood, on one side the hole, as much as will enlarge its diameter to that side to the size of the circle of the shoulder, d, of the coak from which the three ears proceed. The workman now draws the handle of the lever, G, away from the flipple, until the bolt is stopped against the point of the opposite drop-screw a, as it appears in fig. 7. In this situation, the flueave is in that position, that the cutter is so far removed from the centre of the flueave, as to cut out the cavity to contain one of the semi-circular ears of the coak. The lever, G, is now pressed against the other drop-screw b; the catch, f, is relieved from the arm, i, of the chuck, by which it is turned round; and in this motion the cutter enlarges the centre hole to the third of a circle of the proper diameter to receive the coak: when the succeeding arm, g, comes to the detent, it moves the lower, G, out from the centre again to the drop-screw d, and thus cuts the second ear. The lever is now returned; the chuck turned round; and a third cavity formed in the same manner as the former; the lever being returned again to the screw e, the chuck is turned round to where it set out, and thus completes the enlargement of the centre hole, and the cavity is prepared for the reception of the coak. The flueave, being removed from the chuck, is put on again, with the other side uppermost; and to ensure the ears being exactly opposite to each other on the different sides of the flueave, a small button is let into a hole in the centre of the flueave, at the same distance from the centre as the semicircular ears, and of the same diameter as that is; being, therefore, of the same diameter as the cutter, this button is forced upwards by a spring; but while the first side of the flueave was cutting, it was pressed down flush with the surface of the chuck, and was not in use; when the second side is to be cut the flueave is turned round on its centre pin (which is the ring O), before fixing, until the button springs up into one of the cavities for the ears, and is placed in such a part of the chuck, that it determines the position of the flueave upon it, so as to cause the ears to be opposite to each other. Being thus fixed, the operation of cutting the second side is exactly the same as the first. This coaking engine is a very complete and ingenious machine, and operates in the most perfect manner to inlay the coaks, and will serve many different sizes, as will be understood from its various adjustments. These are: the drop-screw b, which regulates the degree of enlargement the centre hole shall have to receive the shoulder of the coak: the screw, f, determines the distance of the centre of the ear from the centre of the flueave; the diameter of the ear must have the cutter s suited to it, for which purpose it screws to the flipple: and lastly, the screw, b, governs
Machinery.

The fixed end of the cutter is fitted in a frame, which is connected by joints with a second frame, having a swinging motion on a vertical axis in the manner of a double folding door, or more exactly like the frames of the great circular saw first described, if the spindle of it was placed vertical instead of horizontal; and it receives its circular motion by similar means. This spindle has not the power of accent and deflect, but it is evident it can, by the two frames, be moved to any spot near the centre of the sheave that is placed beneath it. The cutter is made to cut out the proper shape, by means of a hole cut in a piece of fixed brass plate, which is of such a figure, that a pin or collar, concentric with the spindle, being traced round its interior surface, will guide the cutter so as to excavate the proper figure in the sheave, which is fixed on a chuck beneath it, but cannot be turned round, which, from the construction of this machine, is unnecessary, as the cutter traverses all the space which is to be cut out, but cannot move any further, being limited by the brass plate. The chuck for the sheave is fixed at the top of a frame which rises and falls with the sheave, to adjust the depth the cutter shall cut, and the chuck is let down clear of the end of the cutter every time the sheave is to be shifted. This rising and falling is performed in a very convenient manner by means of a screw which elevates the frame, and has upon it a barrel, round which two cords are wound in opposite directions. These cords are conducted over pulleys to two treads situated beneath the frame of the machine, so that by pressing the foot on one treadle, the chuck and sheave are raised up, and by the other, it is let down, and in either case the screw retains it where it is placed. The frame is provided with a stop-screw, which will determine the height to which it shall rise, and consequently the depth to which the cutter excavates in the face of the sheave.

The bell-metal coaks are cast in sand, in the manner described in our article Casting, from accurate patterns made for the purpose, of which they have a great variety of all forms for the different sizes. The pattern, or core, which is inferted in the sand for forming the hole through its centre, is not a smooth cylinder, but has two projecting threads which encompass it spirally, in the manner of a very coarse screw; so that when cast, the interior surface of the central hole through the coak is not a smooth cylinder, but has two spiral cavities, or chambers, winding round within it, in the manner of the spiral forces within a rifle gun barrel; but these cavities do not reach the ends of the hole, which is therefore circular at the two ends. These chambers are intended to contain a supply of great extent to the centre pin, when the block is in use, as will be more fully described.

The coaks, being put into their places, have holes drilled through the centre of each ear, by a very simple Drilling Machine.—This bears a great resemblance to a common turning lathe, to the spindle of which a small drill is fixed, immediately opposite to it. In the place of the back puppet of the lathe, is a flat plate and table against which the sheave is placed, and by a screw advanced against the drill, which is all the time in rapid motion. The proper place for drilling the hole is determined by marks punched in the pattern from which the coaks are cast, and thus occasion similar marks in the centre of each of the ears of every coak, by means of which the drill point is guided to the right place, and quickly penetrates through both the coaks and the sheave also. The pins to fit into these holes are made of copper wire, which is chopped or cut into lengths, and then inserted, and a close pair of shears, having a flop or guage fixed at the proper distance behind its blade, to stop the end of the wire, and point out the proper mark where it is to be cut. These pins are driven into the holes through the sheave, and in this plate the sheave is ready for rivetting, to fasten the pins in, and to unite the two parts of the coak firmly to each other. This is done by

The Rivetting Hammer.—It is delineated in figs. 1, and 2, of Plate III.; the first an elevation, and the other a plan of the machine. Its frame is a flat iron plate, A, A, which is situated on a strong bench: upon this two standards B, B, are cast, and support an axis a, turned round by means of a bolt on the pulley b. The other pulley, c, is fitted loosely upon the end of the spindle a, and when the ftrap is upon it, the machine stands still, because the pulley turns round upon its axis. On the middle of this spindle is a wheel D, having three cogs, which the fpring, an, is applied to act beneath the tail of the hammer E, which is fixed upon an axis F, supported in the same frame, BB, as the main axis. A small anvil or flake, G, is fixed to the bottom plate of the frame A, immediately beneath the face of the hammer, and the sheave, H, is placed between them to receive the strokes of the hammer, which is lifted by the cogs of the wheel D, and falls upon the sheave three or four hundred times per minute. The hammer would not fall so quickly by its own weight, as to reach the sheave before the next cog of the wheel, D, lifted it up: a spring, I, is therefore applied to act beneath the tail of the hammer, and by raising it up to throw down the face of the hammer. This spring is screwed upon a lever K, which is fixed on an axis, L, extended across the frame, and the other end is furnished with retting on the surface of an eccentric circular wheel M, fixed upon an axis, which also has a wheel, N, fixed by the fide of it, and a rope being fastened round this, extends to a trebble beneath the brace, and the workman pressing this with his foot turns the wheel round, and its eccentric circle acts upon the lever, K, to raise it up, which, in its turn, as it revolves, to lift up the tail of the hammer and to make a more powerful stroke. In using this machine, the workman takes a sheave, and, lifting up the hammer, applies it beneath the face of it; then by shifting the endles ftrap, which is all the time in motion, upon the live pulley b, the axis, a, is turned round, and the hammer beats upon the rivets, fo as to fasten them effectually in a very short time. By this the end of the barrel of one coak is firmly rivetted into the other coak on the opposite side, and the barrel being, at the same time, shortened by the rivetting, the fides of the coak are drawn into their cavities with such force as never to be in danger of getting loose. Some kinds of sheaves are found to do as well by merely rivetting down the end of the barrel without using any pins; these were first applied to prevent the possibility of any coaks getting loose; but having been found, in some years' practice, to be a needless precaution, it is accordingly discontinued, except in some particular instances.

Broaching Engine.—The sheaves, after being coaked and rivetted, are broached, to make the interior surface of the centre hole perfectly smooth and cylindrical. For this purpose, the sheave is fixed on a flat chuck, at the upper end of a vertical spindle, which turns round, and the broach or borer is forced down perpendicularly through the centre hole of the coak, while the sheave is turning round, boring out the hole as it descends to a true cylinder. The manner of fixing the sheave to the chuck in an expeditious manner, and getting it concentric with the axis, is very well contrived. The vertical spindle is hollow for a considerable depth
MACHINERY.

depth down it, and the borer is a cylindrical rod which
exactly fits into this hole in the end of the spindle, and also
fits pretty truly into the centre hole of the coak, in the flate
it comes from the rivetting hammer. This cylindrical rod
has a small tooth of steel fixed into it, and projecting a small
distance from the circumference of the cylindrical rod,
which, as before flated, is of the same size as the hole
through the coak of the sheave, and its tooth projects as
much as the hole is intended to be enlarged in the operation
of broaching.

In fixing on the sheaves, the machine being at rest, the
bend is drawn up (by the screw movement which is used
to force it down into the sheave), so as to be clear out
of the end of the spindle; the sheave is then laid upon the
flat chuck, at the top end of the spindle, which is much
larger than the sheave itself: the cylindrical borer is next
put down through the centre of the sheave, and entered into
the hole in the end of the spindle. By this means the sheave
is placed on the chuck, exactly in the centre of it, and both
being flat, it only requires to be screwed or clamped fast
against the chuck, so as to be turned round at the same time
with it. This is done by a clamp, confining of an iron ring
of a smaller diameter than the sheave, having two short bars
projecting from the opposite sides of it. These bars extend
across the face of the chuck, to which one of them is con-
ected by a joint or hinge, and the other by a screw: or, in
other words, the clamp may be considered as one bar, having
a large hole through the middle of it, one end being hinged
to the chuck, and the other drawn towards it by a screw
similar to a vice screw: but is so constructed as to be quickly
unhooked, and then the clamp bar may be lifted up upon
its joint, in the manner of a book lid, to place the sheave
under it. The ring or hole through the centre of the clamp,
when screwed down upon the chuck, is concentric with the
spindle, and thus leaves the centre of the sheave free and
clear for the operation of the borer. The sheave is thus, by
means of this clamp, fastened down upon the face of the
chuck in a moment, and the workman sets the machine in
motion. He now, by turning a handle, gives motion to a
wheel over head, in the centre of which is a nut, through
which the screw in a line with the borer is fitted to work;
and this screw as well as the borer being prevented from
turning round by appropriate fitting at the end of it, is
caused to descend, and force the borer down till its cutting
tooth meets the bell-metal coak, and cuts its way through,
ensuring the hole to its intended dimensions, and making it
truly cylindrical to fit the pin on which it will turn when
in the block. It is to be observed, that the interior surface
of the hole has two spiral grooves or cavities within its,
which are formed in the casting, as before described. These
are too deep to be taken out in the broaching, and form
receptacles for greafe, which is thus always kept supplied
to the centre pin, both to diminish friction and avoid wear
of the parts. This is a great improvement in the blocks,
as, without such receptacles, the pin, if well fitted into its
centre hole, as it is and should be, would afford no room for
grease, and then the block would require constant attention
to keep it supplied, or would always be in want of it.
The two spiral cavities do not come to the ends of the hole
in the coak, which is therefore a complete circle. By this
means, when the pin is in its place, the cavities have no ex-
ternal communication at which the greafe can escape.

The Face-turning Lathe.—The sheaves in this lathe are
turned to make the two faces perfectly smooth, and the
circumference truly circular, as well as to form the groove
or hollow round the edge of it, to receive the rope. The
turning is performed in a very complete lathe adapted for

Vol. XXII.
screw, L, is turned by its handle P, to bring the point of the tool opposite the centre of the sheave; the screw of the lower ladder is now turned by its handle M, to advance the point of the tool, to touch the face of the pulley, as it revolves, and then the screw, P, is put in motion by this means. The pulley, O, is, as before stated, in constant motion, but slips upon the end of the screw. Thus, at a short distance from the pulley, it is formed into a square, and has a clutch or short lever fitted upon it, such as is shown at Y, fig. 3. This has a center-piece or socket, having a groove formed round it for the reception of pins attached to a forked lever Y, fig. 5, in the manner shown at Z. This admits the clutch to turn round freely within the fork, but is obliged to move an end upon the spindle, to draw it away from the pulley O; and in this state the pulley slips round: but when the lever is moved to thrust the clutch towards the pulley, a pin projecting from it intercepts the arm or lever of the clutch, and turns the screw round with it. In this state the ladder, N, traverses slowly along, and the point of the tool, z, advances from the centre of the sheave to the circumference, turning the face of it all the way perfectly smooth and true; to prevent the screw forcing the ladder, N, too far, and injuring or breaking it, a rod, 5, is provided, which is jointed to the end of the lever y, and is received through the eye, 6, through which the ladder N passes. When the ladder has arrived at the circumference of the sheave, the eye, 6, has intercepted a nut, p, at the end of the rod, and drawing it, removes the lever y, and by this means disengages the screw from the connection with the pulley Q, and thus prevents the danger of breaking the screw: for as soon as the ladder arrives at the end of its motion, the screw is disengaged, and its motion ceases.

The groove round the edge of the pulley is turned, at the same time the tool is turning the face of the sheave, by a gauge which the workman holds over the edge or reef, marked 6', which is fixed opposite the edge of the sheave, in the manner represented in fig. 7, though it is omitted in the other figures. This part of the turning is performed in the usual manner of turning by hand; and the workman has plenty of time to do it, whilst the machine is turning the face of the sheave, which it does without any attention on the part of the workman, except at the first letting out, when he has a little trifle to perform: this is, as soon as the tool has advanced across the face of the metal coal, (and therefore finished the cutting of it,) to double the velocity of the revolving tool, for it is found by experience, that the process of turning will be performed to the greatest advantage, when the work revolves with a certain velocity for brass or bell-metal; but in turning wood, it is proper to move nearly twice as quick, being a softer substance, and not liable to heat and soften the edge of the tool, as metal would, if turned with the same velocity. The change of speed in the machine before us, is effected by the wheel which gives motion to the flaps, turning the spindle of the lathe: it has another wheel situated close to it, upon the same spindle, but revolving with twice the velocity of the other. They are so near each other, in the same manner as the live and dead pulley upon the spindle A, that the flap can readily be shifted from one to the other while they are at work. Thus, when the machine is first set in motion, and as long as the tool continues turning the bell-metal, the flap is upon the flow pulley; but as soon as the workman sees the tool is beginning to cut the wood, he shifts the flap upon the quick pulley, by which its velocity, and consequently that of the lathe, is immediately doubled, and continues so until the sheave is finished turning; and then the workman returns it back again to the flow pulley, and immediately after shifts the flap to the idle pulley upon the spindle A, which flips round upon it, and the motion ceases. The ladder, I, is not fixed to the frame. D D, in a direction perfectly parallel to the spindle, and therefore the flap, N, is not exactly perpendicular to it, by which means it gives a convex surface to the sheave; and when it is fitted into its block, it will be certain to touch it only in the centre, and thus avoid all unnecessary friction. The chuck G, as shown by its fiction in fig. 3, is turned hollow, and the sheave only applies to a prominent edge at the circumference of it, by which means it will receive the convex surface, when the second side is to be turned, as readily as it did the flat surface, when the first side was turned. The angle of inclination of the ladder is very trifling, because the sheave is not required to be very convex; and this convexity will be double the angle the ladder, I, makes with the spindle, or, what is the same thing, the difference of the other ladder from the perpendicular to the spindle. The screws which fasten the ladder, I, down upon the main frame D, are adjustable to increase or diminish the convexity at pleasure.

The turning duffle, which this machine makes, is winnowed in a machine, similar to that used in corn-mills, to separate the wood-chips from the metal-turnings, which are returned to the foundery to be re-melted, and used in casting other coaks.

This machine completes the suit for making the sheaves. All the machines we have described display great ingenuity, and much originality of thought, particularly the expanding chuck for holding the sheaves in the coaking and turning machines. Among all the multitude of ingenious tools, used by turners for chucking or fixing their various works in the lathe, nothing was completely adapted to the circumstances of the present case: for as the coak is to be turned to the very centre, and the sheave all across the face, and also upon its circumference at the same time, so that nothing else than holding it by the inside of the centre hole would succeed. It is a valuable tool for many other similar uses.

The converting machine, or circular fawing machine, is extremely well adapted to its purpose; and the contrivance of turning the log round, while it is fawing, is most excellent, as it enforces a perfect flat surface, and parallel to the former cut; conditions which would be extremely difficult to fulfill in any other manner. Indeed the great reciprocating faw is not found to be at all equal to it, and is given up to other uses, except for such large trees as the circular faws cannot cut through: it would have been unwieldy to have made so large a machine on the construction we have described for the circular faw, many of the trees being eighteen inches and more in diameter. The whole feries are calculated for operating upon large or small work; and this is one of the greatest merits of the machines. More than 100 sizes of sheaves are made by them, of all diameters and all thicknesses. It will be proper for us to review all the suite, and point out the means by which they are adapted to the different sizes. In the first converting or fawing machine, the number of teeth of the ratchet wheel on the screw, which the workman paffes every time, regulates the thickness of the sheave, and this very accurately; for the screw is cut with a coarse or rapid thread, and the ratchet wheel having several teeth, it gives the means, by counting one tooth more or less, to cut them with the greatest precision to any thickness required.

In the rounding and futtering machine, the chuck of the tromban faw is fixed to the spindle, in the same manner as a lathe chuck, and can readily be removed, and another of any size substituted, for the different sizes of sheaves: the drill in the central axis also screws into it, and a great va-
riety of all sizes are provided. The whole of this machine is very ingenious and expeditious in its operation.

The coaking machine is universal, and will cut any size, as we have before described. The coaks are cast from a great variety of patterns, suited to the various sizes.

The riveting hammer, having no parts which are attached to the sheave, will of course apply to any thicknesses indifferently.

The broadening engine holds any sized sheave, and the clamp which fastens them to the chuck adjusts to different thicknesses: the borer or broach is easily changed for any size; it is, as before flated, a cylindrical rod of the size to fit the centre of the rough coak, and its cutter projects enough from it to clear the hole out.

The facing lathe is provided with a variety of expanding chucks, like the coaking machine, and adapted to all sizes. They are put on by merely removing the conical screw in the centre of the chuck, and putting in another ring around it; the lower slider accommodates for various thicknesses of sheaves, and the common turning rell, fig. 7, for the different diameters.

This operation finishes the sheaves, which are now ready to be fitted into their shells or blocks, the manner of forming which we have yet to explain; but we shall first notice the machines for making the iron pins, situated in a small room up stairs. These are of two kinds: first for turning, and others for polishing or burnishing them afterwards. The pins are forged between swages, by two workmen, in the usual manner of such articles, and are cylindrical, except a small part at one end, which is left square, to be inferted into the cheeks of the block, that the pin may not turn round when it is put together, by the friction of the sheave upon its pin.

Pin-turning Lathes.—The lathes for turning the iron pins are the best finshed machines of the whole suite, being the last which are made, and by no means the least important in their use, as they turn the largest iron pins, perfectly cylindrical, from end to end in a very short time, and without attendance, except at first; an operation which is very tedious and laborious, when performed, in the usual manner, by hand. We shall be able to give a tolerable idea of this machine without drawing on purpose, it being compounded of the parts of many machines we have described in our different plates. The reader must suppose a lathe with a triangular bar, in its form similar to that described in our article Lathe, but its rell removed from the bar. This is to be fixed over a strong square iron frame, but the puppets of the lathe not vertical; that is, a perpendicular line let fall from the central line of the mandril, will fall clear before the triangular bar, one side of which is upright. This is necessary, because water is used to drop upon the turning tool; and if it fell upon the bar, it would cause it to rust and spoil the fittings. The square iron frame, over which this lathe is fixed, has on one of its sides a long sliding rell, which is in its properties similar to that belonging to the face-turning lathe, except that its long slider is parallel to the direction of the mandril; the tool being supported by a smaller slider perpendicular to this, and moving along upon the long slider by a long screw, which can occasionally be turned by a motion from the mandril, or may be turned by a handle. The tool itself is a cylinder of steel, cut off obliquely, so as to present an elliptic face, the small end of which is the cutting edge; it is held in a holder at the end of the small slider, of similar form to that used for the flaping engine, as will be particularly described hereafter. The lower or long slider, which, as before mentioned, is parallel to, and as long as the lathe, consists of a rectangular frame (or it may be considered as a large flat bar, with an opening or mortise through its upper side, and extending its whole length, giving it the appearance of a frame), and in this the ferev is fitted.

On the upper surface of the frame two rulers are secreted at the sides, forming between them a dove-tailed groove reaching the whole length of the frame, and in this groove a small flat plate is fitted, and travelles, by the action of the long screw, from one end of the lathe to the other. The flat sliding plate has a cap-piece or socket screwed down upon it, forming between them a socket for the reception of a short triangular bar or prism, which is the upper slider carrying the tool, and travelles through this socket in a direction perpendicular to the former slider; it therefore advances or recedes directly to and from the pin which is turning in the lathe. The end of the triangular slider has a socket or holder in it, which holds the tool in an inclining position, a little removed from the vertical, in the manner of the flaping engine: the slider has a screw behind it to force it forwards towards the work: the flat plate, which moves in the groove of the lower slider, has an iron arm proceeding from it, which turns upward behind the pin in the lathe, and has a little table on the top of it, to support a small vessel of water, which supplies a small stream to drop upon the turning tool. The screw of the long slider has a small wheel fixed on the end of it, which is turned by an endless screw formed on the end of a small spindle, perpendicular to the direction of the lathe, and is turned by a band, which receives its motion from pullies on the mandril of the lathe.

The pivot of the spindle of this endless screw is fixed in a piece of metal which moves on a centre, to allow the screw to fall down clear of the teeth of the wheel; but when the screw is engaged with the wheel, the piece supporting its pivot is kept up by a catch, which is provided with a rod, in the same manner as the facing lathe; this dengages the catch, and conseqently, by letting fall the endless screw, dengages the motion of the long screw, when it has turned the length of the intended pin, so as to avoid the danger of injuring the machine. The pin is, as before flated, forged with a square part at one end; this square end is received into a chuck screwed to the end of the mandril, the form of which is an hollow square prism; but two of its opposite angles are cut clear away, so that it catches the pin by only two of the angles of its square, and by being forced deeper into the prism, it is sure to fit and hold it correctly by these two angles, and with less danger of altering its position, than if there were four angles to the chuck, being certain of a correct bearing. The pin is prepared for turning by a small hole being punched in the cylindric end of it, a simple tool being used to enure the punch being felt truly in the centre of the end of the pin. The operation of this turning lathe is thus: supposing the motion cast off, and the wheel-work of the long screw dengaged, the tool is moved by turning this screw with its handle to stand that at end of the long slider which is farthest removed from the mandril. The pin is now put in, by inferting its square end into the chuck, and screwing the back centre into the hole punchet in the other end of the pin, which being thus mounted, the lathe is put in motion, and the tool advanced, by the screw of the upper slider, towards the pin, until its edge meets it, and cutting it as it turns round to a true circle just at the end. Being thus set in, the wheel at the end of the screw of the long slider is, as before described, engaged with the wheel-work which gives it motion, and this travelles the tool from one end of the slider to the other, cutting a thick flaving off the pin, and turning it cylindric in its whole length; the small vessel of water before
MACHINERY.

before mentioned being attached to the socket for the slider carrying the tool, therefore moves along with it all the way. This cock is set to drop a small stream of cold water on the tool to keep it cool; but the water falls together with the shavings, clear down through the iron frame, and is caught in a cistern below. The motion of the tool, when it arrives at the intended length of the pin, calls itself off, as before stated, so as to be in no danger of breaking the slider or screw. Three of these machines are in constant use for different fixed pins. After being turned, the pins are truly cylindrical and straight, but have spiral lines or frets traced upon them, in consequence of the edge of the tool not being always perfectly keen. To remove these, and make them perfect, the pins are burnished in

The Polishing Machine.—This consists of three fixed dies fixed in a box, and regulated by strong screws to form a triangular opening of any required dimensions. The pin being drawn through these dies, and turned round at the same time, receives a most violent pressure and friction, which burnishes and polishes the whole of its surface in the most perfect manner imaginable. The dies are of course immerged in oil, to avoid the heating of the pin or dies from the friction. This is the general construction of the machine: the pin is hardened, by means of a strong hand vice, to the lower end of a long screw, with which it forms a right line: this screw and pin are placed in a vertical position exactly over the dies, and the screw is enclosed in a nut or female screw, which is made in two halves, and fits up in the manner of a pair of tongs round the screw, so that they can be opened, and then the screw can be raised or lowered at pleasure, it being properly balanced and suspended by tackle, which gives the means of lifting it with ease. Exactly beneath the screw the dies are fixed, being fitted into an iron frame or box containing the three, each fitted into a proper groove, and adjustable by a screw behind it, to form a triangle of such dimensions as the pin will exactly fill. The interior surfaces of these dies are highly polished, and as hard as steel can be made. The box or frame for the dies is contained in a pan which is filled with oil, and has a vertical tube beneath it, to admit the pin to descend into as it passes through the dies. To prevent this tube and pan overflowing by the immersión of a large pin, a copper pipe proceeds from the vertical tube, and communicates with a large pan, fixed at a little distance behind the dies, and on the same level with the pan which surrounds them. By means of this communication, the united surfaces of the two pans are so large, as not to be materially raised by the immersión of a pin.

In the operation of this machine, suppose the screw at the top of its movement, the pin is hardened to it by the vice at the lower end, biting the square end of the pin. One of the slider's of the dies is now screwed back, and this opens or enlarges the triangle between them, that the pin may pass clear through it without forcing. The nut at the top of the screw is now opened, and the pin let down till its square end comes to the dies: the ferrule of the die is now screwed up hard to bite the pin, and the nut is closed round upon the screw. The machine is now put in motion, and the ferrule being turned by it turns the pin round, and at the same time draws it up through the dies, which burthsh the surface in the most perfect manner; and when they come out, have as high a polish as it is possible for iron to bear, and the surface receives a kind of acahardening, which enables them to stand wear in a most effectual manner. It is found to facilitate the process of polishing, to rub the pin over with soap before it is put in, as this prevents any danger of the pin having flakes in it which are not perfectly polished, owing to some properties in that part of the iron which cause the dies to abrade or rub up the surface of the iron rather than burthsh it down to a polish; but the use of a light quantity of soap is found to render the process certain.

Machines for making the Shells of the Blocks.—We have now to notice those machines which are devoted to the fabrication of the shells for the blocks: they are, as before stated, contained in the central building of the mill, in the roof of which is the shaft that drums upon it, giving motion to the whole, with very convenient contrivances for detaching any movement at pleasure. This suite of machines, perhaps, displays the greatest ingenuity, or at least the greatest novelty, of any in the whole work; several of the operations, particularly the mortising and shaping, being new principles of working with machinery, and are valuable inventions, being applicable to many useful purposes, when wood is to be formed into small articles, of which a great number are required of the same kind. The first operation to which the blocks of wood intended to form the different shells are subjected to, is boring in the

Boring Machine.—The pieces of elm to form the different blocks being prepared, and converted to the proper dimension by the fawing machines first described, have two holes perforated through each in different directions; one through the centre of each, which is intended to receive a centre pin from the sheave, and as many others as the block is intended to have sheaves in a direction perpendicular to the former, being intended as the commencement of the several mortices which are to contain the sheaves. 

Figs. 1 and 2 of Plate IV. are elevations of this machine, fig. 3 an end screw of one spindle, fig. 4 is a detached view of some part, and fig. 5 is a plan of the whole machine, the fame letters of reference being every where used. A, B, represent two spindle tubes, with respect to the machinery, and are valuable inventions, being applicable to many useful purposes, both are provided with borers C, D, formed to edges in the manner of a carpenter's centre bit. The block marked X is held in an iron frame, E L L, by the end of a screw, F, being forced down upon the top of it, and the borers are presented to it by the action of two levers g G k and b H i, which move on centre pins fixed in the frame of the machine at g and b (but at different heights from the frame, as is shown in fig. 6.) These levers act upon pins fixed in the frames of the two spindles, which frames are fitted upon dovetailed slides I and K, so that they advance towards the block when the workman moves the handles, i, k, at the ends of the levers in that direction; and the borers, being in rapid motion by their pullies, penetrate the wood very quickly. The proper situation for fixing the block, that the borers may enter at the proper points, is determined in this manner: the frame E L, as the plan shews, consists of three legs rising from the main frame, and uniting together to support the socket in which the ferrule, F, acts. Two of these legs unite together before they reach the socket. (See figs. 2 and I. L, figs. 1 and 5.) In this double leg, three small screws, e, f, g, are inserted, their heads forming a support, against which one side of the block is firmly held, before the screw, F, is screwed down upon it, and holds it fast upon the face of a screw K, which is the support of the block. But these three screws only determine the position with respect to the bore D; and that it shall pierce it perpendicularly to the side of the block, the bore, C, is caulked to penetrate the centre of the block by a gauge, formed out of a piece of iron, shown separate in fig. 4. It has a groove in it, through which the screw, K, passes to fix it down to the
the frame, and a blade, \( R \), standing up perpendicular, just beneath the borer \( D \), fig. 1, as shewn there at \( R \). One side of the block being profiled in contact with this blade, while the other side is held against the heads of the three screws, determines its situation, so that the borers will form the holes in the exact points required, and which being adjusted by experiments for one block, will bore any number of the same size in the same places. The adjustment for blocks of different thicknesses is made by the three screws, \( d, e, f \), being screwed to project more or less from the frame, that when the side of the block is applied to their heads, the borer, \( D \), will perforate the block in the middle of its width, and perpendicular thereto.—In the frame manner, by the gauge, \( R \), being fixed a greater distance from the screw \( R \), the borer, \( C \), may be adjusted to bore exactly through the centre of the side it is presented to. The lengths of different sized blocks is accounted for by putting collars of different thicknesses beneath the head of the screw \( K \), which raises the support for the block to the proper height. The slider, \( I \), on which the frame of the spindle, \( A \), moves, is firmly fixed down upon the frame of the machine, but the slider, \( K \), for the other spindle is formed on the top of a frame \( S S \), which has a motion on an axis formed by the points of two screws, \( T, T \), passing through studs projecting from the frame. This frame, and the slider it supports, can be rendered immovable at pleasure, by the points of two flot-screws \( m \) and \( n \), which may be also let to allow it any required height of motion. In the former case, when the frame is fixed stationery, as we have considered it in what we have before stated, the machine is adapted for boring single sheaved blocks, the borer, \( D \), perforating the block in the centre. When double blocks are to be bored, the points of the blog-screws \( m \) and \( n \) are let at a proper distance smaller, and the frame, being held frist to one of them, bores a hole for one sheave, and being then turned over to the opposite blog-screw, formed a second hole at a proper distance from the first.

The difference of height between the two borers is rather more than the semidiameter of the sheave, because one is level with the centre, and the other, \( D \), is by the end of the mortise, to adjust this difference for the different diameters of blocks; the frame, \( S S \), has several holes in its sides, at small distances apart, to receive the points of the screws \( T, T \), and the frame, being pitched on any of these different centres, will raise or depress the point of the borer, \( D \), to the proper height for the different sized block. The screw, \( F \), has a lever \( N \), fixed upon the top of it, and loaded at the ends with two weights, in the manner of the fly-prest, and the block being, as before-mentioned, held in its true position, the screw is forced fristly down upon it, and by the momentum of the balls prests very powerfully upon the wood. The screw is provided with a fixed ring, fitted upon its point, which has a sharp edge beneath, and this penetrates the end of the block, deeply marking a ring round in it, which is exactly in the centre of the end, and is used to fix the block in a proper position in some of the succeeding machines. The blocks, being thus bored, are subjected to the action of

*The Mortising Machine*, which cuts out the mortises for the reception of the sheaves. It is delineated in Plate V. where fig. 4 is an elevation in front, and fig. 5 a vertical section of the lower parts taken parallel to the former; fig. 1 a horizontal plan, as is also fig. 4 at a different level; fig. 3 is an elevation of the whole machine. The machine works as many chisels as the block is to have sheaves; these, as shewn at \( A \), figs. 2 and 3, are attached to a frame \( B \), a \( B \), which rides and falls with great velocity, forcing the chisels through the block \( X \), fixed in a carriage \( C D \), which advances after every cut the chisels have made, the thickens of the chip, it is intended to cut out of the end of the mortise at the next stroke. But this advancing movement of the carriage cesases as soon as the mortise is enlarged to its proper length. The reciprocating motion of the frame for the chisel is occasioned by a crank \( d \), on the end of the main axis \( E \), which is supported in bearings at each end, one in a cross-bar, \( F \), of the frame, and the other in a standard \( G \), which is erected from the cast iron ground fill, which is the foundation of this whole machine. The axis has a rapid rotary motion communicated to it by an endless strap, encompassing the pulley \( H \), and the velocity of the motion is regulated by the fly-wheel \( I \). The crank, \( d \), has a piece or connecting rod, \( K \), jointed to it, and connected by a joint at the upper end with the sliding frame \( B \), which is formed to a triangle at top, and has a cylindrical rod, \( l \), rising from its vertex, and accurately fitted into a socket, supported by framing, erected on the top of the main columns which form the framing. The sides of the lower part of the frame, \( B a a \), are formed into dovetail sliders, and received into grooves in the edges of metal bars \( b, b, f g, 3 \), attached by screws to the vertical pillars of the frame. By means of this frame slides freely up and down, without being capable of any deviation from the perpendicular, and the chisel, being firmly fixed to it, moves in the same manner when they descend into the mortise. The frame has two bars, \( e, e \), across it, against which the chisels, \( A, A \), are held, by means of a clamp provided to each, which is below the bars, and its two ends, \( z, z \), come over them in front, with holes to receive the chisels and screws to tighten them. By means of these screws, the chisels are pressed forcibly against the bars, and attached to the frame, but in such a manner that they can be fixed at any distance afother, or any number may be put on at pleasure, by their respective clamps, to mortise either single, double, or threefold blocks. The carriage \( C D \), in which the blocks are fixed, is an iron frame, sliding on proper bearing in the main frame, and the advancing movement is communicated to it by means of a screw \( L \), fitted through a nut in the centre of the ratchet wheel \( M \), which turns round in a socket, formed in a cross bar, \( N \), of the framing; thus, when the wheel is turned round, it operates upon the screw to advance it, with the carriage and block at the same time; the ratchet wheel is turned round at intervals, by means of a tooth, formed in a rod \( e \), fig. 5, attached by a joint to the end of a bent lever \( O \), which receives its motion by the other end of the lever, having a roller \( g \), which applies itself to the circumference of an escracter circle or cam, \( h \), fixed on the main axis \( E \). By this means, at every revolution of the main axis, the rod, \( e \), moves backwards and forwards, and in the period when the chisels are nearly at the height of their ascent, the tooth of the pull or rod, \( e \), turns the ratchet wheel one tooth, and by the screw, \( L \), advances the carriage and block the thickness of the chip, the chisels are intended to cut from the end of the mortise, at the succeeding stroke. The ratchet wheel, \( M \), has a cog-wheel, \( P \), fixed to it, which has its teeth engaged by a smaller cog-wheel \( Q \), fixed on a long spindle \( R \), extending to the front of the machine, and has a handle \( n \), fixed upon it, by means of which the workman can, at any time, turn the wheel round so as to bring the carriage to the proper point for the commencement of the mortise. The motion of the screw is caused off at the proper time by this means; the rod is supported at its extremity, by resting upon the extremity of a lever \( n \), the opposite end of which is moveable on a centre pin fixed in the column of the frame. This lever is supported by a second lever \( i \), moving on a centre in a small standard erected

for
MACHINERY.

for it. The opposite end, $o$, of this lever is loaded with a heavy end, that will overbalance the lever, $n$, and rod $e$, and lift them up, so that the tooth of $r$ passes clear over the teeth of the ratchet wheel, without interfering with them, and in this state the carriage $i$ is at rest. The end, $o$, of the lever $o$, on which the machine is mortising, is supported upon a rule of iron $p$, fig. 3, which is fastened by screws to the side of the carriage $c$ and $d$. This Fuller the rod, $e$, to descend to low, that its tooth turns the wheel round at every revolution, and advances the carriage; but when it has proceeded the length of the intended mortise, the fuller gets beyond the heavy end of the lever $n$, which drops down and relieves the screw from any farther motion, so that there is no danger of cutting the mortise longer than is proper.

A very ingenious part of this machine is the contrivance for giving it motion or lifting it at pleasure. The fly-wheel $l$, and also the pulley, $h$, for the stirrup, are fitted upon a round part of the main axis $e$, so as to slip round freely thereon, when the machine is to be at rest. When it is to be worked, the pulley and its axis are united by a wheel $r$, fig. 1, fitted on the axis by means of fillets, so that it is confined to turn round with the axis, but has liberty of sliding along it.

The latter motion is given to it by a lever, $v$, extending across the frame, to which it is connected at one end by the centre pin, and in the middle it has an aperture large enough to receive the centre piece of the wheel $r$, in which a groove is turned to admit the points of two screws, $t$, which operate in the sides of the groove, confine the wheel endways upon its axis; but the wheel turns round without interference with the lever. The wheel, $r$, is formed conical upon its edges, and can be by the lever, &c. jambed to fit in a similar cone formed within the pulley $h$. In this state, the friction of the two conical surfaces is sufficient to turn the machine; but when the wheel, $r$, is drawn back on the axis, so that its conical edge is disengaged from the conical cavity formed within the pulley $h$, the fly-wheel slips upon the axis at the same time the cone on the back of the wheel, $r$, is jambed into an iron ring, $w$, firmly fixed to the frame. It is formed conical within, in the same manner as the inside of the pulley $h$, and when the wheel is jambed into it, fixes the axis motionless. This is a very proper provision, as the friction of the fly-wheel running so quickly upon its axis, when it is call off, might be sufficient to move the machine slowly, and the momentum it acquires would, in addition to this, keep it in motion for some time; but the conical wheel being jambed in the fixed ring, $w$, as soon as it is withdrawn from the pulley, destroys the motion of the machine at once.

The chisels are provided with small teeth $r$, $n$, $f$, fig. 6, which are fitted into dovetailed notches formed in the blade of the chisel. These are called stiflers, as they have a sharp edge projecting a small distance beyond the inside edge of the chisel, and, therefore, in descending through the mortise, the stiflers cut the fissure of the mortise fair, and cut two clefs which separate the chip (which will be cut out at the next stroke) at its edges from the insides of the mortise, so that the chip comes out clear without splitting at the edges, and this makes the insides of the mortise as clean and smooth as possible. Each chisel has a piece of iron $l$, fig. 6, fixed on before the edge, by a screw which projects from the middle of it, and is screwed into the blade of the chisel: the upper end of the piece being received in a notch or groove formed in the chisel attaches it fast thereto. This piece, or nose, is for the purpose of clearing the chips out of the mortise as fast as the chisel cuts them; for, though, in general, when the stiflers are in proper order, the chips fall down through the block like pieces of palleboard, yet it may happen that they will stick in, and then without this noce-piece would clog up with the chips, so that the chisel could not be got down through them. The block is clefted into the carriage by means of a screw $r$, which has on the point of it a ring of the same diameter, as that on the screw of the boring machine, and is inserted into the impregnation made in the end of the block by that ring. There are three of these screws, for the purpose of holding one or more blocks at the same time. The centre screw is used for fixing one double or threefold block; or, the two other screws are used, when two single blocks are to be fixed in at the same time. The centre screw is then useless. By means of these, the true position of one end of every block is determined, so that it will fall exactly beneath the chisels $a$. The other end of the block is gauged into its place by floats: these are attached to a cross-bar, placed across the carriage, its ends being received into notches made in the sides, and these notches afford the means of fixing the bar at any place correspondent to the length of the block which is to be mortised. AGAINST this cross-bar, the ends of the blocks are pressed by means of the screws $r$, and opposite to each is a sharp-edged steel ring to penetrate and hold fast the block: but to prevent it from turning round, on these two rings is a centre piece, and the cross-bar has two smaller rings inscribed within it, which allow it to move the wood, and thus fallen the block in the firmest manner. This is shown at fig. 5. The gauges before-mentioned, for guiding the block to its true situation, are formed on a piece of iron $z$, which has two arms, $j$, $j$, projecting from it. These have other arms rising from them at the ends in a vertical position, and against these one side of each block is applied to make it vertical. A small piece of iron $q$, which is fitted upon two vertical pins $y$, $y$, and can slide up and down upon them, and fall at any elevation by means of two clamp screws, forms the gauge for the height of the block, and is by these screws adjustable for blocks of different breadths. The two arms, $j$, of the piece $z$, are formed at the same distance farther and nearer the centre than the others, and these are the ones fixed by the screw $r$, in the front of the carriage, so that when one is set in the position for a block to be held by one screw, the other block will be at the proper place for the other screw. The adjustment for the different breadths of the blocks, is made by sliding the whole of the pieces, $z$, endways, for which purpose the screw which fastens it to the cross-bar $b$, passes through a groove in the piece which admits this adjustment, and gives means of fastening it at any place corresponding with the breadths of the blocks.

The operation of the mortising machine is as follows: the block brought from the boring machine has the point formed by the screw thereof applied to the end of one of the screws at $r$, in the carriage of the mortising machine, and by screwing it tight, the block is fixed between its point and the double circle points before mentioned on the cross-bar $b$, and the blocks situated on this bar guide the block to its proper position, which is, that the hole bored for the commencement of the sheave hole shall be vertical. The block being thus fixed, the handle, $t$, is turned till the hole is brought beneath the chisel $a$. The machine is now put in motion with the lever $v$, as before described, by jamming the wheel $n$ into the cone within the pulley $h$ of the fly-wheel. At the first descent of the chisels, they cut down through the whole depth of the holes previously bored, so as to cut a flat side to them. When they rise up, the eccentric, circle $b$, moving the bent lever and rod, $e$, moves the ratchet wheel $m$ round one tooth, and advances the block a very minute quantity forwards from the fly-wheel, so that the chisels, in descending, cut a fresh space, and, in ascending, the block advances; and in this manner it proceeds with astonishing rapidity through the whole length of the intended mortise.
The frame is fitted at the side of the carriage C D, and rises the levers r and s, so that the farther advance of the block is prevented. The attendant to the machine, as soon as he observes this, stops the motion by moving the lever V, and he takes care to do it at the instant when the chisels are at the highest point, which is effected by a dextrous movement, for the fixed cone, W, stops the machine instantaneously.

The finished block is now removed, and a fresh one put in the handle, s, turned back to return the carriage, and bring the block to the proper point, when the machine is started, and proceeds as before.

Three mortising engines of different dimensions are used at the mills, corresponding with the different sizes of blocks to be manufactured. The smallest and largest of these is what we have described in our Plate. The intermediate machine was made before the others, and with some difference in its construction, though none in its effect. The motion of the sliding frame for the chisels is communicated to it by means of a long working beam or lever, extending the whole length of the frame and fastened to it. At one end, it is united by a connecting rod with the chiselled frame; and at the other, it is fixed to an axis, which is supported by the framing, and which forms its centre of motion. A connecting rod is joined to it in the middle of the beam; and the lower end of this is worked by a crank, formed in the middle of the main axis, which is situated in a direction perpendicular to that which we have described, and is supported in the framing. It is provided with the cone for cutting off the movement. This machine operates equally well with the others, from which, indeed, it does not differ in any essential point. But the movement of the machine we have drawn, is that which is most complete, and less subject to violent strain in any part. The engine with the beam acts with surprising rapidity, as it makes upwards of 400 strokes per minute, at every one of which it cuts out a chip from each mortise as thick as a palteboard. Its movement is so extremely quick, that the chisels cannot be distinctly seen when it is at work, and the mortises are observed to lengthen, and chips fall out without any evident cause. The blocks, being thus mortised, have their angles fawn off, as a preparation to giving them their elliptical figures.

The Corner Saw.—This is a circular saw, shown at fig. 8 and 9 of Plate IV, where fig. 7 is a plan of the bench, fig. 8 a front elevation, and fig. 9 an end elevation. In these, A is a circular saw, fixed upon a spindle a, mounted in an iron frame B, like a lathe spindle, and turned by a band round the pulley C. The block is placed upon an inclined table D, which presents it to the saw, so as to remove a proper portion of the angle, and prepare it for the flatting engine, which forms the external surface of the block. The block lodges against the ledge, E, of the table, which guides it while it is fawn, by keeping it to the same distance from the saw. It is accommodated for blocks of different dimensions, by placing wooden rollers of proper thicknesses against the ledge E, to bring it near to the saw. In one of these machines, the ledge, E, is fitted with connecting bars in the style of a parallel ruler, so that it can be fixed at any distance from the saw, but always parallel thereto. The saw is fixed on a chuck, which is attached to the spindle for fawning, so that it can be quickly removed to sharpen the saw.

The Shaping Engine.—The shaping engine consists of a double wheel, called its chuck, in which ten blocks are fixed at once. These being turned rapidly round, a gouge is fixed so as to intercept them, and form their external surfaces to segments of the circles in which they all revolve. This is the general principle of the machine. Its particular configuration is explained by Plate VI, where fig. 1 is an elevation; fig. 2, an edge view; and fig. 3, a plan. The detached figure parts we shall soon explain. The separate figures at X and Y, in the corner of the plate, are introduced to explain the shape of the block when it is brought to this ingenious machine, and to shew the change made upon it. Fig. X is a front view, and Y an edge view of a double sheave block. The outlines shew the form of it when finished in the shaping engine, and the dotted lines its form before it is put into it. Thus the four angles are shewn as cut off in fig. X by the corner saw, preparatory to giving it the elliptical figure it is to have. The other view shews nothing cut off by the corner saw, the whole alteration being made by the shaping engine. This figure also shews the shape of the mortises.

The machine, as before-mentioned, contains ten blocks, which are all shaped at the same time, being fitted in a large wheel, or rather, between the circumference of two wheels A A and B B, having a common axis C C. The blocks are shewn at the letters E, E; and the plan, fig. 5, explains the manner in which they are held between the wheels by a screw, a, having a fixed ring fitted upon the point of it, which is exactly the fame in all respects as the ring on the point of the screw of the boring machine; and the ring of the screw a, being inserted into the impression made in the end of the block, secures one end; the other is retained by a ring, b, of the same dimensions, containing two others within it, which enter the impression made in the other end of the block by the double rings in the carriage of the mortising machine, to which they are exactly a counterpart. The double ring, b, is formed in the end of a short spindle, fitted in a socket through the rim of the great wheel A, exactly opposite the screw a, and has on the outside of the wheel a small toothed wheel d. The screw, a, being tightened up by a winch, the block becomes fastened in between the point of it and the spindle b, as it were in a lathe. The compound wheels A A, B B, or more properly the chuck, as we shall in future call it, being thus filled with blocks, has a rapid circular motion given to it by means of an endless rope encompasing the pulley, F, on the main axis. Now it is evident that a cutting tool, being presented to the blocks as they revolve, will form their exterior surfaces to segments of circles, of the size of that which they revolve in. This tool, which is a gouge, is held in a sliding reif, shewn separately in figs. 4 and 5, and is also seen in the other figures. It is fastened to a flat-ting slide G, accurately fitted into a groove, which is part of a frame H, that is attached to a long metal bar I K, curved to a segment of a circle; see fig. 1. At one end, K, it is fitted on a centre piece, fixed in a cross-bar of the frame, exactly beneath the centre of the axis of the chuck; the other end of this bar, which may be called the radius, rests upon a part of the framing L, which is curved to a circular arch, and on this the radius reifs, as it sweeps on its centre from one side to the other of the machine. The slider G, for the gouge g, is advanced towards its work by a lever M, having a handle m, figs. 3 and 4, at one end; and the other is fitted on a centre pin n, fixed in a projecting part of the frame of the groove H. To the middle of the lever a short connecting bar, b, is jointed, and communicates the power of the lever to the slider G, and consequently advances the gouge g, which is held in the end of it, towards its work; but the quantity of this advance is determined by a roller s, the axis of which is fitted in a socket attached to the slider G; it bears against a guide or pattern ruler N, which is supported on two pillars from the frame of the machine. The pattern ruler has such a degree
gree of curvature, as shown in the plan, that when the roller, $e$, of the flider, $G$, is kept in contact with it by a preflure
on the handle, $m$, towards the machine, and the whole flide
reft is swept along its curved reft $L$, the edge of the gouge,
$g$, will decribe that curve which the surface of the block
is intended to have, as shown by the dotted line at $E$. The
manner of action in this machine is easily gathered from
what we have said. The chuck being filled with blocks, as
before related, the sliding reft is moved quite to the end
of its flider $L$, and in this state the machine is put in
action. The workman now holds the handle, $m$, in one hand,
and the long handle, $K$, (which is attached by a joint to the
frame $H$,) by the other hand: with the former he preffes
towards the machine to keep the roller, $e$, in contact with
the ruler $N$, and by the latter he sweeps the gouge flowly
and feadily from one fide of the frame to the other. In
this circuit, the edge of the gouge removes the angles of all
the ten blocks at once, reducing them on the outside to the
figure of the dotted line $E$ in the plan, which, as before
explained, is determined by the curve of the pattern ruler.
This being done, the machine is flopped, and it is neceffary
to turn all the blocks round one quarter upon their re-
fpective axes to prefent another fide outwards, that it may
be shaped to its proper curve in its turn. This is accom-
plifhed in a very ingenious manner. Each of the small
pin-dles, $b$, has, as before flated, a small wheel, $d$, fixed upon
it, and to every one of these an endlefs fcrew is adapted.
The axes of all these fcrews marked $f_j$ tend to the centre
of the chuk, and each has a small bevelled cog-wheel
upon it; and all these are turned by one large bevelled
wheel $O$, which is fitted upon the main axis, but flips
round freely thereupon. It has a pin projecting from a
part of its circumference, which is detained by means of a
flop $Q$, fig. 1, jointed to the frame at the lower end,
and forked at top, to catch this pin when it is moved on its joint
fo as to approach the wheel; but when thrown back by a
fpring in its joint, into the position of the figure, it is out of
action. When the blocks are to be turned round one quar-
ter, this flop is prefled towards the wheel, and the pin, by
turning the chuck round, catches in the forked top of it, and
prevents the wheel from turning. The workman now, by
taking hold of the chuck, turns it round four times, as he
determines by obferving a mark made upon one part of the
run of the chuck coming oppofite to some part of the
frame, or by considering the four turns of the chuck, the
centre wheel, $O$, remaining ftationary, the blocks are, by means of their
endlefs fcrews $f_j$ turned round one-fourth of a circle, and
the next face of each block is turned outwards to be sub-
fected to the action of the gouge. But the fides, now
exposed, being thofe in which the mortifes are made, are of a
more rapid curvature, being of an elliptical figure, as shown
at $X$, in the corner of the plate, while the former was only
flightly rounded. To give this difference of curvature, a new
moulding ruler, $N$, is employed. This is fixed immedi-
ately beneath the other one, as shown by fig. 2, and the
roller, $e$, of the flider, $G$, is adapted to act upon either;
its axis being let down in its focket, and retained at the
proper level to work with either, by a clip or clip (not
shown in the figures,) which enters either of the two grooves
formed round in the spindle of the roller; and for the pur-
pofe of elevating or defoping the roller, its spindle has a
head, $8$, fixed on the top of it. The roller being now
shifted to the proper pattern ruler and all the blocks, the
turning of these fides is performed in the fame manner as
the fird, but, of confequece, giving it a different curvature
corresponding to the difference of the two moulding rulers.
The machine is now flopped, the blocks shifted to another
quarter, the guider roller, $e$, returned to its firft ruler, be-cause the machine is now to form those fides of the blocks
opposite to what were firft done, and therefore the fame
difference. The chuck being again fet in motion, the third fide
is turned. The movement is now flopped, the roller, $e$
shifted to the fame ruler as for the second fide, and the
blocks being turned round another quarter, the left fide is
shifted, and they are removed from the machine to make
way for another fide.

This ingenious machine is adapted to receive blocks of
different dimensions by the following means: the length of
the blocks are allowed for, by placing the wheels, $A$, $A$, $B$, $B$,
of the chuck at a greater or lefs distance afarnder upon their
axis $C$. This is done by the five fcrews, $T$, which unite
them. The wheel, $A$, is fixed fast to its axis, and the other
fides upon it, to regulate their altitude; the fcrews, $T$,
have nuts upon them, both within and without the wheel
$B$, fo that they hold it quite firmly at the intended distance
from the other. The next adjustment, dependent on the size
of the block, is that the edge of the gouge shall decribe
its curve at the proper distance from the centres of the fveral
blocks, to make them of the intended dimensions. This
would be adjusted by placing the pattern rulers, $N$, at a greater
or lefs distance from the blocks; or, what has the fame
effect, altering the distance between the centres of the roller,$e$, which applies to the rulers, and the edge of the gouge,$g$. For this purpose, the focket for the spindle of the roller is
fitted into a groove in the flider $G$, and is regulated by a
fcrew, $P$, at the end of the flider. The trial is made by
fetting the gouge oppofite the centre of the block, as in the
plan, and turning the fcrew $P$, until the edge of the gouge
very nearly touches the block in the centre, because it is in-
tended only to take off the corners of the block, little or
nothing being removed from the middle. This adjustment
is neceflarily made every time the gouge is removed from
the flider to sharpen. The gouge is fafened into the holder,
at the end of the flider $G$, by means of a fcrew, as shown in
fig. 5.

Three moulding rulers are fhewn in the figures, though
we have only explained the use of two. Double and fingle
fliue blocks of the fame lengths have both the fame curvature
on the edges in which the mortifes are, and therefore they may be shaped indifferently from the fame pattern
blocks, by considering them in the other direction, viz., that
in which the plan exhibits them, the gouge is required to
traverse its curve at nearly twice the distance from the centre
of a double block, to that required for the fingle fliue;
and this is effected by providing an additional pattern ruler
for the fingle blocks; therefore, in the machine as repre-
ented, one ruler is adapted for shaping the edges of either
fingle or double blocks, a second for the outsides of the
checks of double blocks, and a third for the checks of fingle
blocks: all the three rulers can be quickly removed from the
machine, and others of a different curvature substituted,
being only fixed by two fcrews to the pillars which rife
from the reft $L$; and a great variety of these patterns are
provided to fuit all kinds of blocks, of which an amazing
number of shapes are in use in the navy. As this shaping
engine is a machine which would be very easily applied to
other purpofes, it may not be ufelefs to defcribe the manner
of forming a pattern ruler to shape any curvta. It is
done experimentally by choosing fuch a block as is of a
proper figure, or forming one by hand to the intended cur-
vature; and fixing it in the chuck; then bifhtuting any
blank tool in place of the gouge, and fixing a sharp tracing
point on in the end of the centre pin of the roller $e$: a piece
of board is fixed in place of the pattern ruler. The tool is
now
now applied to the block fixed in the chuck; and being kept in contact with it, while the fiding reft is swept from one end to the other, the point in the centre of the roller traces a curve upon the board: the block is then to be removed, or turned out of the way. Now by placing the fiding reft successively at different parts of its sweep, and thurfing the rider, G, towards the machine by its lever M, the tracing point will defcribe ftraight lines upon the board, all tending to the centre of the machine, or rather to the centre, K, of the radial bar; and as many of these being made at short intervals as is thought proper, the board is removed. A pair of compasses being now opened to the exact radius of the roller, this distance is set off, from the traced curve upon every one of the radial lines, thus transferring the curve as much nearer to the centre as the femi-diameter of the roller. A curve is now drawn through these points, and the board being cut to it, will have the curve defired, and may be used as a pattern to call a metal rumer from, which being fixed in the fame points as the board was, will shape the blocks to the form of that which was employed as the pattern for it.

Three shaping engines are employed for blocks of different fizes: the largest, which was fift made, is that we have defcribed; the smaller one is very nearly like it; but the intermediate fize, like the mortifing machine, is of a fefs perfect conftruction, and fhoui the progress of invention: it holds but a small number of blocks, and these are turned round on their axles, one by one, by the workman. A circular plate, with four notches in its edge, which are caught by a click, is the gauge for setting them correctly to one-fourth of a turn each time they are shifted. Even this machine is a very excellent one for the purpofe, though greatly improved in the second and third, which were made by the introduction of the wheels and fcrews for letting all the blocks together, which is a molt ingenious contrivance.

The large machine has a contrivance, very familiar to the mortifing machine, for checking its motion as soon as the movement is call'd off; for otherwife the momentum of the chuck loaded with blocks would be confiderable. The machine in our plate is represented with a wheel, V, upon it, which is surrounded by a brake or grate: this is relieved from the wheel by a spring, when the machine is in motion; but when the workman prefles a lever (omitted in the drawing), it encompasses the wheel by its grate, and caufes a friction, which quickly fops the machine. The framing supports a number of iron bars, which enclofe the chuck as it were in a cage. This precaution is very neceffary to the security of the workman; for if the blocks fhould get loose, as has once happened, they would be thrown by the centripetal force with the velocity of bullets, and might do feroius injury. The accident alluded to was occafioned by one of the wheels of the chuck cracking in the rim, fo as to let loose the blocks, and they all flew out behind the machine, paffing through a window, into the steam-engine house, where they brack the governor or regulating halls of it, and broke them in pieces. It is fingular that, in paffing through the window, all the blocks followed each other through the fame pane of glafs with great violence.

Scoring Machine.—We now come to the lathe machine in the feries: this is the scoring machine, which forms the fcore round the block for the reception of the frap or rope, by which it isfpended in the rigging of the ship. The fcore is a groove, deep enough at the ends of the block to receive one-half of the rope or frap, but is diminished to nothing where it crosses the pin of the block. The machine is represented in Plate VII., where fig. 1 is a hori-

Vol. XXII.
MACHINERY.

a centre pin \( m \), which is exactly beneath the pattern \( L \), and also in the middle between the two blocks and cutters; on this as a centre, the upper plate, \( G \), turns round, and is detained by a spring catch \( n \), which is fixed to the lower plate, and falls into a notch made in a projecting part of the upper plate \( G \), when the two blocks are in their proper position. The first quarters of the scores of two blocks being cut as before described, the workman relieves the catches \( n \), and turns the plate, \( G \), half round on its centre, when the catch is returned to its position, by which the blocks are reversed, having exchanged situations, and their finished ends are outward; consequently, the other ends, where the screws, \( l, l \), are, are beneath the cutters; the handle \( I \) being, therefore, depressed as before, cuts the second quarter of the score, and in the same manner as the first, being in the proper way of the grain of the wood to cut smooth. This completes one half, and the blocks are taken out to be turned the other side upwards, to cut the scores in them by a repetition of the same process as we have described. The axis of the frame, \( E \), has a lever proceeding from it behind, which is loaded with a sufficient weight to counterpoise the weight of the frame and cutters, giving them a constant tendency to rise upwards, and thus keep out of the way when the handle is left to itself. The pattern \( L \), which determines the depth of the score, and therefore depends upon the curvature of the block, can be quickly removed from the machine, to make way for any other shape being fixed to the plate, \( G \), by only two screws. A great variety of these patterns is required, as well as for the shaping engine, and their curvature is determined by the same means as we have before described of that machine.

The operation of scoring is the last which is performed by machine upon the shills of the blocks, which are now completely formed, and only require to be rasped and filed to a smooth surface, which the machines will not always do, though they cut them perfectly correct to the intended forms; but the wood is not always so hard and perfect in its texture as to make them smooth, small pits being left in various parts, which require the aid of files and rasps to remove them; though, by a little labour of this kind, they are made as neat as can be wished. The machines will, when their cutters are in order, and the wood of good quality, cut as smooth as anything can be expected. Of this we are convinced by having seen the performance of a number of working models of these machines, which we hesitate not to say are the most perfect and elegant models that have ever been made of any kind of machinery; they are about four times the size of the drawings in our plates, and are all placed upon one large table, so as to exhibit the whole of the operations, as they succeed each other, at one view. A very elegant model of a steam-engine, made on Mr. Mundley’s pattern, actuated the whole. These models are deposited in the Admiralty house. Wellmister. They operate in a more precise manner than the large machines, their cutters being kept exceedingly keen, and the wood they work upon being of a harder and better kind. The blocks at Portsmouth are made of elm, which is a very proper wood for them, not being liable to split; the fheaves, as we have before-mentioned, are made of agnus vitae.

In the operation of drilling the blocks by hand, we must notice a plane, for making the insides of the mortises perfectly smooth and flat; for though the mortising engine will, when in very good order, cut as correctly as possible; yet it is advisable to place the insides, to be certain that they are not rough, for that would occasion a great friction at the sides of the fheave. The plane is of the same form as a carpenter’s, but is made of brass and very thin, that it may enter the mortise. It is fixed projecting horizontally from the edge of a work-bench, and the workman, taking the block by its end, infrets the end of the plane into the mortise, and thrusts it forwards. The plane cuts a shaving from the inside of the mortise, in a direction across the grain, and thus at two or three strokes finisheth them, and they are ready for putting together, which completes the blocks. As connected with this subject we shall describe the

Machine for making dead Eyes.—This is a very ingenious and complete machine, and it forms the whole of the article at once. The pieces of wood being fixed to the fize, have the holes bored through them in the boring machine, for the reception of the ropes which is to be received through them. Two of these holes are equidistant from the centre of the block of wood; and by means of these two holes, it is fixed in the machine, which shapes and scores it at twice fixing. This is represented in Plate VII, where fig. 6 is a plan of the whole machine, and fig. 7 an elevation in front. The frame or bench sustaining it, is omitted, only the working parts being shown. It is a lathe, to which proper mechanism is added. A B is its spindle, supported between the standards Y, Z, and C the pulley for turning it by a hand D. Fig. 6 is a chuck, screwed to the end of the spindle: this chuck has a double screw, \( a, b \), in it; that is, a right and left handed screw, which operates upon two fiders, carrying two round pins, \( x, x \), which project from the face of the chuck: one of these fingers is moved by the right hand part of the fiver, which is the end \( a \); and the other by the left hand part, which is the end \( b \); and the fiver being removed by a collar, the centre of the two pins, \( x, x \), with their fingers, mutually advance or recede, when the screw, \( a, b \), is turned with a wrench applied to the square ends \( a \) or \( b \), fig. 6. By means of these pins, the block, \( f \), is readily fixed to the chuck D. The screw, \( a, b \), is turned till the pins, \( x, x \), are at the same distance and the two holes in the block \( f \), which is then hung on the pins, and the screw being turned, forces the two pins farther from the centre, and thus falls on firmly to the chuck; and as the pins are always equally distant from the centre, they chuck it always truly. The turning tool, which is a gauge, is applied by a sliding tool, and apparatus of the same kind as that of the shaping engine. E is the circular iron bell on which the tool sweeps, and is supported to bear the preasure of the work. F is the radius bar, turning round on a centre pin, fixed in the frame immediately beneath the work, in the line of the spindle; and this radius is in one piece with the frame \( H \), which is the foundation of the sliding tool. This consists of the three-tailed fider, \( G \), fitted into a groove formed on the top of the frame \( H \); this fider is advanced to its work by the lever \( M \), which has a handle, \( m \), at one end, and the other is fitted on a centre pin \( n \), fixed in an arm projecting from the frame \( H \). N is the shape or pattern ruler, supported by two columns, \( O, O \); and is the roller which applies to the shape when the handle, \( m \), is pressed towards the machine, as shown by a dotted circle in fig. 6. The wholebell is swept round on \( E \), a handle similar to that of the shaping engine, but no part of which is shown in these figures. The angles of the block are removed by the corner saw before it comes to the machine in which it is chucked, as before-mentioned, and then the spindle, A B, is put in motion. The workman, by the two handles, as before explained, of the shaping-engine, sweeps the tool one quarter round on the centre of its radial bar, \( F \), and the roller applying to the shape, \( N \), gives the dead eye, \( f \), its intended curvature. The machine being stopped, the dead eye is removed from the chuck, and reversed; the other side being pretented
MAC, in Geography, a town of Russia, in the government of Tards, 16 miles W. of Flomay, in the province of Mancshevo, a name used by Pliny, being the form of the.

He fell in love with a damsel of the same household; the passion was mutual, but effectually concealed from all other persons; and when Macias was absent, the maiden gave her in marriage to a knight who refused in Orphea. Macias on his return grew desperate, which occasioned his imprisonment at Arjonilla; here he employed himself in making verres on his millrefs, some of which were carried to the husband; who, in a fit of rage, mounted his horse with a spear and shield in his hand, rode to the prison, and slew the unfortunate captive as he was singing a song in honour of his love. Other accounts say that he bribed the keeper of the prison to untie a part of the roof, and flew him from above. He was buried in the church of St. Catalina, at Arjonilla, and this short epitaph was inscribed on his tomb "Aquí yace Macias el Enamorado." The lance was preferred upon his grave, and some Spanish verres written under it. In such cases, says the biographer, the Spaniards generally take part with the husband; but Macias was a poet, and the poets took up his cause. Their works are full of allusions to this story. The song which occasioned his murder is preferred in the Escorial, and has been printed by Aragoté de Molina in his "Noblesa de Andalucía," and by Sánchez in his notes upon the marquis of Santillana's letter. MACIGNO, in Mineralogy, the Italian name of a rock, which is employed for the purposes of building at Florence, and throughout Tuscany, where it is said to constitute entire mountains of a stratified structure. Patrin, who calls it "uue pierre marneufle et micacée," has given the following account of this useful stone. There are two varieties of macigno with regard to colour; one of them, called pietra bigia, is of a greenish-yellow; the other, denominated pietra serena, of a blueish-grey colour. This latter, of which most of the houses of Florence are built, has the inconvenience of becoming black when exposed to the air, and at length to decompose. The pietra bigia, which contains much oxide of iron, possesses greater solidity, and is less acted upon by the atmosphere; it is calculated for the exterior of buildings, while the pietra serena should only be employed for the interior.

The upper strata in the macigno quarries are more clayey than the others; they reflect the action of the fire sufficiently well, so that they are made use of for the construction of furnaces and hearths. The same hills exhibit strata or beds, some of which are of a leas solid texture than the macigno, and appear often to be nothing but indurated clay; these layers are called bardellone. The others, on the contrary, are much harder than macigno; they are of a white colour, and bear the name of pietra forte. This latter is the stone which is employed for paving the streets of Florence.

Ferber is of opinion, that the two kinds of macigno, together with the bardellone and the pietra forte, are varieties of one and the same rock, in which clay, calcareous earth, and mica, are by turns predominating. The pietra forte varies as much as the macigno with regard to colour; it is often greyish or blueish-yellow, and sometimes these two colours are even united in the same piece.

In the quarry of Campona, situated two miles from Florence, and yielding the stones with which the streets of Florence are paved, the pietra forte is disposed in horizontal layers that have only a few inches in thickfleds, and are sometimes separated from each other by similar layers of bardellone; and not unfrequently a crust of calcareous spar, of about a line in thickfleds, intervenes between the latter and the pietra forte. Ferber supposes, that it is this calcarious substance which, by penetrating into a layer of bardellone, converts it into pietra forte.

Patrin adds, that this stone exhibits a remarkable appearance in its interior structure; which is, that it divides into rhomboids separated from each other by dillepiments of calcareous spar. This author is of opinion, that the calcareous and argillaceous particles have been deposited at the same time; that afterwards a separation has taken place by elective attraction, and that the calcareous particles, tending to arrange themselves in rhomboidal forms, have imparted to the pietra forte the same character which is comminicated by them to the sandstone of Fontainebleau.

It is in these macigno hills that the beautiful varieties of marbles, exhibiting landscapes, ruins, &c. and known by the name of Florentine marble, are found. See Marble.

The above is all that is known of the nature of the stone of the neighbourhood of Florence; it should, however, be observed in this place, that the bardiglima, properly speaking, appears to be a different substance from that described by Patrin and Ferber under the name of bardellone; the former being the anhydrous sulphate of lime, (anhydrite and würfelpat of Werner,) on which count Bonnorn has given a memoir in vol. i. of the Transactions of the Geological Society.

MAC-INTOSH, in Geography, a county of America, in the lower district of Georgia, between Liberty and Glysha counties, on the Alatamaha river. It is divided into four towns, and contains 2660 inhabitants; of whom 1819 are slaves.

MAC, in Agriculture, a provincial term sometimes applied to a fort or kind of grain, or breed of cattle or live flock.

MACKAL L, in Geography, a town of Bengal; 55 miles S. S. E. of Moorheababad.

MACKENZELL, a town of Germany, in the bishopric of Fulda; nine miles N. E. of Fulda.

MACKENZIE, Sir George, in Biography, an eminent Scotch lawyer and miscellaneous writer, was born of a noble family at Dundee in 1626. He studied at the universities of Aberdeen and St. Andrews, and finished the usual course of classics and philosophy; at the age of sixteen he was sent to Bourges in France, where he paffed three years in the study of the civil law. On his return to Scotland, he was admitted to the bar, and soon became distinguished for his talents as a pleader. He was appointed, in 1651, the advocate for the marquis of Argyile, impeached of high treason, and spoke with so much favour and boldness in behalf of his client, as to draw down upon him a reprimand from the bench. This, however, did not stop his career, and in a short time after he was raised to a seat on that bench in the criminal court. A piece of service which he rendered to the court in 1674, by effecting a reconciliation between the lords of seifion and the faculty of advocates, caused him to be knighted, made king's advocate, and one of the lords of the privy-council in Scotland. In the contentions of that period the zeal of king's advocate, which is analogous to that of attorney-general in England, was equally important and arduous. Sir George, who had embraced the doctrine of passive obedience, exerted so much zeal in his new office, that he obtained from the covenants the title of the "blood-birdly advocate, and the perseveror of the fants of God." Notwithstanding this, he introduced into the form of criminal trials several alterations favourable to the accused, and so far from endeavouring to extend the power of his office, he considerably restrained it. Like other
other officers of the same rank, he has been charged with endeavouring to stretch the law of treason, especially in the cases of Baillie of Jerviswood, and the earl of Argyle, the sentence against the latter of whom was refinded by act of parliament in the reign of William and Mary. When James II. abrogated the penal laws, Sir George, who was sincerely attached to the Protestant religion in the episcopal form, resigned his office. The king, however, gladly restored him to his post, when he was convinced of the necessity of pursuing different means, and he firmly adhered to his master's interest in the subsequent change. He opposed in council the proposed address from Scotland, to the prince of Orange on his landing in 1688, and he wrote also a memorial to that prince exhorting him to adhere to the terms of his declaration. At the convention of the estates he argued very warmly against the declaration of a vacancy in the throne, and the election of William for sovereign, and when he found his opposition ineffectual, he retired to Oxford, where he was admitted a student. He died in London in 1691, and was interred with signal funeral honours in the church-yard of the Grey-Friars in Edinburgh. As a statesman, the character of Sir George Mackenzie stands high for learning and talents, and he was much esteemed for public and private worth. People of different parties and feelings will judge differently of his political exertions, but his integrity and good intentions seem unquestionable. In the midst of all his public business he found leisure to compose several literary pieces, among which are "Aeraison, or a Serious Romance;" "Religio Stoici;" "A moral Essay on Solitude;" "Moral Gallantry," and a play and poems. These pieces gave him the reputation of an elegant writer and found moralist. As a lawyer, he published "A Discourse upon the Laws and Customs of Scotland, in Matters criminal," "Deo Eligentzor forensis hodiernae, una cum Actione forensi ex unanque Juris Parte,;" "The Institutions of the Laws of Scotland," and "Observations upon the Acts of Parliament." As an advocate for monarchy, he wrote "Jus Regium," or the just and solid foundation of monarchy in general, and more especially of the monarchy of Scotland, and several other pieces. As an antiquarian and national historian, he wrote "Observations on the Laws and Customs of Nations as to Precedence, with the Science of Heraldry, as Part of the Law of Nations;" and a Defence of the Royal Line and Antiquities of Scotland:" the latter tract, involved him in a controversy with Dr. Lloyd, bishop of St. Asaph, and Dr. Stillingfleet. He wrote a work likewise respecting an union between England and Scotland, entitled "Reflections upon the Advantages and Disadvantages that would happen by an Incorporating Union between the two Kingdoms." Besides these, several additional moral and miscellaneous treatises sufficed from his pen, which demonstrated the fertility and variety of his speculations; and his aptness as a writer on almost all topics. He was the founder of the advocates' library in Edinburgh.

Mackenzie's River, in Geography, on the N.W. part of America, rises in Slave lake, runs a N.W. course, and after receiving a number of large rivers, discharges itself into the N. sea at White island, in N. lat. 69° 14', and between 130° and 135°; its course from Slave lake having been 780 miles. It derived its name from Mr. McKenzie, who ascended this river in the summer of 1789. The Indian names inhabit the W. side of the river from the Slave lake are the Strongbow, Mountain, and Hare Indians; those on the E. side the Beaver, Inland, Nathanael, and Quarrelers.

Mackmore, a small island near the W. coast of Scotland; about five miles E. from the island of Jura. N. lat. 56° 37', W. long. 6° 43'.

Macketer's Head, a cape on the E. coast of the island of H浒. N. lat. 55° 52', W. long. 5° 59'.

Mackey, John, in Biography, an Englishman, who followed James II. to France after the revolution, and was admitted by that unfortunate monarch to his confidence, which he scandalously betrayed, by giving information to king William of every secret with which he was entrusted. As an author he is known by his "Picture of the Court of St. Germain," which was published in 1691; and his "Memoirs of the Court of England, in the Reigns of William and Anne," published at the Hague in 1733; this work abounds in curious anecdotes. He died in 1726 at Rotterdam.

Macknight, James, a learned clergyman of the church of Scotland, was born at Irvine, in Ayrshire, in the year 1721. Having laid a good foundation in grammatical learning, he was at the age of fourteen sent to the university of Glasgow, where he displayed a most ardent thirst for knowledge, and secured to himself the approbation of his tutors. After he had completed the usual course of his studies at the Scotch college, he crossed the sea to Holland, and attended the lectures at the university of Leyden. His favourite study was theology, and on his return to Scotland he was licensed as a preacher by the presbytery of Irvine, and chosen to officiate at the Gorbals, near Glasgow. From hence he removed to Kilwinning, on the invitation of Mr. Ferguson, then minister of that place, and acted for some time as assistant in the duties of the parish. Here he established a character as a judicious and useful minister, and upon a vacancy taking place at Maybole, he obtained that living. He was ordained pastor in the month of May 1753; and continued to discharge the duties of that office full sixteen years. During this period, and amid his various professional occupations, he compiled his "Harmony of the Gospels," and his "New Translation of the Apoloitical Epistles." Although the plan of the "Harmony" differed considerably from that of former harmonies, in fupposing that the Evangelists have not neglected the order of time in the narration of events, the reception which it met with from the most competent judges was very favourable, so that the author undertook a second edition in 1763, with improvements, and considerable additions; which was a confirmed chief of six discourses on Jewish antiquities. A third edition was called for in 1824, which was published in two volumes 8vo. In the year 1765, Mr. Macknight published another work of great merit, entitled "The Truth of the Gospel History," which was the fruit of his studies and researches during the intervals between the two editions of his "Harmony." Its great object was to illustrate and confirm the internal, the collaterall, and the direct evidences of the gospel history. On account of these publications the degree of doctor of divinity was conferred upon him by the university of Edinburgh. In 1766 he was chosen moderator or president of the general assembly of the church of Scotland, and was in the same year translated to the living of Jedburgh, which he held three years, when he was elected minister of lady Yellor's parish in Edinburgh; from this he was translated, in 1778, to the old church, in which he continued during the remainder of his life. Dr. Macknight now devoted his time and talents to the promotion of various useful institutions as well as to the exemplary performance of his pastoral duties. He took a lead in the management of many different charitable institutions, and particularly of the
fund established by act of parliament, for a provision to the widows and fatherless children of ministers in the church of Scotland. As an author, Dr. Macknight occupied a considerable portion of his time in the execution of his labours and greatest work on the apodictical epistles. This was the result of an almost unremittent labour during thirty years: he had to have studied eleven hours in each day, and that before the work was sent to the press, the whole MS. had been written five times with his own hand. A specimen was published in 1787, being his version of the epistles to the Thessalonians: this was so well received, that in 1796 the whole was given to the public in four large volumes in quarto, under the title of 'A new literal Translation from the original Greek of all the Apocryphal Epistles; with a Commentary, and Notes, philosophical, critical, explanatory, and practical.' The whole is interspersed with essays on several important subjects, and to the fourth volume is added a life of the apostle Paul, which includes a capital compendium of the apologetical history. Having finished this great work, which he had been accustomed to regard as the grand object of his life, he was desirous of enjoying the remainder of his days free from laborious pursuits, and refrained, though earnestly solicited, to undertake a similar work with regard to the acts of the apostles. He probably felt the powers of his mind failing him, and had prudence and wisdom to obey the voice of reason and nature; and in a very short time after the decline of his faculties became manifest to his family. Towards the close of the year 1799 he caught a violent cold, which was the fore-runner of other complaints that put an end to his life in January 1800. *'Dr. Macknight,*' says his biographer, 'had acquired an early taste for classical literature, and studied the writers of antiquity with much critical skill. He was deeply read in metaphysics, moral, and mathematical science. His piety was sincere, rational, and without ostentation, and to be useful in the cause of truth and virtue was his highest ambition. In that branch of the pastoral office, which in Scotland is called lecturing, and confided in a familiar exposition of the sacred writings, his learning and ability were much admired, and never failed to please as well as to instruct and edify in a degree which has seldom been equalled. As a preacher, without pretensions to the grace of eloquence, he had a certain earnestness of manner, evidently proceeding from the heart, and from a sincere anxiety to be useful, which always commanded the attention, and excised the interest of the hearers.' See the Harmony of the four Gospels, third edition.

**MACLAVIN, Colin, in Biography, defended an ancient family, the possiblers of the island of Tiree, upon the coast of Argyllshire, was born at Kilmodan, in the month of February 1668. His grandfather, Daniel, on leaving his island, removed to Inverara, and contributed very much to redore that town, and after it had been almost entirely ruined in the time of the civil wars. John, the son of Daniel, and father to the subject of this article, was minister of Glenderuel;^ where he was greatly distinguished as a faithful and diligent pastor; he was employed by the syndic of his province in completing the version of the psalms into Irish, which is still used in those parts of the country in which divine service is performed in that language. This gentleman, whose character was highly exemplary, died within six weeks of the birth of his son Colin, the care of whom was devolved in a good measure upon an uncle, Daniel, who was minister of Kilnann. He was ably assisted in the charge by Mrs. Maclaurin during her life, which was extended only to the year 1707, when she died, leaving the care of all her children to the management and superintendence of an uncle. In 1709 Colin, though only eleven years of age, was sent to the university of Glasgow, where he continued five years applying himself with the utmost diligence to his studies. As he was a lad of considerable abilities, it need not be added that his success was fully proportioned to his exertions. He was accustomed to keep a diary, in which he entered an account of almost every day, of the commencement and progress of every particular study, enquiry, or investigation, and of his conversations with learned men. In Dr. Robert Simson, and several other distinguished scholars, the youth met with ardent friends, who seemed to vie with each other who should most encourage him in his pursuits by opening to him their libraries, and admitting him into their society and most intimate friendship. The genius of this young man for mathematical learning discovered itself very accidentally, when he was only twelve years of age. He met with a copy of the Elements of Euclid, and in a few days made himself master of the first six books without any assistance, and thence following the natural bent of his inclination, he made such a surprising progress, that very soon after he engaged in the most curious and difficult problems. In his fifteenth year he took his degree of master of arts with much applause, on which occasion he composed and publicly defended a Thesis on the power of gravity. He now turned his attention to theology, and having spent a year in the library, he quitted the university, and lived in retirement with his uncle till the end of 1717, when he presented himself a candidate for the professorship of mathematics in the Marischal college of Aberdeen, which he obtained; and was afterwards the happy means of reviving the taste for mathematical learning, and raising it higher than it had ever been in that university. During the vacations of 1719 and 1721, he went to London, and was, in his first journey, introduced to Dr. Hudal, Dr. Clarke, the illustrious Newton, and several other eminent men, whose notice and friendship he ever after reckoned the greatest honour and happiness of his life. In his first journey he was admitted a member of the Royal Society: two of his papers were inserted in their Transactions, and his book, entitled "Geometria Organica," was published with the approbation of their president. In 1721 he became acquainted with Martin Folkes, esq., afterwards president of the Royal Society, with whom he cultivated a most intimate and unfrequented friendship, frequently interchanging letters with him, and communicating all his views and the improvements in the sciences. In the following year the French natural philosopher of the name of Grendel, who was present at the congress of Cambrai, urged Mr. Maclaurin to become travelling tutor and companion to his eldest son, who was then sent out on his travels. After visiting Paris and some other cities and towns of France, they fixed on Lorraine as the place of their residence, where Mr. Maclaurin gained the esteem of the principal persons of the court. Here he wrote his piece on the perspiration of bodies, which gained the prize of the Royal Academy of Sciences for 1724. The substance
The substance of this tract was afterwards inserted in his treatise of Fluxions, and is likewise to be found in the second book of his "Account of the Discoveries of Newton." Shortly after they quitied Lorrain, Mr. Macaulay's pupil was seized with a fever which terminated fatally, to the great grief of the preceptor, who mourned for him as for a companion and the friend of his heart. He immediately returned to Abbedeen; and was in a short time, by the recommendation and interest of Sir Isaac Newton, chosen fellow to Mr. James Gregory in the professorship of mathematics at Edinburgh. He soon became a very popular lecturer, and seldom had less than a hundred young persons attending his course. These, according to their standings in the university, he divided into classes: in the first he taught the first six books of Euclid's elements, plain trigonometry, practical geometry, the elements of fortification, and an introduction to algebra. With the second class he entered more largely into algebra, read the 11th and 12th books of Euclid; and instructed them in spherical trigonometry, conic sections, and the general principles of electricity. The third advanced in astronomy and perspective, and read a part of Sir Isaac Newton's Principia, and had a course of experiments for illustrating them performed and explained to them. He afterwards read and demonstrated the elements of fluxions: with the next class he read a syllabus of fluxions; and introduced the pupils to the doctrine of chances, and explained the remainder of Newton's Principia.

Besides the labours of his public profession, Mr. Macaulay was engaged in many other important avocations. If a new or uncommon experiment was laid to have been any where exhibited, the curious among Mr. Macaulay's friends were definities of having it repeated by him; or if a comet or eclipse was to be observed, his telescopes were always in readiness. Amidst all the hindrances which he almost peremptorily was experiencing, he continued to pursue his studies with the utmost industry, and took from the ordinary hours of sleep, what he bestowed on his scholars and friends, a circumstance that is thought to have impaired his health and shortened his valuable life. 1739, Mr. Macaulay married Anne, the daughter of Mr. Walter Stewart, solicitor general to king George I. for Scotland, by whom he had seven children; of these, five survived him. In 1734, Dr. Berkeley, bishop of Cashel published his treatise entitled "The Analogy," in which he attempted to overtop the doctrine of "Fluxions," and to charge mathematicians with infidelity in matters of religion. This work was the occasion of Mr. Macaulay's elaborate Treatise on Fluxions, which was published at Edinburgh in 1742, and which is reckoned the most complete treatise on that science that has ever yet appeared. He became a very active and distinguished member of the society which had existed some years at Edinburgh for the improvement of medical knowledge, but which he contrived to extend more generally to the interests of science in all its branches. In conjunction with Dr. Plummer, professor of chemistry, he was appointed joint secretary, and generally at the monthly meetings either read some paper of his own, or communicated the contents of letters received from foreign parts, by which means the society was informed of all the new discoveries and improvements in the sciences. He showed his zeal for promoting the interests of science, by projecting the building of an "Astronomical Observatory," and a theatre for experiments in the university, of which he drew an excellent plan, and would probably have carried it into execution by the munificence of private persons, had not the unhappy divisions of the country intervened. In the year 1739, he was consulted by the earl of Morton with regard to the settling of the geography of the Orkney and Shetland islands, which had been laid down in the maps without attention to real facts deduced from astronomical observations. He drew up a memorial of what was necessary to be done, furnished the proper instruments, and recommended Mr. Short, the celebrated optician, as a fit person for managing the affair. From the account which he received of his visit to those islands, he was made more sensible than before of the errors in their geographical situation, which have proved the occasion of numerous shipwrecks, and he engaged several of his old pupils, who were then settled in the northern counties, to survey the coasts, expecting, as the result of their observations, to obtain a good map of Scotland. He had at this time another scheme for the improvement of geography and navigation, which was the discovery of a passage from Greenland to the South Sea by the north pole; he was satisfied that such a passage existed, and would, if his situation could have admitted of it, have undertaken the voyage at his own expence. A premium was afterwards offered by government for the discovery of a north-west passage, which did not accord with his views, as he was convinced, from all his reading on the subject, that it must he near the pole. In the year 1745, he took a most active part in favour of his majesty's government, in opposition to the rebels who were marching to the south. By the fatigue and anxiety to which he was exposed by his exertions in this cause, he laid the foundation of the disafte which in a few months put a period to his life. When, however, the rebel army got possession of the city, he thought it advisable to make his escape into England, well knowing that he could not expect mercy if he fell into the hands of the enemy. As soon as he arrived in the neighbourhood of York, he was invited by the archbishop to reside with him during his stay, with which he gladly complied, and on account of which he was impressed with the deepest sentiments of gratitude. Upon the march of the rebels into England, he ventured to return to Edinburgh, when it was found his constitution was completely undermined: and that his disorder had already advanced beyond the reach of medicine. His complaint being the dropsey, he was three times tapped, but the operations proved ineffectual, and he died on the 14th of June 1746, having exhibited, through the progress of his disease, a disposition worthy of a philosopher and a Christian.

Mr. Macaulay was not only distinguished by his genius and learning, but by the qualities of the heart: by his sincere love to God and his fellow creatures, and by his universal benevolence and unaffected piety. His favourite studies were the mathematics, which he cultivated with extraordinary success. His peculiar merit as a philosopher was, that all his studies were accommodated to general utility, and in many parts of his works, there is evidently an application of his most sublime theories to the perfecting of mechanical arts. He had resolved, for the same purpose, to compose a course of practical mathematics, and to relieve several useful branches of the science from the treatment which they too frequently meet with in led skillful hands. These designs were prevented by his death: in his life-time, however, he frequently had the pleasure to serve his friends and country by his superior attainments. If any difficulty occurred concerning the construction or perfecting of machines, the working of mines, the improvement of manufactures, &c. Mr. Macaulay was ever ready to resolve them. He was likewise employed to terminate some disputes which had arisen at Glasgow concerning the gauging of vessels; and presented to the commissioners of excise two elaborate memorials, containing rules by which the officers acted, with...
with their demonstrations. He made calculations relative to the fund for the widows of the Scotch clergy, and of the professors in the universities, and contributed very much to perfect the scheme which has been found of eminent utility to a vast number of persons who would otherwise have been left destitute of the means of support. But what seems to have endeared his studies to him, was the use they are of in demonstrating the existence and attributes of the Creator, and establishing the principles of natural religion on a solid foundation. To this use Mr. MacLaurin frequently applied them: and he was equally zealous in the defense of revealed religion, which he would warmly vindicate, whenever he found it attacked either in conversation or writing. Besides the works already mentioned, Mr. MacLaurin was author of many papers in the Philosophical Transactions; "On the Construction and Measure of Curves;" "On Equations with impossible Roots;" "On the Description of Curves;" &c. He gave an Account of the Angular Eclipse of the Sun at Edinburgh in January 1742;3 and shortly after his death were published his "Treatise on Algebra;" and his "Account of Mr Isaac Newton's philosophical Discoveries." The first of these is a capital introduction to the science of which it treats. The author's design with regard to the second seems to have been to explain only those parts of Mr Isaac's philosophy which have been, and which were, for some time, controverted, which was probably the reason that his discoveries concerning light and colours were scarcely touched on.

Such was the life of this eminent person, spent in a course of laborious study; in continually endeavouring to be useful; in improving curious and useful arts, and propagating truth, virtue, and religion among mankind. "He was," says his biographer, "taken from us at an age when he was capable of doing much more, but has left an example, which will be long admired and imitated, till the revolution of human affairs puts an end to learning in these parts of the world; or the fickleness of men, and their fatuity of the best things, have subliterated for this philosophy some empty form of fallacious science; and by the one or the other means, we are brought back to our original state of barbarity." Account of the Life, &c. of the Author prefixed to the work last-mentioned.

Maclaurin, John, Lord Dreghorn; son of the above, born at Edinburgh in December, 1734, was educated at the grammar-school of Edinburgh, and afterwards went through an academical course at the university of that city. He was admitted a member of the faculty of advocate in Edinburgh in 1756. In 1782, a Royal Society was established in Edinburgh, of which Mr. MacLaurin was one of the original constituent members, and at an early period of the institution he read an Essay to prove that Troy was not taken by the Greeks. In 1787 he was raised from the Scotch bar, at which he had practised long and successfully, to the bench, by the title of Lord Dreghorn. He died in 1794. As an author we have "An Essay on Literary Property;" "A Collection of Criminal Cases;" "An Essay on Patronage;" and some poetical pieces; besides which we have in the dramatic line ascribed to him, "Hampden;" "The Public;" and "The Philosopher's Opera." During the years 1792, 3, 4, and 5, lord Dreghorn kept a journal, or diary, in which he recorded the various events that happened in Europe during those years. From this journal he made a selection for publication: and in 1799 a selection of his lordship's works was printed in two vols. 8vo. Biog. Dram.

MACLE, in Mineralogy. "Macle lefaihique, ou fibert en pri m. quadrangulis rhomboideis, Romy de Ville; Chi opholi," Karien; Holship, Werner; Hollow-flar, James; Crucite, Dehame; Argilla chiasfolithus, Lat. (not of Forler.)

This remarkable mineral has hitherto been found only crystallized; but its forms are very different from those of all other mineral substances we are acquainted with, and not easily determinable.

It is generally found in long, slightly rhomboidal prisms of a yellowish, reddish or greenish colour; each prism is apparently produced by four tabular or prismatic crystals, externally straight and more or less exactly joined, internally more or less separated from one another: the space thus left in the centre of the prism, and varying both in form and extent, is filled up with a black or bluish-black substance; whence a transverse section of the complete prismatic crystal represents a black nucleus, generally of a slightly rhombic figure, from each angle of which a black line runs towards the opposite angle of the external sub stance, producing a kind of cross, more or less dilated in the centre, (Macle tetragramme of Hauy, pl. 51. f. 219.) and generally equally dilated at its four extremities (Macle pentakombique, Hauy, ib. fig. 220.) Sometimes the same black diagonal lines branch out into other lines, (Macle polygramme, Hauy, ib. fig. 221.) In the narrow prismatic variety the black substance forms by far the principal part, appearing in the form of a prism, enclosed in a thin case of the same form, and of a greyish to blackish color.

The black rhombic figure in the centre of the horizontal section of the cryroids appears at first sight to belong to a prism; but it is generally the section of a pyramid, as is manifested by the increasing or diminishing face of the rhombic spot, according as the transversal sections are made nearer to one or to the other extremity of the crystal.

The cryroids are generally middle-sized, sometimes very narrow and acicular; they sometimes adopt a cylindrical form.

Fracture more or less foliated, with a double cleavage; the principal one parallel to the lateral planes of the prism.

It is translucent on the edges, at least in those cryroids that have the appearance of feldspar; those that approach to the nature of felsite are opaque.

Hardness variable, according to the substance exhibits the appearances just mentioned.

Specific gravity 2.9444, Hauy; 2.927, Karien.

Before the blowpipe it is converted into a whitish scoria; the internal black substance melts into a blackish glass.

This substance has not subjected to chemical analysis, except carefully tested on the cryroids.

Macle occurs imbedded in clay-flasks. Mr. Buch supposes that the streaked and spotted appearance of some of the varieties of primitive clay-flasks, called fructis or kuk-chief, is produced, not by hornblende, but by minute cryroids of macle or hollow fpar.

It is found at Grefaes, in the margravines of Bayreuth; in clievenant Brittany, in France; and near St. Jago di Compostella, in Galicia. Those of Brittany are more exactly quadrangular. Some of them have about four and a half lines in diameter, and upwards of three and a half inches in length. Those of Spain are generally much thicker, and of a rounded form. According to Hauy, the external surface both of the Spanish and French maclee frequently exhibits something of a partly infare.

It has also been observed by Lelièvre and Dolomieu in the valley of Barages, in the Pyrenees; and by Raimonnod on the plateau de Troumouse, in the High Pyrenees. This substance has also been found by Mr. Dey in the clay-flakes of Cumberland, and in the county of Wicklow in Ireland, where it has likewise been observed by Dr. Fitch. Professor
Mac.

M. A. C.

Professor Link has found it in the mica slate of the Serra de Marao in Portugal.

The macle has been mentioned by Boettius de Boot under the name of lapis cruciger. It was applied at his time as an amulet for droping hemorrhages, &c; and even at the present day it is used for several superstitious purposes.

Werner considers this substance as nearly related to feldspar. Dr. Fiton and Mr. Stephens, in their very interesting "Notes on the Mineralogy of Part of the Vicinity of Dublin," fuppose that a connection exists between the macle and the andalusite (Feldspar aphyre of Hayi); the former gentleman, in particular, has convinced himself that colour, fracture, lustre, and other characters observable in the crystalline part of the former substance, completely agree with those of the andalusite.

Macle, Crifical macle, Macch crystals, are the names by which several mineralogists, and principally Romé de l'Isle, have distinguished the crystals with re-entering angles, formed by the union of two distinct crystals, producing the appearance of two halves of one symmetrical cryystal, which in the act of uniting have turned on each other in such a manner, that the planes of the upper part of the one correspond to those of the lower part of the other, or nearly so. Such crystals are denominated crifial transjlofia and hémîtroxes by Hayi; and Zwillings-krystal by Werner.

M. A. C. Clay, Charles, in Biography, a native of Ireland, probably born in the county of Well Meath, of a family named M'Laughlin, which was anglicized to that by which he was ever afterwards known. He was born about the 1st of May 1692, and in 1708 abscinding from his mother, then a widow, he came over to England. For some misconduct with regard to a female connection he was sent back to Ireland. Here he formed an acquaintance with certain under graduates of Trinity college, Dublin, and took up the employment of bargeman in that college, read much for the improvement of his mind, and remained in that degraded estate till he had attained the age of twenty-one. He then came to London, made a connexion with a flring company of players, and acted the part of harlequin. After leading an extraordinary course of life, he was again restored to his mother, and returned a penitent to his former station in Trinity college. In 1716 he arrived in England for the third time, joined a company of players at Brillock, then attached himself to several flring companies, and afterwards made his entry at the theatre in Lincoln's-in-Fields, where his merit was first discovered in a trifling character in Fielding's "Coffee-house Politician," which, it is said, would in any other hands have gone unnoticed. He now for several successive seasons performed comic characters, and on the tenth of May 1735, had the misfortune to kill Mr. Hallam, an actor in the fame theatre with himself, in a private quarrel. He was brought to trial in consequence; but no malicious intent appearing in evidence he was acquitted. In 1741 he established his fame as an actor, in the character of Shylock in "The Merchant of Venice," and by his fine and imp retiring manner reftored to the stage a play which had been forty years suppled by lord Lainford's "Jew of Venice." The manager and performers having about this time disagreed, Macbl, and several of the most eminent of the company, among whom was Garrick, revolted, and signed a formal agreement, by which they were bound not to accede to any terms which might be proposed to them by the patentee, without consent of the sub scribers. The seceders applied, but without effect, for the grant of a new patent, of course they found themselves under the hard necessity of agreeing to the terms offered by the manager, who ascribed the revolt of the players to the influence and suggestion of Macbl, and resolved to punish him for his ingratitude. To the others he was reconciled, but the sentence of eternal banishment from his theatre was pronounced against the man who had been once his friend and adviser.

A change in the management, by which Mr. James Lacey succeeded Fleetwood, restored Macbl to his usual em ployment. This was in 1747, and in the following spring he accepted an invitation from the manager of the Dublin theatre, by which he engaged his services for two years, but scarcely had he gone through the duties of his station a single month, when he took offence at some insinuations of fupposed neglect, which ended in a separation from that concern.

After various incidents, he, in 1753, obtained from Mr. Garrick the use of his theatre for a single night, and took a formal leave of the stage, in a prologue written for the occasion, in which he introduced his daughter as an actress to the protection of the public. He now projected the establishment of a tavern and coffee-house which was to make his fortune: this he soon after converted into a debating and spouting club, under the name of "The British Inquisition:' but Macbl was wholly unfit for the business of a tavernkeeper, became a prey to every needy and unprincipled villain, and, in Feb. 1755, was seen in the list of bankrupts. On his examination before the commissioners every thing turned to his character, except that he had been mercerly deficient in prudence, and in the end he paid twenty-thillings in the pound. He next joined Mr. Barry in founding a new theatre in Dublin, where, however, he did not remain more than two or three years, and in 1759 he returned to London and made an engagement at Drury-lane, at a very considerable salary, and brought out his farce of Love a-la-Mode, which, though opposed at first, was received in London and at Dublin with unbounded applause. Macbl in a short time transferred himself from Drury-lane to Covent Garden theatre, to which he continued uniformly attached.

He obtained great and almost universal and unbounded applause as an actor in comedy, but in 1773 he was determined to attempt the character of Macbeth in tragedy; in this new line he gave full satisfaction to his friends, but the public, headed by a few violent spirits, probably his personal enemies, were so much enraged at his attempting tragedy, that for a long time they would not admit him in his own comic parts, and he was formally dismissed from the theatre. In 1775 he brought his action against his opponents, and having obtained a verdict in his favour, he willingly relinquished the damages awarded in his favour upon the most liberal terms, a circumstance which drew from lord chief justice Mansfield the following handsonde and well-turned compliment: "You have met with great applause to-day; you never acted your part better." From this period Macbl occasionally performed and paid a visit to Dublin during Mr. Daly's management. In 1788, and again in 1789, while acting his favourite characters, he suddenly lost his memory, and in the second instance he resolved to make no other effort; but by the advice of his friends he published a subscription his two pieces "The Man of the World;" and "Love a-la-Mode:" by the exertions of Mr. Murphy, who superintended the printing, and his other friends, 1500. was raised, with which an annuity of 200. was settled on himself, and 75l. per ann. on his wife, if she survived him.

Mr. Macbl died on the 11th of July 1797, at the age of 107, if he were born at the period before-mentioned, but of this the reader should be apprized there were some serious doubts entertained. His remains were interred under the chancel of Covent Garden church. Mr. Macbl, says his biographer, was in his private character a tender husband, a good father, and a steady friend. To his firmness and re-
multation in supporting the rights of his theatrical brethren, it
was owing that they have been relieved from a species of op-
preflions to which they had been ignominiously subjected for
many years, whenever the caprice or malice of their enemies
chose to exert itself. We allude to the prosecution which
he carried on against a set of insignificant beings, who, call-
ing themselves "The Town," used frequently to disturb the
entrances of the theatre, to the terror of the actors, as
well as to the annoyance and disgrace of the public. As
a comedian his principal and most important parts were for
Gilbert Wrangle in "The Refusal;" for Archy McScar-
casm in his own farce of "Love a-la-Mode;" and for Per-
tinax Mac Seyphant in "The Man of the World," writ-
ten also by himself, and first brought forward in 1781.
Maclain also made a fine figure in the character of Sha-
kpsees's Iago; but the part in which he was allowed to shine
without a competitor was that of Shylock. Besides the
dramatic works already referred to, Maclain wrote a tragedy
of "King Henry VII. or the Popish Impostor;" "A Bill
or no Bill;" "The fupicious Hubbard criticised; or
the Plague of Envy;" "The Fortune Hunters;" and some
other pieces. Biog. Dram.

MACNEN-ABAD, in Geography, a town of Persia, in
Segeltan; 111 miles S.E. of Zareng.

MACOUSA, a fort on the W. coast of Africa, at the
mouth of the St. Domingo river. N. lat. 12° 25'.

MACON, or MAKONKISH, Great, a river of Amer-
ica, which runs into the Mississippi from the north-west,
in N. lat. 42° 24'. Little Mackintosh falls through the E.
bank of the Pearl River about 45 miles above the mouth of
the foremer.

MACOLEE, one of the Querimba islands, in the In-
dian sea. S. lat. 11° 10'.

MACOMER, a town of the island of Sardinia; 16
miles W. of Bofa.

MACON, a town of France, principal place of a dis-
trict, and capital of the department of the Saone and Loire,
near the Saone; before the revolution the metropolis of a
small country called the "Maconnais," which was formerly
a county and the see of a bishop. It contains four churches,
a commandery of Malta, seven convents, a college, and an
hospital. Its trade is considerable. The place contains in
two cantons 5807, and the cantons 20,252 inhabitants, on
a territory of 1771 kilometres, in 26 communes. N. lat. 46°
18'. E. long. 4° 55'.

MACONDERRY ISLANDS, three small islands in the
bay of Guayaquil, in the E coast of the island of
Celebes. S. lat. 0° 30'. E. long. 120° 25'.

MACONIA, a town of Pegu; 20 miles S. of Pegu.

MACOPIN, a small river of America, which runs from
the S.E. into the Illinois, 18 miles from the Mississippi,
20 yards wide and navigable nine miles in the hills: the shore,
which is low, is covered with maple, ash, button-wood, & c.;
the land abounds with timber, and is overrun with high
weeds.

MACORIZ, a small river on the S. side of the island of
St. Domingo; 16 leagues E. of the city of St. Domingo.

MACOTERA, a town of Spain, in the province of
Leon; 18 miles E. of Salamanca.

MACOTÉRA, a town on the S. coast of the island of
Jagoa. N. lat. 15° 12'. E. long. 123° 8'.

MACOU, a town of Persia Armenia; 75 miles S. of
Erivan.

MACOVA, St. Ann, L. E. a town of the island of
Martinico. N. lat. 13° 54'. W. long. 61° 17'.

MACOUBE, in Botany, occurs only in Jullien and
Aublet, the former having taken it from the Supplement of
the latter author's work on the Plants of Guiana, where it is
figured in t. 378.—The only parts of fructification with
which they were acquainted, are Peric. Capsule orbicular,
slightly compressed, sometimes obtusely triangular, of one
cell; hollow within; rough, reddish and marked with
grey spots on the outside. Seeds numerous, oblong, incurved,
valve above, furrowed below, included in a white
membrane, and attached to the internal coat of the pericarp.

—M. guianensis is a tree rising to the height of forty feet.
Its wood is of a greenish-yellow, and in drying has a differ-
agreeable smell. Leaves opposite, on footstalks, ovate,
acute, entire. Fruit as big as oranges, in clusters. In
the diversifications of the branches. The whole tree
abounds with a milky juice. Aublet found it in the woods
of Guiana, bearing fruit in February. Johnson places Macooua
in the natural order of Guttifera on the authority of Aublet's
description.

MACOUCAIU, is the Caribbean name of the plant in
question, as we learn from Aublet.—It is noticed by Jullien
as nearly allied to Illeu, but figured by Lamark under its
vernacular and generic name.—Aubl. Guian. 88. La-
marek Diss. v. 3. 609. Illfrit. t. 75. Juss. 379. Cufa

Gen. Ch. Col. Perianth inferior, of one lobe, cut into four,
short, acute segments. Cor. of one petal, tubular,
flattening upon the receptacle; tube very short; limb
divided into four, roundish lobes. Stam. Filaments four,
within the divisions of the corolla; anthers roundish, of
two cells. Pist. German superior, very small, roundish; style
none; stigma obtuse. Peric. and Seeds unknown.

1. M. guianensis. Aubl Guian. t. 34. Lamark Illfrit.
t. 75. The only species known. A native of woods in
Guyana and Cayenne, flowering in February.—The trunk
of this tree is thirty or forty feet in height, much branched.
Bark thick, hard, brittle, white externally. Leaves altern-
ate, nearly sessile, polished, oval, obtuse and sometimes
ending in a fork of jagged point. Flowers corymbose, axil-
ary, on footstalks, white. Fruit unknown.—The natives
use the bark of this tree merely for fuel.

MACOURI, in Geography, a river of Guiana, which
runs into the Atlantic, N. lat. 5°. W. long. 53° 49'.

MACOWAL, a town of Hindooistan, in the circuit of
Sindah; 50 miles N. of Sindh.

MACOYAQU, a town of New Mexico, in the pro-
vince of Mayo; 70 miles E.N.E. of Santa Cruz.

MACPHERSON, James, in Biography, a modern writer of
verse, was born, in 1738, at Ruthven, in the county of
Invercares. He studied at the universities of Aberdeen and
Edinburgh, and while he was a resident at the latter, he published a poem, entitled "The Highlands," which displayed some genius, though undisciplined by good
taste. He was intended for the church, but never entered
upon its duties. In 1760 he was living as private tutor in
the family of Mr. Graham, of Balgowan, and about this
time he published "Fragments of Ancient Poetry, collected
in the Highlands of Scotland, and translated from the Gaelic
and Erse Languages." The singularity of these pieces,
the novelty of their style and imagery, and the idea that
they were the product of a remote age and rude people,
caused them to be received with great interest by many
lovers of poetry; and as hopes were given that other works
of the same kind might be recovered, a subscription
was set on foot to enable Macpherson to leave his employment,
and visit the Highlands for that purpose. The receipt of
this munificence, or of his own before, was the epic poem of
"Fingal," and several other pieces, which were said to be
composed
MAC

composed by Ossian, the son of Fingal, king of the Highlands. An animated controversy was soon kindled relative to their authenticity: the Scotch were, in general, on the side favourable to the national honour: but many learned and able writers in the southern part of the island rejected their claims to the antiquity affirmed. The arguments urged against their authenticity, were drawn from the improbability of the existence and preservation of regular epic poems among uncivilized people who had not the use of letters; the abundance of poetic ornament, and the elevation and delicacy of moral sentiment, together with the freedom from all mixture of puerility and extravagance. Whatever was their origin, they met with a number of enthusiastic admirers, and were translated into several languages: they were commented upon by critics, and admitted as evidence of manners, habits, and customs by historians and antiquarians. The blind Ossian was placed in company with the blind Homer, and the wild mountains and heaths of the Highlands were converted into classic ground. The originals were now loudly called for, and indirect promises made that they should appear, till at length the supposed translator, instead of convincing orconciliating the sceptical, attempted to silence them by a tone of infolent allusion. The controversy, however, continued during the life of Macpherson, and is not, indeed, at this moment completely terminated, there being still advocates who justify the claims of Ossian as the real author of the works published under his name. Dr. Aikin, in the General Biograpby, observes, that the late matherly discussion of the topic by Mr. Laity seems to have produced a general opinion, that at least the great mass of the poems is modern fiction; and curiosity is now mostly limited to the inquiry how far it may have had a foundation in the traditional stories still current in the Highlands. In 1764, Mr. Macpherson was taken by governor Johnstone to Pensacola, in Florida, as his secretary. After executing his office in settling the government of that colony, he visited several of the West India islands, and some of the North American provinces, and returned in 1766. Refusing his literary perquisites, he published, in 1771, "An Introduction to the History of Great Britain and Ireland," which is elegantly written, and contains much valuable matter. He next published a sort of prose translation of Homer, which obtained for him neither fame nor profit, and was soon diffused to total oblivion. He now devoted himself wholly to historical and political composition, and in 1776 published "The History of Great Britain from the Restoration to the Accession of the House of Hanover," in two volumes, quarto. This was at the same time accompanied with two other volumes of original papers, serving as documents and authorities for the history. Although the author discovered a considerable predilection for the Stuart family, and appeared to place too much confidence in the representations of facts made by James II. in the manuscript memoirs of his own life, yet it certainly made a valuable addition to the knowledge of that period of English history. Mr. Macpherson next engaged in political warfare, and when the relinance of the Americans called forth the pen, as well as the sword of authority, he was engaged as one of the ablest. He published a pamphlet, entitled "The Rights of Great Britain asserted against the Claims of the Colonies," for which he obtained great credit; on account of the style and argument: it was very industriously circulated by the agents and adherents of government. This was printed in 1775, and in 1779 he wrote "A Short History of the Opposition during the last Session of Parliament," which was highly commented. His services were not neglected, and he received from thence, whole canto he vindicated, the lucrative post of agent to the nabob of Arcot, whole concern with the East India company were, at that period, very perplexed. Mr. Macpherson did not receive the emoluments without performing the duties of his office, and wrote several appeals to the public in behalf of this potentate; and it being judged necessary that the nabob should have a representative in the house of commons, he was returned, in 1785, to serve in parliament for the borough of Camelford, and was re-elected in 1784 and 1790. After this we find that his health was in a declining state, he retired to a seat which he had built, called Bellevue, near Inverness, where he died, in February 1796. His remains were deposited in Weftminister Abbey: he bequeathed 300l. to be laid out in a monument of him, to be erected at Bellevue; and 1000l. to defray the expense of printing andpublishing the original Ossian. Gen. Biog.

MACPHERSON'S STRAIT, in Geography, a channel in the Mergui Archipelago, between Banks's Island and St. Savannah. N lat. 10° 37'.

MACQUER, JOSEPH, in Biography, a physician and eminent chemist, was born at Paris in 1710, and became a doctor of the faculty of medicine in the university of that metropolis, professor of pharmacy, and censor-royal. He was, likewise, a member of the Academies of Sciences of Turin, Stockholm, and Paris, and conducted the medical and chemical departments of the Journal des Scavans. He had the merit of purifying chemistiy, not so much with a view of multiplying the preparations of pharmacy, which had constituted the leading enquiries of experimentalists before his time; but engaged in it as a department of natural philosophy, and gained a considerable reputation by the publication of several useful and popular works on the subject. In fact, he was one of the most successful cultivators of the science, upon rational principles, previous to the new modelling which it has received within the last twenty-five years. He died in 1784. The following is a list of his publications: 1. "Elements de Chimie Theoretique," 1749—1753, 12mo. 2. "Elements de Chimie Pratique," two volumes, 12mo. 3. "Plan d'un Cours de Chimie experimentelle et rationnelle," 2 vols., 1757. This was composed in conjunction with M. Baine, who was associated with him in his lectures. 4. "Dictionnaire de Chimie," two volumes, 8vo., 1766. These works have all been translated into English and German; the Dictionary particularly by Mr. Keir, with great additions and improvements. 5. "Formulie Medicae et Alimentarum," 1743; and he had also a share in the composition of the "Pharmacopoea Parisiensis," of 1758. Eloy Diet. Hist. de la Méd. Gen. Biog.

MACQUE, PHILIP, an historical writer, was born at Paris in 1720. He was brought up to the bar, but the weakness of his constitution prevented him from taking an active part in his profession, and he accordingly devoted himself to literary occupations. His principal works were: "Abrege Chronologique de l'Histoire Eclec- tistique," three volumes, 8vo., composed after the manner of Hefnault's Chronological History of France; "Les Annales Romains," and "Abrege Chronologique de l'Histoire d'Espagne et de Portugal," two volumes, 8vo. He had a share in the "Dictionnaire des Arts et Metiers," and other considerale works. He died in 1770, leaving behind him an excellent character for simplicity and unaffected integrity.

MACREUSE, in Ornithology, the Anas Nigra, Scoter or Black Duck. See DUCK.

MACRI, or MACRI, in Geography, a town of Afiatic Turkey, in Notosa, in a bay of the Mediteranean, called the gulf of Macri, anciently "Caelanus Numus," 70 miles S.W. of Sataira. N. lat. 36° 58'. E. long. 29° 30'.

E. 2. MACRIANUS.
MACRIANUS, Titus Fulvius Julius, in Biography, an Egyptian of obscure birth, who, from a private soldier, rose to the highest command in the army, and proclaimed himself emperor when Valerian had been made prisoner by the Persians, A.D. 250. He maintained his usurp power by the influence of his liberality: his two sons, Macrianus and Quietus, were invested with the imperial purple, and during a short period the enemies of Rome were feverishly defeated either by the emperors or their generals. When he had supported his dignity for a year in the Eastern parts of the world, Macrianus marched towards Rome to crush Gallicanus, who had been proclaimed emperor. He was defeated in Ilyricum by the lieutenant of Gallicanus, and put to death, with his sons, at his own desire.

MACRINUS ORILICUS, a native of Caesarea, in Africa, who from the lowest origin rose to the high dignity of emperor of the world. He is said to have been a slave, and to have exhibited in public shows in the character of a gladiator, which facts have been doubted, as he raised himself to reputation as a pleader in the courts. He became the rival of Plautianus, the minister of Severus, and on his disgrace and fall he narrowly escaped with his life, and was banished to Africa, where he maintained himself by the united professions of rhetorician, pleader, and counsellor. After some absence he was recalled from his exile by Severus, who made him post-maister on the Flaminian way. Caracalla afterwards created him a Roman knight, and he rose through the different employments to the high office of pretorian-prefect, an office which he filled with honour and integrity. He at length became an object of the emperor's suspicions, and vow, or imagined that he faw, his own safety entirely depended upon striking the first blow, and accordingly engaged a discontented soldier to stab the tyrant, which he effected. He immediately succeeded to the vacant throne by an election of the soldiery in the year 217, and the senate confirmed the choice of the military. Macrinus was not destitute of qualities and principles worthy of his high station, and by the punishment of informers, and the respect which he himself paid, and which he caused others to pay to the laws, he restored tranquility to his country. These promising appearances did not long continue, and the timidity which Macrinus betrayed in buying a peace of Artabanus, the Parthian, by a large sum of money, rendered him odious to his subjects, and while he affected to imitate the virtuous Aurelius, without possessing the good qualities of his heart, he became contemptible and insignificant. The army, who had raised Macrinus to the purple, now took a decided part against him; the whole army mutinied, and their tumult was increased by the consciousness of their power and numbers. At this time the young Bajianus was produced as the natural son of Caracalla, and was declared emperor by the army. Macrinus, at first, was resolved to oppose his competitor: the two armies met, and a bloody battle ensued: the fortune of the day remained some time very doubtful, when Macrinus, who might probably have been victorious had he been firm and steady, found himself flouted, leaving his enemies in possession of the field, and eventually of the crown. He fled through Antioch, crossed Leffer Afa in dignify, and arrived at Chakedonia with the intention of passing over into Europe; but being there recognised, he was seized and conveyed towards Cappadocia. On the road news was brought him that his son had been taken prisoner and put to death, which so enraged him, that he leaped from the chariot, and in the fall broke his arm; the guards, dreading the loss of their captive, instantly dispatched him, and carried his head to his rival. This circumstance happened in the month of June 218, after a reign of fourteen months.

Historians mention, to the honour of this emperor, that he meditated a great reform in jurisprudence, by abolishing all these imperial edicts which had obtained the authority of laws, though often inufed on particular occasions, and directed by the caprice of the prince on the throne; but the shortness of his reign prevented the execution of this and other plans which he had devised for the public good. Gibbon. Cre-

MACRINUS, Salonius, a modern Latin poet, whose proper name was John Salmon, was born at Loudon, and flourished in the sixteenth century. He obtained so high a reputation as a poet, especially in the class of Lyrics, that he was called the Horace of his time. He was appointed preceptor of the two sons of René, of Savoy, and acquitted himself so well in this employment, that he was received at court, and acquired the friendship of several of the principal persons who frequented it. He wrote a great number of verses, of which some of the best are those by his wife. He died in the year 1557. Several of his poems are contained in the second volume of the "Delicia Poetarum Gallicorum:" and a collection of his elegies was printed by R. Stephens. He had a son Charles, who is said to have surpassd his father in his knowledge of the Greek language, and to have equalled him in his Latin poetry. He was appointed preceptor to Catharine of Navarre, sister of Henry IV., and unfortunately perished in the bloody massacre of St. Bartholomew. Moreri.

MACROBIUS, Aurelius Theodosius, a Latin writer and eminent critic, who flourished towards the close of the fourth century, is supposed to have been a Greek, but the place of his birth is unknown. He is, indeed, claimed by the people of Parma, who shew his tomb, but he refers his birth-place to a country in which the Latin language was not vernacular. He undoubtedly lived at Rome, but it is not known whether he was the same Macrobius who was great chamberlain under Honorius and Theodosius II. It has likewise been disputed whether he was with regard to his religion a Christian or Pagan. The supposition that he held the office of chamberlain under the Christian emperors has been the chief, or, perhaps, the only ground for imagining him to have been a Christian, since the language of his writings and the interlocutors in his dialogue are entirely heathen. He wrote a Commentary on Cicero's "Dream of Scipio," from which it appears he was a Platonist: and a dialogue, entitled "Saturnalia," or Miscellaneous, which was supposed to have been written at a festival of Saturn, by a company of learned persons, whose names are those of some of the most learned scholars of that time. The questions treated of related to topics of antiquity, mythology, history, and poetry, discussed in a pleasing way, and with references to the works of ancient authors, and to the laws and customs of the Romans; and although the style is not pure, and the arrangement cannot be commended, yet it is a work of considerable merit, and of much utility as a help to classical erudition, and as containing some curious obser-

MACROCE-
MACROCEPHALUS, in *Natural History*, a genus of insects of the order Hemiptera. The generic character is, that it has an infected snout; the sheath is one-valved, three-jointed, and furnished with three bristles; it has neither jaws, feelers, nor lip; the antennæ are projecting, very short, submoniliform, clavate; the head is oblong, cylindrical above; the scutel, which is as long as the abdomen, is depressed and membranaceous. There is but a single species.

**Cimicodes**, which is found in North America, and is rather less than the *Cimex eurus*; the body is of a ferruginous grey; the scutel is of a pale auburn colour with a yellow spot; the under wings are purplish-violet, and the fore-throats are thickened.

*MACROCEPHALUS*, *Macrocephala*, composed of *macro*, great, and *cepha*, head, denotes a person with a head larger or longer than the common size.

*Macrophall*, or *long-heads*, is a name given to a certain people, who, according to the account of authors, were famous for the unceasing length of their heads; yet custom so far habituated them to it, that instead of looking on it as a deformity, they esteemed it a beauty, and as soon as the child was born, moulded and fashioned its head in their hands to as great a length as possible, and afterwards used all such rollers and bandages as might seem most likely to determine its growing long.

*MACROCERCI*, the name established by Dr. Hill for a large genus of animaculæ, distinguished from all others by having tails longer than their bodies. See *Animaculæ* and *Vorticella*.

**Gen. Ch.** Cal. Perianthus superior of one leaf, turbinate, five-toothed, permanent; often bearing a foliaceous, filiform, internal appendage. *Cor* of one petal, tubular; its limb small, in five ovules, slightly spreading segments. *Stam.* Filaments five, awl-shaped, villose, shorter than the corolla; anthers ovate, compresse, in the mouth of the flower. *Pil.* Germin inferior, conical; style simple, the length of the anthers; stigma thick, two-lobed. *Peric.* Capsule oblong, somewhat turbinated, two-celled, and two-valved, buruting lengthwise, the partitions from the middle of each valve. *Seeds* numerous, imbricate, on a separate linear receptacle in each cell.

**Eff. Ch.** Corolla tubular, five-cleft. Capsule inferior, oblong, of two cells; the valves buruting longitudinally, with partitions from their centre. *Seeds* imbricate.

**Obf.** This genus is allied to *Cimicosa*, but differs essentially in the structure of its capsule. Its great peculiar constrict in the large, leaf-like, coloured, filiform, solitary appendages, placed within the calyx, and according to *Jacquin*, in his *Hortus Schoenbrunnis*, originating from the very base of the germin, between two teeth of the calyx; but these, which might easily be mistaken for bracts, are not found in every species, nor in every flower of any one. The original species is *Macrocephala*.

2. *M. speciosum*. Jacq. Hort. Schonbr. v. 1. 19. t. 43. —Corymbs shorter than the leaves, hairy. Calycine *bractea* roundish-ovate, its stalk shorter than the corolla. —Native of the Caracades. *Jacquin* had it flowering in his *Flora* in December. This is a most beautiful shrub, five feet high, its inflorescence, and even the calyx and corolla, downy or hairy, as well as the margins of the leaves. The axillary and terminal corymbose panicles compose a large tuft of flowers at the end of each branch, very conspicuous for the long purple mouthed corolla, and the large rosy-coloured, veiny, smooth or downy, appendage to the calyx of most of them, more splendid than the flowers themselves.

3. *M. candidissimum*. Vahl. Symb. v. 2. 38. t. 30. —Corymbs shorter than the leaves, smooth. Calycine *bractea* roundish-ovate, its stalk longer than the corolla. —Found by Von Rohr in the neighbourhood of St. Martha. —This differs from the last in its smaller size, and while calycine *bractea*, whose stalk exceeds the flower in length, the corolla is also of a shorter figure. *Cypal* elliptic-oblong, compressed.

4. *M. casitum*. Vahl. Symb. v. 2. 38. t. 29. —Corymbs dense, the length of the footstalks, in long clusters. Calycine *bractea* elliptical, its stalk much longer than the corolla.

—Native of Trinidadi. Von Rohr. *A tree* with hairy branches. The leaves are from one to two feet long, elliptic-obovate. *Corymbs* short and dense, disposed in very long clusters. One flower in each corymb is furnished with a very large, elliptic, long-flaked, scarlet calycine appendage, looking, at first sight, like a *bractea* to each. The *corolla* is smooth, its limb nearly as long as its tube. *Germen* hairy.

Some species of this curious genus still, we believe, remain undetected.

**MACROCOLUMN**, or *MACROCOLLUM*, formed of *macro*, large, and *collum*, a neck, among the Romans, the largest kind of paper then in use. It measured sixteen inches, and frequently two feet.

**MACROCOSM**, *Macrocospus*, composed of *macro*, long, large, and *cosmos*, world, denotes the great world, that is, the universe.

In which sense it stands contradistinguishing from microcosm, a term used to express man.

**MACRODESPOUR**, in *Geography*, a town of Bengal; 20 miles E.S.E. of Kishenagar.

**MACROLOBIUM**, in *Botany*, was so named, as Professor Martyn conjectures, from having one of the petals very long in proportion to the others, but we are rather inclined to consider it as derived from *macro*, large, and *lobus*, a rod; the large seed-veil most evidently warranting such an application of the name, which was given by Schreber with Aublet's plates before him. Schreb. 30. Wild. Sp. Pl. v. 1. 185. Vahl. Enum. v. 2. 37. Mari. MILL. Dic. v. 3. (Gross.) Aubl. Guian. 28. Julii. 347. Lamarec Ilitr. t. 26. —Vonapéa; Aubl. Guian. 25. Julii. 350. Lamarc Ilitr. t. 26. —Chill and order, *Triandria Monogyna.* Nat. Ord. Lomentaceae, Linn. Leguminoses, Juss.

Gen. Ch. Cal. Perianthus inferior, oblong; the outer of two, opposite, ovate-oblong leaves, adhering to the base of the
the inner, which is of one leaf, turbinate, short, with an
oblique, five-toothed margin. *Cor.* Petals five, unequal;
the upper one large, erect, uncuculate, oblong, obtuse, con-
caved, undulated, inserted into the inner perianth; lower
petals four, small, ovate, spreading, attached to the upper
part of the inner perianth. *Stam.* Filaments four, one of
them short, barrel, flanging under the large petal; the
reft very long, thread-shaped; anthers (treme. *Pfie.* Ger-
men superior, flanked, ovate; style thread-shaped; stigma
obtuse. *Peric.* Legume ovate, compressed, coriaceous, of
outside. Seed solitary, roundish, compressed.
Ef. Ch. Calyx double; the outer of two leaves; the
inner turbinate and obliquely five-toothed. Corolla of five
petals, unequal. Legume single-seeded.
Ohl. Schrebcr remarks that *Outea* and *Vanapa* of Aublet
do not seem to be distinct genera, as the corolla, fertile
flames and the stipult agree in number, form, and situation
in both. In the former indeed, *Outea*, Aublet had never
seen the ripe fruit, and in the latter he appears not to have
distinguished the lefter petals from the calyx. Vahl, how-
ever, has kept these genera distinct, on the authority of
Richard.

t. 9)—Leaves pinnate, obtuse.—Native of woods and fo-
rords in Guiana, flowering in May. *The trunk* of this tree
rises to the height of fifty feet, and is about a foot in
diameter. Bark smooth and greville. Wood which tends
wards the forte, but red at the heart. Branches spreading,
branching, the upper ones erect. Leaves abruptly pinnat-
ate, alternate. *Outea* four, ovate, obtuse, *Stipulat* two,
acute, small, deciduous, at the base of the common leaf.
Flowers in spikes, axillary, of a violet colour. Some emi-
n Builders have suspected that this may be a *Tamarindus*,
and the following a *Hymensea*.

Guian. t. 7)—Leaves binary, pointed, oblique at the bafe.
Legume oblong. Found in the woods of Guiana and Cay-
enne, near the shores of lakes and rivers, flowering in No-
ember and bearing fruit in January. *A tree* sixty feet
high, much branched at the top. *Leaves* alternate, of two
green, strong, and thick, oval, long-pointed leaflets.
Flowers in foliary, terminal clusters from the bottom of
the leaves, of a pale violet colour.

Guian. t. 8)—Leaves binary, pointed, ovate. Legume
roundish compreched.—Native of woods at Couron,
in Guiana, bearing fruit in June. The height of this tree
is eighty feet. *Trunk* thick, much branched at the top.
*Leaves* alternate of two ovate, entire leaflets, reticulated
with veins. The flowers have not been seen, but the fruit
grows in axillary clusters, and is a thick, roundish, leathery,
ferocious legume, of one cell and two valves, containing a
foiliary, roundish, deprecatcd, smooth seed. The wood is
violet-coloured.

MACROLOGY. *M. exaltata,* formed of *max*; *long;* and
*phyr*; *distaff,* in *Rhetoric,* a redundant, or too copious
style; an example of which we have in *Livy,* lib. viii.
*Legati non imperatae pace, retro domum, unde venerant
abiertum.*

The too copious is equally subject to obscurity with the
too concise style, and consequently ought to be avoided.
See BRACHYLOGY, DICTION, and STYLE.

*M. CRONISL.* in Geography, a small island in the Turkish
Archipelago, near the coast of Livadia; formerly called
Helena, because it is said to have afforded an asylum to that
prince. It was anciently very populous, but is now de-
extinct, and only occupied by hinds or other reptiles. In

the interior parts are found many rare plants; 6 miles
N.E. of Cape Caloni. N. lat. 57° 38'. E. long. 24° 17'.

MACROPIEDUM, the long-legs, a name given by bone
writers in natural history to the common tipula.

MACROPIPER, a name given by authors to the *piper
longum,* or long pepper.

MACROPNUS, formed of *max*; *long;* and *phyr,* *breath,*
a word used by Hippocrates, and other old writers in medi-
cine, to signify a person who fetches his breath at long in-
ervals. It is used in opposition to *brachypus,* or short-breathed.

MACROPTERA, derived from *max*; *long;* and *wing,* a
*wing,* in *Ornithology.* The hawks of this genus have their
wings so long, that when closed they reach to the end of
the tail, or nearly so. Of this genus are the bald-buzzard,
the kite, the hen-harrier, the honey-buzzard, and the com-
mon buzzard. the sere, the jerfalcon, &c.

MACROPUS, Kangaroo, in *Natural History,* a genus of
the clafs and order Mammalia-fere. The fore-teeth in the
upper jaw fix, and emarginated; but in the young animal
they are eight; there are only two in the lower jaw, very
large, long, sharp, and pointed forwards: there are five
grinders on each side, both in the upper and lower jaw,
distant from the other teeth; the fore-teeth are very short;
and the hind ones very long; the female has an abdominal
pouch. There are two species, viz. the major, or *M.
giganYES,* ansering to the *Didelphys* gigantea of *Linnaceus*;
and the *M. minor,* or the kangaroo rat.

This genus, as it appears from what has been said, has
hitherto been generally confounded with the *Didelphis,*
which see; it is, however, found essentially to disagree with
that genus in respect to the teeth and other particulars: hence
Dr. Shaw, and other later naturalists, have separated it from
the *Didelphis* tribe.

Of all the animals which the continent of Australasia has
presented to our view, the *Platus* excised, (which see)
the kangaroo must be considered as the most extraordinary:
its size, conformation, teeth, and other particulars, con-
spiring to render it a most interllcting object to every naturalist.

Species.

Major; Great kangaroo. Brownish, with sharp ears
and pentadactylous fore feet. This animal was first dis-
covered by captain Cook's people, while at Botany Bay, in
New Holland, in the year 1770, an interfering account of
which is given in the captain's first voyage. It is thus
described by Dr. Shaw: *"The general size of the kan-
garoo is at least equal to that of a full-grown sheep; the
upper parts of the animal are small, while the lower are
remarkably large in proportion; yet such is the elegance of
gradation in this respect, that the kangaroo may justly be
considered as one of the most picturesque of quadrupeds.
The head bears some resemblance to that of a deer, and the
village is mild and placid; the ears are moderately large,
of a sharpened form, and upright; the eyes large; and the
mouth rather small; the neck is thin and finely proportioned;
the fore-legs are extremely short, with the feet divided into
twol, each of which is furnishcd with a sharp and somewhat
hooked claw. From the breast downwards the body gra-
dually enlarges, and again descends a little towards the
tail; the thighs and hind-legs are extremely stout and long;
and the feet are so constricted as to appear, at first sight,
to consist of but three toes, of which the middle one is by
far the largest, and is furnishcd with a claw of great size
and strength; the extra toe is also furnishcd with a very
strong claw, but far smaller than that of the middle; and
the interior consists of two small toes united under a common
skin, with their respective claws placed close to each
other
either as to appear like a split or double claw: the whole appearance of the foot bears a distinct resemblance to that of a bird. The great kangaroo rests on the whole length of the foot, which is callous, blackish, and granulated beneath. The colour of the animal is an elegant pale brown, lighter, or more inclining to whitens on the abdomen; the ventral pouch, or receptacle for the young, is situated as in the didelphus tribes, and is extremely large and deep. The dimensions of a full-grown kangaroo are these: eight feet from the tip of the nose to that of the tail; length of the tail three feet one inch; of the head eleven inches; of the fore-legs two feet; of the hind three feet seven inches; circumference of the fore-part of the animal, near the legs, three feet nine inches; of the lower part, near the legs, four feet five inches; round the thickest end of the tail thirteen inches. The weight of the largest specimens is said to be 170 lbs., but it is thought to attain a still larger size.

Though the general position of the kangaroo, when at rest, is standing on its hind-feet, yet it frequently places its front-feet on the ground also, and thus feeds in the manner of other quadrupeds. It drinks by lapping. In its natural state it is extremely timid and springs from the flight of mankind by vast bounds of many feet in height, and to a surpassing distance. The female kangaroo has two mammae, situated in the abdominal pouch, and on each side are placed two teats; yet, so far as has hitherto been observed, the animal produces but one young at a birth, and so exceedingly diminutive is the young, when first found in the pouch, as scarcely to exceed an inch in length. The young continues in the pouch till it is grown to a large size, and takes occasional refuge in it long after it has been accustomed to come abroad. It feeds on vegetable fabulances, and chiefly on grass. In their native state, kangaroos are said to feed in herds of thirty and forty together, and one is usually flattered, as if apparently on the watch, at a distance from the rest. One of the most remarkable peculiarities of this animal is its power of separating at pleasure, to a considerable distance, the two long fore-teeth in the lower jaw. The Macrourus maritimus, it must be observed, does the same. It is thought that there are several varieties of the great kangaroo; some being of a much darker colour than the common kangaroo described, and have a coarser fur. This animal may now be considered as, in a great degree, naturalized in England; several having been kept for some years in Richmond park, where they have bred. The flesh of the kangaroo is coarse, and will not be eaten as a luxury; but will serve in case of scarcity to perfons in their foreign travels.

Mixon, Jeffey, or brown kangaroo. Aish-coloured beneath, with rounded ears, and tetradactylos feet. This species of animal has, from its colour and general aspect, obtained the name of kangaroo-rat; it is about the size of a rabbit; the tail is long, tapering, hairy; hind-legs long, three-toed; ears rounded; eight upper fore-teeth, the two middle ones oblong; the lower two long and pointed; three grinders on each side, the fore-mall channelled; fur smooth, dark-brown. The forehead of the hind-feet in this species perfectly resembles that of the great kangaroo. The female is furnished with an abdominal pouch for the reception of the young. Some of this species were imported in a living state from New Holland.

MACROVynchae, long-beaked, derived from μεγίστος, long, and βηκός, a beak, in Ornithology, the character of a large order of the bird kind.

The birds of this order have all of them beaks many times longer than their heads, with oblong nostrils, and a furrow running from them towards the apex of the beak.

MACROTELOSTYLA, in Natural History, the name of a genus of crabs, which are composed of two pyramids, joined to the end of a column; both the pyramids, as also the column, being hexagonal, and the whole body consequently composed of eighteen planes.

The word is derived from the Greek μεγίστος, long, πύραμον, perfect, and κολόνα, a column; expressing a perfect crystal with a long column.

There are only three known species of this genus. Either of the forts found with us, are called by the common name of Cornic$6$ diamonds.

MACROULE, in Ornithology, the name given by many to the largest species of Coot. It is of a deeper black than the common kind, and has a large bald spot on its head. It is also called by some diable de mer. It is found in Lancahire and Scotland. See Fulica atherina.

MACROURUS, in Natural History, a genus of fishes of the order Thoricacei. There is but a single species, which is reckoned by Gmelin as belonging to the genus Coryphena. We have, however, in that article, given reasons why it cannot be admitted in that tribe; indeed, therefore, of denominating the fish under consideration the Coryphena Rugelbris, we follow Dr. Shaw, and others, in naming it the Macrouros Rugefliris, or Long-tailed Immfinet, of which the generic character is, head large, eyes large; body at the hind part attenuated into the tail.

The head of this remarkable fish is large and thick: the upper jaw projecting above into the form of an obtuse front; the eyes are very large, the mouth wide, with five rows of small curved teeth in the upper jaw, and two rows in the lower; the tongue is white, thick, short, and cartilaginous; beneath the tip of the lower jaw hangs a beard or cirrus; the body tapers from the middle part, and at length is continued into a very long, slender, and pointed tail; the whole fish is covered with moderately large rounded scales, each of which is furnished with a strong toothed carina, ending in a pointed tip, which causes a remarkable roughness of surface; so that the hand is wounded by drawing it over the fish from the tail towards the head. The first dorsal fin is situated near the middle of the back, and is furnished with nine or ten rays. The second dorsal fin commences at a small distance from the first, and running to the tip of the tail is united with the vent, which is likewise continued from the tip of the tail to the vent, near the middle of the body. The colour of this fish is a silvery-grey, deepest on the upper parts; its usual length is about three feet, but is occasionally seen of a larger size. It is native of the Northern seas, and is mostly found about the coasts of Greenland and Iceland, and is numbered among the edible fishes of the Greenlanders. It swims swiftly, and when first taken, it struggles with great violence, endeavouring to defend itself by falling with its tail; its large eyes projecting at the same time, to a surprising degree. It is known in some places by the name of Berg-lax, or Mountain Salmon; and the "Greenlanders call it "Igmammit," from which the English generic name has been taken. Shaw's Zoology.

MACQUOR-BEGUI, in Geography, a town of Peru, in the province of Ica; 54 miles E.S.E. of Ipihcan.

MACSWINE'S BAY, a bay of Ireland, in the N part of Donegol bay; 11 miles W. of Donegol. N. lat. 54° 36'. W. long. 8° 17'.

MAC'TEN, one of the smaller Philippine islands, in which, as some say, Magellan was killed. N. lat. 10° 30'. E. long. 123° 48'.

MACYTRA, in Natural History, a genus of the clafs Vermes, and order Tettacca, is thus described: the animal is a Telya.
MACTRA.

A TETHYS, which see; shell bivalve, unequal-sided, equivalent; middle tooth of the hinge complicated, with a small hollow on each side, lateral ones remote, and inserted into each other. There are twenty-seven species inhabiting the coasts of all quarters of the world, and four of them, as will be noticed by artillists in the article, are found on our own coasts. They are of different sizes, from that of a man's hand, downwards, so that some of them are scarcely an inch broad. The shells are likewise exceedingly different, some being smooth, others wrinkled; some are wedge-shaped, others ovate; they are also diaphanous, pellucid, and semi-transparent; some are iridescent, banded, white or fawn-coloured, and some resemble a tellina, others a mya. The following is a brief enumeration of the several species.

SPENGERI. The shell of this is smooth, with a flat anterior margin, on which is a lunate gape; it is found at the Cape of Good Hope, nearly as large as a man's hand, and is a little gaping, pale, sub-diaphanous, sub-triangular. The gape, before the hinge, is lunate, acute, and reaching to the hollow of the hinge; the beaks are incurved, and the teeth of the hinge triangular.

PLICATORIA. Shell with transverse wrinkled plaited, diaphanous; the anterior margin is flatish; behind the beaks is a combed oblong gape. It is found in the Indian ocean, and is from one to two inches long, and two inches and a half broad. The shell of this species is thin as paper, with smooth lanceolate depressions on each side the hinge; the anterior one flatish, with a ridge near the beaks; the posterior impressed, and more ovate; beaks incurved; lateral teeth of the hinge composed of two parallel membranes.

PARYXEA. Shell very thin, pellucid, and white; it is convex, with a little part a little gaping, very finely irritable, and ribbed. It is found in the Nicobar islands, but is extremely rare; it resembles the last, but is more convex and unequal-sided; except in the hinge, it is very like a tellina.

STRIATALA. The shell is smooth and diaphanous; the beaks are subflat, with a smooth marginal imprefion before them, surrounded with a rim. It inhabits the Coromandel coasts, and is found also in the Mediterranean, is about two inches and a half long, and three inches broad; it is white, sub-triangular, rather convex, a little gaping on the fore-margin.

STRIATA. The shell is thick and triangular, with strong thick, crowded, smooth, arched flax; it is white, and glabrous within the beaks. It is found in the Mediterranean, and is about the size of the last.

GLABRATA. This species has a smooth, diaphanous, and irritable shell; the beaks are very smooth; and the margins on each side are irrate. It is found in the African and Indian oceans; it is about the size of the Striata; the colour is white; beaks smooth, and irrate on the border.

ROTUNDATA. Shell obtusely triangular, whitish, with milk-white bands on the beaks; the margins, on each side the beaks, are violet. It inhabits the Mediterranean, and is of the same size as the last.

NITIDA. The shell is snowy and diaphanous; the depressions on each side the beaks are irrate; the anterior ones marked with a ridge. The shell is triangular, and the beaks retroverted and dulant.

CORALLINA. This is an inhabitant of the Mediterranean and Guinea seas; the shell is smooth, sub-diaphanous, and white with paler bands; it is about two inches broad, and an inch and a half long, triangular, with obtuse depressions on each side the beaks.

LACTEA. The shell is thin, pellucid, white, and the fore-part very finely irrate, with paler bands. It is found in the Indian ocean; it resembles the last, but is thinner, and more convex; the anterior part is flatish, with an obtuse margin.

* STULTORUM. The shell is semi-transparent, smooth, and glossy; it is obliquely radiate, white without, and purplish within. This is found on the shores of our own country, and also in the American seas; and is only the size of a hazel-nut; the shell is convex, somewhat triangular, brown, tectaceous or cinereous, with or without faint rays.

GRANDIS. Shell semi-transparent, smooth, fawn-colour, with pale rays; the beak and hinge placed beyond the middle. This is very like the last; is more than three inches broad; and two broad, gaping at the extreme angle; the anterior side more produced.

*SOLIDA. Shell opaque, and smoothish; found very commonly on the European shores; the shell is thick, strong; colour white, to a yellowish-brown, frequently marked with blue or pale orange belts; while alive it is smooth, and when dead it has a few high transverse flaxes, like ribs; the lateral teeth are small, elongated with a large hollow; the middle tooth is small.

*LUTRARIA. The shell is oval-oblong and smooth, without lateral teeth. It inhabits the European coasts, near the mouths of rivers; it resembles a mya gaping at both ends; in colour it is of a dirty-white, or yellowish tinged with orange, and irregularly clouded with brown; hinge with a small and large triangular cavity in one valve, and a similar cavity with an elevated triangular tooth in the other.

CYGNUS. Shell fawn, thick, and three-sided, very finely irrate transversely; the fore-part is flatish, and slightly wrinkled; behind the beaks a broad, heart-shaped, thinly irrate imprefion. It is found on the coasts of Tranquebar; an inch long, and rather more than an inch broad.

MACULATA. Shell obtusely triangular, smooth, thin, with pellucid chefs-tout spots; within white, and very finely irrate.

TURIGA. The shell of this species is inflated, faintly irrate, of an ochre colour, but white within; the beaks are distant purplish; the hinge has a supernumerary triangular double tooth. It inhabits Tranquebar, and is nearly three inches long, and more than that broad; it is thin, pellucid, finely irrate, and wrinkled before and behind.

VIOLECA. Shell thin, obsolescently radiate, finely irrate transversely; margins on each side the beaks whitish; hinge with a supernumerary double triangular tooth. This is found on the coasts of Tranquebar, and is about two inches long, and three broad. The shell is thin brittle, gaping here and there, the anterior margin oblong, elevated, and wrinkled.

CUNEATA. Shell wedge-shaped, blue, finely irrate transversely; the margin crenulate within; it resembles in many respects the last, but is only an inch long, and not so much as that broad; it is sometimes white.

GLACIA. The shell of this is ovate, dirty-white, with glaucous rays, very finely irrate transversely; the anterior part wrinkled. It inhabits the Mediterranean; the same size as the Turgida; the beaks are turned backwards, with a narrow gape between them.

PELLUCIDA. Shell ovate, thin, and of a pellucid white, with unequal transverse flaxes. It inhabits Guinea; is not two inches long, but rather more than this broad; the shell is brittle, a little produced forwards, and gaping.

FRAGILIS. In this the shell is ovate, thin, smooth, pellucid, flatish; the anterior gape transversely irrate, and wrinkled. It inhabits the Nicobar islands, and resembles the last; the shell is gaping, and slightly plaited on the
MAC

fore-part; the margin is acute, subangular before and rounded behind.

RUGOSA. Shell ovate, dirty-white, with elevated longitudinal frowns crossing the transverse ones, which is a little more raised. It is thick and white within, and is about two and a half inches long, and the same in breadth.

Nicolara. Shell ovate, thin, and yellowed on the fore-part; the hind-part with cancellate frowns. Found in and about the Nicobar islands.

Complanata. In this the shell is ovate, thin, with arched plaitts; the plaitts transversely frowns. It inhabits India, and is of a blueish colour, but sometimes white, is an inch long, and a half broad.

Lusitana. Shell very thin, nearly round, white; hinge with a triangular tooth, and large pyriform hollow. Found at the mouth of the river Tese; rather larger than the last.

Piperita. Shell ovate, composed, transversely frowns; teeth of the hinge very minute, with a large oblique hollow. Inhabits the Mediterranean; about two inches long and one and a half broad.

MACUCAGUA, in Ornithology, the name of a Brazilian bird of the gallinaceous kind, called also by fome the gallina fylvofbris, or wild hen. It has no tail; but is a very well tailed fowl, and has twice as much flesh as the European hen; its eggs are somewhat larger than the common hen eggs, and of a blueish-green colour; it feeds on fruit that falls off the trees, &c. and runs well, but cannot fly high or far, and never is seen in the trees. Maregrave. See Triao Major.

MACUIH-YU, in Geography, a small Chinefe island, belonging to the province of Quang-tong. N. lat. 23° 12'. E. long. 116° 27'.

MACUL, a town of Chili; 15 miles S.E. of St. Yago de la Nouvelle Eftramadura.

MACULA, a sea-port of Arabia, in the province of Hadramaut; 150 miles N.E. of Aden.

MACUL, in Medicina, a spot, is a term principally used to denote those detached effluences of the skin, or discouloured patches, of various dimensions and figures, which appear without any considerable elevation or protruberance above the rest of the surface, and with large interlacing of the natural colour. The term includes, therefore, those congenital discolorations, which are called mother-spots, or technically nasi materteri, and which are commonly attributed, without any foundation, to fritches or other affections of the mind or imagination of the mother; as well as molea, petechiae, freckles, &c. See IMAGINATION.

The macula hepatis, or liver-spots of the older authors on medicine, are little elle than large freckles; conftituting of patches of various fizes, affecting chiefly the back, fhoilders, and groins, of a brown colour, and accompanied with a flight roughness of the surface, in confquences of the formation of minute branfy fcales, in which the cuticle partially exfoliates. In the arrangement of cutaneous affections adopted by Dr. Willan, these spots are comprehended in the order of fcaly difeases, under the title of Pityriasis, which fee.

The macula volatice of authors, which occur in infants during dentition, are varieties of the eruption, popularly denominated the red gum, the Strupuleus of Dr. Willan. See that article; also DENTITION, and INFANTS, Difafers of.

The laft mentioned author has confituted an order of macula in his arrangement, which includes thofe chronic affections of the skin, that are unaccompand by scales, pimples, rafes, vehicles, putules, or tuberces, which characterizes the other orders. It comprehends principally, there-

MACUL, in Astronomy, dark spots appearing on the luminous faces of the fun, moon, and even fome of the planets. In which fende macula stand contradiftinguifhied from fcula.

The folar maculae are dark spots of an irregular, changeable figure, oblong in the middle of the face of the fun, first taken notice of by Galileo, 1610, from after he had improved his telescope, and afterwards accurately observed by Scheiner, Hevelius, Mr. Flamleed, Caffini, Kirch, &c. Phil. Trans, vol. i. p. 274, vol. iv. p. i. p. 194.

Many of thefe maculae appear to confift of heterogeneous parts; of which the darker and more dense are called by Hevelius nuclei, and are encompafled, as it were, with atmospheres somewhat rarer, and lefs obfure; but the figure both of the nuclei and entire macula is variable. In 1644, Hevelius obferved a small thin macula, which, in two days time, grew to ten times its bulk; appearing withal much darker and with a larger nucleus, and such sudden modifications are frequent. The nucleus, he obferved, began to fall fuddenly before the spot disappeared; and that, before it was quite vanished, it broke into four, which, in two days, again re-united. Some maculae have lafted two, three, ten, fifteen, twenty, thirty, but seldom forty days; though Kirchius obferved one in 1681, which remained from April 26th to the 17th of July. The fots move over the fun's disk with a motion fomewhat fhrill, nearer the limb than the centre; that obferved by Kirchius was twelve days visible on the fun's disk; for fifteen days more it lay behind it, it being the uflual rule to return to the limb whence they departed in twenty-seven, fometimes in twenty-eight days.

Lastly, it muft be obferved, that the maculae contrata themselves nearer the limb, and in the middle of the disk appear much larger: those often running into one in the disk, which in the limb were separate: that many of them arife in the middle of the disk, and many disappear in the fame: and that none of them are obferved to deviate from their path near the horizon; whereas Hevelius, observing Mercury in the fun near the horizon, found him too low, being thrall twenty-seven seconds beneath his former path.

From these phenomena we collect, 1. That since Mercury's depression below his path arises from his parallax, the maculae, having no parallax from the fun, are nearer him than that planet.

2. That, since they arife and disappear in the middle of the sun's disk, and undergo various alterations with regard both to bulk, figure, and density, they must be formed de novo, and again dissolved about the sun; and hence some have inferred, that they are a kind of folar clouds, formed out of its exhalations.

3. If they are of this nature, as they rise over his body and are fupended at a certain height from it, it appears, from the laws of hydrostatics, that the fun must be encompafbed with fome fluid to drive those exhalations upwards; which fluid must be denser as it is lower, and rarer as higher, like our atmosphere: and, since the maculae difsolve and disappear in the very middle of the sun's disk, the matter thereof, supposing them to be folar exhalations, muft fall back again to the fun: whence there must arife changes in the fun's atmosphere; and consequently in the fun itself.
4. Since the revolution of the macula round the sun is very regular, and since their distance from the sun is very small, it is not properly the macula that move round the sun, but it is himself, together with his atmosphere, where-in the macula swim, that in the space of twenty-seven days, twelve hours, twenty minutes, moves round his own axis; and to the same fixed star in twenty-five days, fifteen hours, sixteen minutes (see Sus); and hence it is, that the macula, being viewed obliquely near the limb, appear narrow and oblong.

5. Since the sun appears with a circular disk in every situation, his figure, as to sense, must be spherical.

The magnitude of the surface of the spot may be estimated by the time of its transit over a hair in a fixed telescope. Galileo reckons some spots to be larger than all Asia and Africa put together; but if he had known the sun's parallax and distance as exactly as we do, he would have found them much larger than the whole surface of the earth. For, in 1612, he observed a spot so large as to be plainly visible to the naked eye; it, therefore, subtended an angle at the eye of about a minute. The diameter of the earth, if removed to the sun, would subtend an angle of but about seventeen seconds. Therefore, the diameter of the spot was to the diameter of the earth as sixty to seventeen, or three one half to one, nearly; and consequently, the surface of the spot, if circular, to a great circle of the earth as twelve one-fourth to one, and to the whole surface of the earth as twelve one-fourth to four, or nearly three to one. Gazzendus observed a spot whose diameter was 5/6 of the sun's, and, therefore, subtended an angle at the eye of above a minute and a half. Its surface was, therefore, above six times larger than the whole surface of the earth. He tells us, that he saw above forty spots at once, but did not perceive that the light of the sun was feebly diminished; nevertheless, the palefefs of the fun mentioned by historians, after the death of Julius Caesar, might have been caused in this manner, if we admit the fact.

The opinions that have been formed concerning the nature, origin, and situation of the solar spots, have been various: Dr. Wilfon, professor of practical astronomy in the university of Glasgow, by attending particularly to the different phases presented by the umbra, or shady zone, of a spot of an extraordinary size that appeared upon the sun, in the month of November, 1769, during its progress over the solar disk, was led to form a new and singular conjecture concerning the nature of these appearances; which he seems to have afterwards confirmed by repeated observations. The results of these observations are, that the solar macula are cavities in the body of the sun; that the nucleus, as the middle or dark part has been usually called, is the bottom of the excavation; and that the umbra, or shady zone, is usually surrounding it, is the shielding fides of the cavity. Dr. Wilfon appears not only to have very satisfactorily as- tained the reality of these immense excavations in the sun's body, but has pointed out a method of measuring the depth of them. He estimates, in particular, that the nucleus, or bottom of the large spot above mentioned, was not less than a semidiameter of the earth, or about four thousand miles, below the level of the sun's surface; while its other dimensions were of a much larger extent. He observed, that when a spot in the middle of the sun's disk, where it is surrounded equally on all sides by the umbra, comes near the western limb of the sun; that part of the umbra, which is next to the sun's centre, gradually diminishes in breadth, and at length, when the spot reaches within about a minute of the limb, totally disappears; while the umbra, on the other side of it, continues nearly of its former dimensions. If, after the period of half a revolution, the spot appears again on the opposite side of the disk, that part of the umbra, which had before disappeared, and which is now on the left hand side of the nucleus, is now plainly to be seen; but the umbra on the other side of the spot, or that which is next to the sun's centre, seems to have vanished in its turn; being hid from the view by the upper edge of the excavation, or by the oblique position of its floping fides, with respect to the eye. As the spot, however, approaches the sun's surface, this umbra, or side of the cavity, comes in sight; it first appearing narrow, but afterwards gradually increasing in breadth, in proportion as the spot moves toward the middle of the disk. These appearances, in particular the gradual diminution and disappearance, as well as the reappearance and gradual enlargement of the umbra, on the same side or the other of a spot, according as it advances near the western limb, or proceeds onwards from the eastern edge of the sun, are naturally accounted for by Dr. Wilfon's supposition, that the umbra are the sloping fides of a cavity, which will appear under different angles, or of different breadth, or totally disappear, according to their position with respect to the eye of the speculator. These appearances, at least, perfectly resemble the phases that would be exhibited by an excavation in a spherical body, made to revolve on its axis; the bottom of the cavity being painted black, and the sides lightly flaxed. From these and other observations it may be inferred, that the body of the sun, at the depth of the nucleus, either emits no light, or emits so little as to appear dark, when seen at the same time, and compared with that refplendent, and probably, in some degree, fluid substance that covers his surface. This manner of considering these phenomena naturally gives rise to many curious speculations and inquiries. It is natural, for instance, to inquire by what great commotion this refluent matter is thrown up on all sides, so as to expose to our view the darker part of the sun's body, which was before covered by it? What is the nature of the slothing matter? and why, when an excavation is formed in it, is the luftre of this slothing substance, which forms the sloping fides of the cavity, so far diminished as to give the whole the appearance of the shady zone, or darkish atmosphere surrounding the denuded part of the sun's body? On these and many other subjects, Dr. Wilfon has advanced some ingenious conjectures; for which we must refer the curious to the Phil. Tranf. vol. lixiv. part i. art. 1. See also some remarks on Dr. Wilfon's Theory, by Mr. Woolfston, in Phil. Tranf. vol. lixiv. part ii. art. 1. p. 337, &c.

M. de la Lande, in the Memoirs of the French Academy for 1776, contends, that the spots of the sun are owing to dark bodies like rocks, which by an alternate flux and reflux of the liquid igneous matter of the sun, sometimes raise their heads above the general surface, and that at other times the same bodies sink below, and that their appearance when they rise above, gives the appearance of the nucleus, while those parts which in each he only a little under the igneous matter, appear to us as the surrounding umbra. See this opinion examined, and Dr. Wilfon's vindicated by himself, in Phil. Tranf. vol. lixiii. pt. i. art. 10.

Dr. Herchel thinks that the sun is an opaque body, possibly inhabited, covered with an atmosphere in which clouds of a luminous nature are floating, and that the spots are interruptions of these clouds. Of these clouds, as he conceives, there are two sorts, the upper of which only is luminous, and the lower stratum, as he supposes, protects the body of the sun from their heat. Phil. Tranf. for 1775, vol. lixxv. p. 46, &c.; and in Phil. Tranf. for 1801, p. 265-334, he endeavoured to shew that the variations of heat...
next of different years is owing to the more or less copious supply of fuel in the sun, which constitutes its fruits. See FACULTY, SPORTS, AND SUN.

MACULIPA, in Geography, a town of Mocumpo; 25 miles S. of Batan.

MACUMBA, a country of Africa, forming the southern province of Mocanga.

MACUNA, in Batany. See DOLICHOGEN.

MACUNA, in Geography, one of the Navigator's islands, in the South Pacific ocean, where several of M. de la Perrouse's crew were massacred by the inhabitants. S. lat. 14° 19'. W. long. 169'.

MACUNGY, a township of America, in Northampton county, Pennsylvania, containing 1844 inhabitants.

MACUPA, a town of Africa, in the country of Mambaba, near the coast; five miles N.W. of Mambaba.

MACURITAS, a town of the island of Cuba; 115 miles W.S.W. of Havana.

MACUTA, in Commerce, a money of account in Guinea, on the coast of Africa, equal in value to 2000 small shells, called cowries, or zimbis. The Sierra Leone Company use pieces of 10, 5, 2, and 1 macutas. The first weighs 16 dwt. 21 gr. contains, in pure silver, 330.3 gr. and is worth 13.5 10/12. d. sterling. The second weighs 13 gr. contains, in pure silver, 167.6 gr. and its value is 13.3 10/12. d. sterling. The third weighs 12 dwt. 7 gr. contains, in pure silver, 65 gr. and is worth 9 d. The fourth weighs 11 dwt. 16 gr. contains, in pure silver, 32.2 gr. and its value is 4 1/4. d. sterling. The 10 macuta piece, or dollar, has on one side two joined hands, with the figures 100 both above and under them, and the inscription “one-dollar piece”; on the reverse, a lion; legend over the lion, SIERRA LEONE COMPANY, and under it, AFRICA. The half-dollar is marked 50; the 1 dollar, 20; and the 1/2 dollar, 10; with the inscriptions, HALF-DOLLAR PIECE, TWENTY-CENT PIECE, and TEN-CENT PIECE; the rest as on the dollar.

MAC, in Geography, a town of Hungary; five miles N. of Tokay.

MAC, a river of America, called also “Pickaw Fork,” which is a rapid branch of the Great Miami, that passes in a beautiful stream with a S.W. course through a pleasant level country of very great fertility.

MACAP, in Geography, a town of Hungary; five miles N. of Tokay.

MACAPPLE, or Malangena, in Botany. See SOLANUM.

This plant is propagated in the gardens of the curious with us; and in Spain, Italy, and Barbary, common in the kitchen-gardens, the fruit of them being frequently eaten there, boiled with fat flesh, putting thereto some scraped cheese, and preserving it through the winter with vinegar, honey, or salt pickle. They thus esteem of great efficacy to provoke venery. In summer also, when the fruit is just ripe, they eat it fresh dressed, with spices, and other ingredients.

The apples being much liked of the mandrake, have induced some moderns to suppost this plant to be the male mandrake of Theophrastus; and supposing them to be deadly to call them mad-apples; whereas in reality they excite no symptoms of madness, but are used by the Italians and Spaniards in their sauces and sweatmeats. They have the taste of the citron.

MACDOG. See Dog and HYDROPHONT.

MAC-Dog, among Miners, is water that has been drawn from a shaft, or any part of the mine, and returns back again to the same place from whence it was drawn.

MAC-Dog, in Botany. See ALYSIUN.

MAC-Dog, in Geography. See ASPERLEGOE.

MACABLOTA. See GERMANIA.

MACADAGASCAR, in Geography, an island in the Indian sea, separated from the coast of Africa by the channel of Mozambique. Its length is rated by De Pagès to be about 960 miles and its breadth 100; but others assign to it 840 geographical miles in length, and about 210 in medial breadth. De Pagès says, that next to Borneo, it is the most extensive in the world. He might also have excepted Papua and New Holland, if the latter may be classed in the number of islands. As it extends from N.N.E. to S.S.E. from the 12th to the 26th degree of south latitude, its climate is mild and agreeable. Of its first discovery, nothing certain is known. The ancients, even as late as Ptolemy, seem to have been unacquainted with it. The first mention of it, upon which we can depend, is by Marco Polo, in the 13th century, who having derived his knowledge of it from the Arabs, describes it by its present name. It escaped the notice of Gama, who coasted along the African shore; and though it is said to have been known to the Arabs and Perians from time immemorial, under the name of “Sarakib,” its first discovery is ascribed to Lorenzo, or Lawrence Almeida, in the year 1566. Hence the Portuguese gave it the name of St. Lawrence; the French, in the reign of Henry IV., called it Isle Damphine; its real name, however, is Madeeiaux, though it is now generally known by that of Madagascar. It is divided into 28 provinces; and its surface, according to Rochou, may be estimated at 200 millions of acres of good and arable ground, celebrated for fertility and for the variety of its productions. All its different parts are watered by torrents and large rivers, and more especially by a number of smaller rivulets, which flow from the vall ridge of mountains that separates the eastern from the western coast. Viggora is the highest mountain in the N., and Botilmena in the S. These mountains contain in their bowels precious minerals and curious foils, and their fummits are crowned with lofty trees, of long duration. The scenery which the island presents is very picturesque and interesting, as it is diversified with preci- pices, cataracts, and immense forests. The vegetation of its hills and plains experiences no obstruction from theviducility of the leasons, nor does it derive much affluence from the labour of the inhabitants. The fragrant commons afford pasturage to numerous droves of oxen and flocks of sheep; and the soil evinces its fertility, with little aid of culture, by yielding a crop of rice in no time that is grown. The woods afford a prodigious variety of trees, such as all kinds of palm trees, woods used in dyeing, ebony, bamboos of an enormous thickness, as well as orange and lemon trees. They also supply timber for building ships and houses. Placourt says, that in the year 1650 he sent to France 52,000 aloe trees of the first quality; and he has given the names of two or three hundred different plants. Of late there have been obtained from this island the Mauritian mulberry with green fruit, and the Aamphiphora Madagascariensis, the juice of which, called by the islanders “tinguera,” concretes into an elastic gum, similar to the caoutchouc of Cayenne. Of edible plants this island furnishes not only rice in abundance, but the banana, yam, nymphaea lutos, several fruits of delicos or kidney beans, gourds, water melons, and cocoa nuts. The fruits are pine apples, tamarinds, oranges, and pomegranates. The spices and other condiments are common and betel pepper, ginger, turmeric, cinnamon, and sugar. The Indian fig grows, as well as cotton and indigo. Many quadrupeds are peculiar to this island, whence some naturalists have, perhaps, too hastily inferred, that it never joined the African continent. Here are no lions, tigers, elephants, nor hares. Many of the most valuable minerals might be supplied from hence; such as the purest rock crystal, beds of which occur, gold ore, topazes, sapphires, emeralds, and
spotted jasper, or blood floras. Here are found numerous black tourmalines of Häuy, which the ancient mineralogists considered as the school of Madagascar. The inhabitants of Madagascar, who call themselves “Malagasy,” or “Madegens,” are in general well-shaped, and above the middling size: the colour of their skin is various, some tribes being of a deep black, others tawny; some having a copper complexion, but the greatest number being of an olive colour. All those that are black have woolly hair, like the negroes of the coast of Africa. The hair of those who have the complexion of Indians or Mulattoes, does not frizzle more than that of the Europeans; their nose is not flat; their forehead is broad and open, their lips not pouting, and every feature of their face is regular and pleasant. Their phytogony bears, in general, the marks of a character replete with frankness and amenity. Rochon compares them, with regard to their disposition and general character, to the savage, whose condition he absurdly extols, because, like the brute animal, he is deficient of all reflection on the past, and forethought with regard to the future. From the hair, complexion, and make of the natives of Madagascar, M. de Puget conceived them to be descended from different races of men. Some who are short, with lank and smooth hair, of an olive complexion, have a strong resemblance to the Malay Indians, and do not seem to have originally sprung from the aborigines of the island. Others, tall and well-proportioned, with crisped locks, large and beautiful eyes, an eafy carriage, and an open, unrevered countenance, appear to be the true posterity of the primitive inhabitants; their colour is nearly black, and differs but little from that of the natives on the Mahbar coast. In their disposition they are lively and obliging, but wholly deficient of genius; vain, whimsical, and interested; dextrous in the use and application of their bodily faculties; but without the powers of combination, and in the general conduct of life, light, precipitate, and incapable of preferring a steady conduct, or of acquiring a decided character. With weak minds, they posse a considerable portion of wit and vivacity, and they blend a variety of good and bad qualities. They wear an apron at the girdle, and something of the same kind on the shoulders, with a bonnet constructed like an umbrella; the hair is combed into small tresses, and the beard is permitted to grow only on the chin. The men are little addicted to agriculture, but more inclined to look after their cattle, which roam in the woods. They construct war canoes, as well as canoes for their ordinary occupations. The latter are small, and navigated only with the oar; but the former, which are the property of the chief, are much larger, and have a fort of rigging. Some of them carry 100 men, and are in condition to sail round the island. The women are generally of the middle fize, with expressive features, and though not entitled to be classed with the handsome part of the sex, few of them are ugly. Round the waist they have a long apron, with a kind of under waistcoat, which barely covers the breasts. They frequently wear, by way of ornament, a large circular plate of silver, and round the neck, falling down upon the bosom, a number of small silver chains. Their hair appears in a multitude of little tresses, dangling over the forehead, or on the corner of the eye, or turned up in the form of a crecent. The women, besides cultivating fields of corn, rice, and other sorts of grain, are employed in planting trees and roots, particularly the caffava, batatas, and the banana or plantain. The leaves of the tree, named rafia, are made to supply them with thread; and with these materials, dyed of various colours, they manufacture a kind of cloth, which is woolly, and affords a very handsome article of drefs. They prefer, however, the cotton fluffs imported by Europeans from the continent. Every family is provided with a loom, and carries on a manufacture equal to its own consumption. From the leaves of a tree, named vacusa, they procure materials for mats, bonnets, bags, and other useful articles. Their common food consists of rice, bananas, and dried fish; they consume little fresh meat or fresh fish; their drink is water, or the juice of the mangosteen, fermented with pimento and mustard. Their houses are small and awkwardly constructed. The walls are formed of bull-rushes, and the roof covered with plantain leaves. The chief part of the timber work consists of mainly pieces of wood, the reed being bamboo, very rudely executed. The floor is laid with the pit of the palm, or some other tree, and is often raised far above the level of the ground, to avoid the exhalations of the soil, and also to guard them from the annoyance of serpents and insects during the rainy months. Although the natives have no regular form of worship, they nevertheless adore some fapreme being, as the patron of justice and good-secfs, who will judge men after death, and reward or punish them according to the merit or demerit of their actions. The rate of circumcision is performed upon males between the 7th and 8th year of their age; and the day of circumcision is observed with festivity, and closed with the singular custom of firing from a musket the forehead of the patient. They believe also in a devil, or evil being, and upon this article is founded the craft of the Panfaret or Magician, who, being supposed to defeat or control the machinations of the invisible enemy, practises a thousand tricks on the credulity of the multitude. Amulets of a species of wood, suspended round the neck, or prefered in a little bag, are supposed to secure the possessor against wounds and the disasters of war. A trumpet or toad, applied with words of incantation to the head of a person afflicted by diseases, is expected to restore him to health. Exposing the sick in a hut of a certain elevation, open towards the east, from which is let fly an amblemage of party-coloured threads, is a sovereign remedy in the most desperate cases. Perfumes are introduced in abundance in all the arts and enchantments of the magicians. All these absurd observances seem to be the barbarous vestiges of religious notions, indiscriminately transmitted to the people from their African neighbours. The rate of circumcision, the common use of perfumes, and the profound veneration for the quarter of the caft, are evidently the remains of religious feelings of the highest antiquity. But the most horrid part of their superstition remains still to be related. When an infant has the misfortune to drop into the world on a day esteemed unlucky, or of bad omen, by the Panfaret, he is exposed or suffered to die of want, or to be devoured by wild beasts. The natives are accustomed to hunt the whale along their coast; and when he is struck with the harpoon, they wait till his strength is nearly exhausted, and then lead him towards the shore. The women assemble on the beach, and vestigate fongs of praise in honour of him who gave the first wound. The whale is then near the land, and surrounded by all the men in the village, when the public orator advances, and having pronounced a long oration on the pre-eminent qualities of the fish, the whale is cut up, and affords a rich repast to the company. When any subject of dispute occurs between the natives of Madagascar and the Europeans, or between Indians of different tribes, it is formally discussed in the “palaver,” or council of the tribe; and the decision is the result of long deliberation.

Property in this island consists of cattle, grain, and slaves of the same nation with their master. Every person who has the misfortune to be made a prisoner of war, man, woman,
er child, is reduced to the condition of slavery, and from that moment is regarded by his own kindred as an object of contempt. Their arms consist of a shield, and the "sagay," a kind of lance, which they throw with considerable accuracy. They are also tolerably well provided with musquets, purchased from the French; and they have also some swivel guns and cannon, obtained from the same quarter. The residence of the chief is within a fort or stronghold, consisting of three rows of large trees, fixed in the ground so close as almost to exclude the light; and fastened together at the top by a cros beam. Their forts in general are mere simple palisades, constructed in the form of an oblong square, though some of them have balisiers and galleries, with openings for the purpose of reconnoitring. On the eve of war, the women, children, and cattle, retreat to the top of these structures, and there conceal themselves, waiting the issue of the campaign. The village is then occupied only by the men, who, previously to any act of hostility, sacrifice an ox. An Indian, of distinguished eloquence, harangues on the injustice of the enemy; and his countrymen, in the mean while, dip their sagayas in the blood of the victim. Their operations in the field are of a very dilatory description, confining chiefly in teasing and harassing the enemy, or attempting to surprize him in the night. They seldom come to a regular engagement. The natives of Madagascar are susceptible of very violent enmities, and sometimes execute on their devoted objects the most deliberate cruelties. The customary use of presents is the same here as in India. It is the business of the inferior to make the first advance, as well as the first present; but he always receives another in return. The natives indulge in all the offices of hospitality; but not to the excess which some travellers have ascribed to them, who have said that it is customary for parents to prostitute their children to the importunities of strangers. This M. de Pages absolutely denies. He acknowledges, however, that chastity in the intercourse of the sexes is little regarded. The young ladies of Madagascar, habituated to intrigue, prompted by the political and pecuniary views of their parents, and captivated by the charm of some new ornament for their persons, cease to be reluctant to the wishes of their admirers. Married women are very little addicted to violate the nuptial engagement. When a woman happens to conceive by a foreigner, the recourse to various drugs, known to the natives, in order to procure abortion. In the language of Madagascar, which is by no means harsh or disagreeable to the ear, M. de Pages perceived some inflections of voice which occur in that of the Philippine isles. It seems to be a compound of different languages, and contains many words borrowed from the Arabic and Portuguese.

The island of Madagascar is divided into a great number of tribes. Its population, says M. Rochon, may be reckoned at 4,000,000 inhabitants; but no precise calculation is possible, as the island is divided into distinct societies, each of which inhabits the country which it likes best, and is governed by its own usages. A tribe consists of several villages, all of which have a particular chief. This chief is sometimes elective, but more frequently hereditary. The land is never parcelled out, but belongs to those who take the trouble of cultivating it. These islanders have neither locks nor bolts, and live in a frugal manner. The French settlement of Fort Dauphin is in the south-east extremity of the island. For an account of it, see Fort Dauphin. The chiefs never go out without their gun, and a stick tipped with iron, ornamented at its end with a tuft of cow-hair. They wear a cap of red wool, by the colour of which they are distinguished from their subjects. In the province of Carcannon, in which Fort Dauphin is situated, the territo-
and is opposite to the easter extremity of Nova Scotia. The north point of the island lies 14 miles S. of St. Peter's harbour, in Cape Breton island; on which island the isles de Madame are dependent.

MADAMPAR, a sea-port town of the island of Ceylon, on the west coast, at the mouth of a river.

MADAMUT, a town of Egypt, on the east side of the Nile; 20 miles S.W. of Kouts.

MADAN, Martin, in Biography, an English divine of the established church, was born about the year 1726, and was brought up to the profession of the bar, which he quitted for the church, though without preferment. The chapel at the Lock-hospital was built chiefly by his exertions; and he officiated many years as the chaplain, without any emolument. He is chiefly known as an author by a work entitled, "Thelyphthora, or a Treatise on Female Ruin," in 3 vols. 8vo., published in 1781, which occasioned a long and very violent controversy. The author maintained the lawfulfasts, or even the duty of polygamy.

Mr. Madan was a good classical scholar, and published a translation of Juvenal and Persius: he also wrote a treatise on "Capital Punishments." He died in 1790, having attained to much popularity as a preacher; and as a man, his moral character was unimpeachable.

Madan's Points, in Geography, a cape on the north-east coast of the island of St. Christopher. N. lat. 17° 28'. W. long. 63° 28'.

MADANA, in Hindoo Mythology, a name of Kama, the Hindoo god of love, otherwise Madamat; which see.

MADAPASSA, in Geography, a town of Bengal; 60 miles S. of Dacca.

MADAPUR, a town of Bengal; 10 miles S.E. of Rajmal.

MADARAVAN, a town of Fuz, in the vicinity of iron-mines, not far from mount Atlas.

MADARGUNGE, a town of Bengal; 82 miles N.N.W. of Dacca.

MADAROSIS, from μαδός, bald, in Surgery, a lot of the eye-lashes.

MADBAH, in Geography, a town of Kemount; 23 miles S.E. of Kigir.

MADBAH, a town of Hindooftan, in Bahar; 37 miles S.E. of Bettiah. N. lat. 26° 25'. E. long. 85° 21'.

MADBURY, a township of America, in Strafford county, New Hampshire, between Dover and Durham, about 10 miles N.W. of Portsmouth; incorporated in 1755, containing 544 inhabitants.

MADAPUR, a town of Bengal; 34 miles E. of Maudilah.

MADADEN, Dr. Samuel, in Biography, was born in Ireland about the year 1686, and educated at Dublin, where he resided the greater part of his life. In 1729 he was in England, and wrote a tragedy, entitled "Themiskees;" and was, as he says of himself, tempted to let it come out, by the offer of a noble fudy of books from the profits of it. In 1732 he published "Memoirs of the twentieth Century," a work which, for some reason not now known, was in a few days totally suppressed. In 1750 we find him in his native country, and setting apart the sum of one hundred pounds to be distributed in premiums for the encouragement of arts, manufactures and science; and the same sum he continued to bestow annually for the like purpose, so long as he lived. The good effects of these well-directed benefactions we are not only felt in Ireland, but their influence was extended to the other country, and, it is thought, gave rise to the "Society for the Encouragement of Arts, Manufactures, &c. in London," of which his grace the duke of Norfolk is now the president. Dr. Madden obtained church preferment in Ireland, and he died in December 1765. He left behind him another tragedy, as a legacy to Mr. Sheridan. Biog. Dram.

MADDER, in Agriculture, the common name of a plant, sometimes cultivated in the field, as an ingredient in the dyeing of a scarlet colour. The sorts commonly cultivated for this use is, the rubia tinctoria, which is a plant of the thick feathy tap-rooted kind.

It is stated by a late writer, that this plant "was formerly much more cultivated in particular districts in this country than it is at present, the importations from Holland having lessened the demands, and reduced the price of it, so much as to render its culture incapable of being conducted with profit to the farmer."  

Soil.—The soile which are the most suited to the cultivation of this plant, according to the same writer, are those of the deep fertile sandy loams that are not retentive of moisture, and which have a considerable portion of vegetable matter in their composition. It may also be grown on the more light descriptions of soil that have sufficient depth, and which are in a proper state of fertility to admit of its being grown upon.

Preparation, and Plants or Sets.—In the preparation of the land for the reception of this crop, "it will be necessary to plough it up deeply before the winter into high ridges, in order that it may be exposed to the action and influence of the frosts, and the atmosphere. Early in the spring these ridges should be well harrowed down by a heavy long-tined harrow, and then ploughed again in the contrary direction to a good depth. And when after this the land is not perfectly clean from weeds, or not rendered sufficiently fine and mellow, another ploughing and harrowing should be given. In the left operations the ground should always be left in as level and even a flate as possible. It is then ready for the reception of the plants. The sets or plants may then be obtained either by sowing the seed upon a bed of earth which is rich, and made perfectly fine by digging and raking in the spring, and then lightly covered in, or from offsets or suckers from the old plants. In the first method, on the plants appearing they should be made perfectly clean by weeding, and be set out to the distance of three inches in the beds by the hoe. In this way, by keeping the ground quite clean and well flared about the plants, they will be ready to set out in the second autumn, though it will more be better to defer the busines till the spring, in this climate, if the sets can be procured, as the plants seldom ripen their feed perfectly, or afford it in a flate to vegetate well. It requires about twenty thousand plants for setting an acre of land. The most suitable time of taking the sets is shown by the plants having attained the height of ten or twelve inches from the ground, and the suckers having thrown out fibrous roots at their bottoms. This may be seen by drawing up a few of the plants, and usually about the latter end of May or beginning of June." Besides 4"it is necessary that the sets have formed root-fibres at the bottoms, before they are removed, as where that is not the case, they never succeed well."

The land being prepared in the manner directed above, and the plants thus provided, a sufficient number of labourers are to be provided, that the work may be performed as expeditiously as possible. In taking off the sets, much care is necessary not to injure them. Some perform it by means of a dibble with a flat edge, and which is lid with iron; this tool, on being thrust into the ground on the side of the roots, divides and separates them by deferring the handle without hurting the fine fibrous roots. The number of plants
MADDER.

Plants that can be set in a short space of time should only be taken up at once. They should be prepared by having about a third of their top parts cut off. A foot of thin batter should likewise be made, by mixing good vegetable mould and water well together, into which the roots of the sets should be dipped before they are placed into the earth, as by this means the necessity of watering the plants afterwards is prevented. This work is executed by a person before the planting commences. Two others are employed afterwards in distributing the plants so as to be convenient for putting them into the ground.

There are different methods employed in setting the plants; in some cases they are put in the furrow by means of the plough, while in others they are set in beds by a dibble. The former is probably the better method, and as being the most expeditious, is best adapted to the culture of the plant on an extensive scale. In this the planter begins by drawing a straight furrow on one side of the plantation to a good depth; a row of plants is then laid in it by a person for the purpose, at the distance of five, six, or more inches from each other, according to the circumstances of the land, in such a manner as to lean off from the plough; another furrow is then formed, by the mould of which they are covered. In this manner the work proceeds until the whole is filled.

In the other method, it is observed, the sets, after the land has been formed into beds, five feet in breadth, with two feet between each for intervals, are put in by means of a line and a dibble, beginning at the distance of six inches from the outsides, and setting a row of plants at suitable distances from each other, as just mentioned; then removing the line two feet farther on them, and putting in another row; after which it is again removed two feet, and a third row of plants set in, which finishes the bed; the work proceeding in this manner till the whole of the plantation is completed. In this way each bed contains three rows of plants, at two feet distance each, three feet being left between the rows on the different beds.

But "in Holland, where the culture of this root is extensive, their method is, it is observed, a little different from the above. The plants, after being taken from the older plantations about the month of May, are immediately set in rows at the distance of three or four inches from plant to plant, and about fifteen inches from row to row, the beds being ten or twelve feet in width, with intervals of only about two feet."

It is suggested that, "as in whatever manner the plants are set, some of them, even in the most favourable situations, are liable to die soon after the work has been performed, it is necessary, in the course of a fortnight or three weeks, to look over the ground and put fresh vigorous plants in the places where the others have been destroyed. By this means the plantations may be rendered more perfect and productive."

But whatever method of planting may be practiced, it is of the greatest importance to the success of the crop, "that it be kept perfectly clean from weeds, and that the mould be occasionally furrowed about the roots of the plants." The first of these is accomplished, according to the survey of Kent, by means of hand-weeding and hoeing during the summer season, and the latter either by the use of a handhoe, or a light plough; this last is the most easy and expeditious. In this manner, or by digging the intervals of the rows, the mould is also laid up to the plants once each year after the stems have been removed in the autumn following. Where the bed practice is followed, they are sometimes earthed up in the autumn after the stems have been cut down, by paring the intervals somewhat in the manner of those of the asparagus kind. This method is, however, in general too expensive and troublesome where the crops are cultivated on an extensive scale.

According to Mr. Young, the best way of performing this culture is "to use the flim, not for turning a ridge against the rows, as the plants will yet be too weak for that operation, but merely to loosen the earth of the intervals, thereby to kill the weeds, and prepare the soil for being thrown up against the rows by a succeeding operation. Hand-hoeing and weeding should depend on the number of the weeds that arise among the plants. Let the cultivator of madder, through the whole process of the crop, remember, says he, that he must be to the full as accurate as a gardener in his tillage; his soil must be rendered little inferior to a dung-hill; all weeds must be for ever eradicated; not one must injure the plants; his land must always be kept perfectly loose and well pulverized; for a crop that depends merely on the quantity of the roots, can never thrive to profit in land that is bound or in an adhesive state."

Whatever practice is adopted, "the crops are to be managed in this manner until the third autumn after planting; when the plants will be in a flate to be taken up; this is known by their stalks beginning to wither, and is generally about October. This business is performed either by trenching the land over with a spade, or by means of the plough. The first is the more certain, though much less expeditious method. In executing it, the workmen dig along the rows to the depth of about two feet, breaking and reducing every bit of earth as perfectly as possible, each being attended by two persons, who pick out the roots of the madder. But when the planting has been done in narrow beds, it is sometimes the practice to take the roots up by turning the earth into the interstices by a spade, or broad three-tined fork. In this way it is fancied that the roots are taken up more perfectly, and with less danger of being injured. But the most ready method is by means of the plough, which, after leaving the earth-board and coultor removed, is passed along each side of the rows, so as to fully loosen the mould; persons being employed to pick out the roots, loosening such parts of the earth as may have escaped the action of the plough by their spades." And "when the roots have been taken up, they should be exposed some time to the air, in order that they may be rendered so dry as to be cleared from dirt. They are then to be conveyed to a kiln, such as is employed for the purpose of drying malt, or hops, when they are to be brought into such a state of dryness as to be perfectly brittle. This is to prevent the danger of their being injured by becoming mouldy, or from running into a state of fermentation; but much caution is necessary in conducting the processes. After this they are packed up in bags, in order to be disposed of to the dyer, who reduces them into a powder by a mill before they are made use of as a colouring ingredient."

Mr. Young, however, observes, that he is "informed, that at present (1803) the largest quantity of madder used in our manufactures, is used without being powdered as formerly, and that it is saleable with common drying, without store-work; but that, that common degree is open to much uncertainty, so that the preceding remarks are not done away. The price of 4d. per hundred weight, marks a considerable defection in his opinion."

It is hinted, that in order to judge of this root, the best is that which, on being broken in two, has a bright red or purplish appearance, without any yellow cast being exhibited.

It is stated, "in order to collect the seed of the madder plant, it is necessary to let the plants remain in the field till the seed is almost wholly ripe, which is generally in the month of September. The heads are then to be separated from
from the fents, and expos'd in a cloth in the sun, till the feed can be easily forced out by lightly beating them. It is then to be rendered perfectly clean, and afterwards placed in a funny situation, until it become quite dry; for if the leaf dampness remain, it will grow mouldy, and its vegetative power be either greatly impaired or wholly destroyed.

When thus properly dried, it should be put in small bags, and hung up to the ceiling of a room where a fire is constantly kept.'

The produce from the root of this plant is different, according to the difference of the soil; but mostly from ten to fifteen or twenty hundred weight, where they are suitable to its cultivation.

It seems not improbable, a late writer says, 'that the cultivation of madder might be rendered a profitable article of field-husbandry in different districts, if the importation of the root from Holland was prohibited; as the event of different trials has shown that full crops of good madder are capable of being raised.' And it is supposed by the intelligent writer of the Survey of Kent, 'that if the price was never lower than 1/4. the hundred weight, it might be grown not only with profit by the farmer, but without injury to the consumer.' As it is supposed, 'from the high degree of culture which land under this fort of crop must necessarily undergo, and its not being so much exhausted as in many other cafes, that it must be an excellent preparation for wheat, or any other crop that requires a clean and fine pulverized condition of the mould or soil.'

But the author of the Farmer's Calendar 'recommends the young farmer to remember that the culture of these plants, applicable only to the use of manufactures, and which are also largely imported from abroad, is rarely advisable. He was a madder planter once, and lovit by every acre he planted. A man may plant at the moment of a high price, and take up his crop three years after at a low one. All such speculations are too hazardous; nor was there even a fair open competition among the purchasers. Tho' who have cultivated madder with the success boasted by the writers of husbandry, should not hold these objections in contempt. There appears to him almost as much use in mentioning trials that were unsuccessful, as in those that are ever so profitable; for it is certainly of as much consequence to tell one man that his soil will not do for madder, as to assure another that his will do. Instead of an acre or two, he might possibly have launched (like many others) into ten or fifteen acres; in which case, the loss would have been no trifle. And it is purely highly incumbent on every one to make known to the world such of his experience as will probably be of any use to it. Bad success of several persons in a culture is too apt to prejudice others in general against it. However irrational, still it is so; and it ought to be a caution not to recommend any thing in general, under the extravagant notion, that because an article of culture is profitable on one soil, it must be the same on very different ones. But the grand obstacle to the culture of madder is the difficulty of sale: for while a man has not a fair market for his unmanufactured madder, none can with any prudence engage in it, unless on so large a scale as to admit the whole apparatus of reducing it to such a flake as to be absolutely a marketable commodity. In answer to this it may be said, that madder really dry is a marketable commodity. But this matters not, if the purchaser has in his power to be a knave: he has a pretence, a screen always at hand that will cloak the greatest knavery, and to a degree known in no other branch of agriculture. Among the gentlemen of trade who have a mutual understanding and providence, such objections appear trivial; but to the exulti-

Madder, in Lavo. See Larceny.

Madder, in the Materia Medica. The roots of madder were employed by the Greek writers with the same medicinal intentions for which they are recommended by most modern writers on the materia medica. Madder differs from some other substances used in dyeing, by its property of tinging with a florid red colour, not only the milk, urine, &c., but the bones of those animals which have fed upon it. This circumstance was first noticed by Antonius Mislas, (Memorab. ut. ac jucunda Cent. 7. Aph. 91. Latut. 1566,) but not known in England till Mr. Belcher published an account of a pig and a cock, whose bones became red by eating madder mixed with their food. (Phil. Trans. vol. xxxix. vol. xii.) Since that time various experiments have been made, by M. Hamel du Monceau and others, from which it appears that the colouring matter of madder affects the bones in a very short time, and that the mottled or harlequin part of the bones first receives the red colour, which gradually extends, ab extra, through the whole ossuous substance, while the animal continues to take the madder; and if the root be alternately intermitted and employed for a sufficient length of time, and at proper intervals, the bones are found to be coloured in a correspondingly number of concentric circles. Mem. de l'Acad. des Scienc. 1739. Med. Eff. Edinb. abr. vol. ii.

According to Lewis (Mat. Med.), the roots of madder have a bitterish, somewhat astringent taste, and a flight smell not of the agreeable kind. They impart to water a dark red tincture, to rectified spirit and to distilled oils a bright red; both the watery and spirituous tinctures taste strongly of the madder.

By medical writers, madder has been considered as a debittering, detergent, and diuretic, and is chiefly used in the jaundice, dropsy, and other diseases, supposed to proceed from visceral obstructions, particularly those of the liver and kidneys; and some modern authors have recommended it as an emmenagogue (Home's Clin. Exp.) and in reckless affections. (Levetr fur les Accouchemens.) With regard to its diuretic quality, for which there are several respectable authorities, Dr. Cullen asserts, that in many trials, both for this and other purposes, such an effect is not constant, as it never occurred to him. As a remedy for

Vol. XXII.

the jaundice, it has the authority of Sydenham, and was formerly an ingredient in the icteric decoction, which the college of Edinburgh directed to be prepared by boiling an ounce of madder, the fame quantity of turmeric, and the fame quantity of the roots and leaves of celandine, in three pints of water to a quart; to which, when strained and cooled, the juice of 200 millepedes are added; and a quarter of a pint of this liquor was ordered to be taken twice a day, or oftener. But as this decoction seemed to be more adapted to the "faces albide," than to the diseased itself, it was expunged from the Pharmacopeia. That some French writers should prefer this madder in a ricketty state of the bones, appears a little surprising, says Dr. Woodville, as the brute animals to which it was given, especially the younger, suffered considerable emaciation and prostration of strength from its effects. Its virtues, as an emmenagogue, rest principally on the authority of Dr. Home, who gave from a tispe to half a dram of the powder, or two ounces of the decoction, three or four times a day. But this medicine failed with Dr. Cullen, who also says, (Mat. Med. vol. ii.) "I know of other practitioners in this country, who, after several ineffectual trials made with it, have now entirely deserted its use." Woodv. Med. Bot.

Madder, Rubia Tinctorum, in the Arts and Manufactures, grows wild in many parts of the Levant, as well as in the south of Europe, and has been more largely cultivated in Holland, particularly in Zealand, and also in the northern parts of Europe, for the use of the dyers and calico printers. (See Dyeing.) The method of cultivating it in Holland is this: in autumn they plough the land, where the madder is to be planted, if it is strong and heavy, laying it up in high ridges, that it may be mellowed by the winter's frosts. In March they plough it again, working it very deep, and laying it in ridges at eighteen inches asunder, and about a foot deep. Then, in the beginning of April, when the madder begins to shoot out of the ground, they open the earth about the old roots, and take off all the fly shoots, which extend themselves horizontally just under the surface of the ground, preferring as much of the root as may be with them. These they plant immediately on the tops of the new ridges, at about a foot distance from each other; and this they usually do in flower weather, when the plants immediately take root and require no more water. In these ridges they let the plants remain two feasons, keeping them clear of weeds; and at Michaelmas time, when the leaves are fallen off, they take up the roots, and dry them for the market. See Rubia.

The madder-plant grows to about three feet in height, but it is the long-spreading fibrous root that is used in dyeing. The madder of the Levant, called "Lizaris," or "Azala," has a somewhat higher and finer colour than that of the Dutch; but that of Holland is more carefully prepared. The Dutch method is as follows: the roots, as soon as they are gathered, are put under a shed, or in a granary, or other sheltered place, and there remain, exposed to a current of air, for ten or twelve days, till they are quite pliable, and till no juice can be pressed out by squeezing them. They are then farther dried, either in a common oven of flack heat, if the quantity be small, or in large floved rooms, constructed for this purpose, and heated with turf, a large opening being left for the escape of all the internal vapours. This procures requires particular attention and management. When the roots are quite hard and brittle, they are laid on a threshing-floor, and beaten with a flail, in order to separate the dirt and outer thin skin; they are afterwards ground in a mill, and the powder, being sifted and sorted, is care-
fully packed in large barrels: it is thus exported, and in this state used by the dyers. For the method of cultivating and preparing madder in England, see the article Ruja.

The method practised in Turkey and Persia for preparing the madder used in the beautiful Adrianople red, is stated by an eye-witness, cited in Akin's Dictionary, to be as follows: For every 100 lb. weight of the fresh root, a steeping liquor is prepared of 2 lbs. of bran, and 1 lb. of honey and alum, in four gallons of water. The roots, having been previously washed clean, are soaked in this liquor for two or three days, and then dried, first under cover, and lastly in the sun. They are afterwards ground and sifted, the powder last produced in the mill being of the best quality.

The powder of madder should not be dry and harsh, but feel somewhat greasy, and adhere together under the fingers. Madder-root consists of three parts, viz. the skin, which is rubbed off under the nail, and is of no use; a thicker bark or cortical part, and within this a woody portion. These two latter parts are of a high red, and both are intermixed with many yellowish particles, which injure the red colour, but cannot be separated in grinding the root. When the colour is extracted in the dyeing vat, the red part is left soluble in water than the yellow, and is not so readily extracted; and, therefore, the beauty of the red colour is deteriorated by long boiling, and by using too large a quantity of the root. In the state of madder, when used by the dyers, it is an orange brown powder, liable to become damp, and to be spoiled in a moist place. As to the chemical properties of madder, we shall detail the following experiments by Mr. Wall, from Berthollet's Element. de Teinture, vol. ii.

Zealand madder of the best quality, was of an orange-brown colour, and in moderately fine powder. This powder, with water, gave an orange-red infusion, by maceration with or without heat, but in the latter case the colour was finer. By slow evaporation of the infusion, or decoction in a shallow vessel, a pellicle is gradually formed, and sinks to the bottom, and is successively replaced by others. The extract, when nearly dry, is of a duny brown, and is only in part again soluble in water. Alum added to the infusion gives a precipitate of a very deep brown-red, and the supernatant liquor assumes a brownish-yellow tinge. If the alkaline carbonates be added to this liquor, they give a blood-red lake, miscible with oils, but very inferior in beauty to the cochineal lake. With an excess of alkali, the precipitate is re-dissolved, and the liquor becomes red. The colour given by soda is not so fine as that by potash. Lime precipitates a brown-red lake, having no beauty. The acids added to all infusions of madder turn it yellow, but form no precipitate. The natural colour is again restored by alkali. Carbonat of magnesia, added to the water in which madder is infused, turns it of a clear blood red colour, which, when spread upon paper, becomes yellow by the sun's rays. The following effects are produced by different metallic solutions: acetate of lead, added to the aqueous infusion of madder, with red precipitate; nitrate of mercury, a purple-brown; sulfit of iron a beautiful clear brown; and sulfit of manganese also a purplish-brown. The solutions of tin, as Berthollet observes, produce a lake void of brilliancy and beauty, owing, as he conjectures, to the precipitation of the yellow as well as the red particles of madder, so that this metal, which serves to heighten the beauty of cochineal, can hardly be used with any advantage for madder.

Sir Henry Englefield has invented a method of extracting the red of madder from lakes, for which he obtained the gold medal from the Society of Arts. (See Trans. of the Society, vol. ii.) His method is founded on the discovery that the red colouring part is scarcely soluble in cold water, but in the usual method of extraction is chiefly suspended by means of the mucilage of the root. His principal process is as follows: Inclose two ounces (troy weight) of the finest Dutch madder, known in commerce by the name of "crop madder," in a bag capable of containing three or four times that quantity, made of strong and fine calico. Put it into a large marble mortar, and pour on it a pint of soft river water, pressing the bag in every direction, and rubbing it as much as possible without danger of bruising; the water will then become quite opaque, and loaded with colouring matter. Pour off the water, and add another fresh pint of water, triturating it with the madder as before; and repeat the operation, till the water, the last added, comes away but slightly tinged. About five pints of clear liquor will afterwards yield a beautiful orange-red lake by alkali, but wanting a sufficient body of colour. A lake equally good with the first mentioned, but of a lighter colour, will be afforded by previously allowing the madder and cold water to stand for a few days in a moderately warm place, by which a flight fermentation will be induced, and a portion of the mucilage of the root destroyed. The process is then to be continued as before. The fame ingenious experiments also succeeded very perfectly in obtaining a still more beautiful and equally durable lake, from the fresh madder-root imported from Holland, packed up in moss. Akin's Dict.

Wool, previously boiled in a solution of alum and tartar, receives from a hot decoction of madder and tartar, a very durable, but not a very beautiful red colour. M. Margraaf (Berlin Mem. 1771) shows how a very durable lake, of a fine red colour, fit for the purposes of painting, may be obtained from madder. The process is as follows: take two ounces of the purest Roman alum, and dissolve it in three (French) quarts of distilled water that has boiled, and in a clean glazed pot. Set the pot on the fire, and when the water begins to boil, withdraw it, and add to it two ounces of the best Dutch madder. Boil the mixture once or twice, then remove it from the fire, and filtrate it through a double filter of paper not coloured. Let the filtrated liquor stand for a night to settle; and pour off the clear liquor into the glazed pot, well cleaned. Make the liquor hot, and add to it gradually a clear solution of salt of tartar in water, till all the madder is precipitated; filtrate the mixture, and upon the red precipitate which remains, upon the filter, pour boiling distilled water, till the water no longer acquires a saline taste; the red
red lake is then to be gently dried. The colour of this precipitate is deep; but if two parts of madder be used to one part of alum, the colour will be still deeper; one part of madder, and four parts of alum, produce a beautiful rose-colour.

**MadooX, Isaac, in Biography, who arrived at the highest honours of the church, was defended from parents of rather mean rank in London. Of those parents he was deprived while very young, and he was placed in a charity-school, where he imbibed a taste for useful knowledge. An attempt was made to put him apprentice to a pastry-cook, but his love of reading, and his desire after learning, seem to have unhitched him for that employment, and he was, by the interest of his friends, allowed to pursue his studies at one of the Scotch universities. It has been said, but the fact seems at least doubtful, that he became a preacher among the dissenters for a short time. It is certain that he refused to take orders in the church of Scotland, and, probably by his talents, obtained the patronage of bishop Gibbon. He was, by the interest of the learned prelate, admitted of Queen's college, Cambridge, and soon after received episcopal ordination. He was first appointed curate of St. Bride's, and then domestic chaplain to Dr. Waddington, bishop of Chichefter, whose niece he married, and was afterwards promoted to the rectory of St. Vedalt, Fother-lane, London. In the year 1729 he was appointed clerk of the chappel to queen Caroline, about which time he was created a doctor by a diploma from Lambeth. In 1733, he was made dean of Wells, and in the same year he published "A Vindication of the Government, Doctrine, and Worship of the Church of England," established in the Reign of Queen Elizabeth." The work was a sort of answer to, or attack on, Neal's History of the Puritans. This defence of the church, together with his interest by marriage and otherwise, paved the way for his preferment, and he was in 1736 consecrated bishop of St. Asaph, from which see he was translated to that of St. Asaph in 1743, and thence to Worcester. Excepting the volume already referred to, the bishop published only fourteen single sermons, preached on public occasions, between the years 1734 and 1752. The bishop died in 1759, about the age of sixty-two. As a prelate, he discharged the duties of his station with fidelity and much diligence; in the government of the clergy he acted the part of a prudent and affectionate father. He was always liberal, and in many instances munificent: during his life, he gave two hundred pounds a year towards the augmentation of the smaller benefices of his diocese. He was a zealous encourager of public and benevolent institutions. To the London hospitals he was a great benefactor, and was among the first promoters of the Worcester infirmary. In his manners he was distinguished for cheerfulness, affability, and good nature, and was at all times above the falle pride of concealing his humble origin. At one of his entertainments he presided the company to taste his pastry, saying he believed it was good, but he could assure them that it was not of his own manufacture. Gen. Biog.

**MADE Streams, in Agriculture, such as are formed by art, as in the case of irrigation, &c.**

**MADEE, in Geography, a town of Hindooftan, in Tel-lingana; 38 miles of Warangole.**

**MADEIRA, a well-known island in the Atlantic, of which Funchal, situated near the eastern extremity of the south coast, is the capital and bishop's see. The first flight of the island is peculiarly magnificent to those who have never travelled beyond the British channel. The entrance to the bay affords a most beautiful prospect of the city of Funchal and of the surrounding country. The rice fields from every part of the coast rise so steep as to bring very distant objects into a fore-ground, like a Chinese landscape. As high as the temperature will admit the hills are clothed with vines, in the midst of which a white mansion, at agreeable distances, is discovered, and on the highest habitable part of the hill is an elegant chapel, dedicated to Nossa Senhora de Monte. To the left of this is a beautiful country seat, with a fine hanging wood, erected by the late confid, Mr. Ch. Murray, and since purchased by a Portuguefe nobleman. Above this the mountain is covered with woods or verdure, as high as the light can distinguish, and indeed in every part, excepting those columnar peaks, the foil of which has been washed away by the violent rains to which those latitudes, and particularly such elevated parts, are liable. The whole island is said to be about 40 miles in length, and in its greatest breadth. The altitude of Pico Ruivo, its highest land, taken by the barometer and thermometer according to M. de la Luc, is estimated at 5068 feet. To Mr. Johnson, called by the Portuguefe the accomplished Englishman, we are indebted for an accurate map of Madeira, and many other very valuable remarks. Though partner in a considerable mercantile house, he was a well-educated man, and always turned his acquirements to the benefit of others. His observations, confirmed, we believe, by the quadrant, estimated the peak somewhat higher. This is, however, nearly an English mile, elevated on a surface of about five miles on each side, which is enough to give an idea of the prodigious steepness of every part of the island. From Pico Ruivo, situated nearly at the eastern extremity of the mountains, part, there is a kind of table land, running westward for more than twenty miles, in some parts extremely narrow, and from its elevated situation fo tempestuous during the winter, that no habitations are found in its whole extent. This is called Paulo da Serra, and is said to be level ground, a comparative term in an island, the surface of which is so universally uneven. The following account of the geology of Madeira is offered as the most recent, though in many respects imperfect, from the short stay of the honourable H. G. Bennet, to whom we are indebted for it. "It confides," says that gentleman, "of a faceceon of lofty hills rising rapidly from the sea, particularly on the eastern and northern extremities. The summits of many of these range preferent the appearance of what has been called a table land; yet occasionally the forms are conical, and surmounted by a peak, which in some instances I found to be of columnar bafalt. Deep ravines or vallyes descends from the hills or ferras (so called from the interiptions of the eye meets with rising from the below the different chains of mountains) to the sea, and in the hollow of most of them flows a small river, which in general is rapid and shallow. The foil of the island is clay on the surface, and large mallees of it as hard as brick are found underneath. Though there are not at present any extinct volcanoes in the island, yet the remains of two craters are to be seen, one on the cañon, the other on the western side, the largest being about a Portuguefe league, or four English miles, in circumference. Every thing around wears marks of having suffered.
suffered the action of fire; yet I was unable to discover any
deposit of sulphur, and was told that none had hitherto
been found in the island.

"The varieties of flata, which I shall term generally lava,
are not numerous. I myself saw but four, and I was in-
formed there were no more to be met with. Three of them
were invariably alternating in the same order. The first or
lowest lava is of a compact species, containing few, if any,
extraneous substanances, is of a blue colour, and of a re-
markably fine grain. Upon that, the second, which is a
red earthy friable lava, rests; sometimes separated by beds
of clay mixed with pumice, and layers of black ashes and
pumice. This red lava contains minute pieces of olivine;
sometimes it assumes a prismatic form, and in one place
was of a moderate degree of hardness: the principal springs
of water in the island issue from this flata. On the top
is the third, a greyish lava, generally compact, though at
times near the surface very cellular, and containing much
olivine. This lava takes principally the prismatic form of
basalt. I have seen it in the most perfect prisms from 30
to 40 feet or more in height, the surface being covered with
feciura, ahi, and pumice. These mailes of lava contain
more or less of what I consider to be olivine, occasionally
carbonate of lime and zeolite, which last assumes either a
crystallized or globular form, or is diffused in a thin coating
between the different layers.

"The fourth species of lava is of a coarser grain, is used for
the making of walls, and the commonest and poorest houses
are built of it, the blue and grey lavas being used for the
copings, &c. It works easier than the two other kinds above
mentioned, is more friable and soft, and its colour is a mix-
ture of brown and red. I observed it in a flata by itself,
and it did not seem to have any connection with the other
three kinds.

"These are the principal stratified lavas of the island
affords; but in the beds of the rivers, particularly in that
which flows in the valley of the Corral, several varieties oc-
cur in isolated mailes, containing olivine and zeolite in
greater or lesser quantity, and exhibiting detached portions of
flata, similar to those that are found in the Fofa Grande on
the east side of Vulcano.

I also examined the coast to the westward of the town
of Funchal. From the beach before the town to Ilhoo Caftle,
and beyond it to the land called the Punta de la Cruz,
the general character of the coast is as follows: The red
flame is the apparent base upon which rests a bed of grey
prismatic lava, the flata being sometimes from 30 to 100
feet in depth. At times this grey lava rests upon a deep
bed of ashes and pumice, agglutinated together like the
peperino and puzzolana in the vicinity of Naples. The feciura
at the surface is remarkably thick, and all the upper parts
of the lava appear to be cellular. The general dip of the
lava on the coast near Funchal is to the north, but near the
fort of Ilhoo it forms with a mass of pumice that is inter-
ferred with flight veins of carbonate of lime and zeolite, a
rapid angle or curve of direction to the cafl. To the west-
ward of the fort, the lava is not found for a little distance,
and there is nothing but deep beds of pumice and the ag-
glutinated mailes above mentioned. These beds of pumice
are of various thickness, the deepest appearing to be about
four feet, and alternating with that flata which I have
called peperino. In different cavities of the pumice bed, there
are large deposits of black ashes. Towards the extremity
of the flata the red flame appears on the surface in a more
solid flate, and lies in prismatic mailes, the prisms being small,
and not exceeding a few inches in diameter. Their substan-
ces is brittle, and crumbles with ease. This flata of red lava
is of a short continuance. Passing a small brook, it dips
rapidly to the westward, and in its place the grey lava is
found in a confused though sometimes prismatic form, and
rises from the beach, while the red lava still runs along the
surface to the height of near 100 feet, the top being covered
with a thick scoria.

"There is also in the vicinity of Funchal, to the eastward
of the town, a fall of water, which, independent of the ro-
mantic beauty of the situation, merits being visited on ac-
count of the exposure of the two flata of lava in their re-

tative position. The hills are composed wholly of lava,
sometimes of a confused, sometimes of a prismatic forma-
tion, the red and grey lavas being visible on both sides of
the valley. Near the head of it, a short distance from the
cascade, the red flata is at the bottom, and about 60 feet
higher it re-appears, and again, about 200 feet higher, alter-
ating with the grey lava. The upper red lava dips rapidly

- Diagram -

"The rock, down which the cascade falls, is also inter-
ferred with a red flata of about three feet wide, that tra-
verses it, and dips to the westward, and is broken off by a
broad dyke of grey lava. It appears about 30 feet higher,
and dips again to the westward. The sublimate of the red
rock in this place is hard, and it breaks into a columnar
form, being by far the most compact of the red flata I met
with in the island. I saw this red lava also in the island of
Teneriffe, to the eastward of Santa Cruz, as well as in the
neighbourhood of Orotava.

From the sides of Pico Ruivo arise three principal rivers,
which traverse the island in different directions. Besides
there are two very considerable fountains on the table land,
and various other tributary streams. This command of
water at such a height is a most munificent blessing of
providence in a country usually free from rain for more
than six months of the year, the fteenth of which renders
the rivers in their natural forms little better than cataracts.
By diverting the water to the sides of the mountains by
regulations long established among the colonists, tracts of
land are fertilized, which might otherwise remain for ever
unproductive, or exhibit only trees and prickly pears (cactus
manillaris) whose roots would often become bare by the
torrents of the rainy season.

The following is the popular tradition of the discovery
of Madeira. One Machin, an Englishman of obscure birth,
had fallen in love with a young damsel, called Anne d'Arift,

- Diagram -

of exquisite beauty, and of a noble family, which dissolving
into low an alliance, though Machin had gained her af-
cidents, obtained a warrant from the king to keep him in
prison, until the lady was persuaded to marry a nobleman,
who took her immediately to his seat near Britot. Machin,
being some time afterwards released, found means to
convey the lady on board a vessel provided to carry them to
France.
France. When they were far at sea, a storm arose, and they were tossed for thirteen days on the waves out of sight of land. At length they perceived something that appeared like an island, overgrown with wood. The ship's men came to anchor, and Machin and the lady, with a few attendants, went on shore. In the Course of the night a tempest drove the vessel from her anchor, and carried her to the coast of Barbary, where she was wrecked, and the feamen made captives by the Moors. The lady, affected by this disalter, died in a short time, and Machin, through grief, soon followed her. Their attendants, rendered desperate by the loss of their conductor, quitted the island, and betaking themselves to their open boat, put out to sea, without knowing what course to steer.

After a series of adventures, they fell in with a Spaniard, who, delighted with their story, communicated it to Goncalves Zargo, sent out by the king of Portugal on a voyage of discovery, and prevailed upon him to fail in search of the island, who in a little time found it.

This story, though unnoticed by De Barros, the Liby of the Portugalne, is not only authenticated by a contemporary historian, but, after a very minute inquiry of the late Rev. Mr. Roberts, we are assured, stands as far a foundation as any other historical fact. The gentleman we allude to, being a clergyman of the Roman Catholic persuasion, and a native of Oporto, had the most favourable opportunities of ascertaining the fact, which diligence, knowledge of the languages, and access to every library, could afford him, and expressed his firm persuasion that the legend of Machin was, if not in all, at least in most, respects true. At Mecheco, a town in the eastern extremity of the island, a small chapel was shewn, of which the following was the history given by the inhabitants. That the Englishman (Machin), on the demise of his wife, had erected a cros, with an inscription, requenting that should hereafter any Christian by chance resort to the island, a chapel might be built, in which masses should be performed for the soul of his Anne: that the above chapel was erected on the spot, and the cros, made of cedar, was preferred near the altar. This cros was always exhibited. It was, however, much diminished, on account of small pieces given gratuitously to different visitors, insomuch that it was at last nailed to another and larger wooden cros, to preserve its form, and keep it together. This chapel had certainly greater marks of antiquity than any other building in that town. It was unfortunately washed away in that memorable flood which occurred in October 1803; so that, at this time, nothing remains to commemorate the event but the picture above alluded to, in the castle hall.

De Barros, who confiders the island as discovered by Goncalves Zargo, informs us, that as soon as it was divided into captainships (Mecheco and Funchal), the first cros taken by the new settlers was to set fire to the trees, the forest being every where impenetrable. Nothing can be better confirmed by every species of evidence than these facts, and that the island derived its name from the quantity of its wood. The word Madeira has the same signification as the Latin materia, from which it is only vernacularised, the Portuguese frequently substituting d for the Latin t, and tranposing the r from its situation with its connecting vowel; of which we need give no more familiar instances than pada and frade for pater and frater, when used in a spiritual sense. "Materia" is the classical term for forest trees, we have the authority of Cæsar in his Commentaries, who remarks of Britain, "Materia conjuque generis, ut in Gallia, ell; prater fagum et abietem." At this time the trunks of immense cedars are often discovered, but all the original trees themselves seem extinct, and, in the inhabited part of the island, to have given place to chestnut trees. The land is supposed to have derived its great fertility from this conflagration, which is said, and with much probability, to have continued in different parts for seven years. But it is well known that no land could be fertilized by such an event for three centuries; and the account we have given of the nature and quantity of the vegetable sitratum, joined to the abundance of water, and a favourable climate, is sufficient to explain all the fertility it really possesses. Though the vines grow luxuriantly, and produce abundantly, wherever they have a sufficient depth of soil, plenty of water, and a favourable aspect, yet the corn-lands require all the cultivation and occasional fallows of other less favoured countries. At the same time, it is no small boast of the islanders that their country produces the best wheat, the purest sugar, and the finest wines in the world, besides being blest with the clearest water, the most palatable air, the mildest climate, and a freedom from all noxious reptiles. Their wheat and sugar are such as are produced in the Mediterranean islands; but their wine, though originally brought from that source, infinitely surpasses all other in strength, delicacy of flavour, and dryness, besides the advantage of improving by being kept for any length of time, and even in a thoroughly cold latitude.

The mode of producing a good crop of wheat, at a distance from the town, is best a previous cultivation of the common broom. This is cut for fuel, and, after a time, grubbed up, and burnt on the foil. By these means, a crop of wheat is made in a succession of yeers, more or less, according to the foil; after which the same proceeds is again referred to. For this purpose, the seeds of the broom are collected, and generally bear the same price by measure as wheat. With all these allilances, the quantity of wheat produced is said not to equal a third of what is consumed, though maize is the principal food of the peafantry. Sugar is no longer cultivated as an object of traffic. Those fidalgos, who have plantations, still keep them up chiefly for their own use, and presents for their friends. Immediately after the sugar harveit, a small trade is carried on by manufaeturing something like barley-fugar, called rapaduras, (probably rapaduras, meaning the rapings or scrapings of the fresh fugar,) with which most of the natives are accustomed to regale themselves and children at this season; but for common use, the island is supplied with sugar from the Portuguese settlements in the Brazils.

The wealth of the country consists in its wines, which are cultivated with a degree of industry proportioned to their value. To preserve the foil, it is found necessary to erect walls along the sides of the hills, at distances regulated by the declivity. These walls are, in some places, erected to the height of sixty feet, so as to leave the bare rock, even here different flages have been erected, to which earth has been brought up, so as to form an artificial soil for this valuable production.

It will easily be conceived that such works as these cannot be accomplished without immense labour. When to this are added the difficulties of the roads, the vast expense and danger with which they are made, which, from the nature of the country, will in very few places admit of whea carriages, and the consequent inconveniences of conveying every article from the town to remote parts of the country, and also of conveying the wine and other productions of the country to Funchal, when all this is taken into account, it will be readily understood that the cultivators of Madeira cannot be a slothful race. Yet because men, who have been hard at work from before fun-rire, are seen refreshing them-
MADEIRA.

felvies with sleep in the open air, and even on the beach, during the interval allowed for rest at noon-tide, they are often confounded as indolent by strangers, who first view them after six hours' labour. Nor are the women less indolent. Those who are young enough climb the mountains to procure broom and brush-wood, which they bring to town, and sell for fuel. Others bring the produce of their gardens; whilst the elder ones are constantly employed at home in spinning or domestic concerns.

It is true, that the increased demand for labour in Funchal has produced a race, somewhat familiar to our long-shore and water-fade men in England, who labour much too hard, and support themselves under it with ardent spirits or wine. But this is far from the character of the people.

The country is cultivated by what are called by the French métayers, that is, by a peafantry who divide the produce with the land-owner. Considering the labour required for first preparing the land, and that the produce of the wine is reckoned as nothing till the third year, such a return to the cultivator is very unequal. He is usually allowed a small space for gardens, or an esculentum, sweet potatoes, convolvulus batatas, or other esculents. These he is expected to share with the landlord. In this there is said to be great collusion; but in the wine this can hardly be the case, on account of the tythes. The cultivators have, however, one very great interest in the land, and consequently a great inducement to engage in these operose undertakings. Whatever necessary improvements they make, become their own; hence the walls, the vines, and even their cottage, as far as is considered necessary, is their own property; and though, in entailed estates, a lease cannot be granted for more than nine years, yet the tenant cannot be dispossessed till he is paid the full value of his improvements. In proportion as the increase of commerce has rendered money of less value, the money-price of these improvements is advanced; and even the vines are estimated, not by number, but by their age and supposed fertility. Hence the tenant not only surveys the property he has acquired by his own labour or expense, but fees that property yearly improving by the common operations of nature.

The tythes of this, in common with the other Portuguese colonies, were given by the pope to the king of Portugal, as sovereign of the order of Christ. Out of them the clergy are paid, and for the most part very poorly. They formerly received all their revenue in kine; but, unfortunately for themselves, petitioned to have a moiety in money. In consequence of this, by the gradual diminution of the value of money, and increased value of every production, they are considerable losers. Some of them make a traffic of wine; and, on the whole, they are much less superfluous than in most Catholic countries. Their number, both secular and regular, is much less than is generally supposed. By some it is said not to exceed 300, including the monks and nuns. Of the former there is only one order in the island; the number of nuns is uncertain. There is a feminary in Funchal for the education of the clergy of the island, with something like an academic establishment, originally, we believe, formed by the Jéfuits, who erected other schools in various parts of the country. The bishop retains his original number of priests of wine, besides other emoluments, which render his situation more lucrative than the governor's. He is expected, indeed, to divide his revenue with the poor; and an infirmity is often mentioned of one whose benefactions exceeded his implied obligations.

The natives of Madeira are a very mixed race. Among the labouring classes in the town we often recognize faces truly English, and even English complexions. This is said to be traceable from the frequent intermixture of the two nations, not only by the English settlers, but by the constant arrival of English sailors. The other inhabitants, excepting the superior classes in some parts of the island, are a mixed race. Besides the colonists from the mother country, Moors in great number were at one time imported. Spanish also repented bither during the union of the two countries; and negroes have been purchased for this, as well as the other European settlements. The last were, however, few in number; their intermarriages with the natives fewer, so that but little vestige remains of their characteristic marks. On the whole, the male inhabitants may be called a comely race; they are, for the most part, about the middle size, well enough formed, with strong masculine features, hair, and complexions. The women are almost universally shorter than the comparative difference would lead us to expect. Such as are engaged in the laborious employments soon lose the few charms which youth might otherwise supply.

The animals, natives of the country, are, as in most mountainous countries, universal. To an Englishman, their beef and mutton is too lean and tasteless; but those who are accustomed to warm climates speak of them in better terms. Of poultry, the common domestic fowls are small; but this is simply made up by their ducks and turkeys, the latter of which are not inferior to those of Norfolk. Pork is peculiarly fine; but the expense of feeding, or the warmth of the seasons, makes it such a rarity, that it is rarely produced excepting at Christmas festivals. It true, hogs are found rambling about the towns, but very few are reared for porkers. Fifth, particularly rock-fish, is plentiful and good of the kind; but the nature of the coast prevents the residence of many shell-fish.

The uneven form of the country renders the island productive of the European as well as more southern fruits; but it is a mistake that the true tropical fruits are readily produced. In the valleys are found guavas, bananas, and oranges. A fingle allegator pair tree has grown for several years, but rarely produces fruit. Pine apples are reared with great difficulty; and the granadilla quadrangularis, spreading to a great extent, and the luxuriantly bearing jack fruit, has not yet been, or will ever be, produced ripened fruit.

The staple commodity of the island is wine, of which the average quantity made about ten years ago was reckoned between 30 and 40,000 pipes. More than half this is exported, principally to the British settlements in the East and West Indies. A quantity, comparatively very small, finds its way to London. Speculations in trade have lately increased this quantity: but there is reason to fear that the quality is not improved by it, as there is said to be constantly a difference between bastard-wine and bill-wine; that is between wine exchanged for marketable articles, and wine which is paid for by bills drawn at a short credit. The best wine grows on the south side of the island, and the belt of that for the most part in the inferior parts, and on that side of the hill which points to the east. This advantage seems entirely attributable to warmth; the well being always cooled by the breeze or mist, which by noon constantly blows from that quarter. The north wine was formerly much undervalued, and principally consumed in the islands either as a beverage of the natives, or distilled into brandy. But the increased demand for the article has encouraged many of the merchants to mix a portion of north wine with the south; and the improvement of its price has given additional encouragement to improving it by cultivation. That the quality of the wine, however, depends principally on the aspect and soil, is pretty clearly proved by the superiority of the cerial. This, though originally
MADEIRA.

Generally produced from the Rhenish grape, is considered the strongest and richest of all the dry wines in the island. The beet wine is almost always mixed with a portion of the vinho tinto. This is at first nearly the colour of red port, but from year to year grows paler. Hence, could we always ascertain the genuine of the wine, the colour would be a considerable means of ascertaining its age. But the addition of the north wine will at any time lower the colour, and to the eye give the appearance of age. Certain it is that the vast demand of late years has nearly exhausted the island of old wine, so that those who wish for such a luxury, will do well to keep it themselves. This should be done, not in a cold underground cellar, but in the warmest part of a dwelling-house, and, if such can be procured, in an apartment open to the south.

The quantity of genuine Malmsey produced annually is very small, and in truth very uncertain, because a good deal is manufactured with refined sugar, and though greatly inferior to the genuine, is, if well managed, truly delicious. We have reason to believe these are the only fashions in which Madeira wine is made. The stories of the importation from Teneriffe and other places are certainly unfounded; at least such is the universal anxiety to preserve the credit of the island, that no quantity can be imported which would pay for the danger and expense.

The other exports from Madeira are trifling; they consist principally of chefnuts, walnuts, preferred citrons, and those occasional supplies of green provisions for vessels touching at the port, which are purchased here much dearer than in England. The imports consist of the greatest part of the provision of the island, excepting fresh meat, and even living sheep and oxen are imported with advantage from Barbary, and the Azores, or Western islands. From America they derive principally their wheat, Indian corn, and, in common with other Catholic countries, vast quantities of salt fish. From England they receive most of their wearing apparel, the quantity and value of which increase rapidly every year.

The crown of Portugal derives its revenue in part from a duty of 20 per cent. on the invoice value of all articles imported excepting provisions. But its principal revenue is from the wine. Besides the tythes, the farming of which is disposed of by auction every year, and which is every year purchased at a higher rate, a duty is imposed on all the wine as it is exported, and a port of excise on what is consumed in the island. A revenue is also derived from the monopoly of snuff, cards, and soap. The aggregate is enough to pay all the expenses of the civil, military, and ecclesiastical establishments, and to remit considerable sums to the crown. But there is always much uncertainty in the latter. We have heard it stated as 50,000 and 50,000; the latter we should conceive must be nearest the truth, when we reflect that a considerable part of the merchants' capital consisted at one time in the manner in which the revenue was remitted to Lisbon.

Of all the complicated mercantile questions, nothing is for the most part equal to that of the money in Madeira. From their intercourse with the English West Indies, or from some other cause, scarcely anything is seen but Spanish silver coins, and by some unaccountable incidents, these have got the name of Portuguese coins. Thus the pelteen is called two teetoons, and five of them are called a milrea, and though five pelteens are as exactly equal to a dollar as 5s. are to a crown, yet the Portuguese have no coin corresponding to dollars, for a long time the five pelteens were more valuable than the dollar, which last was hardly considered current in the island. Though this last absurdity is now done away, yet it has made no other difference in the names of their currency, excepting that the dollar has now the name of milrea, in common with its representative five peltreens. But the coins in Portugal, whose names are thus usurped by the Spanish pieces, are intrinsically worth nearly 20 per cent. more than the latter. Hence, when an ignorant captain sells his cargo for so many thousand milreais, he usually finds his bills produce him about 20 per cent. less than he calculated upon. The currency and use of the dollar are gradually remedying this inconvenience.

The mode of government remittance to Lisbon was by giving Madeira milreas, for which the merchants gave their bills on Lisbon for the same number of milreais, payable at two years. By these means they paid about ten per cent. per annum for the use of money for two years, at the expiration of which they often paid their bills as they became due, by issuing fresh ones. These transactions, though very convenient to the government, and still more so to the merchant, have often been productive of serious injuries, by inducing a mercantile people to overrate their capital, and on the least suspicion of their solvency, the crown has seized their whole; laying, as in England, violent hands on land property, which has been sold by the government-debtor after the debt was contracted.

Besides the above duties on wine, the British consul and factory receive a certain sum on every pipe exported to any part of the British dominions, for the expenses attending their establishment; for the relief of sailors left on the island; and of decayed merchants entitled to such a benefit. This fund should also support a clergyman and Protestant chapel, the erection of which would probably increase the reputation of the British nation among the natives, and might even support itself by voluntary contributions.

We have been thus particular in our account of this island because, however inconsiderable in extent, it cannot be considered in importance. Its climate, productions, its situation by its proximity to Europe, and in the course to the East or West Indies, all render it interesting, but most of all, the present condition of the European continent, and the interest which England feels in whatever may facilitate her connection with her distant settlements. On this account it may not be amiss to add a few words on the advantage which England might derive from such a possession, and the consequences to the island of such a change.

Madeira is already so much connected with England, and the inhabitants of Funchal are so much anglicised, that in many of the Portuguese settlements it is humorously called picheu Londres, or little London. It is not only the quantity of English goods consumed in the island that benefits Great Britain, but the quantity exported from hence to the other Portuguese settlements. It is difficult to say whether England or Madeira is most benefited by this traffic. The only exchange that can be made for every article of luxury is wine, and the necessity of this commodity induces an increase of industry. Should the island become altogether English, it is probable that another source of wealth would be derived from English capital, which, expended in cultivating or improving fresh lands, might prove a profitable, though at first an uncertain, speculation. But whatever might be the consequences to England, the island could not but be benefited by all that is expended on its cultivation. This must however be accomplished by the manual labour of the natives, whose workmen of their land enables them to turn to good account their industry, muscular strength, and great patience under arduous toil. But these are no longer sufficient without capital, since the price of labour is so much increased, and the parts safest cultivated and most profitable to the labourer, are more generally occupied.

The present government is similar to that in the mother country,
country, to which all appeals are made, and to which any alteration in the existing laws are referred for decrees from the prince. It would not be safe suddenly to alter this system; but great pains are wanted to purify the fountains of justice. A people, accustomed only to obey by mandate, and to protect each other from the oppressions of government, could not at once fall into a legislation of which they are themselves a part. They must gradually be taught the blessings of liberty, by the certainty with which their property and persons are secured, and by the restoration of those privileges they once enjoyed; but which now exist only in name. These should be well understood and defined, and the utmost attempted at first should be a careful appointment of enlightened magistrates, or judges, as they are mostly termed, with a proper augmentation of their salaries, and the superintendence of a governor acquainted with the languages, laws, and customs.

From the heavy duties imposed by government, many expenses are supported, which, according to the freedom of our constitution, are defrayed by the public, and regulated by commissioners of their own choice. We refer chiefly to the public works, viz. the building and repairing of churches, the improvement of the ports, and the construction and repair of roads and bridges. These last are paid only in part by the crown, the male inhabitants being obliged to perform certain labours in their different districts. If the work is considerable, a certain pay is allowed, but not at all adequate to the usual price of labour.

If the average amount expended on roads and bridges by government were lodged in the hands of commissioners chosen by the inhabitants; and if, in aid of this, a tax of two guineas per annum were laid on every horse; if the produce of this were added to the former fund, and the commissioners were authorized, as in England, to borrow money on annuities: by these means, the whole island might soon be interfaced with roads, and united by bridges, so as to render every part accessible with ease. Hence the produce of the country should readily be brought to the towns, and from thence, by water, to different parts of the coasts; the gentry would have greater encouragement to remain a considerable part of the year at their country estates; the mansions on which is rendered universally convenient and elegant, and this example would soon extend to the wealthier cottagers, and even to the merchants and tradesmen, who would, as in England, be all ambitious of country residences. That all this may be accomplished, we have a striking example in the pavilion which M. de Carvalhal has erected for himself, at the distance of about three miles east of Funchal. On a spot, at one time scarcely accessible, with only a single clump of trees, and almost without water, he now exhibits large fleets of water, extensive avenues of flowering shrubs, roads in every direction, and the prospect of an English parc orné.

In constructing roads in Madeira, the first object should, of course, be to preserve as level ground as is consistent with the nature of the country, by winding round the hills. But great care should be taken that the alum is never intertured for beacons, but the provisions whatever is brought from the country can be conveyed without difficulty or labour; the hack carriage must always be laborious, but mules with packs may be kept at different pâces, and hired on the spot, like some additional horses in particularly steep roads in England.

One most furious evil must be immediately remedied whenever the island is allowed to use those blessings with which providence has indulged it. We have remarked the advantages derived from the height at which the rivers rise. This not only gives the command of water before alluded to, but furnishes a power by which mills might be multiplied to any extent, or for any purpose. At present, the privilege of erecting water-mills is confined to a grandee, who never saw the island. Hence the mills, excepting near the town, are dilatory, nor is there any inducement to multiply them, as all mill rent to them, however inconvenient. Nor is this all, in order to feed the mills near the town, a considerable quantity of water is lost, which, if expended on the higher grounds, would, in some feasons, add greatly to their fertility.

There are only a few of the benefits which England as a nation, and Madeira as a settlement, might mutually confer on each other. Besides this, a port might be constructed at Funchal, the bay of which, though invariably calm in the summer, is, during the winter, always uncertain, and sometimes dangerous. But the advantages to the individuals of both nations would be incalculable. The only distance might induce many in delicate health to pass the winter in Funchal, where the thermometer is rarely lower than 62°, nor above 65°, and often stationary within doors for twenty-four hours. In the summer about 105° higher, and the air gradually cooler as you ascend the mountains. This city already, we are informed, has its theatres, its coffee-houses, and would soon have its library, its printing-presses, and its own gazettes. Though the expenses of the table are perhaps equal to those of London, yet wine may be procured without an exorbitant duty; there are few other taxes, and the equipages of London will never be necessary in such a climate, nor perhaps manageable in such a country.

If ever the population of Madeira should be so considerable as to render labour cheap, or that employment should be wanted for many superfluous hands, the silk worm seems, of all others, the most promising article. For five, often for seven or eight months, they could feed on the trees in the open air without the danger of rain, and the description given of the rivers would at any time furnish fire-irons which might be sufficient for winding off the web. It is true, the attempts formerly made to introduce the white mulberry have hitherto failed, but this has been rather from a want of general concurrence in the cottagers, than from any difficulty in the soil.

The inhabitants of Madeira were reckoned at the last census about 100,000; of these nearly a tenth part are paid to reside in or near the capital. Funchal has been well fortified since the English have arrived there, which was easily done on account of the barriers provided by nature. The regular force of the Portuguese government was 200 infantry, ill dressed and ill trained. The same number of artillery, whose appearance and discipline are highly respectable. There are three regiments of militia commanded by colonels of districts. These are drest in uniform at their own expense. The rest of the inhabitants, from the age of twelve years and upwards, are expected to furnish themselves with pikes or guns according to their abilities. In short, the whole government may be called military, a striking proof how little danger there is putting arms in the hands of citizens who are not employed, for in Madeira inhabitants are few, and those few rarely among the lower classes; and civil commotions have seldom excited for years past, and never proved fanguary.

The other islands, included under the government of Funchal, are scarcely inhabited, excepting Porto Santo. This has its own governor, but is amenable to the governor of Porto Santo. Its produce is similar to Madeira, excepting that the wine is inferior. A good deal of barley is grown on this, and the small islands, called deférias. Porto Santo also produces the water-melon in abundance, and much
MADEIRA, or Madeira, a river which rises in the government of Charcas in Peru, near Cochabamba, in S. lat. 18', first called "Corderilla!" having received some smaller rivers, it changes its name into "Parapite." Hitherto its course is S.E., till it enters a lake situated in S. lat. 19° 50', after which it takes a northerly direction, with the name of "St. Miguel," afterwards "Sara!" about S. lat. 14°, it is called "Mamore!" and in S. lat. 10°, it leaves Peru, and enters Brazil, from which time it is called Madeira, till it discharges itself into the river of the Amazon in S. lat. 3° 15'. W. long. 60° 40'. Its whole course is about 1200 miles.

MADELA, a town of Asia, in Palestine; 192 miles S.E. of Jerusalem.

MADELAN, a town of Hindoostan, in the Subah of Agra; 10 miles S.E. of Kerowly.

MADELEY MARKET, a market town and parish situated in the hundred of Wenloch, and county of Salop, England. It is finely seated in a widening glen, through which the river Severn flows, at the distance of 147 miles from London, and 51/2 from Shifnal. According to the parliamentary returns in 1801, this town then contained 291 houses, and 4728 inhabitants, being 2432 males, and 2296 females, of whom 1594 were found to be employed in various branches of trade. A navigable canal to the Ketley iron-works, which are among the most extensive in England, and also to a work for the extracting of fusil tar or petroleum from the condensed smoke of pit-coal, passes close to the housetops. Over the Severn, in this parish, is thrown a noble bridge of cast iron, which was erected in 1779, and consists only of a single arch, 100 feet 6 inches in span, and 45 feet in height at the centre above the level of the road level. The road over this bridge is composed of clay and iron flag, 24 feet wide, and one foot deep. Iron top plates project from each side, and serve to support a very noble balustrade of cast metal. The weight of iron, in the whole, is 378 tons 10 cwt. This bridge contributes not a little to enhance the natural beauty of the romantic Vale in which it is placed. (See Bridge, Iron, in vol. v. of this work.) At the foot of this bridge is the market-place, which is nearly two miles distant from its original situation. The market, since its revival in 1763, previous to which period it had been long discontinued, has been regularly held on Friday, and is, for the most part, well supplied with all the articles requisite for the sufficiency of man. This parish includes the populous hamlets of Colchbrook-dale, and Madeley-wood, which are remarkable for their extensive coal works.

MADENNALLY, a town of Hindoostan, in the circuit of Sollapour; 35 miles N. of Sollapour.

MADEIRA, a town of Perugia, in the province of Far-ilijan; 20 miles N.E. of Eftaka.

MADEIRAM-PULLI, in Botany, a name used by some authors for the tree whose fruit is the tamarind of the shops.

MADEINO, CHARLES, in Biography, an eminent Italian architect, was born at Biffona, in Lombardy, in the year Vol. XXII.

1556. He went at a very early age to Rome, where his uncle, Dominico Fontana, was, at that time in full employ as an architect. His inclinations for sculpture became manifest, and he was placed with an artist in that branch of the fine arts. His progress in modelling was such as led his uncle to confide in him the management of some buildings then in hand, which he executed with so much skill, that he was advised to devote himself entirely to architecture. At the death of Sixtus V. Maderno was appointed to design and execute the magnificent tomb for his interment. The public works which were carried on under Clement VIII. were chiefly committed to the care of this artist, and so high was his reputation in the succeeding pontificate, that, on the succession of Paul V. in 1605, he was appointed to finish the building of St. Peter's; his plans being preferred to those of eight competitors, and the work was placed under his direction. He was afterwards employed upon the pontifical palace on the Quirinal mount. Another work, for which he is celebrated, was the raising a fine fluted column found in the ruins of the temple of Peace, and placing it on a marble pedestal in the square of St. Maria Maggiore.

His theory was as one never confined to architecture, he was sent by the pope on a commission to examine the ports of the ecclesiastical states, and afterwards surveyed the lake of Perugia, and surrounding country, in order to divert the inundations of the river Chiana. He was confuluted upon most of the great edifices undertaken in his time in France and Spain, as well as in the principal towns of Italy. His last work of confidence was the Barberini palace of Urban VIII., which he did not live to complete. He died of the stone in 1639, when he had attained to the age of seventy-three. He had seen ten popes, by most of whom he had been regarded with favour. Gen. Biog.

MADENO, in Geography, a town of Italy, on the S.W. coast of Lake Garda; four miles N.E. of Salo.

MADETZ, a town of Waalchia, on the Danube; 30 miles W.S.W. of Girogiev.

MAD-HOUSE. By 14 Geo. III. c. 40, enacted to be in force for five years, and by 19 Geo. III. c. 15, which continued it for seven years farther, and by 26 Geo. III. c. 91, made perpetual, no person, on pain of 50 pounds, shall keep for the reception of lunatics, more than one lunatic at a time, except such lunatics as are committed by the lord chancellor, &c. without a licence to be granted yearly by the college of physicians, within London and Westminster, and seven miles thereof, and within the county of Middlesex, and elsewhere by the justices in fequisitions. The licences are to be granted with a 5s. stamp: every one who keeps a number of lunatics, not exceeding ten, shall pay the sum of 10l. and above ten the sum of 15l. and 6s. 8d. on every licence, as a fee to the secretary of the commissioners. No licence can authorise any person to keep more than one house. The commissioners, confiding of two justices and a physician, may visit licensed houses, and inspect their state as often as they think fit: on application to the commissioners for information concerning any confined person, the secretary is to search his books, and acquaint the persons applying with the name of the keeper in whose house the lunatic is confined. The keeper is required to give notice to the secretary within fourteen days after receiving a patient, who is to be kept in a room or cell, and every keeper admitting a person as lunatic, without an order under the band of some physician or surgeon that such person is proper to be received, shall pay the sum of 100l. No licence shall be granted unless the keeper enter into a recognizance in 100l. with two sureties in 50l. each, or one
one surty in 100l. on the usual conditions, for the good behaviour of the keeper. This act doth not extend to any of the public hospitals. This act contains various distinct regulations for such houses in London, Westminster, and within seven miles of the town, and in the county of Middlesex. By 48 Geo. III. c. 56, several provisions are made for the better care and maintenance of lunatics, being paupers or criminals in England. The first seventeen sections, and some others, relate to the building and conducing of lunatic asylums. As soon as such an asylum is ready, jujtice are, by warrant, to remove lunatics to it, and the parish is chargeable with an allowance. If the overseer neglects to inform the justices, and to apply for such warrant, he shall be fined for every offence, not exceeding 10l. nor less than 4s. When lunatics are committed by justices under the 17 Geo. II. c. 5, the said justices shall order in their warrant, that such lunatic, or mad person, shall be confined in such lunatic asylum, and not elsewhere; but if no lunatic asylum be established, they may order that such person be confined in any house duly licensed under the 14 Geo. III. c. 49. Where the lunatic's legal settlement cannot be ascertained, the justices may order such person to be confined in the lunatic asylum for the county or district within which such person shall have been apprehended, if there be any such, and not elsewhere; if there be none, in some house duly licensed under 14 Geo. III. c. 49, or in some other secure place, as directed by the 17 Geo. II. c. 5. And if such person have not an estate to pay and satisfy the reasonable charges of removing, and of keeping and maintaining and currying such person under 17 Geo. II. c. 5, then those charges shall be paid by the treasurer of the county within which such person shall be apprehended, out of the county rate, by order of two justices directed to him for that purpose. All lunatics, &c. shall be safely kept, nor be suffered to quit the said asylum, until the visiting justices shall order their discharge, and signify the same in writing under their own hands and seals; and if any servant or officer in such asylum shall, by neglect or negligence, permit such person to escape and to be at large, without such order, he shall, for every such offence, forfeit not exceeding 10l. nor less than 4s. In all cases, where by virtue of the 39 and 40 Geo. III. c. 94, any person shall be kept in custody, it shall be lawful for any two justices of the county where such person shall be so kept, to ascertain, by the best legal evidence that can be procured under the circumstances of personal legal disability of such lunatic, the place of the said legal settlement, and the circumstances of such person; and if such person is not possessor of sufficient property for his maintenance, to make order upon the parish where they shall adjudge him to be legally settled to pay such weekly sums for his maintenance in such place of custody as such court or his majesty shall appoint, as shall be from time to time directed and fixed upon by one of his majesty's principal secretaries of state; and where such place of settlement cannot be ascertained, such allowance shall be paid by the treasurer of the county where such person shall have been apprehended; but if it shall appear that such person is possessor of sufficient property, as aforesaid, then such justices shall order the same to be applied to satisfy the excellence and maintenance of such person in the manner directed by 17 Geo. II. c. 5.

MADIAN, or MIDIAN, in Ancient Geography, a town of Arabia, in the province of Hedjaz, which owes its name to one of the sons of Keturah, and was destroyed in the time of Abulfeda. It is seated at a small distance from the Red sea, which at this place is not more than 100 paces wide. The Arabs call it "Megar el Schuaid," or the Grotto of Schuaid, or Jethro: and they suppose that this is the place where Moses tended his father-in-law's flocks. Ptolemy calls it Mduhuma. N. lat. 28° 20'; E. long. 38° 10'. See MIDIAN.

MADINA, in Geography, a river of America, in the illaibles of Durian, which runs into the Spanish Main. N. lat. 9° 23'; E. long. 38° 48'.

MADISON, a county of Virginia, bounded north-east by Culpepper, south by Orange, and west by Shenandoah county; about 30 miles square, watered by the Rapid Ann and Robson rivers, and containing 4886 free inhabitants, and 3436 slaves. — Alto, a county of Kentucky, adjoining Fayette, Clark, Lincoln, and Mercer counties. It contains 10,380 inhabitants, of whom 1688 are slaves. The chief town is Miford. — Alto, a small post-town of Amherst county, Virginia, on the north side of James's river, opposite to Lynchburg; 150 miles W. by N. of Richmond.

Gen. Ch. Common Calyx globoso, of many leaves arranged in a double row, carinated; the eight exterior ones acute, and longer, approximating into a globus. Cor. compound, radiused; flowers of the disk all perfect, numerous, tubular, five-leafed; those of the radius female, eight in number, ligulate, three-toothed. Stem. (in the tubular flowers) Filaments five, capillary, very short; anthers cylindrical. Pyll. (in the tubular flowers) Germen ovate-compressed, most acute at the base, incurved; style simple; stigma two. Petio. none, except the permanent calyx. Seeds futilary, the shape of the germin. Recpd. naked. Down none.

Eff. Ch. Receptacle naked. Down none. Calyx double, the outer one of eight or ten equal leaves, longer than the inner one, which is composed of many leaves.

3. M. melletia. Wild. n. 2.—Leaves embracing the stem, lanceolate, hairy. — A native also of Chili. These two species are adopted by Willdenow from Molina without any further description than is now given. — Cavaiatex also mentions them, but merely to say that 'saftif' differs from them both in having short roots, and serfle leaves, never embracing the stem.
known extent, nearly on a level with the water of the river.

MADISTERIUM, Madripen, a name given by the Greeks to an instrument intended to keep the skin smooth, by eradicateing the hairs.

MADMAR, in Geography, a town of Persia, in Khorasan; 12 miles W. of Herat.

MADMEM. See mental derangement.

MADNESS. See mental derangement.

MADNESS from the bite of rabid animals, the Rabid cainus, and Hydrophobia of medical writers, will be found described at length under the latter title. The term madness, as applied either to the disease in the dog, or other rabid animal, or to that of the human species, when bitten, is an absolute misnomer, and has led to some important popular errors both of opinion and practice; and ought therefore to be discarded. There is neither the violence in the rabid animal, which the term implies; nor the derangement of intellect, or violence in the hydrophobic patient, which has been inferred from the appellation. Yet these mistaken notions have led to the practice of permitting dogs, actually rabid, to go loose, and inflict mischief on the public, as well as to that of murdering sick men by suffocation, from an apprehension of the un gover nable fury which it has been supposed would ensue. See Dog and Hydrophobia.

MADNETTI, in Geography, a town of Hindoostan, in Myfor; 18 miles E. of Bangalore.

MADNING-MONEY; old Roman coins, found about Dumbell, are so called by the country people; and have their name from magistium, used by the emperor Antoninus in his Itinerary, for Dumbell.

MADODENQUIK, in Geography, a river of New Brunswick, which runs into the St. John, N. lat. 46° 19'. W. long. 67° 34'.

MADOLAND, a town of Kemacon; 5 miles N.W. of Kerigar.

MADOMGUINGE, a town of Hindoostan, in Bahar; 7 miles S. of Bahar.

MADONA, a small island in the Mediterranean. N. lat. 36° 31'. E. long. 26° 47'.

MADONDA & Scipia, a town on the east coast of the island of Zante; 2 miles S.E. of Zante.

MADONIA, a mountain of Sicily, in the valley of Mazara; 35 miles S.E. of Palermo.

MADONNINA, in Commerce, a silver coin of Genoa, of which there are the double, single, and half, at 40, 20, and 10 soldi. The double Madonnina (the fingle and half piece being in proportion) weighs 5 dwt. 13/4 gr., contains, in pure silver, 116.2 grams, and its value is 1s. 4d. sterling.

The impression is a whole length figure of the Virgin standing, with her head encircled by a halo; legend, SUB TUTUM FRIAEUIDUM (under thy protection), with the date; and round the figure are SEE DERELINX NOS (do not forsake us); revera, arms of Genoa; legend, DUX ET GUR. REGNI. GENU. (dove and governor of the republic of Genoa).

MADOO, in Geography, a small island in the East Indian seas. S. lat. 7° 31'. E. long. 122° 18'.

MADOOCARRY, or MADOCARRY, a town of Hindoostan, in Coimbetore; 6 miles S.S.W. of Coimbetore.

MADOOR, a river of Hindoostan, which rises in the Myfor, about 20 miles N.N.W. of Ser a, and runs into the Canvery, 36 miles below Seringapatam.

MADOOSAND, a town of Hindoostan, in Robilcund.

MADORE, a town of Hindoostan, in Myfore; 8 miles N. of Seringapatam.

MADRAPPUR, a town of Bengal; 20 miles S.E. of Bhopapur.

MADRAS. Fort St. George; or, as it is called by the natives, China-patam, a town of Hindoostan, on the coast of Coromandel, and close on the margin of the sea. It was about the year 1610 that the English East India company obtained leave of the king of Coconoda to settle at Madras-pattam, where they were permitted to build the fort called St. George; which place has ever since been the company's general factory for their trade to all parts east of Cape Comorin. (And Hist. Com. vol. ii. p. 6. folio.)

Others say, that Madras was settled by the English about the year 1640; and it is also said, that the town was built in the reign of Charles II. by order of the East India company, under the superintendence of sir William Langhorne. As he placed it in the midst of a sandy defect, altogether dry, and where there was no water fit for drinking, except what was fetched from the distance of more than a mile, people were curious to know what reasons could have induced him to make so bad a choice. His friends pretended that his view was to draw thither all the trade of St. Thomas, which has actually been the consequences; while his enemies imputed it to a desire of continuing in the neighbourhood of a mart, of which he had in that Portuguese colony. In the rainy season, the sea threatens destruction on one side, while the river, menacing an inundation, is no less terrifying on the other. From April to September the sun's heat is searing; and if it were not mitigated by the breeze, the place would not be habitable. In the vicinity of the camp, the soil is so dry and sandy, that it does not produce so much as a blade of grass spontaneously, nor any corn without great labour of culture. The roots, herbage, and vegetables, consumed in this place, are brought from a considerable distance. It is still a more unfavourable circumstance, regarding the place in a commercial view, that, in common with all the other European settlements on this coast, Madras has no port for shipping; the coast forming nearly a straight line; and it is also incommoded with a high and dangerous surf that breaks upon it, and induces the recklessness of using the boats of the country for the purpose of landing. There are of a singular construction, being formed without ribs or keel, with flat bottoms, and having their planks fewed together; iron being totally excluded throughout the whole fabric. By this construction they are rendered flexible enough to elude the effects of the violent shocks which they receive from the dashing of the waves, or surf on the beach; and which otherwise, in breaking to pieces a boat of European construction. No port for large vessels occurs between Trinckamy and the Ganges, that is, in an extent of 15 degrees; so that the comparative proximity of the former to Madras and Pondicherry renders it a capital object, both to the English and French. Nevertheless, Madras has been reckoned among the richest ports in India. Notwithstanding local disadvantages, the company find it convenient in other respects, especially as to their trade in calicoes, chintzes, and muslins, diamonds, &c., and in putting up their European wares most oftent after there, viz. stockings, haberdashery, gold and silver lace, looking-glasses, drinking-glasses, lead, wines, coffee, chese, hats, stuffs, ribbons, &c.

Madras is divided into the White Town and the Black Town. The first of these, known in Europe by the name of Fort St. George, is inhabited only by the English. The fort lies N.N.E. and S.S.W. in the middle of the White or English Town. It is a regular square, about 400 yards on each side. The White Town is about a quarter of a mile to the west.
length, and half as much in breadth. North of the fort are three straight streets, and on the south an equal number. The houses are flat-roofed, built with brick, and covered with a plaster made of sea-shells, which no rain can penetrate. The walls are thick, and rooms lofty; but few of them exceed one floor, though some are raised a floor above the ground. Opposite to the well gate of the fort is a barrack, for lodging the company's soldiers when off guard; and adjoining to this, a very convenient hospital. At the other end of the barrack is a mint, where the company coin gold and silver. There is a town-house, where the magistrates assemble, and in which courts of justice are held. The whole is encompassed with a strong wall of the same stone with that used for building the fort. This is defended by batteries, bastions, half-moons, and flankers; the whole being mounted with about 200 pieces of cannon, and three mortars, including the guns on the outworks, besides field-pieces. Round it, on the well side, is the river, by which and a battery it is defended. South of the White Town is a little suburb, the residence of the black watermen, who are its sole occupants. This consists of little low thatched cottages; and beyond it is an outguard of blacks, to give notice of any danger. Indeed it cannot be well attacked, except on the south and north sides; for towards the sea, the swell and surges are a perfect security. Madras is now, perhaps, fays major Rennell, one of the best fortresses in the possession of the British nation; and although not so regular a design as Fort William, in Bengal, yet from the greater facility of relieving it by sea, and the natural advantages of ground, which leave the enemy left choice in the manner of conducting his attacks, it may, upon the whole, be deemed at least equal to it.

The Black Town, called Madras, and sometimes Chinapatam, was formerly quite open, but, since the year 1767, it has been surrounded with a strong wall, and a ditch full of water. The wall is of brick, 17 feet thick, with bastions at proper distances. On the west is a river, and on the east the sea; north is a caulk cut from the river to the sea, which answers the purpose of a moat on that side. The town is a mile and a half in circumference, and might be reckoned a strong place, with a garrison proportioned to it; and attention has lately been given to this circumstance, so that it neither wants men, nor stores and provisions for its security and defence. This town is inhabited by Centoos, Mahometans, and Indian Christians, i.e. Armenians and Portuguese, and also a number of Jews. The streets of the Black Town are wide, and dotted with trees from the sun's heat. Some of the houses are of brick; the others are mean cottages. The abbe Raynal reckons the whole number of inhabitants of Madras at 300,000.

The town is in general very populous, each of the cottages containing a family of seven, eight, or nine persons; and yet, numerous as they are, and mean in their appearance, the place abounds with wealth. The bazaar or market is every day crowded, and exchanges of property are made to a great amount, which they transfer with as much facility as it is done on the Exchange of London. In the Black Town is an Armenian church, with several little pagodas or Indian temples, to which belong a number of priests and female choristers. From the beginning of March 1777 to the end of February 1778, the temperature of this coast was upon a mean 81° 44'; that of the Standard is 81° 33'; the greatest heat was 102°, the least 64°. Kirwan. N. lat. 13° 5'. E. long. 80° 25'.

The company's lands, or Jaghire, extend from Madras to the Pallicatte lake, northward; and to Alempur, southward; and westward, beyond Conjeeveram; that is, about 128 British miles along shore, and 47 inland, in the widest part. This Jaghire is understood to be held in perpetuity. It contains about 2,440 square miles, and its revenue is reckoned at about 150,000/. per annum. Rennell's Mem.

MADRE DE DIOS, an island in the South Pacific ocean, near the coast of Patagonia, 180 miles in circumference. S. lat. 51°. W. long. 77° 46'. See also Resolution.

MADRE de PAPA, a town with a convent, in South America, in the province of New Grenada, situated on the river Grande, or Magdalena. The pilgrims in South America refer in great numbers to the convent in this place, regarding it with a veneration similar to that with which Santa Cafa is respected in Europe. Many miracles are reported to have been wrought here by the holy virgin, in favour of the Spanish fleets and their sailors, who are therefore very liberal in their donations at her shrine; 34 miles E. of Cartagena. N. lat. 10° 51'. W. long. 76° 15'.

MADREBOMBO. See Scherbro.

MADREPORA, MADREPORA, in Natural History, a genus of the class Vermes, and order Zoophyta; resembling a medusa; coral with lamellate flar-shaped cavities. There are about 120 species scattered through the different seas on the globe, some of which, as will be noted, are common to our coasts. These are usually distributed into five subdivisions, as follow:

A. Composed of a single Star.

Species.

Verrucaria. Star orbicular, flatish, sessile, with a convex disk full of tubular pores and a radulate border. This species is found in the Red, Mediterranean, and Northern seas, adhering to marine vegetables, and the softer zoophytes. It is the size of a split pea, and appears an intermediate species between the madrepore, tubipore, and millepore; white or yellowish, with aggregate tubes on the disk, like florets of a composite flower, and a flattened flarate border, like the rays of these flowers.

Turbinaria. This is described as tubuline, sessile, smooth, with an hemispherical concave flar. It is found in Gotland and Campania.

Porifera. Without a flar; the flar is convex, orbicular, with a depressed centre, beneath flat, margined, smooth.

Fungites. Orbicular, convex, with simple longitudinal laminae or gills, beneath concave and papillons. It is found in the Indian and Red seas; sometimes with and sometimes without footstalks; is from one to six inches in diameter; white, with a concave centre, and rough beneath; the gills are acute, alternately shorter and irregularly ferrate.

Patella. Without a flar; gills granulated at the sides, denticulate at the margin, and placed in a triple order; the third reaching from the centre to the margin. It inhabits the Mediterranean, and is about an inch and a half in diameter. All the gills are denticulate at the margin, and very rough at the sides: the younger specimens are flat, but the full-grown ones convex.

Cyathus. Clavate, turbinated, with a tapering base; flar rather conic, with a double, prominent, jagged centre. It inhabits the southern coasts of Europe, it is about two inches long, and three quarters of an inch in diameter. In substance it is white and hard; it has about forty gills, with as many intermediate smaller ones, the latter reaching to the margin, but not extending to the centre like the larger ones.

B. With
B. With numerous separate Stars, and continued Gills.

Species.

**Pileus.** Without item, oblong, convex, beneath concave, with longitudinal rows of concatenate flars; gills crowded, abbreviated. This species inhabits the Indian ocean. In the frow of the middle is a line of flars with their gills disposed on each side in a radiate form; under these on each side are two rows of flars, as it were linked together, with their rays nearly parallel and pointing upwards and downwards; margin all round terminated by sharp erect laminae, or gills.

**Cristata.** Foliaceous, crested, with rows of flars impressed in the centre; the foliations broad and flattish. It inhabits the Indian and South seas.

**Lactuca.** Sefille, with large, crowded, fronded flars, the fronds perpendicular, waved, jagged. This is a rare species, but is occasionally found in the American ocean.

**Ficoides.** This species is foliaceous, crested, with scattered flars; the lateral foliations flattish, marginal ones carinate; gills foliaceous. It inhabits the South sea.

**Acrods.** Foliaceous, crested, with scattered flars; lateral foliations flat, terminal ones subcarinate; gills needle-shaped.

**Lichen.** Foliaceous, crested, with obconic rounded rows of flars, and very acute, carinate, subflaxes, or, apparently placed foliations. Found in the South sea.

**Agricites.** This is without item; with carinate grooves and concatenate flars. Found in the American islands; is about five or six inches in diameter; cinerea in colour, consisting of various divergent semi-irregular gills, with numerous concentric gills, in the bottom of which are placed the flars.

**Elephantotus.** Somewhat turbinate, with granulated parallel gills, and scattered prominent flars within. Inhabits the Indian ocean, and is an intermediate species between the **Lactuca** and **Agricites**; it resembles a thin, seifile, undulate curled lammas, with flars disposed nearly in the form of a quincunx.

**Crustacea.** Foliaceous, with a flat redlute surface, composed of thick-toothed concatenate flars. Inhabits the American ocean; obtusely conic, with the flars dilated in a quincunx form.

**Incrustum.** This is unequal, with prominent, conic, truncated, hollow flars, which are dilate at the tip and laminate within. It inhabits the Red sea. Stars about the size of a pea at the base, and half the size at the tip.

**Exesa.** Foliaceous, with reticulate, concatenate flars, and abrupt, conic, acute intertices. Inhabits the Pacific ocean. It is white, with conic warts, smooth at the tip; gills rough, unequal.

**FiloGrana.** This is without item,imple, with a very thin, serpentine, labyrinthic flar, with an acute future, and flat perforated spaces. Found in the Indian ocean.

**Natans.** Simple, without flar; ilar serpentine, labynothic, with the als of the undulations very broad; future obtuse, coral porous. Inhabits the Indian and American seas.

**Anthophyllum.** Simple, with an ovate flar; ilar terminal, hemispherical, concave, with radius thicker gills at the bottom. It inhabits the Mediterranean.

C. With numerous united Stars.

Species.

**Labyrinthica.** Without flar; ilar with serpentine undulations, and obtuse future. Found in India, and like-
**MADREPORA.**

**Cavata.** This is subglomerate, with flar-shaped, angular undulations, and simple narrow divisions; the gills are denticleate.

**Eulissis.** In this the flars are dilated, round or ob-long, unequal and elevated at the margin, the intericles are formed with somewhat concave, radulate wrinkles.

**Anaxas.** With annular convex flars, which are concave on the diks. It inhabits the Mediterranean and South American seas, and is frequently found in a foliile flate. It is gibbous, and when dissected transversely, resembling a white net with hexagonal spots, including a white ring, and itrate between the net and the ring.

**Hyades.** With crowded, oblong, rounded, and somewhat angular flars, and thick porous divisions; the centres are flatish and convex.

**Sideres.** With crowded, rounded, and angular flars, and thick, rather convex, divisions; alternate gills nearly united at the margin; centres simple.

**Galaxa.** This is rather crowded imprinted flars, and thick, flatish, nearly distinct divisions; the gills are very thin, and the centres a little worn. The gills are formed by fours, reaching to the centre; the three intermediate ones are conrattent at the base.

**Pleodes.** The flars are roundish with acute, elevated margins; the intericles are concave, smoothish, and in some parts a little cavernous.

**Papillosa.** This is somewhat aggregate; the flars are cylindraceo-papillos, with thickened, rounded, oblique margins. It resembles the *Muricata,* of which it may probably be the embryo, but the papilles are contiguous, and disposed in a single row.

**Radiata.** Stars cylindraceous, with elevated margins, the intericles broad, concave, and radiate with grooves.

**Latebrosa.** Stars roundish, with many rays and elevated margins; the intericles are radiate with grooves, a little narrowed and unequal. It is found in the Well India islands.

**Polygona.** With minute crowded flars, intermixed with larger perforated ones, the bottom concave, cylindraceous. It inhabits the Indian seas, and resembles a white crust about two inches thick; the smaller flars are minute, rather oblique, and twelve-rayed, the larger ones as big as the end of a finger, more gibbous, with an empty cavity between them.

**Arenosa.** This, which is contigious, flatish, ochraceous flars, is found in Algiers; is white, with large flars, sometimes a little elevated and verrucose.

**Intersecta.** With round, dilatant, immedecylindraceous flars, the intericles are porous. It inhabits India, America, and Norway.

**Spongiosa.** This is somewhat dilated, with craggy foliations, obtuse above and flat beneath; the flars are funnel-formed, deep, and unequal.

**Polio.** This is likewise dilated, with foliations something craggy and verrucose above, beneath flatish; flars unequal and small. It is found in the Indian ocean. It is large and roly.

**Porcellata.** The flars of this species are oblong, with acute margins, and in some places remote; the intericles are smooth, and the gills every where granulous. It is very rare, and is of a greyish-white.

**Stellata.** With round, dilatant, equal cylinders of flars elevated at the margin; the intercles are rather flat and rough.

**Astreites.** This is sub-globular, with very numerous immedealed flars, the intercles are porous. It inhabits South America, in large mafles, and is whiteish.

**Stellata.** Solid, rough outwardly, with scattered convex flars imprefsed in the middle; it inhabits the Indian ocean, is grey with rough minute points.

**Nodulosa.** This has crowded oblong flars; the intercles and gills are rather sharp and rough; the coral is a little nodulous.

**Acropora.** Hemispherical, with crowded, annular, prominent, crested flars, which are small, elevated with a deeper centre.

**Cavernosa.** The flars in this species are imbacced, falver-shaped with a fricate border, and separated by an elevated future; it is found in South America and the Mediterranean; the flars are elevated, and the future forms a pentagonal not-flow.

**Punctata.** This has crowded flar-like points composed of ten dots; inhabits the European ocean, and also the Mediterranean; it is rounded, white, friable, with small unequal flar-like dots.

**Cylindrical.** In this the cylinders are united; the flars are concave, with a rather prominent centre; it inhabits the Mediterranean; it is roundish and brown, with distinct lateral cylinders, transversely wrinkled outwardly; the inhabitant is an actinia, and is a large and very flagellum animal.

**Trencata.** Joints tubinate, profuse, coalescing at the extreme margin; flars truncate, with a concave cylindrical dilk. It is found in a foliice flate; a little rugged, with joints of equal length and breadth.

**Stellata.** Joints profuse, central, solitary, flars connected by a dilated margin; found foliice on the shores of Gotland; forms simple, parallel, erect, as thick as a finger, and four or five inches long; dark obliquely frigate, with cup-shaped joints an inch long.

**Organum.** Corals cylindrical, smooth, dilatant, combined, with deflected membranes. It inhabits the Red sea, but is more frequently foliice; the cylinders are parallel, and as thick as an out-draw.

**Divergentia.** Sub-globular, with divergent cylinders standing out beyond the surface twice their diameter; this is also found in a foliice flate.

*Musicalis.* Corals cylindrical, frigate, dilatant, united by numerous transverse dispositions; it inhabits the Indian ocean, and is sometimes cast on the Irish coasts, and often found petrified; coral white, and often very large.

**Denticulata.** Stars unequal, the gills have an elevated margin, the larger ones acute with a precice at the base; the intericles are grooved.

**Foveolata.** The flars of this species are somewhat angular, many-rayed, and here and there doubled when cut longitudinally.

**Retepora.** The flars are rather angular with filamentous gills, and reticulate when cut longitudinally.

**Rotulosa.** Stars cylindraceous, with few rays; the gills erect and acute towards the margin, with an erect spine at the base.

**Cespitosa.** Corals round, slightly branche, frigate, approximate, with turbinate concave reticulate flars; the coral is white, flary, very large, and often soft; it is frequently found in a foliice flate.

**Flexuris.** Corals cylindrical, rough, flexuous, approximate, with concave frigate flars. Found cast on the shores of the Baltic.

**Fuscularis.** The corals are straight, cylindrical, glabrous, and divergent. It is found in the Indian ocean; white, flary, solid, unequal; frequently found folfie in different parts of Europe.

**Pectinata.** The flars of this species are orbicular, with a tumid, dilatate, radiate margin, the intercles are dotted.
cotted. It is found in Silesia; the flars are flat, with about
30 unequal denticulate gills.

Rotulatels. The coral of this species is of many shapes, with
foliary, orbicular, flat, unequally radiate flars, with a
smooth, flat, and hardly prominent margin. This is found
in the Red Sea, frequently growing to other marine sub-
stances, white, yellow, sub-globular, or flattened, the flars
about a line in diameter.

Tubulars. In this the tubes are cylindrical, very en-
tire, a little prominent and expanded into an unequally ra-
diate flar. This is frequently found fossile; the tubes are
about the size of a crow-quill; the flars have six thicker
gills, between each of which are three leffer ones.

Mamillate. Stars orbicular, prominent, wart-like,
excavated. Found near Frankfort in a fossile flar; the
flars are without a border.

Patejloides. Glabrous, flars large and many-rayed,
being a little elevated with a minute centre. This is found
fossile; the flars have from 30 to 40 thick equal rays.

Globulars. Stars large, rounded, equally rayed, with
a large perforated centre.

Filum. The flars in this species are rounded, large and
somewhat crowded, with a very minute and partly exca-
ted centre. This is found in a fossile flar near Baffin.
This is continued. Stars crowded, minute, excavated, with
perforated gills. The coral is sometimes hemispherical,
and nearly a foot in diameter; the flars are twelve-rayed.

Verruculars. Stars with unequal, undulate, smooth
rays; it is found fossile; the flars have about eight prin-
cipal rays, four of them are forked.

Aramoides. Stars crowded, minute, flattened, with
subundulate, short, equal rays. It is found fossile; coral
hemispherical; the flars have twelve contiguous rays.

Undulata. Stars large, elevated, with elongated curved
rays; found fossile; flars about half an inch wide, with 24
rays.

Solid. Stars every where contiguous, with united
membranaceous margins. It inhabits the Red Sea, where
it forms vast rocks, and is used in building, and burnt into
lime; the flars are concave, with a very thin brittle margin;
the centre is orbicular and rough, with a row of small
tubercles.

Solen. Stars funnel-formed, without disk, covered
with gills and divisions; gills equal, radiant, denticulate,
and curved into the next flar. Found in a fossile flar in
Arabia; flars as large as a pea; the centre less than a muf-
terd-feed.

Dedalica. The flars of this species are somewhat
hexagonal, with united reticulate divisions toothed internally,
and at the margin. Inhabits the Red Sea; the flars are
snowy, very thin, and toothed within.

Monostriata. Divisions between the old flars elevated
into rough lanceolate tongue-shaped precedes; this is found
in the Red Sea; is fpongy, tough, snowy.

Confignata. This is flatfish and orbicular, with lin-
ear flars at the circumference tending to the centre, the
middle ones ovate, divaricate, and nearly contiguous. An
inhabitant of the Red Sea; is sometimes found a foot in
diameter.

Cristata. Corals ventricose-conic, smooth, but rough
towards the tin; flars angular-rounded, labyrinthic, and fur-
nished with alternately flatter rows of gills. Is found on
the shores of China.

Pseudopamba, with fpongy musilage, and superficial
flattish distant flars. It inhabits the Red Sea.

Cupulata. Corals cone, grooved; flars turbinate,
with straight, elongated, acute gills. It is found in China.

E. Branched, with distinct Stars and tuberculoida punono
Undulations.

Species.

Porifer. Slightly branched, composite, rough, with
subfusiform crowded pores. Inhabits India and South Ame-
rica; is of a clear white, outwardly often grey; the
branches are patulous, obtuse, and rough, with eminent
dots.

Digitata. Branches clavate, flattened; flars scattered,
six-rayed, with a projecting, vaulting, upper margin. In-
habits the Indian ocean; resembles the last; the coral is
white, outwardly yellowish-grey.

Damiornis. This species is very much branched; the
branches are tapering and subdivided; flars crowded, blind,
and ciliate. It inhabits Africa and India.

Verrucosa. This also is very much branched, and the
branches are obtuse, and furnished with numerous fimpler
wart-like sub-divisions; the flars are scattered, and also
crowded and ciliate.

Muricata. This is a composite and sub-imbricate spe-
cies, with obliquely truncate prominent ascending flars;
there are six varieties of this species, viz. 1. With long
pointed branches, and without smaller sub-divisions. 2. With
divaricate branches, and short divergent pointed sub-
divisions. 3. With ascending straight branches and sub-
divisions. 4. With decumbent lower branches, and ascend-
ing, short, acute sub-divisions. 5. In this variety the
branches are united into a palm at the base, with divergent
sub-divisions. 6. This has numerous divergent branches
and sub-divisions; the cylinders of flars are turbinate,
with thickened rounded margins. Inhabits India and South
America.

Fastigiata. In this the flars are decurrent out-
wardly. Inhabits South America; is white and nearly a
foot high.

Ramea. The branches are fritate, cylindrical, truncate,
with terminal flars; it is found in the Indian, Mediterranean,
and Atlantic seas, is about two feet high; fllory,
ferruginous, and marked with fine longitudinal flines, some
of which are undulate.

Oculata. This is tubular, glabrous, flexible, ob-
lique, fritate, with alternate branches and concave flars
pointing two ways. Inhabits the Indian ocean, and is found
in European countries in a fossile flar; the coral is white,
perforated within.

Virginea. This is sub-dichotomous, straight, solid,
with alternate eminent flars. It inhabits the Mediterranean,
American, and Norway seas; it is milk-white, and about
the thickness of one's finger.

Kosea. This species is, according to its name, of a rote
colour, much branching, with numerous prominent mar-
gined flars; it inhabits the Indian ocean, and is about four
inches high; the coral is of a beautiful rote-colour when
recent, and afterwards fading to a paler tinge; the branches
taper towards the base.

Hirtella. Stars every where alternate, prominent,
with exerted acute gills. It inhabits the Indian ocean,
and is white.

Limitata. Branches a little flattened, with scattered
six-rayed flars, equal at the margin.

Bothioidea. With thick, interlaced, obtuse, clustered
branches, and reticulate cragged undulations.

Granosa. This species is a little branching, crested,
and somewhat finged; with the branches obtuse; all the
undulations are acutely carinate; the flars are linear and
irregular.
Prolifera. This is sub-dichotomous, coalescing, with flars at the fide proliferous, terminal, concave. This is an inhabitant of the Norway sea; it is white and very solid; the flars are funnel-formed with about eight gills.

Serrata. This species is branching, with subulate subdivisions and flar-like pores in longitudinal rows. Inhabits the Eastern ocean; it is white, florny, about the fize of a large quill, and nearly a foot high.

Cactus. This has compressed, divergent, dichotomous branches, carinate at the edge; the flides with contiguous flars. It is found foffile in Arabia; is about a foot high; the branches are a little eieft, and in transverse rows.

Corimbosa. The branches of the corimb are thicker at the tip and marked with prickly ftrix; the flars are terminal, and solitary; the branches are as thick as a finger; the flars are an inch wide.

Gemmascens. This species has prominent, obconic, bud-like flars. It inhabits the Indian ocean, and is snow-white.

Problematica. With oblique, minute, immerfed, diferent flars, and broad punctured margin. Is found about the Antilles ifland; it is florny, rough, fea-green, sometime as thick as a man's arm, and full five feet high; the interfaces of the flars are marked with lines.

Spuria. This is slightly branched and dichotomous, with cylindrical tubes filled with small, irregularly dispofed, longitudinal divisions.

Infundibuliformis. This is turbinate, firlate, funnel-formed, with slightly prominent flars within. It inhabits the Indian ocean; and is white and solid.

Angulosa. Dichotomous, faltigate, with terminal, turbinate, angular flars, and toothed gills. It inhabits the American seas; is short, thick, cellular, smooth, and white.

Discoides. This species is flat-fihed, somewhat pedunculate, and roughfih, with marginal facifulate flars. It is found in the Indian ocean.

Chalcidicum. This is known by its prominent, remote, cylindrical tubes of flars, lamellate without and within. It is found in the Red sea.

Concamerata. This is flat, with remote flars, a little prominent at the margin; the interfaces are lamellate. It is found in a foiffile flate.

Rosacea. Furnifhed with a stem, and branched; the lefter branches are cylindrical, afcending; flars terminal; it is sometimes rofy, sometimes white, and sometimes grey.

We shall conclude this article with fome general obfervations, taken chiefly from the 47th volume of the Philofophical Tramflactions. In speaking of the animal that fills the cavities of the madrepor, it is faid its feet are numerous, and terminate efenually in two conical productions, which, being placed on each fide of every one of the lamellae that give the flellar form to the cavity of the coral, serve to affix the animal to the circumference of its cell, and may, with propriety, be confidered as the instruments by which the little animal forms the lamellae themselves. The bafes of these conical productions unite and form round bodies, which poife somewhat of the figure, and of the properties of muscles; they ferving to lengthen or to shorten the feet, and alfo mofl probably to regulate the force with which they clafp the lamella, on which they exert their plastic powers. The other ends of these round bodies terminate in small cylindrical tubes, which are attached to the fhefl of the animal, in the centre of which is seen its head, capable of moving with great quicknefs, and ornamented with feveral rays, which are mofl probably the arms or claws with which it fizes and secures the animalcules on which it feeds. Admitting that the formation of these corals is the work of the madreporean polype, it may be thus traced through its wonderfhl labours. It is found that each of the legs of the polype is provided with two proceffes, which are applied to each fide of one of the perpendicular laminae, while a mulfular pyriform body, attached to the other end of the leg, gives it the power of employing that motion which is neceffary for the accomphfishment of its talk. The young polype may be confidered as completing its operation by two diftinct proceffes; the fecretion and feparation of carbonatofe of lime from sea-water conveyed through the pyriform body; and its difpofition, at the moment of fecretion, by the two small proceffes, where the economy of the animal directs. As proportional to the number of legs possessed by the infant animal, is probably the number of perpendicular laminae, or pillars, converging in the centre, which it begins to eieft; when, raifed to a certain height, appear to be connected together by a horizontal plate of the fame fubfance; on thefe the animal eieft similar pillars, and places on them a covering, similar to that with which he has comphled the firt compartment. Thus seem to proceed the labours of this minute artift; and as the number of its legs or instruments increafes, and as they extend in length, fo much the number of the perpendicular laminae, and the circumference of the horizontal plates, augment.

Madrepore Stone; Madrepore ftein, Mol. Kar-le; Chaux carbonatée madrepore, Brong.

This rare fubfance, which was difcovered by baron Moll in the valley of Rufbach, in the territory of Salzburg, is confidered by fome mineralogifts as a variety of lime-flone, while Klaproth and others confider it as a diftinct species of the calcareous genus.

Externally, and on its longitudinal fracture, its colour is greyfih-black; on the crofs-fracture, it is of a pitchy black colour.

Has been found hitherto only in massive, blunt-cornered, rounded, and oblong, sometimes flattened pieces, of from three inches to one foot in diameter.

Its surface is more or less finely furrowed, and sometimes small shallow holes are seen in it; furrows often radiating, and marked with tranfverse minute flrix.

Externally this fubfance is glimmering, passing into dull; internally, on the longitudinal fracture, partly glimmering, partly glifhen; but on the tranfveral planes of fracture it Shews a pitchy folid, oftentimes approaching to metallic. It gives a grey tfile.

It is not particularly hard; it is brittle, and easily frangible. Fragments opaque, indifteminately angular, not very sharp-edged, always of a staright or divergingly columnar fimtiture. They oftentimes contain copper pyrites, finely diffeminatcd, and in pellicles.

It is not particularly heavy; lefs fo than compact lime-flone.

Before the blowpipe, the black colour of the madrepore ftone is converted into greyfih-white.

According to the analysis of Meffrs. Schrol and Heim, the confinituent parts of this fubfance arc, lime $37\frac{3}{10}$, alumine $19\frac{2}{10}$, filex $12\frac{7}{10}$, iron $15\frac{3}{5}$; and the fame con- finituent, and their proportion, are quoted in the French fyltems of mineralogy, as the refults of an analysis of madrepore made in the Ecole des Mines. But Klaproth, who analyzed a fpecimen lent by baron Moll himfelf, obtained the following refults:

Carbonate

The structure of the separate pieces of this mineral, remembering the aggregation of madrepores, has given rise to its name. Some mineralogists have, indeed, supposed that the fulness and its origin from a species of madrepores; but Klaproth observes, that this opinion is not supported by any certain mark indicative of preceding organic structure.

Patrin considers the madrepore stone as a facicular variety of aragonite.

The geognostic situation of this mineral is not known.

MADRET, in Geography, a town of Arabia, in the province of Yemen; 10 miles N.E. of Chamir.

MADRID, a city of Spain, in the province of New Caljile, and capital of the kingdom; seated on the river Manzanares. The access to its several gates is by streets and avenues, planted with trees; of these, the gate of Alcala is the most grand, being constructed in the form of a triumphal arch, and the entrance to the city by this gate is the most interesting. As soon as you pass this gate, you are presented with an avenue, having on one side a row of low but uniform houses, and on the other railings, through which are seen extensive gardens; the end of it is closed by the promenade of the Prado; and the view terminates in the extended street of Alcala. The origin of this city is not satisfactorily ascertained. Some pretend that it was founded by the Greeks, who never penetrated so far into Spain; others say that it was the ancient Mantua Carpenetorum. It was at first known, however, by the palace, or pleasure-house, possessed here by the kings of Castile; and the foundation of the town is said to have been laid by Alphonso, the 6th of Leon and 1st of Castile, who reigned at the end of the 11th century. We find that it was sacked by the Moors in 1269, and that it was overthrown by an earthquake towards the middle of the 14th century, under the reign of Peter the Cruel, and rebuilt by Henry II., the successor of that prince. Charles I. selected it for the place of his residence, which occasioned its increase from small beginnings, and his son, Philip II., transferred the seat of government to it in 1563. Its first limits were very narrow, and not extended beyond the vicinity of the king's palace; but in process of time it was enlarged by the addition of several suburbs.

Madrid is situated on several low hills near each other, in the midst of an extensive plain, bounded, on the side of old Castile, by the mountains of Guadarrama, and undivided by any fixed boundaries on any other side. The plain is dry, parched up, and naked, without trees, and uneven; and the city is situated at a considerable height above the level of the sea. Its situation for the government of the kingdom is convenient, as it lies in the centre of the kingdom, and equally within reach of the distant provinces. Its present extent is 41,333 feet, or two leagues in circumference; its figure is a square; and it has 15 gates of granite, 506 streets, 42 squares, large and small, 7308 houses, 133 churches, convents, colleges, seminaries, or hospitals, 65 public edifices, 17 fountains, and several promenades. It is divided into eight districts, each district into eight wards, to each of which an alcade is attached, a sort of commissary of police, chosen annually from among the inhabitants. The population, according to the account of 1788, amounted to 56,272 persons; and if the garrison be included, which consists of 8 to 10,000 foreigners, and Spaniards from the provinces, the population may be reckoned at 200,000. Towns and reckons 13 parishes, 7,298 houses, 99,745 families, amounting to a population of 147,542. The number of deaths in 1788 was 5915; and that of the births 3,807. In 1797, the deaths were reckoned to be 4,444, and the births 4,911. The Plaza Mayor, which is near the centre of the city, and from which several streets branch out, is the most populous and best frequented place in Madrid, the centre of commerce, and particularly of retail trade. It is likewise the place where public fêtes are given, and at that time acquires, from its decorations, illuminations, and crowds of spectators, a grand appearance. Madrid is well laid out; and though it has many narrow, and crooked streets, the greater number are handsome, and there are some which would do honour to the finest cities in Europe. That of Alcata is the most distinguished, as it extends in a straight line from the Prado to the Puerta del Pol, and is broad enough to admit ten carriages abreast; but the houses are not lofty in proportion to the breadth of the street. The streets, though roughly paved, are kept very clean, and well lighted by lamps placed on both sides over the houses, opposite to each other, at equal and little distances. Many of the private edifices, especially in the large streets, though displaying no magnificence of architecture, exhibit an agreeable appearance. The interior of the houses of persons of superior rank is handomely and magnificently furnished; some of them being adorned with chef-d'oeuvres of the fine arts.

The city of Madrid is in the diocese of Toledo; and the spiritual administration is directed by the grand vicar of that city; a bishop in paribus infidelum, auxiliary to the archbishop, also resides there, with the powers of that prelate. In Madrid they reckon 15, or, as Townend says, 13 parishes and six chapels of ease; and a number of monasteries, convents, &c. which it is needless for us to specify. The secular clergy are 395 in number; and the regular clergy, including those of the monks and nuns, amount to 2718; amounting in the whole to 3115. The establishments, under the name of hospitals, and benevolent associations for the relief of indigence and distress in this city, are very numerous. The head of the civil administration of Madrid is a military governor, who bears the honours of captain-general of a province; and the police is under the superintendence of different magistrates. Since the expulsion of the Jesuits, Charles III., in 1770, established an enlarged plan for the instruction of youth, the execution of which is committed to a number of secular priests, who, in one of the houses formerly occupied by the Jesuits, superintend the college of St. Isidore. This establishment includes fourteen masters, or prefeblers, for the languages and sciences, and a good library. There is another college appropriated to the instruction of the young nobility. The academies are numerous: amongst these we may reckon four for jurisprudence, and another for medicine; a Spanish academy, founded in 1714, by Philip V., for the improvement of the Spanish language; an academy for history, instituted in 1735, by the same prince, for the elucidation of historical subjects, in connection with geography and chronology; the academy of St. Fernando, devoted to painting, sculpture, and architecture, which originated in the munificence of Philip V. Among the libraries, we may enumerate the royal library, formed in 1712, and containing a great
MA\(\text{D}\)RID.

great number of printed volumes, a large collection of MSS., a variety of modern medals, and a collection of antiques: the cabinet of natural history was formed by Charles III., and is receiving continual additions. To the cabinet of curiosities and useful edifices in Madrid, we may refer several of its churches, its gates, the cullom-house, erected in 1760, the house of the academy of St. Fernando, and of the cabinet of natural history, the Cafa de Correos, or post-office, the Caracce de Corre, or state-prison, erected under Philip IV., the Cafa del Ayuntamiento, or town-hause, the Palacio de los Conojos, or council-house, which is the seat of a supreme tribunal, the Armeria Real, or royal magazine, and the king's palace. The latter stands on an eminence at one of the extremities of Madrid, commanding a distant view of the beautiful country, which is watered by the Manzanares: founded by Alphon. VI. in the 11th century, sacked by the Moors in 1190; afterwards destroyed by an earthquake, but repaired by Henry II. and completed by Henry IV., much enlarged by Charles V., and his successors; totally consumed by fire in 1734; and, in 1737, rebuilt on its present plan by Philip V. and Ferdinand VI. This new palace presents four fronts, 470 feet in length, and 166 in height, enriched with numerous pillars and pilasters. The interior of this palace is ornamented by several productions of the arts. Its walls and ceilings are covered with allegorical paintings by the best masters; and the apartments are filled with pictures by the most eminent artists, among which we may select an Adoration of the Magi by Rubens, and a Bearing of the Cross by Raphael. Among the paintings we may also select a piece by Titian, of Venus binding the Eyes of Cupid, an Apotheosis of Hercules by Mengs, and an Adoration of the Shepherds by the same master. There is also a group of nymphs dancing round the statue of Praxipus by Poufiau. One of the most magnificent apartments in the palace is the king's hall, in which his majesty gives public audience to foreign embassadors; it is a double cube of 90 feet, hung with crimson velvet, and adorned with a sumptuous canopy and painted cieking; it is embellished with mirrors of an extraordinary size, with several antique heads, and a small equestrian statue of Philip II., in gilded bronze. The palace is the depository of the crown jewells and regalia; among which we may mention a fine throne, with its canopy, constructed for Philip II. The Buen-Retiro is another royal mansion, situated in another extremity of Madrid, opening on the promenade of the Prado, and extending to the country that borders on the road from Alcala to Madrid; erected by Philip IV. This palace is environed by beautiful gardens, which occupy an immense area, in one of which is placed an equestrian statue of Philip II. in bronze. Madrid has several promenades, but their distance renders them inconvenient of access. Of these the Prado is that which is most frequented.

Madrid does not possess one manufacture, from which it can derive any advantage. It has, indeed, three for hats, and another for flamed paper, but they are barely sufficient to answer the demands of the capital. There are also three others of greater note, for inlaid work in 1t, for tapestry, and for porcelain; but as they are appropriated to the king, they are wholly unproductive to commerce. A considerable manufacture of salt-petre was also established in 1779, and in 1785 it occupied 4000 men, the number of which has since been increased. Madrid is so destitute of commerce, that it is absolutely dependent for support on remote provinces or foreign countries for every article of use or ornament, for clothes and corn, for all the luxuries and necessaries of life. This city has no discriminating character with regard to manners or customs. Its amusements are numerous; but that which most interests the inhabitants is the bull-fight. In Madrid are three theatres, which fearcely receive from those who attend them sufficient encouragement for the support. On Corpus Christi day there is a grand procession, composed of the secular and regular clergy of Madrid, followed by the king, his ministers and court, each bearing in his hand a wax taper. As to the climate of Madrid, we observe that the sky is almost always serene and free from clouds; the air is dry, pure, and bracing, especially in the winter season, but it is highly injurious to hectic subjects. The air is so piercing, as to give rise to the proverb, that the air of Madrid destroys a man, when it does not extinguish a candle. The winds most prevalent are, the north in winter, the south and west in spring. In summer the heat is intense, and during the months of July and August almost insupportable. The usual heat in summer is said to be from 75° to 85°; at night the thermometer seldom falls below 70°; the mean height of the barometer is 27° 60. It seems to be about 1900 feet above the level of the sea. Upon the whole, Madrid may be considered as a healthy residence. The various articles of food consumed in this capital are supplied by different parts of Spain. Its bread is excellent, and its water is pure and good. For the supply of water, the capital schemes have been adapted for rendering the small streams of Manzanares the channel of communication with the provinces. With this view it has been proposed to form a junction between the Manzanares and the Xarama; and at length under the auspices of Charles III., a canal was formed from the bridge of Toledo near Madrid to the Xarama, near the village of Manzanares, which includes a distance of four leagues. N. lat. 40° 25' 18". W. long. 3° 12'. Laborde's View of Spain, vol. iii. Townend's Travels in Spain, vol. i. and ii.

MA\(\text{D}\)RID, a town of America, in the northern part of Louisiana, seated on the W. bank of the Mississippi, settled some years ago by Col. Morgan, of New Jersey, under the patronage of the Spanish king, and called by the name of the capital of his European dominions. The spot on which it was proposed by the settlers to found a great city, is situated in N. lat. 36° 30', and 45 miles below the mouth of the Ohio river. Its limits were proposed to extend four miles S. and two W. from the river, so as to form a beautiful deep lake of clear spring water, called St. Anne's, 100 yards wide, and several miles in length, emptying itself by a constant and rapid narrow stream through the centre of the city. On each side of this lake it was proposed to lay out streets, 100 feet wide, and to continue a road round it of the same breadth. A street, 120 feet wide, was to be formed on the bank of the Mississippi; 12 acres of land were to be reserved for the central part of the city, to be laid out and ornamented for public walks; and other lots of land were destined for other public uses. For the completion of this plan, the country round this spot presents several inducements. It is singularly fertile and productive. The natural growth consists of mulberry, locust, saffraff, walnut, hickory, oak, ash, logwood, &c. besides grape vines in great abundance. The meadows are fertile in grass, flowering plants, strawberies, and with culture produce good crops of wheat, barley, Indian corn, flax, hemp, and tobacco, and are easily tilled. The climate is favourable to health, and to the production of various kinds of fruits and vegetables. Iron and lead mines and salt springs are plentiful; and the banks of the Mississippi, for many leagues, commencing about 20 miles above the mouth of the Ohio, are a continued chain of lime-dine. A fine tract of high, rich, level land S.W., W., and N.W. of New Madrid, about 25 miles wide, extends quite to the river St. Francis. The situation of New Madrid is excellently
MAD

ly adapted to its being rendered the great emporium of the western country.

MADRIDEOS, a town of Spain, in New Castile; 30 miles S.E. of Toledo.

MADRIB, in the Military Art, a thick plank, about 18 inches square, strengthened on one side with a strong band of iron, and a strong iron hook, and having, on the other side, a cavity sufficient to receive the mouth of a petard when charged; with which it is applied against a gate, or other body designed to be broken down. See PETARD.

MADRILIER also denotes a long and broad plank, used for supporting the earth in mining, carrying on faps, making caponiers, galleries, and the like.

There are also madriers lined with tin, and covered with earth; serving as defences against artificial fires, in lodgments, &c. where there is need of being covered over head.

MADRIGAL, in the modern Italian, Spanish, and French poetry, denotes a little amorous piece, containing a certain number of free unequal verses, not tied either to the herpulous regularity of a sonnet, or the fuldety of an epigram, but confiding of tender and delicate, yet simple thought, suitably expressed.

Menage derives the word from mandra, which, in Latin and Greek, signifies a sheepfold; imagining it to have been originally a kind of pastoral, or shepherd's song; whence the Italians formed their madrigale, and we madrigal. Others rather choose to derive the word from madrugari; which, in the Spanish, signifies to rise in the morning; the madrigals being formerly sung early in the morning, by those who had a mind to serenade their mistresses.

Huet supposes it to be a corruption of martegaps, a name given to the inhabitants of a district of Provence, who either invented or excelled in this species of composition. If the origin is deduced from the Spaniards, it may have taken its name from a town in Spain, called Madrigal. Others, supposing that its first application was to religious poems addressed to the Virgin, alta Madres, derive from thatence madriale, and madrigale.

The madrigal, according to M. le Brun, is an epigram without any thing very brist and sprightly in its fall, or close: something very tender and gallant is usually the subject of it; and a certain beautiful, noble, yet chaste simplicity, forms its character.

The madrigal is usually looked on as the shortest of all the latter kinds of poems, except the epigrams; it may consist of fewer verses than either the sonnet, or roundelay. There is no other rule regarded in mingling the rhymes and verses of different kinds, but the fancy and convenience of the author. This poem, however, really allows of less licence than many others; whether we regard the rhyme, the measures, or the purity of expression. The term is also applied to a musical composition of three or more parts for different voices, adapted to the words of such poems.

Madrigal is likewise a musical term for a vocal composition, seldom in less than four parts. The etymology of this word has been much disputed. But it seems as if its first application had been to short religious lyric poems, or hymns, addressed to the Virgin, alta Madres; whence madriale and madrigale; but being afterwards applied to poems on love and gallantry, by the Italians, French, and Spaniards, the original import has been forgotten. Indeed, the words of all the madrigals which we have seen of the 16th century, when they were most in vogue, seem to belong to the mother of love and gallantry; alta madre, della gana, madre galante, matre letitie, than to the Virgin, or religious subjects. It never can have meant a morning song, as some have imagined; the Italians having been long in possession of the term matinata, lover's matins under the windows of his mistress; as they have of fenrata, an evening song. This species of music seems to have been brought to its highest degree of perfection in Italy, by Luca Marenzio, at the latter end of the 16th century, after which time it soon declined, and lost the favour of the public.

Few Italian composers of eminence produced madrigals after Luca Marenzio, except Stradella, and Alessandro Scarlatti, which are admirable.

MADRIGAL, in Geography, a town of Spain, in Old Castile, 27 miles N. of Avila.—Alto, a town of Spain, in Old Castile, near Olmedo, on the Adaja; 30 miles S. of Valladolid.—Alfo, a town of Popayan, in South America; 110 miles S. of Popayan. N. lat. 0° 50'. W. long. 75° 45'.

MADRIGOLO, a town of the duchy of Parma; six miles W. of Parma.

MADRISIO, a town of Italy, in Friuli; 30 miles N. of Venice.

MADROGAN, or BANARATAPA, a town of Africa, in the kingdom of Mocaranga, in which is a palace of the king. S. lat. 18°. E. long. 20° 50°.

MADROV, a town of Hindoostan, in Myalore; 18 miles E. of Seringapatam.

MADRUSAVA, a town of Japan, in the island of Nippon; 36 miles S.E. of Xenday.

MADRIZZO, a town of the Tyrolese; 4 miles W.S.W. of Trent.

MADS, in Agriculture, a provincial term applied to earth-worms.

MADSJAS, in Geography, a town of Arabia, in the province of Oman; 20 miles S.E. of Solah.

MADUE, a large lake of Hinder Pomerania, drained in 1770, and now inhabited.

MADUGAR, a town of Hindooftan, in the circuit of Jeynagar; 10 miles S. of Jeypore.

MADURA, a province of Hindooftan, about 180 miles in length, and 80 in breadth, annexed in 1742 to the dominions of the nabob of Arcot.—Allo, the capital of the above-named province, fortified with square towers and parapets, and well furnished with cannon. In 1757, this town was purchased by the British troops for 175,000 rupees. The pagoda of this place is one of the most superb in Hindooftan; 80 miles S.S.W. of Tanjore. N. lat. 9° 52'. E. long. 78° 11'.

MADURA, an isleand and principlea in the Eait Indian sea, reckeoned the fith empire of Java, thought not properly belonging to it, as it is a separate island, divided from Java by a narrow strait. It is about 75 miles in length, and from nine to fifteen in breadth. It is very fertile in rice, for which it is one of the granaries of India; and while Java was in possession of the Dutch (now, i.e. 1811, surrendered to the English) it was under the government of a prince, who was the valial of the Dutch company. Its capital of the fame name lies on the S. coast. S. lat. 6° 44' to 7° 15'. E. long. 112° 14'.

MADZAR, a town of Ruffia, in the government of Caucaus; 56 miles E.N.E. of Ekaterinograd.

MACENAS, CUISUS CILNIUS, in Biography, an illustrious Roman knight, descended from the kings of Etruria, has rendered himself immortal by his liberal patronage of learned men and of letters, and to his prudence and advice Augusus acknowledged himself indebted for the security which he enjoyed. His love of pleasure removed him from the reach of ambition, and he preferred to die, as he had been born, a Roman knight, to all the honours and dignities which either the friendship of Augusus or his own populari-
rity could heap upon him. He attended the emperor through his various fortunes, and in former military actions he is said to have displayed both liberal and civil skill. He, however, chiefly served his master in a civil capacity, and was one of the three intimates, who were delegated by him to effect an accommodation with Antony when he had laid siege to Brundusium. During a long period he held the important post of prefect of Rome, to which his political talents were peculiarly adapted, and with perfect fidelity to the emperor, and vigilance to maintain his interests, he was not chargeable with any acts of cruelty and oppression. It is to the honour of Augustus that he received the private admonitions of a certain Mæcenas in the same friendly manner in which they were given, and he was not displeased with the liberty which he once took of sending to him a paper with these words written upon it, “furse caninex, “rie butcher,” while he was sitting on his judgment seat, and betraying revenge and impatience in his countenance. He was struck with the admonition, and left the tribunal without passing sentence of death on the criminals. No minister was more the personal friend of his sovereign than Mæcenas; for this it is thought he was partly indebted to the attachment of the emperor to Teogoni, to which he owed his grace and favour, and which he granted graciously. It is said that a coolness took place in his latter years between him and the emperor, but at his death, which happened about the eighth year before the birth of Christ, he exulted him his general heir. Though a zealous patron of learning and learned men, he was a man addicted to the pursuit of pleasure. “Where vigilance was required,” says Velleius Paterculus, “he was idle, provident, and active, but as soon as a relaxation from business could be permitted, he disdained in a more than feminine indolence and delicacy.” The style of his own compositions was infected with the same effeminacy which characterized his manners, but the found sheets of his journal with respect to the writings of others, seems apparent from the merit of those on whom he bestowed his patronage. His name is perpetuated by the two great Roman poets, Virgil and Horace; with the latter he lived upon a footing of freedom and familiarity, which does equal honour to both, and whose name appears with so much distinction in his works as that of Mæcenas. Virgil dedicated to him his Georgics, which appear to have been composed at his request, but whose authorship is unknown; and that name of Mæcenas has ever since been applied to its liberal patrons. Of his own writings a single specimen only has come down to our times, the sense of which is, that he would be contented to live, though oppressed by almost any bodily sufferings and infirmities that could be accumulated, a sentiment which a Roman philosopher would despise, but which has been avowed by persons of our day, whose names will be perpetuated to distant ages by the works which they have left behind them; among these may be mentioned the celebrated Dr. Johnson, and the author of the Leda et Edmundice; the one from a dread of death, the other from an attachment to life: the latter, indeed, enduring much bodily pain, and very great infirmities for many years, in the midst of them all, never ceased to wish for a prolongation of life, nor to express a lively sense of the obligations he was under for a large balance of happiness in his favour; and on the tomb, intended by himself for his lifeless body, he inscribed, while living, the expressive epitaph, “Contented and Grateful.” The historian Dio has attributed to Mæcenas the introduction of warm baths at Rome, and also the invention of a species of short-hand writing, by the aid of which orations could be taken down from the mouth of the speaker; other writers, however, ascribe this to Cicero’s freedman Tiro. He is supposed to have been the author of “a history of animals;” a journal of the life of Augustus; a treatise on the different natures and kinds of precious stones, besides the two tragedies of Octavius and Prometheus, and other things that are lost. Univer. Hist.

MÆGOA, or FREMONA, in Geography, a town of Abythia; 9 miles from Axum.

MÆL-CARHAIX, a town of France, in the department of the Northern Coasts, and chief place of a canton, in the district of Guingamp. The place contains 1767, and the canton 7395 inhabitants, on a territory of 225 kilometres, in eight communes.

MÆL CORONDES, in the Language of the Celto-Saxons, the flowering-cinnamon-tree. This is a name given to a peculiar species of the cinnamon-tree, which is all the year round full of flowers. The flowers are not easily to be distinguished from the very fine cinnamon-flowers, but they produce no fruit, which the flowers of the fine cinnamon always do. The bark is much like that of the beet cinnamon, in external appearance; but it has very little tallow or smell. The tree grows very large, and the inhabitants sometimes tap it, by boring a hole in the trunk, at which it bleeds a thin watery sap, with which they make birch-bread.

MÆANDER, in Geography, a river of Turkey, in Asia, which rises N. of the ancient city of Apamea, and runs in a winding stream, about 250 British miles, and not far from its mouth, is about 190 feet broad. It is called by the Turks Boone Minder, or Great Mæander, to distinguish it from another little stream, which resembles it in its course.

MÆATÆ, in Ancient Geography, a general name, which comprehended the following five British nations, viz. the Otoceni, Gadeni, Selgovæ, Nevante, and Dumnonii, who possessed the country between the walls of Severus and Antoninus Pius. This name, used by the Greek and Roman writers, was probably not unknown to the Britons themselves; and is supposed by some to have been derived from two British words, mæi, a plain, and attich, inhabitants, and by others from mean, middle, and attich, as being situated in the middle, between the provincial and conquered Britons. We have sufficient evidence, that the Roman armies, under Julius Agricola and the emperor Severus, penetrated a considerable way into that part of Britain which lies in the N. of the wall of Antoninus Pius, between the forths of Forth and Clyde. Tacitus (Vit. Agric. c. 21 to 39.) gives a very distinct account of the flight of these famous expeditions in Caledonia, and Dio Nicius of the second. (Xiphilin. e Dione in Sever.) Many Roman coins have been found in several parts of that country, and there are still remaining in it very distinct vestiges of several Roman camps. But it is not less evident, that the Romans never formed any solid or permanent establishment beyond the wall of Antoninus, which was always considered as the utmost limit of the Roman empire in Britain.

MÆLER, in Geography, a very beautiful lake of Sweden, containing several islands rich in wood and pasture, with hilly shores, diversified with trees, villas, and farm-houses. It is usually frozen in winter, and opens an easy communication, by means of fheads, with Stockholm. See ARBÖGA, CANAL, and TROILHETTA.

MÆLLA, a town of Spain, in Aragon; 15 miles E. of Alcoons.

MÆLSTROM, a whirlpool in the North sea, near the island of Møkøre. Its noise is heard at the distance of several leagues, and it is so violent, that a vessel which comes near it is drawn irresistibly into the vortex, and carried immediately to the bottom, where it is dashed to pieces against the rocks. At flood tide the stream runs up into the country with a boisterous rapidity; and at ebb, it returns to the sea with
with a violence and noise not equalled by the loudest cata-
raea. Whatever it carries down, it instantly absorbs; but
at the turn of ebb and flood, when the water becomes still,
the shattered fragments rise to the surface. When this
whirlpool has been agitated by a storm, it reaches velefs to
the distance of five or six English miles, at a time when the
crews have thought themselves perfectly secure. N. lat. 67°
40'. E. long. 11° 44'.

M.EMACTERION, M.EMACTERIUM in Chronology, the
fourth month of the Athenian year. It contained twenty-
ine days, and answered to the latter part of our September
and beginning of October. The Bœotians called it al-
ackmonius.

It took its name from the festival Menaëtheria, sacred
to Jupiter, kept at this time.

M.EMACILON, in the Materia Medica, a name given by
Dioscorides, and the ancients in general, to the fruit of
the arbutus, or strawberry-tree.

M.ENA, in Ethnology, the name of a small fish, caught
in vast abundance about the shores of the Mediterranean,
and common in the markets of Italy, where they are ac-
counted but a poor sort of fish, and sold at a very cheap rate.
It is somewhat of the figure of the perch, but broader
and thinner, and is seldom above four or five inches in
length.

M.ENA Candida, a name given by many authors to the
smaris. It is not very improper, for they are both of
the same genus of the fparus, and are very nearly allied
to one another; the principal difference confining in the
tail and belly fins of the smaris being red. See Sparus.

M.ENALUS, in Ancient Geography, a mountain of the
Peloponnese, in Arcadia, mentioned by Strabo, Pliny, and
Virgil. This mountain was particularly consecrated to Pan.
Several towns were situated on the extent of this, which
were destroyed, and whose inhabitants assembled at Me-
galopolis.

M.ENONIA, a country of Aisa Minor, formerly com-
prehending that part of Lydia which lay eastward towards
mount Tmolus, and which was the source of the Pactolus.—
Allo, a town of this province, situated at the foot of
mount Tmolus.

M.ETO., E.ETO, a Scythian people who inhabited the banks
of the Pallas Mazois, and who gave their name to this
lake.

M.ETOTIS, or M.ETOS Pulus. See Sea of Azof.

MAEHUET, in Geography, a town of Sweden, in
Smalnd; 31 miles N.W. of Calmar.

MAERRNA, a town of the Tyrol; 23 miles W.S.W. of
Trent.

MAERSE, a town of Holland, in the department of
Utrecht; 5 miles N.W. of Utrecht.

MAEVA, in Botany, so called by Forskohl from its Ara-
bian name Meru, is one of his genera, adopted by Jussiff, Vahl
and Willdenow.—Vahl Symb. p. 1. 36. Wildl. v. 2. 1659.

Gen. Ch. Cal. Perianth of one leaf, tubular, coriaceous,
four-cleft; tube square, short, broader upwards; segments
of the limb oblong, obtuse, reflexed, a little longer than
the tube. Cor. none. Nectary at the mouth of the tube
of the calyx, entire or divided, shorter than the calyx,
convving, covering the flalk of the germs. Stam. Filaments
numerous, at the base of the germs, thread-shaped, twice
as long as the calyx; anthers oblong, incumbent. Pyl.
Germen cylindrical, shorter than the filaments, smooth, on
a thread-shaped, square flalk, the length of the tube,
swelling upwards; style none; stigma obtuse. Peric. and
Seeds unknown.

Eff. Ch. Calyx four-cleft, with the nectary in its tube.
Corolla none. Stigma fesille.

Obf. This genus is closely akin to Grewia, as Vahl ob-
serves, but differs sufficiently from that in having a four-cleft
calyx, a nectary crowning the mouth of the tube, and a
fesille stigma.

A native of Arabia Felix.—This shrub is furnished with
round, spreading, very smooth branches, and a purplish bark.
Leaves alternate, on footstalks, scattered, often many from
the same bud, oval, entire, pointed, thick. Flowers axil-
ary, each placed on a solitary, thread-shaped flalk, twice
as long as the leaves. Nectary divided into many thread-shaped
segments.

Nectary undivided.—Also a native of Arabia Felix.—
Branches round and smooth. Leaves on footstalks, remote,
pendent, oval, acute, retuse, entire, smooth, half an inch
long; footstalk shorter than the leaf. Cluffs of flowers
terminal, drooping. Nectary undivided.

MAES, GODEFREY, in Biography. Amidst those who
practised the art of painting in the Flemish school, after
the astonishing powers of Rubens were developed, this artist held
a considerable rank. He was born at Antwerp in 1660, and
having received early instructions from his father, he improved
and perfected himself by studying and copying the fine pic-
tures placed in the great churches and cabinets of his native
city.

His works, when he began to practife upon his own in-
vention, were highly approved; and he was much employed
both publicly and privately, till at last he was appointed to
the distinguished station of director of the academy at
Antwerp.

MAESA, in Botany, so called by Forskohl, and by him
alone; all succeeding authors having agreed that the plant
in question is not generically distinct from E.Boehnys, (see
that article)—Willdenow, Vahl and Martyn call the Mafa
of Forskohl B. luxicola.—Jussiff fugges the affinity of this
genus to Thunberg's Acomba.

MAESK, in Geography, a town of France, in the de-
partment of the Lower Meufe, seated on the Meufe; 39
miles N.E. of Liege. N. lat. 51° 5'. E. long. 5° 47'.

MAESLAND, or MAESLAND SLUYS, a town of Hol-
land, on a canal that forms a communication between Delft
and the Meufe; the inhabitants of which are principally oc-
cupied in the herring and whale fisheries; 7 miles S. of
Delft.

MAESTLINUS, Michael, in Biography, a German
astronomer, was born in the duchy of Wirtemberg, and be-
came mathematical professor at Tubingen, where he died in
1592, at the age of forty-eight, leaving behind him several
works on mathematics and astrology.

In early youth he made a speech in favour of Copernicus's stystem, which is
said to have brought the afterwards celebrated Galilea out
from the philosophy of Ariflotle and Ptolome, to whose
system he had been previously devoted. Kepler was one of
the pupils of Maestlinus, and has, in his own work entitled
"Altronomia Optica," commended several of his inventions.
Martin, Biog. Phil.

MAESTRO, in the Italian Music, majestic, spirited,
but not quick.

MAESTRIYCH, in Geography, a town of France, and
principal place of a district, in the department of the Lower
Meufe.
MAF

MAEVA, a town of Ruffia, in the government of Iruñia, on the Léva: 20 miles N.N.W. of Verycholénk. 

MADFAMEDE, a small island in the Indian sea, near the coast of Africa. S. lat. 16° 20'.

MAFARECK, a town of Egypt; 30 miles N.E. of Kous.

MAFFÆUS, Veggio, in Geography, a Latin poet, was born at Lodì, in the Milanese, in the year 1407. He was educated for the law, but soon showed an attachment to the belles lettres, and in future life had the happy art of blending the charms of poetry with the gravity of jurisprudence. 

He obtained the professorship of the law at Pavia, from whence he was called to Rome, where he held some considerable offices at the church of St. John de Lateran. He died in 1458: his chief works are, 1st, "De Educatione Librorum," and, 24ly, "Poetical Pieces," of which the most remarkable was a poem called a continuation of the Æneid of Virgil, which has been translated into English burlesque by Mr. John Ellis.

MAFFÆUS, Bernard, a learned cardinal, who died at Rome, at the age of 40, about the year 1553. He is known as the commentator on Cicero's epistles, and as the author of a treatise on medals and inscriptions. Moreri.

MAFFEE, or Maffei, John Peter, was born at Bergamo in 1536, and was instructed by his uncles Basil and Chrysotom Zanchi, nobles of that city, in the ancient languages, and in philosophy and theology. In 1563 he was appointed professor of eloquence at Genoa, with an ample salary. During the two years which he continued in that office he acquired great applause, and was chosen to the office of secretary of state; in 1565, he returned to Rome, where he entered into the society of Jesuits. He spent five years as professor of eloquence in the Roman college, during which he translated, into the Latin language, the history of the Indies by Acosta, which was published in 1570; after this he was invited to Lisbon by cardinal Henry, to draw up, from papers and other documents with which he was to be furnished, a complete history of the Portuguese conquests in the Indies, and of the progress of the Christian religion in those countries. He returned to Italy in 1581, and spent several years, partly at Rome and partly at Sienna, in learned labours, and at length was placed, by Clement VIII. in the Vatican, for the purpose of continuing, in the Latin language, the annals of Gregory XIII. begun by him in the Italian. He died at Tivoli in October 1603. He wrote the life of Ignatius Loyola, but his principal work is entitled "Hilariam Indicarum, Lib. xvi," which has been frequently reprinted. The best edition is in two volumes 3to, printed at Bergamo in 1747. His works are chiefly to be regarded on account of the purity of the style in which they are written. Moreri.

MAFFEO, Francis-Scipio, an Italian marquis, and elegant writer in his native language, was born at Verona in 1675. His early education was entirely conducted by his mother, a woman of very superior accomplishments, but as soon as he was of a proper age, he was sent to the Jesuits' college at Parma, where he distinguished himself by his attachment to poetry. Having completed his studies, he visited Milan, Genoa, and Rome, and at the last named city he was admitted into the Academy degli Arcadi. He now devoted himself to the pursuits of polite literature. Uniting the spirit of philosophy with that of gallantry, he maintained, before an assembly of both sexes in the academy of Verona, certain "Conclusioni d'Amore," in which the elegance of his language and the vivacity of his sentiments were equally admired. For a short time he quitted the arts of peace and joined

MAESTRO, a town of Italy, in the Paduan territory; 8 miles N.W. of Venice.

MAESTRO, a maker; as "Maestro di cappella," the master of a choir, or the composer in a cathedral. It is likewise a title given, by courtesy, to the composer of an opera, the master who presides at a harpsichord in a concert, and sometimes to a mere music maker.

MAESWINES BAY, in Geography, a harbour of Ireland, in the county of Donegal, being one of the many inlets in the bay of Donegal. It lies W. of St. John's Point and E. of the harbour of Killybegs.
joined the army, in which he served as a volunteer at the battle of Donawart in 1704, under the command of his second brother, who was general of the Bavarian troops in alliance with France; during the campaign he had an opportunity of saving his brother's life, by disarming an officer whose pistol was pointed at him. At the conclusion of the campaign he returned to Verona, and resumed those literary occupations which he never forsook. He continued to reform the stage, and produced, by way of model, his tragedy of "Merope." About the same time he undertook the more important task of reforming the moral principles of his countrymen, especially with regard to the practice of duelling, to which his brother had nearly fallen a sacrifice. On this subject he published two works, of which the latter, entitled "Della scientia chiamata cavallerescia," he dedicated to pope Clement XI. This was a performance of much learned research and solid argument, and so well written in every respect, that it acquired general applause, and passed through several editions. His "Merope," already noticed, was exceedingly popular, and was translated into most of the modern languages. By some of his contemporaries it was severely criticized and violently denounced: among these was Voltaire, who afterwards attempted to rival it by a tragedy of the same name, which is reckoned one of his best pieces. Maffei soon after wrote a comedy, entitled "Commedia delle Cerimonie," and a drama, called "La Fida Ninfa." He was indefatigable in his studies of antiquity and theology, with the view of promoting the honour of his native country, and the spreading of the Roman Catholic religion. One of his most useful works on the subject of antiquities was his "Ilustria Diplomata," being an introduction to the critical knowledge of pieces distinguished under the name of diplomas, with a collection of several documents hitherto inedited. In 1732 he railed a ducal monument to the fame of his native city, by a learned work, entitled "Verona Illustrata." This piece is comprised in four parts, and is replete with curious information relative to the history and antiquities of the north of Italy, and ranks among the ablest and most interesting of topographical works. His principal object in a tour undertaken through foreign countries, was the collection of ancient inscriptions, with the design of uniting them with those collected by Gruter, and other writers on the same subject. In his journey he visited every place where the relics of antiquity and the cabinets of the curious were to be found. On his arrival at Paris, he printed an account of what he had seen under the title of "Galizie Antiquitates quaedam illustris." Here he was elected a foreign member of the Academy of Inscriptions, and was a frequent attendant on its meetings. The disputes concerning the bull Unigenitus interested him so warmly, that he indignantly inveighed against the doctrines of the pope with the utmost zeal, and in a short time produced an elaborate folio volume, the refutation of his theological reading. In this he appeared as the champion of the Molinists against the Jansenists, and the defender of the bull Unigenitus. This was not published till the year 1742, and previously to it he passed from Paris to London, where he was distinguished by the notice of the royal family, several of the nobility, and by the most eminent men of letters. He visited both universities, and received at Oxford, in compliment to his literary merit, the degree of doctor of laws. From England he went to Holland and Flanders, and proceeded through Germany to Vienna, where he had a most gratifying reception from the emperor Charles VI. He returned to Verona in 1736, and immediately began to publish the "Offizvazion Letterarie," intended as a continuation of the Italian literary journal. Several original pieces of Maffei, relative to his history and antiquities, appeared in the successive volumes of his works. The true members of the church of Rome having maintained, in opposition to the Jefuits, that taking interest of money to any degree was the crime of usury, Maffei opposed this doc- trine in a work entitled "Dell' Impiego del Danaro," which was a learned and rational dissertation on the employment of money, in ancient times, and the true principles of morality and policy on this head. For this he incurred the charge of heresy, and was banished the city; the flornet at length passed over, and he returned in triumph. After this he published many other pieces on various topics; among the most important was his edition of the "Iliad," with commentaries and conjectures, and inquiries into the generation of lightning and other physical phenomena in nature. Ever actuated by a desire of advancing the glory of his native city, in which he had already promoted the liberal studies, by transplanting a colony of learned teachers from the Arcadi at Rome, and establishing a literary assembly in his own house, he exerted himself in laying the foundation of a museum of antiquities and curiosities, which became considerable, and was announced to the public by a catalogue entitled "Mufo Veronese." In 1749 he endeavoured to correct the popular notions concerning magic and witchcraft, by a treatise, "Arte magica dileguata," which brought upon him a host of enemies, of whom fourteen replied to his rejoinders. He was not, however, to be intimidated, and justified himself by the publication of two other pamphlets on the same subject. His next work was entitled "De' Teatri Antichi e Moderni," in which he attempted a vindication of theatrical spectacles, in opposition to those who maintained that they were all unlawful. He continued to devise new plans, to augment and confirm his literary reputation till the year 1754, when the effects of old age and the severity of winter threatened him with immediate dissolution. As soon as his danger was known in the city, the council ordered public prayers to be put up for him during three days. His valuable life was protracted a few weeks only, and on the 11th of February 1755, he expired, in the 70th year of his age. He was interred amidst a vast concourse of mourning fellow citizens, and a statue was erected to his memory in the principal square, by the side of those of Fra Cataldo, and others who had conferred honour on Verona. Gen. Biog.

MAFFAH, Old and New, in Geography, two towns of the island of Madagascar; the first situated on the N.W. coast, in lat. 15° 22'. E. long. 51' ; and the second, 25 miles S.E. of the other.

MAFFERSDORF, a town of Bohemia, in the circle of Boleilow; 10 miles N. of Tarnau.

MAFFRA, a town of Portugal, in the province of Estremadura, containing about 1400 inhabitants; near which king John V. erected a magnificent building; in consequence of a vow, made in a dangerous fit of illness, to found a convent for the use of the poorest persons in the kingdom, which was found to be that of Maffra. The building was designed to exceed even the Efeurial; it is constructed of white marble, contains 37 windows in front, and is nearly a square of 528 feet; in the centre is the church, with the palace on one side and the convent on the other. This structure was commenced by order of king John V. in 1717, and finished in 1742, the architect being a German, named John Frederic. In the whole building, it is said, there are 370 rooms, and 530 windows; five miles N.W. of Lisbon.

MAFMALA, a small island in the Indian sea, near the coast of Africa. S. lat. 16° 20'.

MAFORITUM, among the Romans, a veil or head-dress worn by the married women.

MAFRAGG, in Geography, a river of Africa, in Algiers, which
which runs into the Mediterranean, near Cape Rota; anciently called "Rubriculus."

MAGADINO, or English River, a river of Africa, which runs into Delagoa bay, navigable for large vessels; its channel is about a mile wide; and ships lie commonly about two miles up the river, where, in good depth of water, they are safe from all winds and supplied plentifully with provisions, such as beef, goats, fowls, fish, lemons, oranges, sweet potatoes, and other vegetables, with good water on both sides of the river. S. lat. 26°.

MAGACELA, a town of Spain, in Estramadura; 18 miles E.S.E. of Merida.

MAGADA, in Mythology, a title under which Venus was known and worshipped in Lower Saxony; where this goddess had a famous temple, which was treated with respect even by the Huns and Vandals, when they ravaged the country. It is said to have been destroyed by Charlemagne.

MAGADINO, in Geography, a town of Italy, in the bailiwick of Locarno, on the lake of that name; five miles S. of Belfinza.

MAGADIS, MAGAS, from μαγας, to mag, or play in unison or octaves, the name of a musical instrument in use among the ancients.

There were two kinds of magades, the one a stringed instrument, formed of twenty chords, arranged in pairs, and tuned to unison or octave, so that they yielded ten sounds; the invention of which is ascribed by some to Sappho; by others to the Lydians; and by some to Timotheus of Miletus. The other was a kind of flute, which, at the same time, yielded very high and very low notes. The former kind was, at least, much improved by Timotheus of Miletus, who is said to have been impeached of a crime, because, by increasing the number of chords, he spoiled and discredited the ancient music. Among all obscure terms in the ancient Greek music, which have bewildered modern inquirers, few have perplexed them more than this, and its meaning is still so far from settled, that we have yet to learn whether it was a wind or a stringed instrument; or, indeed, whether it was any instrument at all, or any thing more than a monochord, or the bridge of an instrument. Rouffeau affirms that the verb, to magadire, in the Greek music, implied to sing in the octaves, as a man and a woman, or a boy, naturally do; and adds, that as the word comes from magas, the bridge of an instrument, by extension it was applied to an instrument with double stringed unisons to each other, like the unisons and octaves in our old double harp-chord.

MAGADOXO, MAGADISH, or Maldehyde, in Geography, a kingdom of Africa, situated along the coast of the Indian sea, from the river Juba, near the equinoctial line, to beyond the fifth degree of north latitude. Its name is derived from its capital, which is situated in a large bay, formed by the mouth of a river of the same name, called by the Arabs, "the Nile of Magadoxo," on account of its annual overflowing. The source of this river is not ascertained, but its course is concluded to be long, from its considerable channel and large bay, and also from its extensive inundations, which supply various canals, and fertilize the country through which it runs, so that it produces in abundance wheat and barley, and a variety of fruits, and supplies food for numbers of hores, oxen, sheep, and other animals which are bred near its banks. The city of Magadoxo is a place of great commerce, and vast resort from Aden and other parts; whence their merchants bring cotton, silk, and other cloths, spices, and drugs, which they exchange with the inhabitants for gold, ivory, wax, and other commodities. The inhabitants are chiefly Mahomets, among whom are many Bedouins Arabs, who retain their ancient superstitions, and farther inland there is a greater number of Abyssinian Christians, subject or tributary to that empire. The king and his court are Mahomets; his subjects, of whom some are white, others tawny and olive, and others black, all speak the Arabic tongue. They are stout and warlike, and use, among others, poisoned arrows and lances. The town is situated in lat. 24° S. 115°. 15' E. 45° 50'.

MAGALAWAUK, a town of Hindostan, in Myssor; 10 miles W.S.W. of Punganoore.

MAGALHAENS, FERDINAND DE, in Biography, commonly known by the name of Magellan, an eminent navigator, was by birth a Portuguese. He served with much reputation during five years under Albuquerque, in the East Indies, and particularly distinguished himself at the conquest of Malacca in the year 1510. After this, thinking his services had been but miserably requited by his own court, he entered into the employment of Charles V. king of Spain, who gave him the command of a fleet, with which, in 1519, he discovered the straits called after himself at the extremity of South America. Soon after this he took possession of the Ladrone and Philippine islands in the name of the monarch in whose service he was engaged. At one of the latter, named Zebu, Magalhaens obtained the conversion of the king, having assured him that by becoming a Christian he would be rendered superior to his enemies. Under the farther condition of his becoming a vassal to Spain, the Portuguese aided him in his attempts to reduce to subjection the neighbouring chieftains, and the holy cross was erected over the smoking ashes of some villages that had been plundered and destroyed. In one instance his authority was set at nought, and he determined to inflict a summary vengeance on the rebellious chief; he accordingly landed with about fifty of his men upon the island of Matan, and was met by the chief and his people, who, though rudely armed, and subject to no regular discipline, made a formidable resistance during the greater part of a day. At length the fire of the Spaniards blackened from want of ammunition, and the islanders prefling on, a retreat became necessary. Magalhaens received a wound from an arrow in the leg, and being ill supported by his men, he was beaten down and slain by a lance. This happened in 1521, and by this act of impiety he lost the honour of being the first circumnavigator of the globe. He has, however, secured to himself a high reputation among maritime discoverers, by the commencement of this great enterprise. Barney's Discovery in the South Sea.

MAGALOTTI, COUNT LAWRENCE, a celebrated philosopher and mathematician, was born at Rome in 1637. Having been initiated in the elements of learning, he was sent to the university of Pisa, for the purpose of studying jurisprudence, in which he made a great and very rapid progress, but the bent of his genius led him to devote his main attention to the study of mathematics and natural philosophy. He cultivated these branches of science at Florence, during three years, under the celebrated Vincent Viviani, and was, by his recommendation, and that of Borelli, made secretary to the Academy del Cimento, which had been established, in 1657, by prince Leopold of Tuscany, for the express purpose of elucidating philosophical science by a series of experiments. The duties of this appointment Magalotti discharged with the utmost fidelity and care, and being directed by the prince to draw up an account of the experiments made there, he aimed at rendering his work popular, as well from its elegance as from
from the periphery of its style. The work was accordingly published in the year 1666, and was received with universal applause by men of science. The subjects which it embraces are the prejudice of the air; natural and artificial freezing; the various effects of heat and cold; the compulsion of water; magnetism; the nature of colours; of sounds; the projection of bodies, &c. While the secretary was engaged in drawing up his account of the experiments of the academy, he obtained leave from Leopold to pay a visit to his father at Rome, where he wished to consult the learned Angelo Ricci on the subject of that work; but the chief object of his journey was to obtain some ecclesiastical promotion. Having failed in this object, he determined to return to Florence, and to apply for a place at the court of the grand duke Ferdinand II. In this he was successful; and shortly after a pension was given him by pope Alexander VII., to whom prince Leopold had presented a considerable part of the instruments used in making the experiments at the academy. He attempted a work on electricity, but the science was too much in its infancy to be developed on the scale he thought it warranted to admit of much being done in it. While engaged in these pursuits he did not neglect his favourite study astronomy, and at the same time paid some attention to theology, particularly to the writings of the fathers. About the year 1666, he drew up and published a small volume relative to the history and peculiarities of China, which was received with great applause; and at the same time he published a small, but elegant Compendium of the Moral Doctrine of Confucius. He was a good poet, and the first person who published a good translation of the Odes of Anacreon in Italian verse. He was very conversant in many of the modern languages, and could write and speak French, Spanish, and English, with the correctness and ease of the natives of those countries. Of this he gave abundant evidence in different visits which he paid to them either in a private or official character. In England he was the intimate friend and bosom companion of the illustrious Mr. Robert Boyle, whom he attempted to convert from the errors of the Protestant faith, but the English philosophers in the opinion of historians attribute his conversion to be moved by the eloquence of his Catholic friend. He was employed in several missions to foreign princes, and at length, in 1654, he was appointed ambassador to the imperial court. At Vienna he was received in the most honourable manner by persons of all ranks, and acquired the particular favour of the emperor. Here he formed an intimate connection with the men most eminent for science and literature, and spent his time agreeably in learned leisure, till he was embarrassed by the delay of the necessary pecuniary remittances from his court. He now determined to return to Florence without waiting the permission of the duke. Shortly after, that prince superseded him in his embassy to Vienna, and gave him apartments in his palace, with a considerable pension. This was not exactly the thing which he wished, and which his services seem to have claimed; he therefore withdrew into retirement, and gave himself up entirely to his studies. In 1654, he composed fifteen Italian odes, in which he has drawn the picture of a woman of noble birth, and exquisite beauty, distilling not only by every external part, but by every mental charm, and yet rendering herself chiefly the object of admiration and delight by her manners and conduct. Not believing that such an original existed in nature, he gave this piece the title of "The Imaginary Lady." His next work confuted of Letters against Atheists, in which his learning and philosophy appear to great advantage. In the year 1689, he was appointed a counsellor of state to the grand duke, who lent him his ambassador into Spain to negotiate a marriage between one of his daughters and king Charles II. Soon after he had accomplished the object of this mission he sunk into a temporary melancholy, which led him to exclude himself from all intercourse with the world for nearly a year, till by the interreats of the grand duke he was induced to return to his post at court. He now resumed very successfully his literary labours, and published works upon various subjects, and left others which were given to the world after his decease, which happened in the year 1712, when he had attained the age of 75. Magalotti was as eminent for his piety as he was for his literary talents; unimpeachable in his morals, liberal, beneficent, friendly, polite, and a lively and cheerful, as well as very instructive companion. His house was the conjoint resort of men of letters from all countries, whom he treated with elegant hospitality. He was deeply conversant with the writings of the ancient philosophers, and was a follower of the Platonic school. In his natural and philosophical investigations he discarded all authority, and submitted to no other guide but experiment. Among the moderns he was particularly attached to Galileo. After his death a medal was struck in honour of his memory, with the figure of Apollo raised on the reverse, and the inscription OMINI LUSTRAT. In the General Biography is given a long list of his various publications, taken from the third vol. of the well known work entitled "Fabroni, Vit, Italorum doc. excell." MAGAME, in Geography, a town of the island of Ceylon, near the E. coast; 96 miles S.E. of Candy. MAGAN, a town of Spain, in New Castile; 8 miles N.N.E. of Toledo. MAGANIA, a river of Africa, which runs into the Zambeze, S. lat. 16° 20'. E. long. 33° 40'. MAGAPERAM, a town of Hindoostan, in the circuit of Cuddapa; 14 miles N.N.E. of Combam. MAGARABA, a mountain of Africa, in Algiers, extending about 30 miles along the coast of the Mediterranean, inhabited by a race called "Magaribis." Descended from the Barbare, who live in tents, feed large flocks, and pay a tribute to the devil of Algiers. MAGARZAN, an island in the Red sea, near the coast of Nubia; it is high, and the largest of three forming a triangle, about five miles in length. N. lat. 21° 10'. MAGAS, in the Ancient Muses, is used to denote the bridge of any instrument. See MAGASIS. MAGASSA, in Geography, a town of Tyrol; 24 miles W.S.W. of Trent. MAGATII, Cæsar, in Biography, (or, as he was called in his Latin writings, Magatus), an eminent surgeon, was the son of a respectable citizen of Scandiano, in the duchy of Reggio, where he was born in 1579. He distinguished himself by his early proficiency in philosophy and medicine at Bologna, at which university he received the degree of doctor in both these sciences, in March 1597, in the 18th year of his age. He ill remained at that place, however attending the public hospitals, under the direction of the most eminent physicians, for some time, till he went to Rome, where he united the study of anatomy and surgery, with that of medicine. Returning to his native country, he commenced the practice of his profession, where he soon acquired so much reputation, that the marquis of Bentivoglio induced him to settle at Ferrara, as professor of surgery in the university of that city. Here, however, he met with considerable opposition and enmity from the established practitioners, who intrigued him from prac-
MAG}
tifying, unless he would submit to their examinations; with
which he at length complied, and gave abundant proofs of
superior talents and acquirements. He soon attained the
highest professional reputation at Ferrara, and gained the
greatest applause from numerous classes of students by his
able conduct in the chair, until he was seized with a severe
illness, under the impression of which he was induced to
enter into the fraternity of Capuchins, and afterwards af-
sumed the habit of the order. He still continued, how-
ever, to practice medicine and surgery, in his new condition,
with a success that assisted him to the confidence of persons
of the first rank, especially of Francis I. duke of Modena.

But the severity of his sufferings from the stone induced
him, in 1647, to repair to Bologna, for the purpose of re-
lieving himself by undergoing the operation of lithotomy;
but he survived it a very short time, and died at the age of
sixty-eight.

Magius was the author of a considerable improvement in
the art of surgery, by his work entitled "De rara Medic-
catione Vulc numer, etc., de Vulcherus rarò tractantis," 
Venice, 1616, which he also fluently inculcated in his
lectures, and the good effects of which he had often wit-
nessed during his attendance at Rome. This was the re-
exjection of tents in the treatment of wounds, and the recom-
mandation of a simple cafy method of dressing, without the
irritation of frequently cleansing and rubbing the tender
granulations; a practice which he supported at great length
by bound and rational arguments, tinctured a little, how-
ever, by the Galenical theories. His work contains also a
number of valuable observations respecting particular wounds;
and it has an appendix, relating to gun-shot wounds, in
which he refutes the notion of their being envenomed, or
attended with cauterization. Sennertus published a criti-
cism on his work, containing a defence of the use of tents;
to which Magius, now a monk, replied, in the name of
his brother John Baptifl, (if that was not his own conven-
tual name) by publishing a pamphlet, with the title of
"Tractatus, quo rara Vulcerum description contra
Sennertium," 1627, which is to be found in the Venice edi-
tion of the former work, published in 1676. Eloy Dict.

MAGAZINE, Literary, a miscellaneous, periodical
pamphlet, containing a variety of essays, in prose and verfe.
The term, as applied to literature, is modern, but is now
become of extensive and popular import. In England it
was first employed in "The Gentleman's Magazine," the
first number of which was published January 1, 1731; and
this has been regularly continued every month from that
time to the present. This was not the earliest periodical pub-
ication in monthly numbers, as one had appeared in the
year 1681, under the title of "The Monthly Recorder of
all true Occurrences both Foreign and Domftic." Soon after
"The Gentleman's Magazine," a rival work, under the
title of "The London Magazine," was published, but this
was discontinued in the year 1785.

"The invention of this new species of publication," ob-
erses Dr. Kippis, in his memoir of Edward Cave, in the
Biographia Britannica, "may be considered as something
of an epocha in the literary history of the country.
The periodical publications before that time, (i. e. 1731)
were almost wholly confined to political transactions and
to foreign and domestic occurrences: but the magazines
have opened a way for every kind of inquiry. The intel-
ligence and diffusion contained in them are very extensive
and various; and they have been the means of diffusing a
general habit of reading through the nation; which in a
Certain degree hath enlarged the public understanding.

Many young authors, who have risen to considerable emi-
nence in the literary world, have here made their first at-
ttempts in composition. If it were not an invicious task,
the history of them would be no incurious or unenteraining
subject." In a former part of this dictionary, we have
given a brief history of Newspapers, Magazines under the
term "Journal," but if the reader be desirous of obtaining
an ample account of periodical literature, he will find it
fully narrated in "Nichols's Literary Anecdotes of the
Eighteenth Century," 6 vols. 8vo.

MAGAZINE, in the Military Art, a place in fortified
towns, where all forts of flowers are kept; and where carpen-
ters, wheelwrights, smiths, &c. are employed in making
things needful to furnish out the train of artillery.

MAGAZINE, Powder, is a building constructed for keep-
ing large quantities of powder. These magazines were
formerly towers erected in the town walls; but many in-
conveniences attending this situation of them, they are now
placed in different parts of the town. They were at first
constructed with Gothic arches; but M. Vauban, finding
these too weak, constructed them in a semicircular form, of
the following dimensions, viz. sixty feet long within, and
twenty-five broad; the foundation eight or nine feet thick;
and eight feet high from the foundation to the spring of the
arch; the floor about two feet from the ground, to pre-
vent damp; and consequently fix feet for the height of
the story.

The thinnest part or hanches of the arch is three feet
thick, and the arch made of four lolecular ones over the
other, and the outside of the whole terminated in a slope
to form the roof; from the highest part of the arch to the
ridges is eight feet, which makes the angle somewhat
greater than ninety degrees; the two wings, or gable ends,
are four feet thick, raised somewhat higher than the roof,
as is customary in other buildings; as to their foundations
they are five feet thick, and as deep as the nature of the
ground required.

The piers or long sides are supported by four counter-
forts, each foot broad, and four feet long, and their
interval twelve feet; between the intervals of the counter-
forts, are air-holes, in order to keep the magazine dry and
free from dampness; the dices of these air-holes are com-
monly a foot and a half every way, and the vacant space
round them three inches made fo, as the in and outides be-
in the same direction. The dices serve to prevent an enemy
from throwing fire in to burn the magazine, and for a
farther precaution, it is necessary to flop these holes with
several iron plates, that have small holes in them like a
skimmer, otherwise fire might be tied to the tail of some
small animal, and do drive it in that way; this would be no
hard matter to do, since, where this precaution had been
neglected, egg-shells have been found within, that have been
carried there by weasels.

To keep the floor from dampness, beams are laid long
ways, and to prevent these beams from being soon rotten.
Large floors are laid under them; these beams are eight or
nine inches square, or rather ten high and eight broad,
which is better, and eighteen inches distant from each
other; their interval is filled with dry sea coals, or chips of
dry flones, then over these beams are others laid cross-ways,
four inches broad, and five high, which are covered with
two-inch planks.

M. Behidor would have brick walls made under the floor,
instead of beams, and a double floor laid on the cross-beams;
which does not appear to be so well as the manner proposed
here; the reader is, however, at liberty to choose the method
he likes best.
To give light to the magazine, a window is made in each wing, which is shut up by two shutters of two or three inches thick, one within and the other without it; that which is on the outside is covered with an iron plate, and is fastened with bolts, as well as that on the inside. These windows are made very high, for fear of accidents, and are opened by means of a ladder, to give air to the magazine in fine dry weather.

There is likewise a double door made of strong planks, the one opens on the outside, and the other within; the outside one is also covered with an iron plate, and both are locked by a strong double lock; the store-keeper has the key of the outside, and the governor that of the inside: the door ought to face the south nearly, if possible; in order to render the magazine as light as can be, and that the wind blowing in may be dry and warm. Sometimes a wall of ten feet high is built round the magazine about twelve dintat from it, to prevent any thing from approaching it without being seen. Mr. Muller has proposed some alterations by way of improvement, in M. Vauban's construction, for which see his Practical Fortification, p. 219, &c.

If large magazines are required, the piers or side-walls which support the arch should be ten feet thick, seventy-two feet long, and twenty-five feet high; the walls, which supports the two small arches of the ground floor, eight feet high, and eighteen inches thick, and likewise the arches: the thickness of the great arch should be three feet six inches, and the counterforts, as well as the air-holes, the same as before. Magazines of this kind should not be erected in fortified towns, but in some inland part of the country near the capital, where no enemy is expected. It has been observed, that after the centres of semicircular arches are struck, they settle at the crown and rise up at the hanches; now as this shrinking of the arches must be attended with ill consequences, by breaking the texture of the cement after it has been partly dried, and also by opening the joints of the vousoirs at one end; Dr. Hutton, in his Treatise on Bridges, has proposed to remedy this inconvenience, with regard to bridges, by the arch of equilibration; and as the ill effect is much greater in powder magazines, he has also proposed to find an arch of equilibration for them also; and to construct it when the span is twenty feet, the pitch or height ten, which are the same dimensions as those of one of the piers of the magazine, on the exterior wall, at top, forming an angle of 113°, and the height of their angular, point above the top of the arch equal to seven feet; this curious question was answered in 1755, by the Rev. Mr. Wildbore, and the solution of it may be found in Hutton's Miscellanea Mathematica.

Magazine, Artillery, or the magazine to a field battery, is usually made about fifty or sixty yards behind the platform. This is a cavity dug in the ground about four feet deep, and the earth thrown between the pit and the platform; the sides of the pit are sometimes planked round to keep it dry and to prevent the earth from crumbling in; and the powder-barrels placed here are covered with hurdles and earth, or tanned hides, to preserve the powder from wet or fire. The communication to the magazine is by a sloping trench beginning to descend about five or six yards behind the platform; and the earth is thrown on that side where it will most conveniently cover the percons who remove the barrels of powder from the great magazine to the battery or small magazine. When there are many canons in the battery, and the service is quick, it is customary to have, for every two pieces, a small magazine to hold twenty or thirty barrels of powder; this is placed about fifteen or twenty yards behind the platform, and against the merlon between the cannon; and as these barrels are used, they are replaced by others from the great magazine. At each magazine a centinel is placed to prevent accidents; and in order to prevent percons from coming into the battery and magazines who have no bunifins there, a trench is sometimes dug behind the magazine and carried into the trenches, which communicate between the magazine and battery.

Magazine, the apartment used to keep the powder in; which in large ships is situated forwards, and in small ships abaft. It should always be situated as low down as possible.

Magbote, or Magbotie, formed of the Saxon mag, i.e. cognatus, and bot, compensation, in our Old Writers, a compensation for the slaying or murder of one's kinman, in ancient times, when corporal punishments for murder, &c. were sometimes commutated into pecuniary fines; if the friends and relations of the party were so satisfied.

Magdala, in Ancient Geography, a town of Palestine, on the western bank of the lake Tiberias.

Magdaleine, in Geography, the name of an island situated at the bottom of Falke bay, near the Cape of Good Hope, in which is a great retort of sea wolves, and of penguins, named "Manchots."

Magdalen Church. Religious of St. Magdalen, is a denomination given to divers communities of nuns, confilling generally, or penitent courtesans; sometimes, also, called MagdalAncien.

Such are those at Metz, established in 1452; those at Paris, in 1492; those at Naples, first established in 1324; and endowed by queen Sanchia, to serve as a retreat for public courtesans, who should betake themselves to repentance; and those of Rouen and Bourdeaux, which had their original among those of Paris in 1618.

In each of these monasteries there are three kinds of persons and congregations; the first consist of those who are admitted to make vows, and those bear the name of St. Magdalen; the congregation of St. Martha is the second, and is composed of those who it is not judged proper to admit to vows; finally, the congregation of St. Lazarus is composed of such as are detained there by force.

The religious of St. Magdalen at Rome were established by p.p. Leo X. Clement VIII. settled a revenue on them, and further appointed that the effects of all public profits, and other stipends, should fall to them; and that the testament of the ref is to be invalid, unless they bequeathed a portion of their effects, which was to be at least a fifth part, to them.

Magdalen Hospital. See Hospital.

Magdalen Islands, in Geography, a cluster of islands in the gulf of St. Lawrence, N.E. of the island of St. John's, and N.W. of that of Cape Breton. They are inhabited by a few fishermen, and are dangerous to ships sailing near them in foggy weather. The largest, which gives name to the cluster, is situated in N. lat. 47 25'. W. long. 61° 20'.

Magdalen River, a river of Canada, which runs into the river St. Lawrence. N. lat. 49 12'. W. long. 65° 5'.

Magdalen, a small island in the South Pacific ocean, being one of the Marquesas; situated nearly in S. lat. 10° 29'. W. long. 138° 50'. See Marquesas.

Magdalen, a town of the island of Cuba; 30 miles S. of Havana.

Magdala River. See Magdala.

Magdalen, Cape of, a promontory in the centre of Canada, which has an iron mine abounding with ore and yielding excellent metal.

K 2
MAGDALEO, a word used by dispensary writers, to
express any thing made up into a cylindrical form. The
common rolls of pilasters which the apothecaries make up to
be ready for spreading upon occasion, are thus called, as
also the rolls of sulphur or common brimstone.

MAGDALAGAD, in Ancient Geography, a town of Pa-
leistine, in the tribe of Judah. Josh. c. xv.

MAGDALLA, or MAGDAILIDES, the same as Magdala-
elons, rolls of sulphur, platter, &c.

MAGDALEM, in Ancient Geography, a place of Egypt,
on the coast of the Red sea, between Bial-Zephon and Phil-
habirth.

MAGDEBURG, in Geography, a duchy surrounded by
the Mark of Brandenburg, the duchy of Brunswick, the
principalities of Halberstadt and Ascholt, the county of
Mansfeld, and the electorate of Saxony. The country
belonging to this duchy is, in general, level. Although soil
is scarce, it has several mines of pit-coal, and by means of
its rivers, particularly the Elbe, which pervades the duchy,
obtains wood from the neighbouring provinces. Its salt
springs afford a supply of salt sufficient for the demands
of all Germany. In 1703, the whole duchy contained 35
towns and 431 villages. From the years 1750 to 1756, the
number of inhabitants, estimated by the burials, amounted
to 330,000. According to Hock's account in 1801, the
number is stated at 275,262. The states of the country
confined of prelates, the nobility, and the cities. The Re-
formation was introduced into this duchy in the sixteenth
century, and about the middle of the succeeding century
Lutheranism was the only religion that was tolerated; but
since that time French and German Calvinist refugees have
been received, and under king Frederick-William, the pri-
mary exercised of the Roman Catholic worship was tolerated
both at Magdeburg and Halle. The bishopric of
Magdeburg was formed out of a Benedictine convent, founded
by the emperor Otho I, in 957, and converted into an arch-
bishopric in 967. By the peace of Weilphalia, in 1648,
the house of Brandenburg obtained, under certain stipu-
lations, the reversion of this archbishopric, and in 1680 the
actual possession of it. The duchy had its own regency,
which, in 1714, was removed from Halle to Magdeburg,
and confined of two senates; but the cathedral chapter
was afterwards excluded from any part in the government.
The annual revenues amounted to above 800,000 rix-dollars.
By the peace of Tilsit in 1807, that part of the duchy, which
lies on the left side of the Elbe, was ceded by the king of
Prussia to the new kingdom of Weilphalia.

Magdeburg, a city of Weilphalia, the capital of the
above-mentioned province, in the circle of Lower Saxony,
on the left bank of the Elbe. This was formerly one of
the principal trading towns in Germany. It is strongly for-
tified, and has a citadel on an island in the river Elbe. It
is well built, and the cathedral square is ornamented with
large and elegant houses. Among the principal edifices
may be reckoned the king's palace, formerly the episcopal
refidence, the armoury, the governor's house, and the guild-
hall, to which we may add the Lutheran cathedral, which
is a superb structure, in the antique style. The Lutherans
have also three collegiate, and six parochial churches, and
a convent. The manufactures, which are numerous, consist
of woolen cloths and fluffs, silk fluffs, cotton, linen, Rock-
ings, hats, leather gloves, tobacco, &c. The
function of the Elbe, and the road connecting High and Low
Germany, render it convenient for trade. Magdeburg, as
early as the time of Charles the Great, was a place of some
note; and it attained a considerable degree of prosperity
in later times, and became one of the Hanze towns. In the
year 1807, it was taken by the French. The number of inhab-
abitants, in 1798, is stated by Hafel at 56,614, and in 1802,
by Krug, at 32,000; 52 miles E.S.E. of Potzdam. N.lat.
52° S. E. long. 11° 50'.

MAGDELA, a town of Germany; in the principality
of Weimar; 7 miles S.E. of Weimar.

MAGDELAIJE, a cluster of small islands in the Me-
diterranean, near the N. coast of Sardina. N. lat. 41° 11'.
E. long. 0° 36'.

MAGDELOUS, or MAGDON, in Ancient Geography,
a town situated towards the middle of the frontiers of Lower
and also by Herodotus ii. xi. c. 49. It was not far from
the sea. The Itinerary of Antonius places it in the vicin-
ity of the Delta, E. of it, about 13 miles from Pelusium,
the mouth effectually mouth of the Nile.

MAGEDAN, a town of Judaea, situated E. of the lake
of Genemarch.

MAGEDO. See MEGIDO.

MAGEE, in Geography, a town of Hindoostan; 25 miles
E. of Bawares

MAGEEYONCOLLA, a town of Burma; 42 miles N.
of Prone.

MAGEGODEVICH, or EASTERN RIVER, a river of
America, which falls into the bay of Patamaskablod, and
supposed to be the true St. Croix, which forms part of the
call boundary line between the United States and New
Brunswick.

MAGEGOWN, a town of Hindoostan, in Concan; 25
miles S. of Severndroog.

MAGELHOLM, a small island of Denmark, in the
Baltic, near the S. coast of the island of Zealand. N. lat.
54° 43'. E. long. 11° 15'.

MAGELLAN, STRAITs, a passage between the
Atlantic and Pacific oceans, at the southern extremity of
the continent of America; estimated by Bougainville at
342 miles from Cape Virgin Mary, in the Atlantic, S. lat.
52° 42'. W. long. 68° 22', to Cape Pillar, in the Pacific,
S. lat. 52° 45'. W. long. 75° 10'. The breadth of it is
various in different parts; and it has many capes and bays,
affording places of anchorage and security to ships that pass
through it. On the north it is bounded by Patagonia, and
on the south by Terra del Fuego. These straits were first
discovered by Ferdinand Magellan, or Magalhães, in the
service of the crown of Spain, who, in the year 1520, found
a passage through them from the Atlantic to the Pacific
ocean, (see his biographical article.) Admiral Del Rio also
passed these straits in his voyage round the world; and they
have been since passed by several other navigators, e.g. com-
modoro Byron in 1564, Wallis in 1566, and Carteret in
1577, Bougainville in 1768, &c. They have been care-
fully examined by the navigators just mentioned, with
regard to their bays, harbours, and headlands; the nu-
merous islands which they contain, and the coasts on both
sides, that incline them; and the tides, currents, and found-
gings that occur in them, through their whole extent. Of
the transferences of Byron, Wallis, and Carteret in these
straits, we have details in the accounts of their respective
voyages, and these, together with the chart, founded on
their observations and discoveries, are a very valuable ac-
cession to geography. Commodoro Byron cludes his ac-
count of the voyage through these straits, with the fol-
lowing general remarks. "It is probable, that whoever
shall read this account, of the difficulties and dangers which
attended our passage through the strait of Magellan, will
conclude, that it ought never to be attempted again; but
that all ships which shall hereafter fail a western course from
Europe
Europe into the South seas, ought to go round Cape Horn. However, I, who have been twice round Cape Horn, am of a different opinion. I think that at a proper season of the year, not only a single vessel, but a large squadron might pass the strait in less than three weeks; and I think, to take this proper season, it should be at the full moon, entrance for some time in the month of December. One great advantage of this passage is, the facility with which fish is almost everywhere to be procured, with wild celery, scurvy grubs, herrings, and many other vegetables in great abundance; for to this I impute the healthiness of my ship's company, not a single man being affected with the scurvy in the highest degree, nor upon the sick list for any other disorder, notwithstanding the hardship and labour which they endured in the passage, which cost us seven weeks and two days, as we entered the strait on Sunday the 17th of February, and quitted it on Tuesday the 6th of April. Wood and water are also to be procured almost at every anchoring place beyond fresh-water bay. Our sufferings I impute wholly to our pulling the strait just as the sun approached the equinox, when, in this high latitude, the world weather was to be expected; and indeed the weather we had was dreadful; beyond all description." (Hawkesworth's Voyages, vol. i.) Capt. Wallis's account of his passage through this strait terminated with this reflection: 'Thus were we to a monastery and an inhospitable region where we were in almost perpetual danger of shipwreck for near four months, having entered the strait on the 17th of December 1766, and quitted it on the 11th of April 1767; a region where, in the midst of summer, the weather was cold, gloomy, and tempestuous, where the prospect had more the appearance of a chaos than of nature, and where, for the most part, the valleys were without herbage, and the hills without wood.' To the account of captain Wallis's voyage is annexed, a table of the courses and distances from point to point, in this strait, as compiled.

**MAGELLANIC Clouds**, in Astronomie, whitish appearances like clouds, seen in the heavens towards the south pole, and having the same apparent motion as the stars.

They are three in number, two of them near each other. The largest lies far south from the fourth pole, but the other two are not many degrees more remote from it than the nearest conspicuous star, that is, about eleven degrees. Mr. Boyle conjectures, that if these clouds were seen through a good telescope, they would appear to be multitudes of small stars like the sky way. Boyle's Works, 4to. vol. i. p. 297.

**Maggellanic Cloud**, in Astronomy, whitish appearances like clouds, seen in the heavens towards the south pole, and having the same apparent motion as the stars.

**MAGELLANICA Terra**, in Geography. See Patagonia.

**MAGERGONG**, a town of Hindoos, in Candia; 54 miles S. of Indore.

**MAGGERI**, a town of Hindoos, in Myrorge; 21 miles W. of Bangalore.

**MAGGERÓE**, a large island near the coast of Lapland, separated from it by a strait of the North sea called "Magger Sound." This island is said to be the most northerly land in Europe. N. lat. 71° 15'. E. long. 24° 55'.

**MAGGI, Jeano**, in Biography, a lawyer, philologist, and engineer, was born at Angharre, in Tukey, in the earlier part of the sixteenth century; he studied at the principal Italian universities, and while young acquired an intimate acquaintance with antiquities and polite literature. He had scarcely attained to the age of manhood, when he was selected by his townsmen as their embassador at the court of Florence. In 1558, he was appointed judge at Amastrica, in the kingdom of Naples, but his usual residence was in the city of Venice, where he wrote the greater part of his learned works. Of his legal studies, the fruit was "A Commentary on the four Books of Justinian's Institutes." In general literature, his principal work was "Varia et Lectionum seu Miscellaneorum," which was elegantly written, and which proved him to have been thoroughly acquainted with the best ancient and modern authors. He appeared as a theologian, in a treatise "De Mundi eruditione, et de Die Judicium," commended by Dupin for its learning and elegance. He gave signal proofs of his talents as a poet, but the work by which he acquired the greatest reputation, was relative to the subject of military engineering, entitled "Della Fortificazione di una Citta," which contains a description of many ingenious machines and instruments of his own invention. On account of his skill in this department of science, he was sent to Cyprus, when threatened with invasion by the Turks, and his services as an engineer were of great use in the celebrated siege of that place, and enabled it to hold out a long time, and with valiant defence to the enemy. At length it fell, and Maggi was carried by the Turks as a flame to Constantinople, where he underwent much hardship. In the gloomy solitude of a dungeon, he wrote two pieces, entitled "De Timmmabulis," and "De Epitoma," the latter, "On the Rack," was probably suggested to him by the reflection on the tortures to which he was daily liable. He was at length, and at the moment when negotiations were carrying on for his deliverance, strangled in his prison, in the year 1572. Bayle.

**Maggi, Charles Maria**, an Italian poet of the 17th century, and one of the reflores of good taste in Italy, after the barbarous raving of the school of Marini. He was born at Milan in 1630, and was secretary to the Senate of that city. He died in 1690, and his works were published in the following year by Muratori, at Milan, in four vols. 12mo.

**Maggi, in Geography, a town of Tunis; 40 miles S.W. of Gabas.**

**MAGGIA VAL**, an Italian bailiwick, belonging to the Swiss cantons, containing 22 parishes, and 25,000 inhabitants of the Catholic religion. It is partly bounded by the duchy of Milan, and the bailiwick of Livernon and Locarno, and terminated by mountains of eternal snow. — Albo, a town of Italy, in the bailiwick of Bellinzona; seven miles W.S.W. of Bellinzona. — Albo, a river of Italy, which runs into lake Maggioro, at Locarno.

**MAGGIORE, Lago. See Lake.**

**MAGGIORE, an Italian adjective, from major, Lat. a word now naturalized in the English language, and synonymous with greater, as major threem implies a greater or thrice as, a minor does a less or a flat third. These degrees of comparison are of very frequent use in music, the variable intervals amounting to five; as the semitone, the tone, the third, the sixth, and the seventh. With regard to the tone and the semitone, their difference of major and minor can only be expressed in numbers, as we have no notes to express them in our system. The semitone major is the interval of a second minor, as from B to C, or E to F, and its ratio is 15 to 16. The major is the difference between the fourth and fifth, and its ratio 8 to 9. The three other intervals, namely, the third, sixth, and seventh, differ continually from each other by a semitone from the major to the minor, thus, the third major confounds of a tone and a half, and the third major of two tones. There are also three smaller intervals, which are called major and minor in theory, as the quarter tone, and the comma; but as these intervals can only
only be expressed in numbers, they are imaginary diluc-
tions, and useless in practice.

A mode or key is also said to be major, when the 3d
above the key note is major; that is, consisting of four
semitones above the base. To modulate from a major key
to a minor, and e contra, are common musical expre-
sions.

MAGGOT, the common name of the fly-winged bug,
placed in the egg of the great blue fesh-fly. Notwith-
tanding the difficulty for this animal, its figure and struc-
ture of parts are greatly worth attending to, and may serve
as a general history of the class of worms produced from the
eggs of flies.

This animal is white and feathery; its body is composed of
a number of rings, like the bodies of caterpillars, and other
the like insects, and is capable, at the pleasure of the animal,
of assuming different figures, being at times more or less
extended in length, and consequently more or less thick.

Notwithstanding that this creature has no legs, it is able
to move itself very swiftly, and, in its first attempt to move
its body, is extended to its greatest length, and affumes
something of the figure of a pointed cone. The pointed
part of this cone is the head of the animal, and is not sepa-
rated from the next ring by any deeper furrow than the reil
of the rings are from one another. In some flates of the
animal one may see two short horns thrust out from the
head; but what are more constantly observable, are two
brown fealy hooks; these are, however, sometimes hid,
and have each of them a sheath, or case, into which the
animal can retract them at pleasure. These hooks are bent
into an arch, the concavity of which is toward the place on
which the creature is placed, and they are thickened at their
infection in the head, and thence diminish gradually, till
they terminate in a fine thorn point.

These two hooks are placed in a parallel direction, and
can never come together, and therefore cannot serve in the
place of teeth to grind the food between, but merely to pull
and fever it to pieces, that it may be of a proper size for
the mouth of the creature.

The creature has, besides these two hooks, a kind of
dart, which is of about a third part of their length, and is
placed at an equal distance between them. This also is
brown like them, and fealy; it is quite straight, and ter-
minates in a fine point. The hooks, have, if it were, the
fealy thorns at their points, and this dart seems intended,
by reiterated strokes, to divide and break the pieces of flesh
these have separated from the rest, into smaller parts.

Immediately below the apertures for the egress of the
hooks, is placed the mouth of the animal; the creature
does not thrust this little opening unless pressed; but if the
pressure be properly managed, it will sufficiently open it,
and there may be discovered within it a small protuberance,
which may very naturally be supposed either the tongue,
or the fucker of the animal.

The hooks in this creature not only supply the place of
teeth but also of legs; since it is by fastening these hooks
into the substance it is placed on, and then drawing up its
body to it, that it pulls itself along.

The back of the creature lowers itself by degrees as it
approaches the extremity of the belly; and near the place
where the back begins to lower itself, are placed the crea-
ture's two principal organs of respiration. One may per-
cieve there two small roundish brown spots; these are very
easily distinguishable by the naked eye; because the rest of
the body of the creature is white; but if we take in the
assistance of glusses, each of these spots appears to be a
brown circular eminence raised a little above the rest of the
body. On each of these spots one may also discover three
oblong oval cavities, something in the shape of button-holes;
these are situated in a parallel direction to one another, and
their length nearly in a perpendicular direction to that of
the body of the animal.

These apertures are so many figmata or air-holes, open-
ings designed to admit the air necessary to the life of the
animal. The creature has fix of these figmata, three in
each side of its body.

The great transparency of the body of this insect, gives
us an opportunity also to distinguish that it has on each side
a large white vesel running the whole length of the body.
It is easy to follow the course of these vesels through their
whole length, but they are most distinct of all toward its
hinder part, and they are always seen to terminate each in
the brown spot before described; this leaves us no room to
doubt but that they are the two principal trachebe.

These posterior trachebe have been well known to the la-
ter naturalists; but there are two others besides these which
they seem not to have distingished. These are situated in
the anterior part of the animal, and are easily discovered by
following the course of the trachebe on each side; for though
they are all of the same length, in their diameters as they ap-
proach the head of the animal, yet it may be easily enough
seen where they terminate, which is (taking the head for
one ring) in the junction of the second and third ring.
In this place the naked eye easily discovers a small spot at
the extremity of each, which viewed with a good microscope
appears to be a plain figma, of the figure of a funnel with
half of it cut off, and very elegantly indented, and as it were
fringed at the edges.

These figmata in the anterior part of the body, are as
confant in this creature as the posterior ones, but it seems
to have none of those which the caterpillar clafs are fur-
ished with along their sides; though it seems from the
structure of the fly it afterwards transforms itself into, that
it ought to have them, since that has figmata in their places.

The ramifications of the two great trachebe are very
beautifully seen in this creature, especially on his belly;
and it is remarkable that no vesel analogous to the great
artery in the caterpillar clafs can be discovered in these;
though, if there were any such, their great transparency
would render them very easily distinguishable; nor could
its dilatations and contractions, if so considerable as in
that clafs of animals, be felt so. Malpighi imagined that
artery, in the caterpillar clafs, a series of hearts; in its
place, however, there may be seen in these animals a true
heart. It is easy to observe in these creatures, about the
fourth ring of the body, a small feathery part, which has al-
ternate contractions and dilatations, and is not only discover-
able in the body by means of the creature's transparence;
but, on making a proper section of them in the second,
third, and fourth rings, will be thrown out of the body of
the creature, and will afterwards continue its beats for some
See Lyrva, Papu, &c. under the article Entomology.

MAGHERA, in Geography, a poll-town of the county
of Londonderry, Ireland; 96 miles N. from Dublin.

MAGHERAFELT a poll-town of the county of
Londonderry, Ireland, near Lough Neagh; 83 miles N.
from Dublin.

MAGHEREE, a clatter of islands on the coast of the
county of Kerry, not far from Tralee bay.

MAGI, or MAGIANS, a title which the ancient Persians
gave to their wise men or philosophers.

The learned are in great perplexity about the original of
the word Magus, &c. Plato, Xenophon, Herodotus,
Strabo, &c. derived it from the Persian language, in which
it signified a *priest*, or person appointed to officiate in holy things; as *Druid*, among the Gauls; *Gymnosophi*s, among the Indians; and *Levite*, among the Hebrews. Others derive it from the Greek μουσαγες, *great*; which they say, being borrowed of the Greek Myth, the Persians, was returned in the form of μουσαγος, but Volfius, with more probability, brings it from the Hebrew נָבִיא, *began to meditate*; whence מַגִּים, *magi*, in Latin meditandi, q. d. people addicted to meditation. See the sequel of this article.

Magi, among the Persians, answer to σατράπες or σατράπαι, among the Greeks; *papientes*, among the Latins; *Druid*, among the Gauls; *Gymnosophi*s, among the Indians; and *prophets*, *priests*, among the Egyptians.

The ancient Magi, according to Arificote and Laertius, were the sole authors and conservators of the Persian philosophy; and the sophists principally cultivated among them, was theology and politics; they being always esteemed as the interpreters of all law, both divine and human; on which account they were wonderfully revered by the people. Hence, Cicero observes, that none were admitted to the crown of Peria, but such as were well instructed in the discipline of the Magi; who taught μαθήματι, and swayed princes how to govern.

Plato, Apuleius, Laertius, and others, agree, that the principal of the Magi related principally to the worship of the gods; they were the priests who were to offer prayers, supplications, and sacrifices, as if the gods would be heard by them alone.

They teach their doctrine concerning the nature and origin of the gods, says Laertius, whom they think to be fire, earth, and water; they reject the use of pictures and images, and repudiate the opinion, that the gods are male and female; they discourse to the people concerning justice; they think it impious to confuse dead bodies with fire: they allow of marriage between mother and son; they practice divination and prophecy, pretending that the gods appear to them; they forbid the use of ornaments in drefs; they clothe themselves in a white robe; they make use of the ground as their bed, of herbs, cheese, and bread for food, and of a reed for their staff. Strabo also relates, that there were in Cappadocia a great number of Magi, who were called "Perreth," or worshipers of fire, and many temples of the Persian gods, in the midst of which were altars attended by priests, who daily renewed the sacred fire, accompanying the ceremony with music; with more probability, it is said, than the sacred fire was the emblem of fire. These people were held in such veneration among the Persians, that Darius, the son of Hyllafres, among other things, had it engraven on his monument, that he was the master of the Magi.

Philo Judeus describes the Magi to be diligent inquirers into nature, out of the love they bear to truth; and who, setting themselves apart from other things, contemplate the divine virtues the more clearly, and imitate others in the same mysteries.

The Magi, or Magians, formed one of the two grand sects into which the idolatry of the world was divided between 3 and 600 years before Christ. These abominated all those images which were worshipped by the other sect, denominated Sabians, and paid their worship to the Deity under the emblem of fire. Their chief doctrine was, that there were two principles, one of which was the cause of all good, and the other the cause of all evil. The former was represented by light, and the latter by darkness, as their truet symbols; and of the composition of these two, they suppos'd, that all things in the world were made. The good god they called Yazdan, denominated by the Greek's Oromalades; and the evil god Ahraman, whom the Greeks called Arimanius. (See Arimanius.) Concerning these two gods, there was this difference of opinion among them; that whereas some held both of them to have been from all eternity, there were others who contended, that the good god only was eternal, and that the other was created. But they both agreed in this, that there will be a continual opposition between these two, till the end of the world; when the former shall overcome the latter; and that from thenceforth each of them shall have his world to himself; that is, the good god shall have his world with all good men with him; and the evil god his world, with all evil men with him. The good god they always worshipped before fire, as being the caue of light, and especially before the sun, as being, in their opinion, the most perfect fire, and causing the most perfect light; and for this reason they had in all their temples fire continually burning on altars, erected in them for that purpose. Before these sacred fires they performed all their public acts of devotion, as they likewise practised their private devotions before their own private fires in their own houses. And if we look to the tenets of this sect, when Smerdis, who was the principal leader of it, having usurped the crown after the death of Cambyses, was slain by seven princes of Peria; and many of the Magians, who adhered to him, shared likewise the same fate. In consequence of this event, those who adopted the sentiments of this sect, were called, by way of derision, Magians, from mecys-yleus, which signified, in the language of the country then in use, "one that had his ears cropped." The whole sect of the Magians would soon have sunk into utter extinction, if it had not, in a few years after this period, been revived and reformed by Zoroaster. This celebrated philosopher, called by the Persians Zerdushta, or Zarathush, began about the thirty-sixth year of the reign of Darius to reform and reframe the Magian fyltem of religion. He was not only excellently skilled in all the learning of the East that prevailed in his time; but likewise thoroughly versed in the Jewish religion, and in all the sacred writings of the Old Testament that were then extant, whence some have inferred, that he was a native Jew both by birth and profession; and particularly, as he was wont to speak of the prophets, probably Ezekiel or Daniel. (See Zoroaster.) He made his first appearance in Media, in the city of Xiz, now called Aderbijan, as some say; or according to others, in Ecbatana, now called Tauris. Instead of admitting the existence of two first causes, with the Magians, he introduced a principle superior to them both, one supreme God, who created both thefe, and out of these two produced, according to his sovereign pleasure, everything else. See Isaiah, v. 5, 6, 7.

In order to avoid making God the author of all evil, he taught that God originally created only light or good, and that darkness or evil followed it by consequence, as the shadow doth the perfon. According to his doctrine, there was one supreme being independently, and self-existing from all eternity; under him there were two angels, one the angel of light, the author and director of all good; and the other the angel of darkness, who is the author and director of all evil; these two, out of the mixture of light and darkness, made all things other wise; and they are in a state of perpetual conflict; so that where the angel of light prevails, there the most is good; and where the angel of darkness

MAGI.
darkness prevails, there the most is evil: this struggle shall continue to the end of the world; and then there shall be a general retribution, and a day of judgment; after which, the angel of darkness and his disciples shall go into a world of their own, where they shall suffer in everlasting darkness the punishment of their evil deeds; and the angel of light and his disciples shall go into a world of their own, where they shall receive in everlasting light, the reward due unto their good deeds; and henceforward they shall for ever remain separate. See EMMATION.

Plutarch, speaking of the improvement of the religious system of the Magi by Zoroaster, says, (Lis et Ofris, tom. ii. p. 155) "some maintain, that, neither is the world governed by blind chance without intelligence, nor is there one mind alone at the head of the universe; but, since good and evil are blended, and nature produces nothing unmixed, we are to conceive, not that there is one store-keeper, who, after the manner of an host, dispenses adulterated liquors to his guests; but that there are in nature two opposite powers, countervailing each other's operations, the one accomplishing good designs, the other evil. To the better power Zoroaster gave the name of Arimanus, and affirmed, that, of fabulous objects, the former most resembled light, the latter darkness. He also taught, that Mithras was a divinity, who acted as mediator between them, whence he was called by the Persians the Mediator." After relating several fabulous tales concerning the contrels between the good and evil demons, Plutarch, still reticent the doctrines of Zoroaster, proceeds, "The fated time is approaching, in which Arimanus himself shall be utterly destroyed; in which the surface of the earth shall become a perfect plain, and all men shall speak one language, and live happily together in one society." He adds, on the authority of Theopompus, "It is the opinion of the Magi, that each of these gods shall subside and be subdued by turns for 6000 years, but that, at last, the evil principle shall perish, and men shall live in happiness; neither needing food, nor yielded a shadow; the God who directs these things taking his repose for a time, which, though it may seem long to man, is but short." Diodorus Lycus, after Herodotus, gives it as the doctrine of Zoroaster, that the gods (meaning, doublets, those of whom he last speaks, Ormuzd and Arimanus) were derived beings. Those who remain of this sect in Persia and India, in the present day, retain the same doctrines. Zoroaster also caused fire temples to be erected wherever he came: for having feigned that he was taken up into heaven, and there instructed in the doctrines he taught by God himself, out of the midst of a great and most brilliant flame of fire, he taught his followers, that fire was the true sheehinh of the divine presence; that the sun being the most perfect fire, God had there the throne of his glory, and the residence of his divine presence in a peculiar manner; and next to this in our elementary fire; and, therefore, he ordered them to direct all their worship to God, first towards the sun, which they called Mithra, and next towards their sacred fires; and when they came before these fires to worship, they always approached them on the west side, that having their faces towards them, and also towards the rising sun at the same time, they might direct their worship towards both. And in this posture they always performed every act of their worship. Zoroaster also pretended, that he brought some of the heavenly fire with him on his return, and placed it on the altar of the first fire-temple, which he erected at Xiz, in Media, whence it was propagated to all the rest. And on this account, their priests carefully watch it, and never suffer it to be extinguished.

Zoroaster, having assumed the character of a divine prophet and reformat of religion, retired into a cave, devoting himself to prayer and meditation, where he composed the book called the Zend, in which his pretended revelations were contained. From Media he removed into Bactria; and he went also into India among the Brahmans, and having acquired all their knowledge in mathematics, philosophy, and astronomy, returned and communicated the knowledge he had acquired to his Magians; and thus they became famous for their skill in these sciences; so that a learned man and a Magian were equivalent terms. The vulgar conceived of them as persons actuated and inspired by supernatural powers; and hence thefe, who pretended to wicked and diabolical acts, affixed the name of Magians; and the term magician acquired its evil meaning. Moreover, this distinguished knowledge was confined to those, who were by way of eminence, the Magi, or the priests; who, like thole of the Jews, being of the same tribe, appropriated their learning to their own families. These priests were distributed into three orders, viz. the inferior priests, who conducted the ordinary ceremonies of religion: the superintendents, who governed them, and presided over the sacred fire; and the archimamus, or high-priest, who possessed supreme authority over the whole order; and their churches or temples were also of three farts, parochial or oratories, in which the people performed their devotions, and where the sacred fire was kept only in lamps; fire-temples, in which fire was kept contually burning on a sacred altar, where the higher order of the Magi directed the public devotions, and the people assembles to perform magical incantations, hear interpretations of dreams, and practice other superfluities; and lastly, the fire-temple in which the archimamus reigned, which was visited by the people at certain feasts with peculiar solemnity, and to which it was deemed an indefensible duty for every one to repair, at least once in his life. Zoroaster at length carried his religious system to the royal court of Sufa, and made Darius a procluye, together with most of the great men of the kingdom. Darius was so attached to the Magian system, that he became an archimamus, and ordered, that, among other titles, it should be engraven on his monuments; that he was master of the Magians. Hence the kings of Persia were considered as pertaining to the sacred tribe, and were always initiated in the sacred order of the Magians, before they took on them the crown, or were inaugurated into the kingdom.

No images or statues were permitted in the Persians worship. Hence, when Xerxes found idols in the Grecian temples, he, by the advice of the Magi, let them on fire, saying, that the gods, to whom all things are open, are not to be concealed within the walls of a temple.

Zoroaster, after this facet, returned to Bacth, in Bacthria, where, according to his own intimation, he was obliged to reside, as archimamus or head of the sect, and there he reigned in spirituals, with the same authority, over the whole empire, as the king did in temporal; and from hence probably arose the mistake of making him king of Bacthria. The principal temple erected at Bacth by Zoroaster remained till the 7th century, when his followers being driven by the Mahometans into Carmania, another building of the same kind was raised, to which those who adhered to the ancient Persia religion repaired. Zoroaster, at length, fell a sacrifice to his zeal; for having concerted an enterprize against Aragia, king

placed, as that the object is very near its focus, the image will be exhibited on the wall, exceedingly magnified.

**Magic Lantern, Theory of.** The lamp being placed in the focus of the concave speculum, or any convex glass, the rays will be propagated parallel to each other, and the image will be strongly illuminated, and will therefore emit a great number of rays upon the lens. But, being supposed to be placed near the lens, the inverted image of the picture inverted must be formed on the opposite wall, exceedingly magnified, after its refraction through the lens; and it will be still more magnified, as the lens is a segment of a lens sphere, and as the picture is placed nearer the focus of the lens; in a dark place, therefore, the picture will be represented prodigiously large and extremely vivid.

To heighten the light, specula are preferred to lenses; the focus of a speculum being nearer than that of a lens. De Chales orders the diameter of the lens, $I$, to be two, four, or five digits, and in a subduplicate proportion to the other $K$, i.e., if $I$ be five digits, $K$ must be ten; and the diameter of the speculum, according to the same, is to be two digits. Zahnius chooses to have the diameter of $I$ to be of a foot; and that of $K$ one foot and a half, &c.

Little animals being included in the magic lantern, in the manner observed in speaking of the microscope, or any little transparent objects fastened to a slice of tale or glass, and sublimated instead of images, the magic lantern will become a microscope.

A view of the instrument itself may be seen in fig. 2, in which $b$ is the lens that throws the light of the candle or lamp, $a$, on the object $d$, and $k$ is the lens that magnifies the image, $f$, on the white wall, $F H$, in a dark room. It is plain, that if the tube, $b k k l$, be contracted, and the glass, $k l$, be brought nearer the object $d$, the image, $f$, will be enlarged; and hence, this lantern has been called the *lanterna magnalographica*. On the contrary, if the tube be protracted, the image of the object will be diminished. In some magic lanterns, instead of the single lens $k l$, two lenses are used of lens curvature, and at a little distance from each other; and these produce a somewhat better effect than a single lens. Between them is placed a perforated diaphragm.

M. Euler proposed a scheme to introduce vision by reflected light into the magic lantern, as well as the solar microscope, by which many inconveniences to which these instruments are subject, might be avoided. For this purpose, he says, nothing is necessary but a large concave mirror, perforated as for a telescope, and that the light be so situated, that none of it may pass directly through the perforation, so as to fall on the images of the objects upon the screen. He proposes to have four different machines for objects of different sizes; the first for those of six feet long, the second for those of one foot, the third for those of two inches, and the fourth for those of two lines. An idea of this construction is given in fig. 3, in which $O D$ represents the concave mirror, $E$ the object, $l$, the lights, and $A$ the lens, through which the rays are transmitted to the screen. Nov. Com. Petrop. vol. iv. p. 3/5.

**Magic Square.** A square figure, formed of a series of numbers, in mathematical proportion, so dispersed in parallel and equal ranks, as that the sums of each row, taken either perpendicularly, horizontally, or diagonally, are equal.

The several numbers which compose any square number (for instance, 1, 2, 3, 4, 5, &c. to 25 inclusive, which compose the square number 25), being disposed after each other, in a square figure of 25 cells, each in its cell; if then you change the order of these numbers, and diffuse them in the cells in such a manner, as that the five numbers which fill an horizontal rank of cells, being added together, shall make the same sum with the five numbers in any other rank of cells, whether horizontal or vertical, and even the same number with the five in each of the two diagonal ranks; this disposition of numbers is called a *magic square*; in opposition to the former disposition, which is called a *natural square*. See the figure following.

One would imagine, that these magic squares had that name given them, because this property of all their ranks, which, taken any way, make always the same sum, appeared extremely surprising, especially in certain ignorant ages, when mathematicians puffed for magic; but there is a great deal of reason to suppose, that these squares merited their name still farther, by the supersitious operations they were employed in, as the contruction of talismans, &c., for, according to the childish philosophy of those days, which attributed virtues to numbers, what virtues might not be expected from numbers so wonderful?

However, what was at first the vain practice of makers of talismans and conjurers, has since become the subject of serious research among mathematicians; not that they imagine it will lead them to any thing of solid life or advantage. Magic squares favour too much of their original to be of much use; but only as it is a kind of play, where the difficulty makes the merit, and it may chance to produce some new views of numbers, which mathematicians will not lose the occasion of.

Fman. Moschopulas, a Greek author of no great antiquity, is the first that appears to have spoken of magic squares; and, by the age in which he lived, there is reason to imagine he did not look on them merely as a mathematician. However, he has left us some rules for their construction. In the treatise of Corn. Agrippa, so much accused of magic, we find the squares of even numbers, viz., from three to nine inclusive, disposed magically; and it must not be supposed that these even numbers were preferred to all the other without some very good reason: in effect, it is because their squares, according to the fifteenth of Agrippa and his following, are planetary. The square of 3, for instance, belongs to Saturn; that of 4, to Jupiter; that of 5, to Mars; that of 6, to the Sun; that of 7, to Venus; that of 8, to Mercury, and that of 9, to the Moon. M. Bachet applied himself to the study of magic squares, on the hint he had taken from the planetary squares of Agrippa, as being acquainted with the work of Moschopulas, which is only in manuscript in the French king's library; and, without the assistance of any author, he found out a new method for those squares whose root is uneven; for instance, 25, 49, &c., but he could not make any thing of those whose root is even.

After him came M. Frenicle, who took the same subject in hand. A certain great algebraist was of opinion, that whereas the sixteen numbers which compose the square might
be disposed 2022789888000 different ways in a natural square (as from the rules of combination it is certain they may), they could not be disposed in a magic square above sixteen different ways: but M. Frenicle showed, that they might be thus disposed 878 different ways: whence it appears how much his method exceeds the former, which only yielded the 55th part of magic squares of that of M. Frenicle.

To this inquiry he thought fit to add a difficulty, that had not yet been considered; the magic square of 7, for infancy, being confirned, and its 49 cells filled, if the two horizontal ranks of cells, and, at the fame time, the two vertical ones, the most remote from the middle, be renchred, that is, if the whole border or circumference of the square be taken away, there will remain a square, whose root will be 5, and which will only confit of 25 cells. Now, it is not at all surprizing, that the square should be no longer magical, because the ranks of the large ones were not intended to make the fame sum, excepting when taken with all the seven numbers that fill their seven cells: fo that being mutilated each of two cells, and having lost two of their numbers, it may be well expected, that their remainders will not any longer make the same sum. But M. Frenicle would not be satisfied unless when the circumference or border of the magic square was taken away, and even any circumference at pleasure, or, in fine, several circumstances at once, the remaining squares were full magical: which last condition, no doubt, made these squares vastly more magical than ever.

Again, he inverted that condition, and required that any circumference taken at pleasure, or even several circumstances, should be inseparable from the square; that is, that it should cease to be magical when they were removed, and yet continue magical after the removal of any of the rest. M. Frenicle, however, gives no general demonstration of his methods, and frequently seems to have no other guide but chance. It is true, his book was not published by himself, he did not write it till his death, e£. in 1693.

In 1723, M. Poignard, canon of Bruffel, published a treatise of sublime magic squares. Before him there had been no magic squares made but for serires of natural numbers that formed a square; but M. Poignard made two very considerable improvements. 1°. Instead of taking all the numbers that fill a square, for infancy, the thirty-six successive numbers, which would fill all the cells of a natural square, whose side is fix, he only takes as many successive numbers as there are units in the side of the square, which, in this case, are fix; and these fix numbers alone he disposes in such manner in the thirty-six cells, that none of them are repeated twice in the same rank, whether it be horizontal, vertical, or diagonal: whence it follows, that all the ranks, taken all the ways possible, must always make the same sum, which M. Poignard calls repeated progression. 2°. Instead of being confined to take these numbers according to the series and succession of the natural numbers, that is, in an arithmetical progression, he takes them likewise in a geometrical progression, and even in an harmonical progression. But with these two last progressions the magic must necessarily be different to what it was in the figures filled with numbers in geometrical progression, it confits in this, that the products of all the ranks are equal: and, in the harmonical progression, the numbers of all the ranks continually follow that progression: he makes squares of each of these three progressions repeated.

This book of M. Poignard gave occasion to Mr. de la Hire to turn his thoughts the same way, which he did with such success, that he seems to have well-nigh completed the theory of magic squares. He first considers uneven squares; all his predecessors on the subject having found the construction of even ones by much the most difficult; for which reason M. de la Hire refers those for the last. This excess of difficulty may arise partly from hence, that the numbers are taken in arithmetical progression. Now in that progression, if the number of terms be uneven, that in the middle has some properties which may be of service; for infancy, being multiplied by the number of terms in the progression, the product is equal to the sum of all the terms.

M. de la Hire proposes a general method for uneven squares, which has some resemblance with the theory of compound motions, so useful and fertile in mechanics. As he is at liberty to dispose, and resolving them into others more simple; so does M. de la Hire's method consist in resolving the square that is to be constructed into two simple and primitive figures. It must be owned, however, it is not quite so easy to conceive those two simple and primitive squares in the compound or perfect square, as in an oblique motion to imagine a parallel and perpendicular one.

Suppose a square of cells, whose root is uneven, for infancy 7; and that its forty-nine cells are to be filled magically with numbers; for infancy, the first 7. M. de la Hire, on the one side, takes the first seven numbers, beginning with unity, and ending with the root 7; and on the other 7, and all its multiples to 40, exclusively: and as these only make fix numbers, he adds 0, which makes this an arithmetical progression of seven terms, as well as the other; 0, 7, 14, 21, 28, 35, 42. This done, with the first progression repeated, he fills the square of the root 7 magically; in order to this, he writes in the first seven cells of the first horizontal rank, the seven numbers proposed, in whatever order he pleases, for that is absolutely indifferent; and it is proper to observe here, that those seven numbers may be ranged in 5040 different manners in the same rank. The order in which they are placed in the first horizontal rank, be it what it will, is that which determines their order in all the rest. For the second horizontal rank, he places in its first cell, either the third, the fourth, the fifth, or the sixth number, from the first number of the first rank; and after that he writes the fix others in order as they follow. For the third horizontal rank, he observes the same method with regard to the second, that he observed in the second with regard to the first, and so of the rest. For infancy, suppose the first horizontal rank filled with the seven numbers in their natural order, 1, 2, 3, 4, 5, 6, 7; the second horizontal rank may either commence with 3, with 4, with 5, or with 6; with 3; the third rank therefore must commence with 5, the fourth with 7, the fifth with 2, the sixth with 4, and the seventh with 6. The commencement of the ranks which follow the first being thus determined, the other numbers, as we have already observed, must be written down in the order wherein they stand in the first, going on to 5, 6, and 7, and returning to 1, 2, &c. till every
every number in the first rank be found in every rank underneath, according to the order arbitrarily pitched upon at first. By this means it is evident, that no number whatever can be repeated twice in the same rank; and by consequence, that the seven numbers 1, 2, 3, 4, 5, 6, 7, being in each rank, must of necessity make the same sum.

It appears, from this example, that the arrangement of the numbers in the first rank being chosen at pleasure, the other ranks may be continued in four different manners: and since the first rank may have 5040 different arrangements, there are no less than 20,160 different manners of constructing the magic square of seven numbers repeated.

The order of the numbers in the first rank being determined; if in beginning with the second rank, the second number 2, or the last number 7, should be pitched upon, in one of those cases and repeated; and in the other case, the other diagonal would be false, unless the number repeated seven times should happen to be 4; for four times seven is equal to the sum of 1, 2, 3, 4, 5, 6, 7; and, in general, in every square consisting of an unequal number of terms, in arithmetical progression, one of the diagonals would be false according to those two contractions, unless the term always repeated in that diagonal were the middle term of the progression. It is not, however, at all necessary to take the terms in an arithmetical progression; for, according to this method, one may construct a magic square of any numbers at pleasure, whether they be according to any certain progression, or not. If they be in an arithmetical progression, it will be proper, out of the general method, to except those two contractions, which produce a continual repetition of the same term, in one of the two diagonals; and only to take in the case, wherein that repetition would prevent the diagonal from being just: which case being absolutely disre-
MAGIC SQUARE.

are 0, 7, 14, 21, 28, 35, 42. M. de la Hire proceeds in the same manner as in the former; and this may likewise be constituted in 20,160 different manners, as containing the same number of terms with the first. Its construction being made, and of consequence all its ranks making the same sum, it is evident, that if we bring the two into one, by adding together the numbers of the two corresponding cells of the two squares, that is, the two numbers of the first of each, the two numbers of the second, of the third, &c. and dispose them in the forty-nine corresponding cells of a third square; it will likewise be magical, in regard to its rank, formed by the addition of equal sums to equal sums, which must of necessity be equal among themselves. All that remains in doubt is, whether or not, by the addition of the corresponding cells of the two first squares, all the cells of the third will be filled in such manner, as that each not only contains one of the numbers of the progression from 1 to 49, but also that this number be different from any of the rest, which is the end and design of the whole operation.

As to this it must be observed, that if in the construction of the second primitive square, care has been taken in the commencement of the second horizontal rank, to observe an order with regard to the first, different from what was observed in the construction of the first square; for instance, if the second rank of the first square began with the third term of the first rank, and the second rank of the second square commence with the fourth of the first rank, as in the example it actually does; each number of the first square may be combined once, and only once, by addition with all the numbers of the second. And as the numbers of the first are here 1, 2, 3, 4, 5, 6, 7, and those of the second 0, 7, 14, 21, 28, 35, 42, by combining them in this manner, we have all the numbers in the progression from 1 to 49, without having any of them repeated; which is the perfect magic square proposed.

The necessity of constructing the two primitive squares in a different manner, does not at all hinder but that each of the 20,160 constructions of the one may be combined with all the 20,160 constructions of the other; of consequence, therefore, 20,160 multiplied by itself, which makes 404,256,000 is the number of different constructions that may be made of the perfect square, which here consists of the 49 numbers of the natural progression. But as we have already observed, that a primitive square of seven numbers repeated may have above 20,160 different conjunctions, the number 404,256,000 must come vastly short of expressing all the possible constructions of a perfect magic square of the 49 first numbers.

As to the even squares, he constructs them like the uneven ones, by two primitive squares; but the construction of primitive is different in general, and may be for a great number of ways, and those general differences admit of a great number of particular variations, which give as many different constructions of the same even square. It feebly seems possible to determine exactly, either how many general differences there may be between the construction of the primitive squares of an even square, and an uneven one; nor how many particular variations each general difference may admit of; and, of consequence, we are still far from being able to determine the number of different constructions of all those that may be made by the primitive squares.

See the Memoirs of the Royal Academy of Sciences, for 1705 and 1710, where this subject is almost exhausted by M. de la Hire and M. Sauveur. See also Saunderson's Algebra, vol. i. p. 354; &c.

The ingenious Dr. Franklin seems to have carried this curious speculation farther than any of his predecessors in the same way. He has constructed not only a magic square of squares, but likewise a magic circle of squares, of which we shall give some account for the amusement of our readers. The magic square of squares is formed by dividing the great square, as Plate XI. Analysis, fig. 6. The great square is divided into 256 small squares, in which all the numbers from 1 to 256 are placed in 16 columns, which may be taken either horizontally or vertically. The properties are as follow:

1. The sum of the sixteen numbers in each column, vertical and horizontal, is 2056.
2. Every half column, vertical and horizontal, makes 1028, or half of 2056.
3. Half a diagonal ascending, added to half a diagonal descending, makes 2056; taking these half diagonals from the ends of any side of the square to the middle thereof; and so reckoning them either upward, or downward; or sidewise from left to right hand, or from right to left.
4. The same with all the parallels to the half diagonals, as many as can be drawn in the great square; for any two of them being directed upward and downward, from the place where they begin to that where they end, their sums will make 2056. The same downward and upward in like manner; or all the same if taken sidewise to the middle, and back to the same side again. N. B. One set of these half diagonals and their parallels are drawn in the same square upward and downward. Another such set may be drawn from any of the other three sides.
5. The four corner numbers in the great square added to the four central numbers therein, make 1028; equal to the half sum of any vertical or horizontal column, which contains 16 numbers; and equal to half a diagonal or its parallel.
6. If a square hole (equal in breadth to four of the little squares) be cut in a paper, through which any of the fifteen little squares in the great square may be seen, and the paper be laid on the great square; the sum of all the sixteen numbers, seen through the hole, is equal to the sum of the sixteen numbers in any horizontal or vertical column, viz. to 2056. The magic circle of circles (fig. 7.), is composed of a series of numbers, from 12 to 75 inclusive, divided into eight concentric circular spaces, and ranged in eight radii of numbers, with the number 12 in the centre; which number, like
like the centre, is common to all these circular spaces, and
to all the radii.
The numbers are so placed, that the sum of all those in
either of the concentric circular spaces above mentioned, to-
gether with the central number 12, make 360; equal to the
number of degrees in a circle.
The numbers in each radius also, together with the central
number 12, make just 360.
The numbers in half of any of the above circular spaces,
taken either above or below the double or horizontal line,
with half the central number 12, make 180; equal to the
number of degrees in a semicircle.
If any four adjoining numbers be taken, as if in a figure,
in the radial divisions of these circular spaces; the sum of
these, with half the central number, make 180.
There are, moreover, included four sets of other circular
spaces, bounded by circles which are excentric with respect
to the common centre; each of these sets containing five
spaces. The centres of the circles which bound them are:
A, B, C, and D. The set, whose centre is at A, is bounded
by dotted lines; the set whose centre is at C is bounded
by lines of short unconnected strokes, and the set round
D is bounded by lines of unconnected longer strokes,
to distinguish them from one another. In drawing this
figure by hand, the set of concentric circles should be drawn
with black ink; and the four different sets of excentric
circles with four kinds of ink of different colours; as blue,
red, yellow, and green, for distinguishing them readily from
one another.
These sets of excentric circular spaces intersect those of
the concentric, and each other; and yet, the numbers
contained in each of the excentric spaces, taken all around
through any of the 20, which are excentric, make the same
fam, as those of the concentric; namely, 360, when the central
number 12 is added. Their halves also, taken above or below
the double or horizontal line, with half the central number,
make 180.
Observe, that there is not one of the numbers but what
belongs at least to two of the circular spaces; some to
two, some to four, some to five: and yet they are all
so placed as never to break the required number 360, in
any of the twenty-eight circular spaces within the primitive
circle.
To bring these matters in view, all the numbers as above-
mentioned are taken out, and placed in separate columns, as
they stand around both the concentric and excentric
circular spaces, always beginning with the outermost and
ending with the innermost of each set; and also the numbers
as they stand in the eight radii, from the circumference
to the centre; the common central number 12 being placed
the lowest in each column.

1. In the eight concentric circular space.

If now we take any four numbers as in a square form, either from No. 1. No. 2. (as suppose from No. 1.) as in the margin; and add half the central number
MAG

number 12 to them, the sum will be 180; equal to half the numbers in any circular space, taken above or below the double horizontal line; and equal to the number of degrees in a semicircle. Thus, 14, 72, 25, 63, and 6, make 180. See Franklin's Exp. and Obf. p. 350, &c. edit. 4to. 1769; or Ferguson's Tables and Tracts, 1771, p. 318, &c.

Magical Picture, in Electricity, was first contrived by Mr. Kinnersley, and is thus made: having a large mezzotinto with a frame and glafs, e. g. of the king, take out the print, and cut a pannel out of it, near two inches diamant from the frame around; with thin paste or gum-water, fix the border that is cut off on the inside of the glafs, pressing it smooth and close; then fill up the vacancy by gilding the glafs well with leaf-gold, or brafs. Gild likewise the inner edge of the back of the frame all round, except the top part, and form a communication between that gilding and the gilding behind the glafs; then put in the board, and that side is finished. Turn up the glafs, and gild the forehead exactly over the back gilding, and when it is dry, cover it, by pasting on the pannel of the picture that hath been cut out, observing to bring the correspondent parts of the border and picture together, by which means the picture will appear of a piece, as at first, only part behind the glafs and part before. Hold the picture horizontally by the top, and place a little moveable gilt crown on the king's head. If the picture be moderately electrified, and another person takes hold of the frame with one hand, so that his fingers touch its inside gilding, and with the other hand endeavour to take off the crown, he will receive a terrible blow, and fail in the attempt. If the picture were highly charged, the conflagration might be as fatal as that of high treason. The operator, who holds the picture by the upper end, where the inside of the frame is not gilt, to prevent its falling, feels nothing of the shock, and may touch the face of the picture without danger. If a ring of persons take the shock among them, the experiment is called the conspirators. Franklin's Exp. and Obf. p. 30.

MAGICIAN, one who practises the art of magic. See Divination, Magic, and Sorcery.

The ancient magicians pretended to extraordinary powers of interpreting dreams, foretelling future events, and accomplishing many wonderful things, by their superior knowledge of the secret powers of nature, of the virtues of plants and minerals, and of the motions and influences of the stars. And as the art of magic among the Pagan nations was founded in their fyllen of theology, and the Magi who first exercised it were the priests of the gods, they pretended to derive these extraordinary powers from the affinities of the gods; which affinities they fought by a great variety of rites and ceremonies, adapted to their respective natures, by the use of charms and superstitious words, and also by ceremonies and incantations: they pretended likewise, in the proper use of their art, to a power of compelling the gods to execute their desires, and commands. An excellent writer has shewn, that the scripture brands all these powers as a shameful imposture, and reproaches those who affirmed them with an utter inability of discovering or accomplishing any thing supernatural. (See Isaiah, xlvii. 11, 12, 13. chap. xvii. 9, 10. chap. xxiv. 25. Jer. x. 2. 6. 8. 14. chap. xiv. 14. chap. xxvii. 9, 10. chap. lx. 5. 6. chap. iii. 6. 7. 8. 9. 10. and chap. i. 36. P. xii. 6. 7. 8.) Nevertheless, many of the Christian fathers, as well as some of the heathen philosophers, ascribed the efficacy of magic to evil demons; and it was a very prevailing opinion in the primitive church, that magicians and necromancers, both among the Gentiles and heretical Christians, had each their particular demons perpetually attending on their persons, and obsequious to their commands, by whose help they could call up the souls of the dead, foretell future events, and perform miracles. In support of this opinion, it has been alleged, that the names by which the several forts of diviners are denominated in scripture, imply a communication with spiritual beings; that the laws of Moses (Exod. xxviii. 18. Lev. xix. 24, 31. chap. xx. 27. Deut. xvi. 7, 11.) against divination and witchcraft, prove the efficacy of these arts, though in reality they prove nothing more than their execrable wickedness and impiety; and that pretensions to divination could not have supported their credit in all the heathen nations and through all ages, if some instances of true divination had not occurred. But the strongest argument, deriving from the scripture history of the Egyptian magicians who opposed Moses. With regard to the works performed by thee magicians, some have supposed that God himself empowered them to perform true miracles, and gave them an unexpected success; but the history expressly attributes the effects they produced, not to God, but to their own enchantments. Others imagine, that the devil afflicted the magicians not in performing true miracles, but in deceiving the fenses of the fpectators, or in presenting to them delusive appearances of true miracles: against which opinion it has been urged, that it tends to disparage the credit of the works of Moses. The most common opinion is, that the time of St. Austin, has been, that they were not only performed by the power of the devil, but were genuine miracles, and real imitations of those of Moses. In a late elaborate inquiry into the true fene and design of this part of scripture history, it has been shewn, that the names given to the magicians seem to express their profession, their affections of superior knowledge, and their pretences both to explain and effect signs and wonders, by observing the rules of their art; and therefore, that they are the perfons, whose ability of discovering or effecting any thing supernatural the scripture expressly denies. The learned author farther investigates the design, for which Pharaoh employed them on this occasion: which, he apprehends, was to learn from them, whether the sign given by Moses was truly supernatural, or only such as their art was able to accomplish. Accordingly it is observed, that they did not undertake to outdo Moses, or to control him, by superior or opposite arts of power, but merely to imitate him, or to do the same works with his, with a view of invalidating the argument which he drew from his miracles, in support of the sole divinity of Jehovah, and of his own mission. The question on this occasion was not, are the gods of Egypt superior to the God of Israel, or can any evil spirits perform greater miracles than those which Moses performed by the affinities of Jehovah? but the question was, are the works of Moses proper proofs, that the God of Israel is Jehovah, the only sovereign of nature, and consequently that Moses acts by his commission; or, are they merely the wonders of nature, and the effects of magic? In this light Philo (de Vita Mofis, lib. i. p. 616.) and Josephus, (Antiq. Jud. lib. ii. cap. 13.) place the subjed. Moreover, it appears from the principles and conduct of Moses, that he could not allow the magicians to have performed real miracles: because the scripture represents the whole body of magicians as impostors; the sacred writers, Moses in particular, declare all the heathen deities, in the belief of whose existence and influence the magic art was founded, as unsupported by any invisible spirits, and utterly impotent and senseless: the religion of Moses was built on the unity and sole dominion of God, and the sole divinity of Jehovah was the point which Moses was now about to establish, in direct opposition to the
the principles of idolatry; so that if he had allowed that the heathen idols, or any evil spirits supporting their cause, enabled the magicians to turn rods into serpents, and water into blood, and to create frogs, he would have contradicted the great design of his mission, and overturned the whole fabric of his religion; besides, Moses appropriates all miracles to God, and urges his own, both in general and separately, as an absolute and authentic proof, both of the sole divinity of Jehovah, and of his own mission; which he could not justly have done, if his opposers performed miracles, and even the fame with his. On the other hand, it has been urged, that Moses describes the works of the magicians in the very same language as he does his own, (Exod. vii. 11, 12. chap. v. 22. chap. viii. 7.) and hence it is concluded, that they were equally miraculous. To this objection it is replied, that it is common to speak of professed jugglers, as doing what they pretend and appear to do; but that Moses does not affirm, that there was a perfect conformity between his works and those of the magicians, but they did so, or in like manner, using a word which expresses merely a general similitude; and he expressly refers all they did, or attempted in imitation of himself, not to the invocation or power of demons, or of any superior beings, but to human artifice and impotence. The original words, translated *incantaments,* (Exod. vii. 11, 22. and chap. viii. 7, 18.) import deception and concealment, and ought to have been rendered, *secreto factis* or *juggling.*

Our learned writer farther shews, that the works performed by the magicians did not exceed the cause, or human artifice, to which they are ascribed. Farmer's *Diff. on Miracles,* 1774. chap. 3. § 3. chap. 4. § 1.

MAGIEROW, in *Geography,* a town of Poland, in the palatinate of Belz; 22 miles S.S.W. of Belz.

MAGILICUDDY'S Reeks, high mountains in the county of Kerry, Ireland, lying near Killarney. They are supposed to be higher than Mangerton, which is 2500 feet above the level of the sea.

MAGILLIGAN Point, a cape of Ireland, in the county of Londonderry, at the entrance of Lough Foyle. N. lat. 55° 12'. W. long. 6° 50'.

MAGINI, John Anthony, in *Biography,* an Italian mathematician and astronomer, was born at Padua in the year 1550. He acquired an early reputation for acquaintance with the sciences, and was appointed professor of mathematics in the university of Bologna. He was decidedly in favour of the Copernican system, but had not courage openly to avow his opinions; and to prevent any doubts that might occur, and to avoid the penalties of heresy, he taught the doctrine of Ptolemy. He was a practical philopshor, and made the instruments which he used with his own hands, among these were large concave mirrors, full five feet in diameter. He died in 1617, in the sixty-third year of his age, leaving behind him many works that reflect much credit on his memory; among these the most important were his "Ephemerides," in three volumes, from 1580 to 1630: "Theoria Planetarum juxta Copernicam Observationes;" "Problemata Astronomica, Geonomica, et Geographica;" "Italica Descriptio Chorographica," illustrated with sixty maps. Bayle.

MAGISI, in *Geography,* a town of Brazil, in the government of St. Paul; 36 miles N.E. of St. Paul.

MAGISTER, Master, a title frequently found in old writings; noting the person who bore it to have attained some degree of eminence in *scientia abaca, prefectui in litteraria.*

In old times, those we now call doctors, were called magistri, or masters.

MAGISTERY, in *Chemistry,* a term formerly used to signify a precipitate. Since the new nomenclature of chemistry has been introduced, it has become obsolete.

MAGISTERY of *Bipineth.* See BESMITH.

MAGISTERY of *Land.* See *LED.

MAGISTERY of *Subterr. See *SUBTERRI.

MAGISTRATE, is the name of any public officer, or ruler, to whom the *executive power* of the law is committed, either wholly or in part. Of magistrates some are supreme, in whom the sovereign power of the state reposes; others are subordinate, deriving all their authority from the supreme magistrates, accountable to him for their conduct, and acting in an inferior secondary sphere. In all tyrannical governments, the supreme magistracy, or the right both of making and of enforcing the laws, is vested in one and the same man, or one and the same body of men; and whenever these two powers are united together, there can be no public liberty. The magistrate, may enact tyrannical laws, and execute them in a tyrannical manner, since he is puffed, in quality of dispenser of justice, with all the power which he, as legislator, thinks proper to give himself. But when the legislative and executive authority are in distinct hands, the former will take care not to entrust the latter with so large a power as may tend to the subversion of its own independence, and therewith of the liberty of the subject.

With us in England, therefore, the supreme power is divided into two branches; the one legislative, viz. the parliament, consisting of king, lords, and commons; the other executive, consisting of the king alone. See *King, Parliament, Sheriff, Justice.*

MAGIUS, *Al., in Geography,* a town of Peræa, in the province of Paphlagonia; 45 miles S.W. of Yezd.

MAGLASEAN, a town of Peræa, in the province of Adiabætum; 66 miles W. of Tamin.

MAGLEBIE, a town of Denmark, in the island of Zealand; four miles S. of Copenhagen.

MAGLIA, a town of the island of Candia; 16 miles E.S.E. of Candia.

MAGLIABECCHI, Anthony, in *Biography,* a person remarkable for his knowledge of books, was born at Florence in 1532. Having attained the elements of the Latin language, he was apprenticed to the binfrets of a goldsmith and jeweller, but his passion for reading induced him to employ every leisure moment in improving his mind, and in laying in large stores of useful knowledge; and at the death of his parents in 1573, he entirely abandoned trade, and devoted himself wholly to the pursuits of literature. By means of an attaining memory, and almost incessant application, he became more conversant with literary history than any man of his time, and was appointed librarian to the grand duke of Tuscany. He kept up a correspondence with the most learned men in Europe, from many of whom, even in the very highest ranks of life, he received tokens of respect and esteem. Lewis XIV. always commended the French literati who visited Italy to salute Magliabecchi in his name. To those who visited him through motives of mere curiosity, he was distant and reserved; but to the truly learned, no man was more communicative of his knowledge, and many of the most eminent scholars of the time have expressed their obligations to him. He could most readily direct an author to all the works which treated upon the subject on which he was writing. So exact and accurate was he in this respect, that he has been called a living library. He was taken seriously ill in 1708, and upon his recovery Ferdinand wished him to lodge in the palace, and prepared for him a commodious apartment, and a large room for his books. Here he resided a few months, and then returned to his own cottage, where he died, at the age...
also contain very considerable mitigations of those feudal rights claimed by the king over his tenants, and by them over their’s, which either were the most burthensome in their own nature, or had been made so by an abusive extension. In short, all the liberty, that could well be consistent with the safety and interest of the lord in his fief, was allowed to the vassal by this charter, and the profits due to the former were settled according to a determined and moderate rule of law. According to the words of one of our greatest antiquaries, Sir Henry Spelman, "it was the original of king John’s Magna Charta, containing most of the articles of which, though particularly expressed, or in general, under the confirmation it gives to the word of Edward the Confessor."

So mistaken are they, says lord Lyttleton, who have supposed that all the privileges granted in Magna Charta were "innovations" extorted by the arms of rebels from king John—"a notion which seems to have been first taken up, not so much out of ignorance, as from a base motive of adulation to some of our princes in later times, who, endeavouring to grasp at absolute power, were defirous of any pretence to consider those laws, which flowed in their way, as violent encroachments made by the barons on the ancient right of the crown; whereas they were in reality restitutions and functions of ancient rights, enjoyed by the nobility and people of England in former reigns; or limitations of powers which the king had illegally and arbitrarily stretched beyond their due bounds. In some respects, says our author, this charter of Henry I. was more advantageous to liberty than Magna Charta itself. (See Henry I.) In confirmation of Sir Henry Spelman’s opinion above-mentioned, we may allege the testimony of an ancient historian. Matthew Paris tells us, that, in the year 1215, the barons came in arms to king John at London, and demanded of him that certain liberties and laws of king Edward, with other liberties granted to them, and to the kingdom and church of England, should be confirmed, "as they were contained and set down in the charter of king Henry I. and in the laws above-mentioned." And the same historian, where he mentions the "capitula," or rough draught of the great charter, delivered to John by the barons, says, that the articles thereof "were partly written before, in the charter of king Henry I. and partly taken out of the ancient laws of king Edward." These passages, and also what he says before, of the barons having sworn at St. Edmund’s Bury, to make war on the king, till he should conform to them, by a charter under his seal, the laws and liberties granted in the charter of Henry I. sufficiently threw, that they understood and intended this charter to be the original and foundation of that which they demanded and obtained from John. With regard to another passage that occurs in Matthew Paris, relating to the charter of Henry I. and connected with his account of a convention or synod held in London under Stephen Langton, archbishop of Canterbury, in the year 1215, it imports that the charter of Henry was then a "novelty" to the barons, and that they expressed a surprize of joy at hearing a copy of it read, which the archbishop told them was "just found." But from the same historian we learn that, after the charter was given, the king ordered as many transcripts of it to be made as there were counties in England, and to be laid up, as records, in the abbeys of every county. Besides, the first charter of Stephen "confirms the liberties and good laws, which his uncle king Henry gave and granted, and all good laws and good customs, which the nation had enjoyed in the time of Edward the Confessor," words which evidently refer to the charter. It was also confirmed more expressly by king Henry II. "How is it possible then," says lord
MAG

Lyttelton, "that in the reign of his fon it should be so difficult to produce a single transcript of it, and that even the remembrance of what it contained should be so totally lost among the principal nobles? The strong objections to so strange a story did not obscure the penetration of the learned and judicious Dr. Blackstone. In his accurate edition of the charters, he takes notice of the great improbability of it; and further observes, that it is mentioned by no other contemporary historian; but that, on the contrary, all of them affign quite different reasons for the confedercy of the barons."

Our noble author adds, "that the credit of this story is still more weakened, by its being only delivered upon common fame (ut fuma referre), though it is said to have paid in secret."—How can one suppose that the particular words of a speech made in secret, could be accurately reported by common fame?—"That the archbishop should produce to the barons a transcript of the charter, as a proper foundation for their confedercy, and for the demands, or claim of rights, they were to make to the king, I think (says lord Lyttelton) is very probable. But that there could be any difficulty in finding such a transcript, or that it should be regarded by them as a novelty, appears to me quite incredible."

"How far Matthew Paris, or rather Roger de Wendover, (from whom the former has transcribed this part of his history), is from being exact in his account of these affairs, we need no better evidence, than the copy he gives us of the charter of king John, which is essentially different from the originals in the British Museum and at Salisbury, and from the entry in the Red Book of the Exchequer. No hypothesis, therefore, can reasonably be built on this passage in that writer; though some have been induced to infer from it, that the charter of Henry I. became obsolete almost as soon as it was given, and was so totally neglected, as to be in a manner forgotten."—But to return from this digression, the successors of Henry I. king Stephen, king Henry II. and king John, confirmed or re-enacted the same; but the last prince violating his charter, the barons took up arms, and his reign ended in blood. Henry III. who succeeded him, after having procured an inquisition to be made by twelve men in each county, what the liberties of England were in the time of Henry I., confirmed, with some alterations, the charter, obtained sword in hand from king John, in 1215, being the present Magna Charta; which he several times confirmed and as often broke again; till in the thirty-seventh year of his reign, he came to Westminster-hall, where, in the presence of the nobility and bishops, with lighted candles in their hands, Magna Charta was read, the king all the while laying his hand on his breast, and at last solemnly vowing faithfully and inviolably to observe all the things therein contained, as he was a man, a Christian, a soldier, at 13 king. Then the bishops extinguished their candles, throwing them on the ground, crying, "Thus let him be extinguished and flunk in hell who violates this charter."

Nevertheless, king Henry in the next year invaded the rights of his people, till the barons levied war against him; and, after various sucesses, he confirmed this charter and the charter of the forefathers, in the parliament of Marlbridge, and in the fifty-seventh year of his reign. Afterwards, by flatute 25 Edw. I. called Confirmatio chartarum, whereby the great charter is directed to be allowed as the common law, all judgments contrary to it are declared void; copies of it are ordered to be sent to all cathedral churches, and read twice a year to the people; and sentence of excommunication is directed to be as constantly denounced against all those that by word, deed, or counsel, act contrary thereto, or in any degree infringe it. Sir Edward Coke observes, that it was confirmed so less than thirty-two times, from the first Edward to Henry IV. Then, after a long interval, by the Petition of Right, by many salutary laws, particularly the Habeas Corpus act of Charles II. by the Bill of Rights, and lastly by the Act of Settlement.

The Magna Charta is the basis of the English laws and liberties: besides those provisions, which redressed many grievances incident to feudal tenures, care was also taken therein to protect the subject against other oppressions, frequently arising from unreasonable amercements, from illegal dixrets, or other procés for debts or services due to the crown, and from the tyrannical abuse of the prerogative of purveyance, and pre-emption. It fixed the forfeiture of lands for felony in the same manner as it still remains; prohibited for the future the grants of exclusive fisheries, and the erection of new bridges, so as to oppress the neighbourhood. With respect to private right, it established the parliamentary power of the subject over part of his personal estate, the rent being distributed among his wife and children; it laid down the law of dower, as it continued ever since; and prohibited the appeals of women, unless for the death of their husbands. In matters of public police and national concern, it enjoined an uniformity of weights and measures; gave new encouragement to commerce, by the protection of merchant-strangers; and forbade the abetment of lands in mortmain. With regard to the administration of justice; besides prohibiting all denials or delays of it, it fixed the court of common pleas at Westminster, that the fators might no longer be harassed with following the king's person in all his progresses; and at the same time brought the trials of issues home to the very doors of the freeholders, by directing affizes to be taken in the proper counties, and establishing annual circuits; it also corrected some abuses then incident to the trials by wager of law and of battle; directed the regular awarding of inquest for life or member; prohibited the king's inferior ministers from holding pleas of the crown, or trying any criminal charge, whereby many forfeitures might otherwise have unjustly accrued to the exchequer; and regulated the time and place of holding the inferior tribunals of justice, the county-court, sheriff's torn, and court-leet. It confirmed and established the liberties of the city of London, and all other cities, boroughs, towns, and ports of the kingdom. And lastly, (which alone would have merited the title that it bears of the Great Charter) it protected every individual of the nation in the free enjoyment of his life, his liberty, and his property; unless declared to be forfeited by the judgment of his peers or the law of the land. Blackit. Comm. vol. iv.

MAGNALLIAVAL, in Geography, a town of France, in the department of the Upper Vienne, and chief place of a canton, in the district of Belle; 24 miles N. of Limoges. The place contains 2654, and the canton 6559 inhabitants, on a territory of 162 square kilometres, in five communes.

MAGNANINA, in Ornithology, the name of a small bird described by Aldrovanus, Geiner, and some other authors, and seeming to be the same with our hedge-sparrow, commonly known among authors by the name of curvus. See Motacilla vulgaris.

MAGNANO, in Geography, a town of the duchy of Piacenza; 13 miles S.S.E. of Piacenza.

MAGNENTIUS, Magnus, in Biography, a German by birth, but who, from being a private knight, rose to the chief employments in the Roman empire. He owed his distinguished dition to the circumstance of his having been made a prisoner of war. To free himself from this he joined the Roman troops, and became distinguished for valour. He was commander of the Jovian and Herulian bands, stationed to guard the banks of the Rhine, at the time
MAG

time when Conflans I. emperor of the West, had incurred the contempt of the army on account of his indolence and voluptuousness. In 350, he ascended the throne, and on the murder of Conflans, he was left without a rival in the Gallic and Italian prefectures. At Rome, Magnentius acted with great tyranny, and by his various extortions, he was enabled to levy a very powerful army to maintain his usurped authority. So formidable did he appear, that Conflans, emperor of the East, and brother of the deceased Conflans, fought a peace, on the terms of leaving him in possession of Gaul, Spain, and Britain, but his proposals were rejected. Magnentius now determined to attack him; a bloody battle ensued, which terminated in the total defeat of Magnentius. He fled to the foot of the Julian Alps, and collected the scattered remains of his army, polled them advantageously to defend the passes, and spent the winter in Aquileia. After this he went to Gaul, and obtained a victory over the van of the pursuing enemy at Pavia. His troops, however, soon sustained another defeat, after which he took refuge in Lyons, where he disarmed himself with his own sword. This event took place in the year 353, after a reign of nearly four years. The example of suicide was imitated by Decentius, who strangled himself on the news of his brother's death. A severe inquisition was extended over all who, either from choice or compulsion, had been involved in the cause of Magnentius. The most innocent people were exposed to exile and confiscation, to death and torture, and, says Gibbon, "as the timid are always cruel, the mind of Magnentius was inaccessible to mercy." Gibbon.

MAGNES, in Geography, a town of the island of Candaia, on the N. coast, supposed by Dr. Pococke to be the ancient Dictamus, or Dictyna; 12 miles N.W. of Cairo.

MAGNES Carneus, in Natural History, a name given by Cardan and some other authors to a white earth dug in Italy and some other places, and called also by many calamina alba. It is an indisputable earthy substance of the hardness of oolcocola, and is of a white colour variegated with black lines. It adheres very firmly to the tongue, and is harder red to asp and both in the form of the earth and in the magnet does iron. It is even pretended, that if an iron flybus be rubbed over with this flony earth, and then plunged into the flesh, the virtue of the earth will heal the wound as soon as made, and when the weapon is taken forth, there will remain no appearance of hurt. Cardan affirms that he saw this tried with success, but suspects witchcraft in the cafe.

MAGNESIA, in Agriculture, a substance which has not yet been found in a pure state in nature; it is constantly combined either with acids in the form of earthy salts, or mixed with other earths, as serpentinites, flexites, talcs, sphenites, &c. With a view to most purposes, it is commonly prepared by the decomposition of bitter salts, by the fixed mild alkalies, and subsequent separation of the carbonic acid by calcination.

But the experiments of Mr. Tennant seem to show, that this substance, when in combination with calcareous matter, such as that of lime, &c. is unfriendly to vegetation. It is, however, observed by Lord Dundonald, that it is found in a variety of earths and stones, and that it combines with acids, forming neutral salts, all of which are very volatile, and the greater part of them promotes, in a very considerable degree, the growth of plants. Magnesia earths, he conceives, may be applied with peculiar advantage to soils generally, and not improperly, called four soils, containing green vitriol, arising from the decomposition of pyrites. It will decompose the metallic salt by superior affinity, and form with the acid Epson salt, known in a high degree to promote vegetation; while the earth of iron will be separated in the state of an ochre, or iron combined with fixable air.

In has been suggested by a writer, in the Farmer's Magazine, likewise, that he tried the vegetative power of this substance, by growing oats in a pot containing one-tenth part of magnesia, and the rest common earth, in which they grew and thrived extremely well; but in another pot containing magnesia alone, they would not vegetate at all, which might, he thinks, be expected. It is likewise supposed to extirpate forrel, when applied on lands that abound with it, probably by neutralizing the acid, which is the face with lime. This writer has, however, applied it to lands overgrown with forrel, without its producing such beneficial effects.

MAGNESIA, in Chemistry, one of those substances that pass under the general name of earths. It is left abundant in nature than lime, alumina, or silica, but more abundant than any of the other earths. It forms a considerable part of the lime-flour, commonly called magnesia, from which it may be obtained by dissolving the flour in muriatic acid, and precipitating the magnesia with pure ammonia.

This earth was little known before its nature was investigated by the experiments of Dr. Black. It was before frequently confounded with lime.

It exists, in combination with muriatic and sulphuric acids, in sea water. The latter salt is found in some mineral waters, particularly the waters in the vicinity of Epson, known by the name of Epson salt.

It is from this salt that the magnesia of commerce is generally procured. The salt is first dissolved in water; then to the clear solution a quantity of common carbonat of potash is added. The magnesia is precipitated in the state of carbonate, which, when washed and dried, constitutes the magnesia commonly used in medicine. It is sometimes exposed to a strong red heat, in crucibles, by which the carbonic acid is expelled. In this state it is called calcined magnesia.

If the precipitation be made with pure ammonia instead of potash, the earth will be obtained in a state of tolerable purity.

Magnesia, in a pure state, appears in the form of powder, soft to the feel, and perfectly white. It has no taste, but when taken into the mouth it excites a peculiar sensation, arising from the rapid absorption of the saliva. It is diastatic of smell, but emits a peculiar odour when moisture is applied to it. Its specific gravity, according to Kirwan, is 2.3. Like the alkalies, and the alkaline earths, it changes the blue colour of some vegetation to that of green. It does not undergo any rapid change by exposure to the air. It slowly combines with water and carbonic acid; the former may be detected by distillation, and the latter by its effervescence with an acid.

It is nearly insoluble in water; since, according to Kirwan, it requires 7,000 parts of water to dissolve one of magnesia.

Like the other earths, when strictly pure, it is not fusible at any known degree of heat, although it is capable of fusion when mixed with other earths. Lime and magnesia, in the proportion of four to one, runs through the crucible at 150° Wedgewood. But one of lime to four of magnesia did not melt at 165°. In the proportion of one of the latter to three of the former; they melted into a greenish-yellow glass. For these facts we are indebted to Kirwan.

Magnesia has long been suspected to be a compound body, but not with much ground of probability, till the late interesting experiments by Mr. (Sir Humphrey) Davy, in which the alkalies and some of the earths appear to be compounds. Berzelius is said to have succeded in decomposing magnesia by
the agency of the Galvanic battery. The earth was placed in contact with mercury, and he supposed that the bale of the magnesia, which was thought to have metallic, combined with the mercury, forming a peculiar alloy. Mr. Davy has repeated this experiment, with the phosphat of this earth, with a similar result. Attempts have since been made to decompose magnesia in various ways, by Guy Lufic and Thenard, but without any satisfactory result.

In the experiments of Mr. Davy, although he did not succeed in obtaining the metal from the alloy with mercury, he found that magnesia was produced by throwing the alloy into water. It is highly probable, therefore, that this earth, like lime and barytes, is a compound, a peculiar metal united with oxygen, between which the affinity may be so great as not to be obtained, but with great difficulty. It is, therefore, to future experiments that we must look for the final establishment of the compound nature of this earth.

It is an useful medicine for taking up acidity in the stomoch; and has lately been recommended by Mr. Brandt as a solvent for the urinary calculus constituted by the uric acid.

Magnefia combines with sulphur, but very imperfectly; if two of the earth with one of sulphur be exposed to heat in a crucible, the mass becomes yellow. It affords a small quantity of sulphuric hydrogen when thrown into water. If the heat at which it is formed be a little increased, the sulphur is expelled, leaving the earth pure. It does not combine with phosphorus, carbon, nitrogen, nor the metals, nor with any of the metallic oxides.

There is no action between magnesia and the alkalies.

The solubility of magnesia by the carbonates of the alkali, is occasioned by the carbonic acid which leaves the alkali and combines with the earth.

Salts of Magnesia.—The greater proportion of the magnesian faults are of no known use, and have in consequence been little examined. The phosphat is the only one with which we are much acquainted, from its well known virtues as a purgative.

Sulphat of Magnesia.—This fault is found native in sea water; in the waters of Epson, from which it has been called Epson salts, and in many mineral waters. That used in medicine is obtained from the above sources. Several calcite stones contain sulphur and magnesia, which being exposed to air with moisture, the sulphur is converted into sulphuric acid, and, combining with the magnesia, forms this fault, which is separated from the heterogeneous matter by crystallization.

The efflorescence formed on brick walls is principally found to be sulphat of magnesia, sometimes mixed with nitre.

Sulphat of magnesia dissolves in its own weight of water at 60. On evaporation and slow cooling, this salt crystallizes in the form of four-sided prisms; it has a bitter and disagreeable taste. The crystals have the property of double refraction. When exposed to the air they soon lose their water of crystallization, and appear in the form of white powder. When exposed to a strong heat, it first fuses in its water of crystallization, which soon effaces. If the heat be continued, and raised to high temperature, it melts into a vitreous mass. It is composed, according to the analysis of Bergman, of 33 acid, 19 magnesia, and 48 water; according to Wenzel, 32.64 acid, 16.86 magnesia, and 52.5 water. Dalton makes the atom of magnesia to be 17, that of sulphuric acid 34. Then \[
\frac{34 + 17}{34} = \frac{100}{67.8},
\]
which gives 67.8 acid, and 32.2 magnesia. If we take the acid and base only, in the analysis of Wenzel we shall have

\[
\frac{30.64 + 16.86}{30.64} = 100, \text{ or } 64.5 \text{ acid, and } 35.5 \text{ magnesia.}
\]

This fault has the property of combining with some other of the sulphats which form compounds, having peculiar properties. These, like the rest of the compounds called triple faults, perhaps in all cases, owe their existence to the circumstance of their crystallizing together, from the analogous form of their crystals, and ought not to be considered as distinct species, since on analysis they are found to consist of certain proportions of the two faults, rather than of two bases united to one common quantity of acid. There is little doubt but that these faults, when in solution, would possess the individual properties of the two faults, being in this situation a mere mixture.

The phosphat of magnesia and potash is said to be composed of three parts of sulphat of potash, and four of phosphat of magnesia. These crystals are of a rhombohedral form.

The phosphat of magnesia and soda is composed of six of phosphat of magnesia, and five of phosphat of potash. Its crystals are prismatic.

Sulphat of Magnesia and Ammonia is in the form of octahedrons, and consists of 68 of sulphat of magnesia, and 32 of sulphat of ammonia.

Nitrat of Magnesia.—This fault is formed by saturating the nitric acid with magnesia. On evaporating the solution to a certain extent, and fuffering it to cool, the fault crystallizes in the form of rhombohedral prisms, which, when small, have the appearance of needles. The colour of this fault is unfeafively bitter, like most other of the magnesian faults. It dissolves in its own weight of water at 60; it is also soluble in nine times its weight of alcohol of the specific gravity of .94. When evaporated to crysals, and exposed to the air, it speedily becomes liquid, by attracting moisture from the air.

When exposed to a strong heat, it affords oxygen and nitrous oxide, the acid being decomposed, leaving the earth behind in a state of purity.

Its composition by the analysis of Bergman is 43 acid, 27 magnesia, and 50 water; by Richter's, 49.6 acid, and 35.4 base; by Kirwan's, 46 acid, 22 base, and 32 water; and by Wenzel, 72 acid, and 28 base.

The weight of the atom of acid is 17, that of the base 17. Then, since the nitrates are super faults, we have

\[
\frac{17 + 19 \times 2}{19} = \frac{100}{69}, \text{ or } 69 \text{ acid, and } 31 \text{ magnesia, nearly.}
\]

Muriat of Magnesia.—This salt abounds in sea water, and in some mineral waters. It may also be formed by adding carbonat of magnesia or muriatic acid, till the efflorescence ceases. When the solution is evaporated to the confidence of syrup, and exposed to a temperature of 32°, crystals of a needle shape are formed, although in small quantity and with difficulty.

It has a pungent bitter taste. It is soluble in one-half its weight of cold water, and in almost any proportion of boiling water. It is also very soluble in pure alcohol.

This fault is very delightful from its great attraction for moisture. In consequence of the same property, a portion of it is evaporated with the water in which it is dissolved, when exposed to a boiling heat. It is decomposable by heat, the acid being expelled.

By the analysis of Kirwan, its composition is 34-59 acid, 31.7 base, and 34.34 water. By Wenzel's, 57 acid, and 43 base. The atom of muriatic acid being 33, we have
MAGNESIA.

\[
\frac{22 + 17}{22} = \frac{100}{56.4}, \text{the acid is therefore 56.4, and 43.6 base.}
\]

The acid and base of Kirwan's analysis, reduced to the 100, will be 52 acid, and 48 base.

Hyperoxymuriat of Magnesia.—When the oxymuriatic acid gas is passed through a mixture of water and magnesia, we do not obtain an oxymuriat, but the common muriat mixed with the hyperoxymuriat. This salt has similar properties to those of the hyperoxymuriat of lime, the substance at present in use for bleaching.

Phosphat of Magnesia.—This salt may be formed by directly adding the base to the acid, as in the muriat of magnesia; or it may be formed more perfectly, by adding a solution of sulphat of magnesia to a solution of an equal weight of phosphat of soda. In a few hours, the salt in question will appear in beautiful transparent crystals.

These crystals are in the shape of hexagonal prisms, soluble in 15 parts of water at 60. It has but little taste. When exposed to dry air, it loses its water of crysallization, and assumes the state of white powder. It is not decomposed by heat, but melts and becomes vitreous.

A compound salt, denominated the phosphat of magnesia and ammonia, has been found by Foureroy in the calcined concretions found in the colon of the horse.

It may be prepared by mixing solutions of the two salts together. A salt of difficult solubility is precipitated. This salt is found to be an ingredient of urine, and will appear in crystals, when that fluid is exposed in cold vessels for some time. It is partly from this salt that phosphorus is obtained by the distillation of urine. The ammonia is given out, leaving the phosphoric acid, which is deprived of its oxygen by the carboaceous matter of the urine.

According to the analyses of Foureroy and Vaaquin, it is composed of 33 phosphat of ammonia, 33 phosphat of magnesia, and 33 water.

Flux of Magnesia.—When magnesia is added to the fluoric acid, by a little at once, it is for some time diffused, but as it approaches saturation, it falls down in the state of white powder. This shows that the salt is soluble in excess of acid. In its neutral state, it is insoluble in water. No analysis has been given of this salt. It ought, however, to be composed in the neutral state, of 15 acid to 17 acid, or by the 100 it will be \(\frac{15 + 17}{15} = \frac{100}{47} \text{ or 47 acid and 53 base.}\)

Borat of Magnesia.—This salt may be formed by dissolving magnesia in boracic acid. It affords crystals by evaporation. It dissolves partly in water, and is soluble in acetic acid. Alcohol is sure to dissolve the boracic acid from it, while the earth falls down. This salt is found native in Germany. It has the property of becoming electrical by heat; the truncated angles being plus, and the opposite ones minus.

Carbonat of Magnesia.—This salt may be formed by adding a solution of carbonat of potash to sulphat of magnesia. A white powder is precipitated, which, when washed and dried, constricts the magnesia ued in medicine. (See CARBONAT OF MAGNESIA.) It is slightly soluble in water, at least more so than the earth itself. If, however, the supercarbonat of potash be added to the solution of sulphat of magnesia, a supercarbonat of magnesia will be formed, which is more soluble and capable of crystallization by evaporation, their form being that of hexagonal prisms. It is said to be soluble in 48 parts of cold water, but left soluble in hot water. It is, however, in all likelihood much more soluble when it is first formed, or when the decomposition of the sulphat takes place by the supercarbonat of potash. There appears much insolvency in the analysis by different chemists. The carbonat by theory should consist of 19.4 acid, to 17 base, or in the 100, 53.3 acid, and 46.7 base. The supercarbonat consists of 2 \(\times 19.4\) acid, and 17 base. In the 100, 60.5 acid, and 39.5 magnesia.

Acetat of Magnesia.—This salt may be formed by dissolving magnesia in the acetic acid. It does not crystallize when evaporated to dryness, itsoon attracts moisture from the air. It is very soluble both in water and alcohol.

Its component parts, according to Richter, are 70.65 acid, and 29.35 base.

Oxalat of Magnesia.—This salt is nearly insoluble in water as well as alcohol.

Tartrat of Magnesia.—The tartaric acid dissolves magnesia, forming a salt which crystallizes in needles.

Citrat of Magnesia.—This salt may be formed like the last, by adding the base to the acid. It does not afford crystals. It is composed of 66.66 acid, and 33.34 base.

Malat of Magnesia is a deliquescent salt.

Camphorat of Magnesia.—When magnesia is boiled with crystals of camphoric acid in water, they unite, forming a salt, which, on evaporation and cooling, falls down in small scales. The root of the magnesian salts are not known to be of any importance.

MAGNESIA Alba, P. L. 1707, Magnesia Carbonatas, or Carbonate of Magnesia, in the Materia Medica, a fine white powder, which formerly at Rome bore the name of the Count of Palma; though many are of opinion, that the preparation was carried from Germany into Italy. It was used for several years, as a celebrated secret, in poisons of some particular persons, till the method of preparing it was made public by Lancisi in the year 1717, and afterwards by Hoffman in 1722. It was then extracted from the mother-lob, or the liquor which remains after the crystallization of rough nitre; either by precipitation with a solution of fixed alkaline salt, or by evaporating the liquor, and calcining the dry residue, so as to distil off the acids by which the earth had been made diffusible. As quicklime is commonly much employed in most of the German, French, and other European nitre-works, the substance obtained from the mother-lob of those works is rather a calcareous earth than magnesia, and appears to be fitch by its burning into quicklime, and forming a feluncates with the vitiroic acid. Magnesia was called the miraculon chemicum, because from two reduced liquors a coagulum is formed, which contains this substance.

From the experiments of Dr. Black, related in the Edinburgh Phisf. and Lit. Ed. vol. ii. art. 8. we learn, that magnesia is soluble, with effervescence, in vitriolic, nitrous, marine, and acetic acids; forming, with the vitriolic acid, crystals similar to those of the Epson salt, and with the nitrous acids, crystals which deliquate in a moist air; with marine acid it forms no crystals; but the saline matter being evaporated to dryness, soon deliquates by exposure to air; with diluted vinegar it forms no crystals by evaporation, but a saline mass, viscid when warm, resembling glue in colour and consistence, and brittle when cold. Magnesia was found to lose, by calculation, seven-twentieths of its weight, and was thus deprived of the power of effervescing with acids; whence the substance lost by calculation was gas, or fixable air; nevertheless this gas, and almost the whole weight lost by calculation, were restored to it by solution in vitriolic acid, and precipitation from them by a mild fixed alkali; the gas of which it absorbed in this last respect
peculiarly analoguous to the calcareous earths, but differed from them in other properties; particularly in these, that when calcined, it was not soluble in water, nor communicated any sensible impregnation to it, and that it did not, like them, when calcined, become cauful or acid.

Dr. Black also found, that magnesia was precipitated from acids by volatile alkali; that, when uncalcined, it precipitated calcareous earth from acids; but when calcined, or in any other way deprived of its gas, it did not precipitate these earths; when uncalcined or united with gas, it precipitated lime from lime-water; which shews that the calcareous earth had a stronger power to combine with the gas, than the magnesia had, since the former earth took gas from the latter; by which means the former was rendered mild and insoluble in water, and therefore was precipitated. This property suggested to Dr. Alton a method of procuring sweet water at sea, by adding magnesia to water, the pustrefaction of which has been prevented by the previous addition of quick-lime. M. Monnet observes, that magnesia, combined with sulphur, generally involves strata of coal: M. Margrafit has discovered that the ferpentine earths in Saxony contain magnesia: and M. Monnet adds, that the marly and also the alum earths contain it.

The directions for preparing it, given in the last London Pharmacopeia, are as follow: Take of sulphat of magnesia, subcarbonat of potash, of each a pound, and water three gallons. Diffuse the subcarbonat of potash in three pints of the water, and strain; diffuse also the sulphat of magnesia separately in five pints of the water, and strain: then add the rest of the water to the latter solution; apply heat, and when it boils, pour in the former solution, stirring them well together; next strain through a linen cloth; lastly, wash the powder repeatedly with boiling water, and dry it upon bireous paper in a heat of 200°. The double decomposition of the salts used in this process yields carbonat of magnesia and sulphat of potash, the first of which it is the object to collect as free as possible from the latter. Hence, as the newly formed sulphat of potash requires a large proportion of water for its solution, such a proportion is directed in the first instance, and it is afterwards well washed with more. If water be impregnated with carbonic acid gas, it will diffuse carbonat of magnesia; and hence the liquor is made to boil, for the purpose of detaching it. If the two solutions be mixed cold, and the precipitate left for some days upon the filter without artificial drying, many large and perfect crystals of carbonat of magnesia will be formed in it. The subfrequent heat, by which the powder is dried, should not be great enough to detach any of the carbonate acid. The present process will yield a pure and elegant preparation: its form is that of a white powder, easily friable, and, according to Fourerey, if the base be fully satuated with carbonic acid, as in the crystals, (for in its ordinary form it is a subcarbonat,) 100 parts contain of carbonic acid 50, of magnesia 25, of water 25; and if not so satuated, but in its state of sub-fact, of carbonic acid 45, of magnesia 40, and of water 12. In commerce, the marrit of magnesia contained in the refuse liquor, after the crystallization of marrit of soda from sea-water, is decomposed by a similar process, and yields a large proportion of the ordinary magnesia of the markets. The dose of carbonat of magnesia to adults is from 3 to 5, and of sulphat from 5 to 10. See CARBONATE OF MAGNESIA, and the preceding article.

Mr. Henry, an ingenious apothecary at Manchester, has communicated the following process for making the magnesia. Dissolve any quantity of sal carthatis anauris in its own weight of water; filter and add to it by degrees a filtered solution of pearl or pot-ashes, in an equal quantity of water, stirring them gently, until the mixed liquors have acquired the appearance of a complete coagulum; then de
dit from adding any more of the alkaline lixivium, and immediately throw the mixture into a large vessel of boiling water; keep it boiling for a quarter of an hour, then take it out, and put it into glazed earthen vesseis; as soon as the powder hath subsided, and before the water is quite cold, pour it off, and add a fresh quantity of boiling water: repeat these aubitions with hot water several times, till the liquor hath entirely lost its taffe tatte: then let it be agitated as to suspend the finer parts of the powder, in which flate decant it to other vesseis, and having separated the water from the magnesia, by inclination, put it on large chalk-frames, till a considerable part of the humidity is absorbed; then wrap it up in sheets of white paper, and dry it before the fire. Pour hot water upon the remaining powder, stir and decant it in its turbid flate, and separate the magnesia from the water as before: thus the whole, or mow of it, will be reduced to an equal degree of finenes. The larger the quantity of water into which the precipitated powder is cast, the more speedily and perfectly will the vitriolated tartar, which is formed by the union of the alkali with the acid of the fall. cath. be wash'd off. The neutral salt should be washed off as quickly as possible; otherwise, by allowing the mixture to stand for some time, the powder concretes into minute grains, which, when viewed with a microscope, appear to be alligaments of needles diverging from a point. These concretions cannot be re-dissolved by any washing, however long continued. Dr. Black orders four times the quantity of water to that of the solution for throwing the coagulum into; but Mr. Henry observes, that this quantity is much too little. The water should be pure, and distilled water is the best, provided it be kept till its empyreuma is gone off. Hard or impure water makes magnesia coarser and disagreeable. The chalk-frames on which the magnesia is dried should be exposed to a moderate heat, that the moilure may evaporate quickly: and cleanlines should be particularly attended to through the whole proceps.

The magnesia is recommended by Hoffman, as an useful antacid, a safe and indifferent laxative in doses of a dram or two, and a diaphoretic and diuretic, when given in smaller doses of fifteen or twenty grains. It is now much in use, particularly in heartburns, for correcting acidity in the stomach, and for preventing or removing the many disagreeable orders to which children are liable on this account. It is preferred to all common astringents, on account of its laxative quality, which it manifests when it meets with an acid in the stomach and bowels. If it is mixed with rhubarb, it prevents the rhubarb from leaving a colicaneous behind. If the magnesia is neither accompanied, nor met with by an acid, it is not purgative, but simply astringent.

Objection has been made to the use of magnesia by Hoffman and others, that it frequently produces flatulencies, gripings, and other uneasy motions, particularly in weak bowels. It is now well known, that these symptoms must have been produced by the great quantity of fixed air contained in it, and discharged from it in consequence of its meeting and effervescing with an acid in the stomach or intestines. Dr. Percival, therefore, suggested to Mr. Henry the idea of depriving it of its air, with a view of obviating these troublesome symptoms occasionally attending the use of it. For this purpose the magnesia should be exhausted by putting it in a common crucible, placing it in a glowing fire, and keeping it red-hot for the space of two hours. The magnesia thus treated was found to be equally purgative,
It had been denominated Æneasia and also Magnesia campus. The peninsula on which it was situated bounded on the S.W. the Sinus Pelasgeticus, the entrance of which formed a strait, having on the N.E. the Æcantum promontorium in Magnesia, and to the S.W. the Antron in Phthisis. Magnesia extended as far as mount Oliana, and as some say, to the valley of Tempe; and M. d’Anville places to the N.W. of it, the country called Pafalgocis. In Magnesia were found the following towns, viz. Magnesia, Phere no Sidero, Jerufat or Fanifar, Meliboea para, Icous, Denetriada, Pagafa, and Tempe Thessalia. Its mountains were Oliana now Colovo, and Pelion, and its promontories were those of Magnesia and Sepias.

Magnesia, the capital of the above province, situated on the easterly coast, at the bottom of a small gulf.

Magnesia ad Macedoniam, a town of Asia Minor, in Ionia, on the northern bank of the Meander; 15 miles S.E. of Ephesus. This, according to Diodorus Siculus, was one of the cities given by Artaxerxes to Themistocles. According to Pliny, this town was a colony of Magnesians of Thebally, united with the Cretans. The Turks call it " Güzeli Fıyar," or the beautiful castle.

Magnesia ad Sipyllum, or Magnesia Sipyll, a town of Asia Minor, in Lydia, at the foot of Mount Sipyllus, S. of the confluence of the rivers Hyllus and Phrygus, and the Hæmus. The victory obtained by the Romans over Antiochus near this city, rendered it famous. Strabo says, that under the reign of Tiberius, it was destroyed by an earthquake. Near it was a beautiful plain of the same name, at the foot of Mount Sipyllus.

Magnesite. Native Magnesia; Native Talc Earth, Jam; Réine ou Naturelle Talc-erde, Wern.; Magnésit, Karlen; Magnése naturel, Bruch; Magnésia de Mitchell, Bronny; Magnése carbonaté, Haury.

The following description is derived from the original native magnesia of Mr. Mitchell, and that of Piemont described by Gibert. All the others we find mentioned by authors are dubious.

Colour yellowish-grey, or a dirty-yellowish white, that of Piemont bluish-white before it has been much exposed to the air; that of Moravia is marked with blackish-brown stains, penetrating from the surface into the interior, and also marked with grey and blueish grey spots.

It is always found massive, generally in rounded pieces, sometimes of the size of a man’s head, and of earthy aspect; these pieces are sometimes found with fissures, but not with rounded cells.

Its hardness variable; in its more compact state the Moravian variety scratches calcareous spar, but is scratched by fluor spar; the most compact Piedmontese varieties are still harder. It is also found in a friable state, when it falls with the fingers.

Fracture flat conchoidal, approaching to even; dull. Its tenacity is incomparable, especially in those varieties that contain no silica.

MAGNÉSIE, or Sélité, a town in Thessaly, a province situated on a peninsula, E. of Thessaly, and S.E. of Macedonia; which some geographers have annexed to the former country, and others have described as part of the latter. Strabo and Pliny place this province in Macedonia, and in their time the Romans had annexed it to this country: but before the kings of Macedonia had extended their conquests beyond Mount Olympus, Magnesia was reckoned a portion of Thessaly.

tive, when given in half its former dose, and is deprived, by this process, of the disagreeable qualities above mentioned, and acquires likewise new properties, which render it likely to answer some other important practical purpose. By calculation it is not only rendered incapable of generating air in the stomach and bowels, but it is qualified to absorb, or render fixed, that which it finds there, and which is produced, sometimes in too great quantities, in the process of digestion; and it is consequently adapted to relieve those colics or other disorders, which are commonly called flatulent. In this respect it promises, as Mr. Henry observes, to be much more efficacious than the whole tribe of carminatives, from which it essentially differs with regard to its mode of operation and effects. It appears likewise to be the most proper cathartic for patients afflicted with the stone, who are under a course of the opium-ley; as it cannot, like the vegetable purgatives, counteract the lividity, by throwing air into it; but, on the contrary, will absorb a part of that earth, which is already in the prime, viz. and which would otherwise be attracted by the caustic alkali, and render it less capable of acting on the calculus. In order to produce these effects, it is of great importance that the magnesia, intended for calculation, should be perfectly free from any admixture of calcareous earth; as in that process, this last mentioned substance must necessarily be deprived of its air, or rendered caustic; and the magnesia which contains it will accordingly impregnate the water in which it is infused with the tallow and qualities of lime-water. Mr. Gilfs’s magnesia, which has been so highly extolled, appears, by Mr. Henry’s experiments, to contain no inconsiderable portion of calcareous earth. Lond. Med. Transf. vol. ii. art. 16. Henry’s Exp. and Obs. 1773.

MAGNÉSIE, or Magnesia, in Chemistry. See MAGANESE.

MAGNESIA, Opaling, Opalin, or ruby-coloured magnesia of antimony, is made, according to the directions of Lemery, of equal parts of antimony, nitre, and decretipated sea-felt. It is a much weaker emotive than the liver of antimony.

MAGNESIA Ufina, P. L. 1757. Magnesia in the Matrix Medicis, is prepared by burning four ounces of carbonat of magnesia in a strong fire, for two hours, or until acetic acid, being dropped in, extinguishes no bubbles of gas. Here it may be noted that a definite quantity has been preferred merely for the sake of precision, and not as influencing the quality of the product. This preparation was the "magnesia alta" of the former Pharmacopoeia; but as the term "magnesia" is correctly used to express only the pure earth, so it has been thought proper to apply it decidedly in the present instance, although in common language, the same term may be most generally applied to the carbonat, and the epithet caltined added to express the pure preparation. The process depends upon the expulsion of the carbonic acid of the carbonat by heat, and in the form of gas, and hence the carbonat yields about half its weight, or rather 3/4 the of the pure magnesia. It may be considered as insoluble in water; for Kirwan states 7000 times its weight to be necessary for this purpose at 60. The dose of magnesia for adults is from 3 to 5.

MAGNÉSIE, or Sélité, in Geography, a province situated on a peninsula, E. of Thessaly, and S.E. of Macedonia; which some geographers have annexed to the former country, and others have described as part of the latter. Strabo and Pliny place this province in Macedonia, and in their time the Romans had annexed it to this country: but before the kings of Macedonia had extended their conquests beyond Mount Olympus, Magnesia was reckoned a portion of Thessaly.

It is a strong heat it loses its carbonic acid, contracts and acquires a sufficient...
MAG

a sufficient degree of hardnes to scratch glass. It dissolves
with effervescence in concentrated acids; but Giobert informs
us that the variety of Castellamonte contains no carbonic
acid when in the bottom of the earth; whence, as in all other
respects it is like the magnesia from Baudiffere, he is of
opinion that also the latter is originally delituite of carbonic
acid, and that it only contains it, when, after a long expo-
sure to contact with the air, it can absorb it from the at-
mosphere.

The following are the results of the analyses that have
been lately given of the different varieties of this substance.
Those of Hrubfchitz, in Moravia, according to the expe-
riments of the accurate Bucholz, contain

Variety I.

| Magnesia | 0.48 |
| Carbonic acid | 0.52 |

100

Variety II.

| Magnesia | 45.59 |
| Carbonic acid | 51 |
| Alumine | 1 |
| Oxyd of iron and manganese | 0.25 |
| Lime | 0.16 |
| Water | 1 |

100

Variety III.

| Magnesia | 45.42 |
| Carbonic acid | 47 |
| Silica | 4.50 |
| Water | 2 |
| Alumine | 0.50 |
| Oxyd of iron and manganese | 0.50 |
| Lime | 0.08 |

100. Ann. de Chem. tom 74.

The analyses that were first given by Mitchell, Lampadius,
and Klaproth, of the Moravian magnesite, agree pretty ex-
actly with those of Bucholz, but they all differ considerably
from that published by Wondrazech, who obtained mag-
nesia 33, carbonic acid 30, silica 8, lime 0.5, manganese acid
iron 1.5, water 20, lods 7.

Giobert and Guyton's analyses of the Piemontese magne-
site again offer different results. That of Baudiffere contained
in hundred parts

100. Guyton.

The two known localities of magnesite are Hrubfchitz di-
strict of Gromau, in Moravia; and Baudiffere and Castell-
amonte, villages in the vicinity of Turin. The Moravian va-
riety was brought by Dr. Mitchell from Vienna, and pres-
tented to Werner, who gave it its present place in the sytem.
The Piemontese varities puzzled a long time for pure alu-
mine; till Giobert discovered their true nature.

The geognostic situation of this fossil in either of the
above countries, is nearly the same. At Hrubfchitz it is
found in a bed of decomposing serpentine; accompanied
with common and earthy tale, meehlochum, and magnesian lime-
stone. That of Turin occurs in a fiaiar serpentine rock,
accompanied, according to Giobert, by hornstone in decom-
position, to which latter this chernill is inclined to ascribe
the origin of the magnesite.

According to Giobert, the magnesite of Baudiffere forms an
excellent porcelain with filex. He also made crucibles and cap-
ules of it, having added some of the argilaceous earth of Cas-
tellamonte, sufficient to unite it into a paste. The crucibles
were exposed for 48 hours in the furnace of a glas house;
the earth did not appear to have formed a sufficient union;
nevertheless, the hardness of the crucibles was such that
they could not be affected by the file.

It may also be employed with advantage for producing
sulphat of magnesia by means of sulphat of iron, which
likewise abounds in the same places of Piemont.

MAGNET, Magnes, the Leadstone; a sort of ferrugi-
rous stone, in weight and colour resembling iron ore, hard,
so as just to afford irparks when struck with file, and heavy;
endued with divers extraordinary properties, attractive, di-
rective, inclinatory, &c.

The magnet is also called lapis Heraclei, from Heraclia,
a city of Magnesia, a part of the ancient Lydia, where it is
said to have been first found, and from which it is usually
supposed to have taken its name. Though others derive the
word from a shepherd named Magner, who first discovered it
with the iron of his crook on mount Ida. It is also called
lapis nauticus, by reason of its use in navigation; and fide-
riftes, from its attracting iron, which the Greeks called
crates.

The magnet is indeed a true iron ore, from which a con-
siderable portion of iron may be extracted, and is usually
found in iron mines, and sometimes in very large pieces,
half magnet, half common ore. This species of iron ore
contains a greater quantity of iron, either in the metallic
state, or not much oxygenated, than most other ores. Ne-
evertheless, though every magnet seems to contain some iron
in a metallic state, it does not follow that every kind of ore,
which contains iron in that state, is magnetic; many iron
ores having been found, which had the appearance of being
good magnets, and yet were not poffessed of the magnetic
properties. The natural magnets often contain, besides par-
ticles of iron, a portion of quartz and argill, and probably
fomum furphur; whence they have, when made red hot, a ful-
phorous smell; and also some other substanices. Magnets
 differ with regard to their specific gravity, according to the
nature and proportion of the other ingredients which are
mixed
MAGNET.

mixed with the iron or martial part; but they are generally about seven times heavier than distilled water. The colour of the magnet is different, white, blue, red, black, but mostly ferruginous, or a dull brownish-black, according to the different countries it is brought from, the admixture of heterogeneous substances, and the flake of the iron contained in them. Norman observes, that the belt are those brought from China and Bengal, which are of an iron or fangtigue colour; those of Arabia are reddish; those of Macedonia blackish; and those of Hungary, Germany, England, &c. of the colour of unworked iron. Neither its figure nor bulk is determined, but it is found of all forms and sizes.

It has been observed, that, in general, those magnets which have a fine clove grain, are more powerfully magnetic, and retain the virtue much longer than those that are of a coarser grain; and even longer than the artificial magnets which are made of steel.

The ancients reckoned five kinds of magnets, different in colour and virtue: the Ethiopian, Magnetian, Bactrian, Alexandrian, and Natural. They also took it to be of two kinds, male and female; but the chief use they made of it was in medicine; especially for the cure of burns, and defluxions on the eyes. The moderns, more enlightened and happy, take it to conduct them in their voyages.

As the propertiespossessed by the natural magnet may be communicated to iron, steel, and other ferruginous substances, these bodies, after having acquired the magnetic properties, are called Artificial Magnets; which see.

The most distinguishing properties of the magnet, whether natural or artificial, are, that it attracts iron, and other ferruginous substances, thus serving the purposes of the chemist in discovering or separating small particles of iron, mixed with other matters; and that it points towards the poles of the world; that it is inducted in certain cases with attractive and repelling powers; and in other circumstances, also dips or inclines to a point beneath the horizon, directly under the pole; and that it communicates these properties, by proper methods, to iron, steel, and other ferruginous substances. On which foundation are formed the mariner's needles; both the horizontal, and the inclinatory, or dipping-needles.

Magnet, the attractive Power of the was known to the ancients, and is mentioned even by Homer, Pythagoras, Aristotle, and by Plato and Euripides, who call it the Heronian Plume; because it commands iron, which fulfills every thing else. The Jews were acquainted with it. This property is finely described by Plato: "Quid lapides rigores pingunt? Ecco fenus manufac tribuit illi. Quid ferri duotine pugnas? Sed eo, et patitur non obtinuatur; manuque a magnete lapide, domitorque has rerum omnium materia ad ipsum nascitur quid currit; atque ut proprius venit, adhicit in teretumque, complexumque hancet." Lib. xxxvi. cap. 16.

The ancients feem also to have been acquainted with the communicative virtue of the magnet. Plato has described a chain of iron rings suspended by one another, the flirt of which is contained by the load-from: Lucertius, Philo, Pliny, Galen, and Nemecius, have likewise described the same phenomenon; but the knowledge of its directive power, whereby it directs its poles along the meridian of every place, and occasions needles, pieces of iron, &c. touched with it, to point nearly north and south, is of a much later date; though the exact time of its discovery, and the discoverer himself, are yet in the dark. The flirt tides we hear of it are erroneously referred to the year 1269, when Marco Polo, the Venetian, is said by some to have introduced the mariner's compass (see Contra); though not as an invention of his own, but as derived from the Chinoese, who are said to have had the use of it long before; though some imagine that the Chinoese before that had borrowed it from the Europeans. Flavio de Gioia, a Neapolitan, and a citizen of Amalfi, is the person usually supposed to have the belt title to the discovery, about the year 1325, and he, if not the inventor, was the first who used it for the guidance of vessels in the Mediterranean; and yet for G. Wheeler mentions that he had seen a book of astronomy much older, which spoke of the use of the needle: though not as applied to the uses of navigation, but of astronomy. And in Guyot de Provins, an old French poet, who wrote about the year 1180, there is expressly mention made of the load-stone and the compass, and their use in navigation is obliquely hinted at. The Spanish Jesuit Pineda and Kircher affirm, that Solomon knew the use of the compass, and that his subjects did actually use it in their navigation. See Compass, Mariner's.

It appears from a Latin letter, written by Peter Adiger, on the description of the nature of a magnet, and dated in 1269, from which Mr. Cavallo has made copious extracts in his "Treatise on Magnetism." 1850, that most of the properties of the magnet, with which we are now acquainted, were known in his time; though they were not applied to the same useful purposes. From these extracts we learn that the laws of magnetic attraction, and of the communication of that power to iron, the directive property of the natural magnet, as well as of the iron that has been touched by it, and even the declination of the magnetic needle, were particularly described by Adiger with a view to the instruction of a friend. See Mariner's Compass.

Magnet, Variation of the, or its declination from the pole, is said to have been first discovered by Sch. Cabot, a Venetian, in 1500, who first served our king Henry VII. then the king of Spain, and lastly returning to England, was confructed grand pilot by king Edward VI. with an annual salary of above 1662; though Ferdinand, the son of Columbus, affirms that his father observed it on the 14th of September, 1492: and the variation of that variation by Mr. Gellibrand, an Englishman, who published his discovery in a small quarto pamphlet, intituled "A Discourse Mathematical on the Variation of the Magnetic Needle," printed in 1575. See the preceding article, and Declination.

Lastly, the dip or inclination of the needle, when at liberty to play vertically, to a point beneath the horizon, was first discovered by another of our countrymen, Mr. R. Nor- man, who, in 1581, published the discovery he had long before made, in a small pamphlet, called the "New Attractor," where he shews how to determine its quantity. See Dipping and Dipping-needle.

Magnet, Phenomena of the. 1. In every magnet there are at least two poles, one wherein points southward, the other northward; one of these is called the north pole, and the other the south, and that is called the north pole, which, if the magnet was put into a little boat of wood, or other materials large enough to support it, and set afloat in water, or suspended by a thread, &c. as to be at liberty to move itself easily, would turn itself towards the north pole of the earth, or towards a point not much distant from it; and that is called the south pole which would turn in similar circumstances, towards the south. The property itself is called the magnet's directive power, or magnetic polarity; and when a magnetic body places itself in that direction, it is said to "traverse." A plane perpendicular to the horizon, and passing through the poles of a magnet when standing in their natural direction, is called the "magnetic meridian;" and the angle made by the magnetic meridian and the plane of the meridian of the place where the magnet stands, is called the "declination of the magnet," or more commonly the "declination"
"declination of the magnetic needle;" because the artificial magnets, commonly used for observing this property, are generally made slender, and somewhat in the shape of a needle, or because the poles having fixed, have often been used for this purpose. The north pole of one magnet always attracts the south pole, when placed opposite to one another, and repels the north pole of another, and vice versa. In short, magnetic poles of the same name repel one another, whereas those of a different name attract one another. It is observed that the poles of magnets are not at their extremities, but at a little distance from thence; and if the magnet be divided into ever so many pieces, the two poles will be found in each piece, and sometimes more than two; though each of the parts has not always the same number of poles. The poles of the fragments generally, but not always, answer to the poles which were nearest to them in the original magnet. We may add, that in some natural magnets there are more than two poles, inflections having occurred of some in which there are eight, nine, and even ten. M. Mulpchenbroek says that he has seen a cube, each side of which was polar. The figure, and also the heterogeneous nature of the magnets, are the principal causes of their having often more than two poles. In order to determine the number and position of the various parts of its surface to be presented to one of the poles of another magnet that is freely suspended; then those parts of the magnet which repel the other that is suspended, have the same polarity, and those which attract it have a different polarity. E. G. If the magnet be presented to the north pole of the other suspended magnet, then those parts of the former which repel the latter are poissled of a north polarity, and those which attract it are poissled of a south polarity.

By the following method also, the situation of the poles, and the direction of the (supposed) magnetic effluvia in passing out of the stone, may be exhibited to the sight: let A B, C D, (Plate VI. Magnétisme, fig. 1.) be the poles of the stone; about every side gently lay some iron or steel filings on a sheet of white paper; these small particles will be affected by the effluvia of the stone, and so difpersed as to show the course and direction of the magnetic particles in every part. Thus, in the middle of each pole between A B and C D, it appears to go nearly straight on; towards the sides it proceeds in lines more and more curved, till it bends the last line at a right angle to the adjacent pole, and the poles in the same plane. This is then the real course of the pole to which the moving fluid directed its course.

A small artificial magnet may be used in this experiment instead of the real magnet, with a similar effect. If the table on which the paper rests receives a few gentle knocks, so as to shake the filings a little, they will move readily and diffuse themselves round the magnetic bar; otherwise, the action of the magnet will not have power sufficient to diffuse properly those particles which lie at a considerable distance. This phenomenon, which has been observed from time immemorial, has led various persons to believe, that a certain fluid circulates from one of the poles of every magnet to the other, in consequence of which the iron or steel filings are thus arranged round the magnet. A little consideration will make the absurdity of this suppos'd circulation, because if the fluid, of whatever nature it may be, did really circulate from one pole to the other, and had any action on the filings, these would be all driven to the middle to one pole to which the moving fluid directed its course. The true cause of the arrangement of the filings is, their becoming actually magnetic, and their two extremities being poissled of different polarities. Suppose, first, that only one oblong particle of iron be affixed to the various parts of the surface of the magnet, it is evident, from what has been already said, that on the poles this particle of iron, A B, (Plate VI. Magnétisme, fig. 2.) would stand perpendicular to the surface, because its farther extremity B, having the same polarity as the extremity, C, of the magnet, is equally repelled by it on every side, and is far from the influence of the other extremity D; on the sides near to the poles the said particle will stand inclined, because the farthest pole of the magnet begins now to act upon it; and on the middle of the magnet the wire will lie quite close to it, or, if it be kept at some distance, will be parallel to the magnet, because the two poles of the magnet, being equidistant from the extremities of the iron particle, have an equal action upon it. Now, when there are many particles of iron, vis. the filings, near the magnet, those particles which touch its surface are rendered magnetic, consequently they attract other particles, and these being made also magnetic, attract others, and so on; forming filings of small magnets, which gradually decrease in size as they recede from the magnet. As each of thesé particles has two magnetic poles, by a little consideration it will appear, that the farthest ends of the rings or lines which proceed from the parts adjacent to one of the poles of the magnet, for instance, the northern pole, are likewise poissled of the northern polarity, and the farthest extremities of those rings which proceed from the parts adjacent to the south pole of the magnet, are poissled of the south polarity; hence, when they come sufficiently near, they attract the extremities of the former rings, and consequently form the curves delineated on the figure.

The situation of the poles may be also determined by placing over the magnet a very fine needle, which will stand perpendicular over each pole, being more strongly attracted by it, and no where else.

When a magnet that is freely suspended, has only two poles, it will place itself very readily in the magnetic meridian, or in that place in which other good magnets are wont to place themselves; but when it has more than two poles, it may happen that these poles are so situated, as that the magnet will not traverse it; that is, it will have no directive power, and yet it will attract, repel, &c.

Two circumstances deserve to be noticed with respect to magnetics: that there are two poles, and that the parts adjacent to one pole are poissled of a contrary polarity; and the other is, that the number of poles of one denomination in a magnet is either equal to, or differs from, the number of poles of the other denomination by one; thus, if the magnet has four south poles, then it will have either four, three, or five north poles. It is observed, that good magnets of an uniform texture and proper form, have only two poles, and they lie in opposite parts of their surfaces, so that a line drawn from the one to the other passes through the centre of the magnet. The polarity of a magnet, however, must not be understood to reside only in two points of it; for, in reality, it is the half, or a great part of the magnet that is poissled of one polarity, i. e. has the property of repelling the contrary pole of another magnet; and the rest of the magnet is poissled of the other polarity; the poles being, therefore, those points in which that power is the strongest.

In magnets, such as we have just described, the line between the two poles is called the "axis;" and a line formed round the surface of the magnet by a plane, which divides the axis into two equal parts, and is perpendicular to it, is called the "equator of the magnet." Hence it appears, that philosophers have appropriated to the magnet the poles, the equator, the meridian, in imitation of the terraqueous globe; and to complete the similitude, magnets have been...
often made of a fpherical shape, with the poles and the equator marked on their surfaces. When so shaped, they have been called "terrellas," i.e. small earths.

The poles of any given magnetic body may be ascertained by presenting the various parts of its surface successively to one of the poles of a magnetic needle, and you will soon discover which parts of the given body are pos-

ted of a contrary polarity, by the needle's standing perpen-
dicularly toward them. Then present the various parts of the surface of the same body to the other pole of the needle, &c. The magnetic body, in this operation, should not be brought too near the needle, for fear of changing its polarity. The distance is various for producing such an effect, according to the strength of the magnetic body; so that it is impossible to state it, but the operator never mitake, if he keeps the magnetic body so far from the needle, as just to affect it sensibly.

2. These poles, in different parts of the globe, are dif-
dantly inclined towards a point under the horizon. Thus, when a magnet is placed so as to be at liberty to move itself very easily, it generally inclines one of its poles towards the horizon, and of course it elevates the other above it. This property is called the "inclination" or "dipping" of the magnet, or more commonly of the "magnetic needle." See Dipping.

3. Thee poles, though contrary to one another, do help mutually towards the magnet's attraction and suspension of iron.

4. If two magnets be spherical, one will turn or con-
form itself to the other, so as either of them would do to the earth; and after they have so conformed or turned themselves, they will endeavour to approach or join each other; but if placed in a contrary position, they will avoid each other. This property may be illustrated by placing two magnets on small pieces of wood, formed in the shape of boats, and swimming freely on magnetized water, undisturbed by wind, and at such a distance as to be within the sphere of each other's activity: both the boats will swim towards each other with an accelerated motion, and meet exactly in the middle of the distance between them, provided that the boats and magnets were exactly of the same weight and bulk: but if either boat be turned, so that its magnet may present a contrary end to that by which it was attracted by the other magnet, they will both recede from each other with an equal velocity. The same phenomenon may like-
wise be exhibited by suspending a magnet, C, from the end, B, of a balance (Plate VI. Magnetism, fig. 3), and forming an equilibrium with a weight in the scale A, place another magnet, D, under C, and C will be found to rush towards D, and to lift the weight in the scale A: but if the opposite end of D be presented to C, C will be repelled by it, ascend, and the scale, A, will descend: if D be placed above C, as in E, the effects will be just the contrary.

M. Mufchenbroek has found by a variety of experi-
ments, that two magnets attract one another with different forces at different distances; that they act most strongly in mutual contact, in which case their force has been equal to the weight of three hundred and forty grains, but at the distance of twelve inches, equal only to twenty-three grains: nevertheless, they observe no regular proportion in their decrees, but the ratio is less than the inverre of their dis-
tances, and different in different magnets and at different times. There are some whose sphere of activity reaches even to fourteen feet, and others in which it is not sensible at the distance of eight or nine inches. He has also found, that the sphere ofrepulsion varies in different magnets, and at different distances; and that the repulsive force is much less than that of attraction; the latter in contact being equal, to three hundred and forty grains, whereas the former is equal only to forty-four grains. It appears also from another experiment of the same author, that the repelling forces of both poles of the same magnet, are very con-
derable at the distance of twelve lines, being equal to thirty grains, that they increase to the distance only of seven lines, where they are equal to thirty-fix, but that in immediate contact they are equal only to thirteen grains. Mr. Mitchell, however, differs much in his deductions from those above-
mentioned: he maintains, that each pole acts, attracts, or repels exactly equally, at equal distances in every direction; and that the magnetic attraction and repulsion are exactly equal to each other. He adds, that the mistake of those who think otherwise, arose from their not attending to the different degrees of strength, which magnets have in different circumstances; for two magnets that are placed with their attracting poles towards each other, will have their power, by that means increased; and on the contrary, if their re-
pelling poles be placed towards each other, their power will thereby be diminished: and this increase or diminution of power will be in a greater or lesser degree, according as the magnets are nearer to, or farther from, each other; whence in all the experiments made on this subject, the attraction and repulsion come perpetually nearer to an equality, the greater the distance of the two magnets is, with which the experiments are made, and vice versa.

And so great is the effect of magnets on each other, that when the repellent poles of a large magnet and a small one are brought into contact, the small one shall sometimes have its repellency changed into attraction. Mr. Mitchell also infers from other experiments, that the attraction and repulsion of magnets decrease as the figures of the dis-
tances from the respective poles increase. The differences of opinion in this respect are ascribed by him to the want of making proper allowances for that property of magnets, in consequence of which they attract or repel equally at equal distances, together with the increase and diminution of power in the magnets with which the experiments were tried.

We shall here subjoin a few more observations on magnetic attraction and repulsion. If a piece of iron, or steel, or other ferruginous substance, be brought within a certain distance of one of the poles of a magnet, it is attracted by it so as to adhere to it with a considerable degree of force; and this attraction is mutual, the iron attracting the magnet as much as it is attracted by it; so that if they were placed on pieces of cork or wood and made to swim on water, the iron would be found to advance towards the magnet as well as the magnet towards the iron; and if the iron were kept steady, the magnet would move towards it. A smaller degree of attraction than that which is observed by means of water may be discovered by placing the given body to swim upon quicksilver, and by presenting the magnet to it; in which case it will move with surprising velocity. In this method the following particulars must be minded, viz. the aperture of the vessel, in which the quicksilver is kept, must be at least six inches in diameter; otherwise, as the surface of the quicksilver descends near the sides of the vessel, and that curvature is proportionally greater in narrow vessels than in larger ones, the floating body, when the quicksilver is kept in a vessel of three or four inches, will be perpetually running towards the sides. The quicksilver must be very pure; but, as it is very difficult to find it, or to preserve it pure, it must be frequently passed through a funnel of paper, viz. a piece of writing paper rolled up conically, and hav-
ing a small aperture of about a fourth of an inch in diame-

ter;
MAGNET.

ter; for, if the quicksilver be impure, the floating body will move with less facility upon it than upon water. The air about it must not be disturbed much, in order to keep the body without motion; in which state one of the poles of a strong magnet is to be presented on one side of it, in the same manner as when the experiment is tried on water, following the same precautions. The force of magnetic attraction varies according to the strength of the magnet, the weight and shape of the body presented to it, the magnetic or unmagnetic virtue of that body, the distance between it and the magnet, and some other circumstances. A piece of soft and clean iron is more powerfully attracted by a magnet than any other ferruginous body of similar shape and weight. The iron ores are attracted more or less forcibly, as they contain a greater or less quantity of metallic particles, as that quantity is in a more or less perfect metallic state, and as it is of a softer or harder nature; but all these, as well as hard iron and steel, are less forcibly attracted than soft iron. By presenting a piece of iron successively to the different parts of the surface of a magnet, the attraction will be found strongest at the poles of the magnet, or those points that are directed, when the magnet is freely suspended, towards the north and south; it will be found to decrease as the part towards which the iron is presented recedes from the poles, and it will be very little, or not at all, perceptible about those parts of the surface which are equidistant from the poles. The attraction, as we have observed before, is most powerful near the surface of the magnet, and is diminished in receding from it, so that if a piece of iron be placed in contact with one of the poles of a magnet, it will require a certain degree of force to separate them; at the distance of an inch from the pole, the attractive power, though much diminished, will be perceptible; and at a greater distance, it will be still less. However, the law of this diminution has not been satisfactorily ascertained; so that it is not known, whether it is twice, thrice, or any other number of times greater than at double that distance. In some cases, the attraction has seemed to decrease in the inverse ratio of the distances; but in others it has decreased much faster, or in different proportions at different distances; and the only general conclusion that has been deduced from a variety of experiments is, that the decrease of magnetic attraction is not slower than the inverse ratio of the distance, so that at double the distance it is half as strong, &c.

In some other experiments with magnetic needles, the attraction appeared to decrease in the ratio of the cubes of the distances of the magnets. Mr. Whiston states, that the absolute attractive power of different armed load-foines is, ceteris paribus, according to the quantity, not of their diameters or solidities, but of their surfaces, or in a duplicate proportion of their diameters. Whereas, the power of good magnets ranged, not sensibly different in strength, similar in figure and position, but unequal in magnitude, is sometimes a little greater, sometimes a little less, than in the proportion of their similar diameters. He says, that the load-foine attracts needles that have been touched, and others that have not been touched, with equal force at unequal distances; viz., where the distances are to one another as live to two. According to his account, the attractive power of load-foines, in their similar position to, but different distances from, magnetic needles, is in the fesquiplicate proportion of the distances of their surfaces from their needles reciprocally; or as the mean proportionals between the squares and the cubes of those distances reciprocally; or as the square roots of the fifth powers of those distances reciprocally. Thus the magnetic power of attraction, at twice the distance from the surface of the load-foine, is between a fifth and fifth part of that power at the first distance; at thrice the distance, the power is between the fifteenth and sixteenth parts at four times the distance, the power is thirty-two times as small; and at six times the distance, eighty-eight times as small. Where it is to be noted, that the distances are not taken, as in the laws of gravity, from the centre; but from the surface: all experience affords us, that the magnetic power resides chiefly, if not wholly, in the surfaces of the load-foines and iron; without any particular relation to any centre at all. The proportion here laid down was determined by Mr. Whitton, from a great number of experiments of Mr. Haubtieck, Dr. Brook Taylor, and himself. The force they measured by the chords of those arcs, by which the magnet, at several distances, draws the needle out of its natural direction, to which chords (as he has demonstrated) it is ever proportional. The numbers in some of their most accurate trials is given us in the following table; letting down half the chords, or the lines of half those arcs of declination, as the true measures of the power of magnetism.

Sir Isaac Newton supposes magnetic attraction to decrease nearly in the tribaric ratio of the distance. Mr. Martin observes, that the power of his load-foine decreases in the fesquiplicate ratio of the distances inversely. Dr. Hellam found it to be as the squares of the distances inversely, which ratio agrees well with that of the ingenious Mr. Michell; others, as Dr. Brook Taylor and Mr. Mufchenbrock, are of opinion, that this power follows no certain ratio at all, but that it is much quicker at greater distances than at small ones, and that it is different in different foines. Mufchenbrock has made the following experiments in relation to this subject, and as they were accurately made, we shall here annex them. Introd. Nat. Phil. c 16.

Exp. 1.—A cylindrical magnet, two inches long, and weighing 16 grains, was suspended to one scale of an accurate balance, and under it there was placed, upon a table, a cylinder of iron, which was exactly of the fame bulk and shape. Things being thus prepared, the cylinder of iron was successively placed at different distances from the magnet, and at each distance the degree of attraction between the iron and the magnet was ascertained by weights put in the opposite scale of the balance. The results were as follows, viz.

From the second and third experiments it appears, that,
when in contact, a magnet attracts another magnet with less
force than a piece of iron. This has been confirmed by
many other experiments. But the attraction between two
magnets begins from a greater distance than between the
magnet and iron; hence it must follow a different law of
decrement.

The attraction between a given magnet and a piece of
iron, is subject to a variation arising from the weight and
shape of the iron; there being a limit, in the weight and
shape of the iron, in which the magnet will attract it more
forcibly than either a greater or a smaller one; but this most
advantageous weight and extension of the piece of iron can
only be determined by actual experiment, it being various
according to the various nature, strength, and shape of the
magnet, as well as of the iron.

Magnetic attraction takes place between the magnet and
such ferruginous bodies as are not magnetic before, or be-
tween the contrary poles of two magnets; but when two
magnets are placed with their poles of the same name toward
each other, then, instead of attracting, they repel each other.
However, it often happens, that though the north pole of
one magnet be placed near the north pole of another mag-
net, or the south pole of the one be placed near the south
pole of the other, yet they attract each other; and some-
times they show no attraction nor repulsion.

In order to reconcile this apparent contradiction, it is ne-
cessary to mention first another phenomenon, which takes
place whenever a piece of ferruginous substance is brought
near a magnet; and which indeed is the foundation of, and
serves to explain a great many, other appearances, otherwise
unintelligible, in the science of magnetism.

The phenomenon, in short, is this: when a piece of iron,
or any other substance that contains iron, is brought within
a certain distance of a magnet, it becomes itself a magnet,
having the poles, the attractive power, and in short every
property of a real magnet. That part of it which is nearest
to the magnet acquires a contrary polarity; thus, if an ob-
long piece of iron, A B, be brought within a proper dis-
tance of a magnet, so that the extremity, A, of the iron may
be opposite the north pole of the magnet, then this same
extremity, A, will become a south pole, and the other ex-
trémity, B, will become a north pole.

The magnetism acquired by being placed within the influ-
ence or the sphere of activity of a magnet, in soft iron lasts
only whilst the iron continues in that situation, and when re-
moved from the vicinity of the magnet, its magnetism
vanishes immediately; but with hard iron, and especially
with steel, the effect is quite different; for the harder the
iron or the steel is, the more permanent is the magnetism
which it acquires from the influence of a magnet; but it
will be in the same proportion difficult to render it magnet.
If, for instance, a soft piece of iron and a piece of hard
steel, both of the same shape and size, be brought within
the influence of a magnet at the same distance, it will be
found that the iron will appear much more magnetic than
the steel; but if the magnet be removed, the soft iron will
instantly lose its magnetism, whereas the hard steel will pre-
vail for a long time.

From these observations two consequences are evidently
deduced, viz. first, that there is no magnetic attraction but
between the contrary poles of two magnets; for the iron,
or other ferruginous body, that is presented to the magnet,
must become itself a magnet before it be attracted: and se-
condly, it appears why a magnet must attract a piece of soft
iron more forcibly than hard iron, and much more than hard
steel, viz. because the hard iron, and more especially the
hard steel, does not become so strongly magnetised as soft
iron, when presented to a magnet.

We may now resume the subject of magnetic repulsion,
and shew why the magnetic poles of the same name may re-
pel, attract, or not act at all, upon one another.

Indeed, the law of repulsion being always exerted between
magnetic poles of the same name, nearly as strongly as the at-
traction between those of different name, remains certain
and immutable; but it often happens, that one of the mag-
nets, being more powerful than the other, will change the
pole of that other magnet, in the same manner as it gives
magnetism to any other piece of iron which is exposed to its
influence, and then an attraction will take place apparently
between magnetic poles of the same names; though in fact it
is an attraction between poles of different names, because one
of them has been actually changed. Thus, suppose that a
powerful magnet be placed with its north pole very near the
north pole of a weak magnet; it will be found, that instead
of repelling, they will attract each other, because that part
of the weak magnet, which before was a north pole, has
been changed into a south pole by the action of the strong
magnet.

As those bodies which are poiffed of any magnetism can-
not be very readily affected by the influence of another mag-
net, for the very same cause which renders them capable of
retaining any magnetism at all, namely, the hardness; and,
as the power of a magnet diminishes in proportion to the
distances from its surface, it follows, that when the north
or south pole of a weak magnet is from a considerable dis-
tance, gradually brought near the like pole of a powerful
magnet,
Magnet.

magnet, the pole of the weak magnet cannot be changed very easily; hence, beyond a certain distance, viz. before the said pole be changed, the two magnets must exert a repulsion against each other; but when the small magnet has been brought to near the powerful one, as that its pole may begin to be changed, then neither an attraction nor a repulsion will take place; and when the two magnets are approached nearer than that limit, then, the pole of the weak one being changed, an attraction will ensue.

After these observations, the ingenious reader may easily imagine that the decrease of repulsion between homogeneous magnetic poles must be at least as much, if not more irregular than the decrease of the attraction at different distances. It is likewise evident, that many objects must be had in view, in attempting to investigate the law of attraction.

5. If a magnet be cut through the axis, the parts or segments to the flone, which before separated, will become contrary poles; one in one, the other in the other segment. 7. Iron is not only attracted by a magnet, even more than another magnet, and equally attracts it, but also receives virtue from the magnet by application to it, or bare iron, from an approach near it, though it do not touch it; and the iron receives this virtue variously, according to the parts of the flone it is made to touch, or even but to approach to; the part of the iron or steel which is nearest to the magnet acquiring the contrary polarity, &c.

In order to communicate the magnetic virtue more effectually, the following methods are made use of: viz. it has been discovered, that iron rubbed upon one of the poles of the magnet acquires much greater virtue than from any other part of it; and this is more confiderable from an armed magnet than from a naked one. Farther, the difficulty of excitation is much greater the iron is prelled, and the nearer it is placed against the pole, the more will its virtue impart itself. Again, if it is more convenient to impregnate iron on one pole, than on both sides successively; because the iron receives magnetic virtue from each pole, in contrary directions, which destroy each other's effects. Moreover, the iron is much better impregnated by prelssing it uniformly and in the same direction, according to its length, than by rubbing it by the middle; and the extremity which touches the pole last, retains the greatest virtue: it is also of importance, that the length of the iron be considerable. Besides, a piece of polished flone, or of pointed iron, receives more virtue than bare iron, or iron of the same figure: and, ceteris paribus, a piece of iron that is long, small, and pointed, is more strongly impregnated than that of any other form. 8. If an oblong piece of iron be any way applied to the flone, it receives virtue from it, only as to its length. The magnet loses none of its own virtue by communicating any to the iron, but has it rather improved; though this is doubted by Mr. Savery; and this virtue it can communicate to the iron very speedily: though the longer the iron touches or joins the flone, the longer will its communicated virtue remain in it; and a better magnet will communicate more of it, and sooner, than one not so good.

It is obvious that when the iron, steel, or any ferruginous body is applied in contact with the magnet, it acquires a stronger power than if it be placed at some distance from its surface. A magnet cannot communicate a greater power than itself possesses, or even an equal degree of it; but several magnets, of nearly an equal degree of magnetism, when joined together, have a stronger power than one of them singly: hence, in order to impart a stronger magnetic power to a given body A, by means of a weak magnet B, we must first render several bodies, C, D, E, F, &c. weakly magnetic; and then, by properly joining C, D, E, F, &c. together, we may communicate to another body, or several other bodies, a stronger magnetism, till, at last, we shall be able to communicate to A the required degree of magnetic power.

The late Dr. Gowin Knight practised a method, which he never published, of communicating to iron a very considerable magnetic virtue, and also of increasing that of feeble magnets. From a report delivered to the Royal Society in 1744, it appears that he had prepared a small eight-cornered bar of steel, three inches and almost 1/3 this long, and about half an ounce troy in weight, which lifted by one of its ends about eleven of the same ounces; that another plain bar of steel, of a parallelopiped form, 5/8 inches long, 1/8 of an inch broad, and 1/8 of an inch thick, weighing 2 ounces 8 1/2 penny-weights, lifted, in like manner, by one of its ends, twenty troy ounces; that a steel bar, almost of the same form as the last, but only four inches in length, capped or armed with iron at each end, cramped with silver, and weighing all together one ounce fourteen penny-weights, lifted by the feet of the armour full four pounds troy; and that a single block of steel, of a parallelopiped form, almost four inches long, 1 1/2 high, and 1/8 of an inch thick, armed with iron, cramped with brass, and fulpended by a ring of the same, and weighing all together fourteen ounces one penny-weight, lifted by the feet of the armour 14 pounds 2 1/2 ounces troy weight. He also exhibited a compound artificial magnet, consisting of twelve bars of steel armed, which lifted by the feet of the armour, as the last, 23 troy pounds 2 1/2 ounces. At the same time he presented before the Society a small armed load-flone, which, with its armour, weighed seven penny-weights fourteen grains, and when cramped, but "unarmed" by his method, it sustained fix ounces eighteen penny-weights and three grains. See Armed Magnet, and Artificial Magnet.

10. Iron will receive magnetism more easily than steel; the soft steel receives it much more easily than the spring-tempered, and the spring-tempered much more easily than the hard: but a piece of spring-tempered steel will not retain near so much magnetism, and is therefore incapable of being excited to the same degree as hard steel; soft steel will retain it ill all; and iron, which is the softest of all, and in which the acquired magnetism is the strongest, scarcely retains any, when it is removed from the influence of the magnet. Other ferruginous bodies preserve it for a longer or shorter time, according as they participate more of the nature of hard steel, or of that of soft iron. Mr. Michell has evinced the truth of these observations both by reasoning and experiment. There are other bodies, besides iron and steel, which are susceptible of magnetism; these are probably no other than iron in some shape or other, or bodies that have a mixture of them; such as all sorts of iron ore after ignition, and some before. It is observable, that several of the hard ores of iron, which are not affected in the least by the magnet in their natural state, are vigorously attracted by it when moderately roasted; that the calecs of iron, by flight roasting with inflammable additions, are made to obey the load-flone, and revived into their metallic form, each particle appearing now to be perfect iron; whilst the calecs of other metals are in no degree revived, without being brought into fusion.

The ores of iron are attracted more or less readily, according as they contain a greater or a smaller quantity of metal, and as that metal is in a more or less perfect metallic state. By the action of fire, iron ores are generally put into a flake
MAGNET.

a state of being much more readily attracted. The scales which are separated from the surface of red-hot iron when hammered, and the particles of burnt steel that are produced from the colliion of a flint and iron, are attracted by the magnet nearly as well as pieces of good iron that equal them in bulk. The black cals of iron is attracted very weakly. The red cals, or ruff, whether it be produced by the action of acids, of fire, or by exposure to the atmosphere, is attracted very little; but it never becomes quite infensible of the magnet’s action, though it be repeatedly washed and purified. It is observable, that a quantity of iron is attracted with the least force, when reduced into the smallest bits, or fine powder. The ores of other metals are generally, though weakly, attracted by the magnet; thus indicating that they contain some iron: tuch are the ores of lead, of tin, and of copper. Native cinnabar is likewise attracted; but the factitious cinnabar is not. The pure metals are not attracted. Of the pure metals, zinc, bismuth, and particularly cobalt, as well as their ores, are all modestly attracted by the magnet. Antimony, unless it be first exposed to a gentle fire, is not attracted. Arsenic is not attracted at all. A certain kind of bismuth poises a singular property of being repelled on every side by the magnet. The other minerals, besides the metallic, are all modestly attracted by the magnet, at least after having been exposed to the action of fire. Of the pure earths, the calcareous is least, or not at all, and the siliceous the most frequently, attracted.

There are also several sorts of heavy, shining, opaque, black, or dark-chocolate-colored sand, most of which, if not all, are iron ores, which are susceptible of magnetism. Of this kind is the dark-brown sand in emery: we may all refer to this class all sorts, and several other metals; and bricks that have been much burnt in the fire. The magnetism of these is probably owing to a small quantity of iron mixed with them. What is in the brash, Mr. Michell conjectures, may come from the lapis calaminaris, which is said to have often a small mixture of iron in it; but Mr. Arderon, who has succeeded in giving magnetism and polarity to brash, has doubts as to the mixture of iron with brash: particularly, because brash fluxes with a much less degree of heat than iron, and iron naturally swims in fluid brash. Phil. Trans. vol. 1. p. 774.

Mr. Cavalcio made several experiments, with a view of ascertaining the magnetism of brash, and investigating the cause of it. The result is as follows: It appears, he says, "31. That the acquired magnetism is not owing to particles of iron or steel imported to the brash by the tools employed, or naturally mixed with the brash.

32. Tho. pieces of brash which have that property, retain it without any diminution after a great number of repeated trials, viz. after having been repeatedly hardened and softened. But I have not found any means of giving that property to such brash as had it not naturally.

33. A large piece of brash has generally a magnetic power somewhat stronger than a smaller piece; and the flat surface of the piece draws the needle more forcibly than the edge or corner of it.

34. If only one end of a large piece of brash be hammered, then that end alone will disturb the magnetic needle, and not the rest.

35. The magnetic power which brash acquires by hammering has a certain limit, beyond which it cannot be inerased by further hammering. This limit is various in pieces of brash of different thicknesses, and likewise of different quality.

7thly. Though there are some pieces of brash which have not the property of being rendered magnetic by hammering, yet all the pieces of magnetic brash, that I have tried, lose their magnetism, to a certain degree, when the needle, by being made red-hot; excepting indeed when some pieces of iron are concealed in them, which sometimes occur: but in this case, the piece of brash, after having been made red-hot and cooled, will attract the needle more forcibly with one part of its surface than with the rest of it; and hence, by turning the pieces of brash about, and presenting every part of it successively to the suspeded magnetic needle, one may easily discover in what part of the iron is lodged.

8thly. In the course of my experiments on the magnetism of brash, I have twice observed the following remarkable circumstance: A piece of brash, which had the property of becoming magnetic by hammering, and of losing the magnetism by softening, having been left in the fire till it was partially melted, I found, upon trial, that it had lost the property of becoming magnetic by hammering; but having been afterwards fairly fused in a crucible, it thereby acquired the property it had originally, viz. that of becoming magnetic by hammering.

9thly. I have likewise often observed, that a long continuance in a fire for a long time is to be little short of melting-hot, generally diminishes, and sometimes quite destroys, the property of becoming magnetic in brash. At the same time, the texture of the metal is considerably altered, becoming what some workmen call rotten. From this it appears, that the property of becoming magnetic in brash by hammering, is rather owing to some particular configuration of its parts, than to the admixture of any iron; which is confirmed still farther by observing, that Dutch plate brash, which is made not by melting the copper, but by keeping it in a strong degree of heat whilst surrounded by lapis calaminaria, allo polishes that property; at least, all the pieces of it, which I have tried, have that property.

From these observations it follows, that when brash is to be used for the construction of instruments wherein a magnetic needle is concerned, as dipping needles, variation compasses, &c. the brash should be either left quite soft, or it should be cozen of such a sort as will not be made magnetic by hammering; which sort, however, does not occur very frequently."

For the remarks of Mr. Bennett on Cavalcio’s experiments, and the reply of the latter, we refer to the Phil. Trans. for 1732, and the appendix to Cavalcio’s Magnetism. This author examined other metallic substances, viz. copper, zinc, and platina. The two former manifested no signs of magnetic: and of various pieces of platina, none did not acquire any magnetism by hammering, and others were rendered evidently attractable by the magnet by three or four strokes, and about ten strokes gave them the full power of which they were susceptible. But when the grains of platina that were capable of being attracted by the magnet under the operation of hammering were put upon a charcoal fire, and made red-hot by means of a blowpipe, and were afterwards presented first to the magnet and also to the suspeded needle, they shewed not the least sign of attraction. Heat, therefore, deprives them, as well as brash, of the property acquired by hammering. Mr. Cavalcio concludes upon the whole from experiments of this kind, that the power of being attracted by the magnet may exist, or may belong to other substances, independent of iron; and therefore that the attraction of a few
MAGNET.

Some particles of any unknown substance by the magnet is not a sure sign of the presence of iron. Although it be true, that iron is always attractable by the magnet, yet it does not hence follow, that whatever is attracted by the magnet must be iron.

Amber, and other combustible minerals, are generally attracted by the magnet, especially after burning. Of the precious stones, those that are transparent, as the diamonds and crystals, are not attracted. The amethyst, topaz, chalcedony, and generally those which are deprived of their colour by fire, are not attracted. The other precious stones are all attracted, viz. the ruby, especially the oriental, the chrysolite, and the tourmaline. The emerald, and particularly the garnet, are not only attracted, but frequently acquire an evident polarity from the influence of a strong magnet, so that afterwards they are attracted from one side, and repelled from the other. The opal is but weakly attracted. Almost every part of animal or vegetable bodies, after combustion, is in great measure attracted by the magnet. The flesh, and especially the blood, after burning, are attracted most, but the bones are attracted least powerfully. The vegetables, after burning, are almost all, though not with equal force, attracted by the magnet. But unburned and moist animal or vegetable substances very seldom, if ever, show any perceptible attraction towards the magnet. Even foot, and the duft which usually falls upon whatever is left exposed to the atmosphere, are feebly attracted by the magnet. Hence it appears that iron, though divided into exceedingly small particles, is in some state or other mixed with every substance; that it is to be found in all substances, in vegetables, in minerals, and even in the air; that in every state of existence it always shews some attraction towards the magnet; that its existence in several substances can be discovered by no other method besides the magnet. But we have already observed, that there is reason for supposing, that some bodies independently of iron, are attracted by the magnet.

11. A needle touched by a magnet will turn its ends in the same way towards the poles of the world, as the magnet itself does. 12. Neither the load line nor needles touched by it do conform their poles exactly to those of the world, but have usually some variation from them; and this variation is different in divers places, and at divers times in the same place. (See Declination, Dipping, and Variation.) 13. A load-line will take up much more iron when armed or capped, than it can when naked. See Arms and Armed Magnet.

It has also been observed, that amongst the natural magnets, the smallest generally poifes a greater attractive power, in proportion to their size, than those which are larger. There have been often seen natural magnets not exceeding the weight of 20 or 50 grains, which could lift a piece of iron that weighed 40 or 50 times more than themselves. Mention is made of a small magnet wore in a ring, which weighed about three grains, and was capable of taking up 746 grains, or nearly 250 times its own weight; and we have seen one which could not weigh more than fix or seven grains, and was capable of lifting a weight of about 300 grains. But magnets of above two pounds weight seldom lift up ten times their own weight of iron.

It often happens, that a natural magnet, cut off from a larger load-line, will itself be capable of lifting a greater weight of iron than the original large load-line from which it was cut off. This must be imputed to the heterogenous nature of the large load-line; for, suppose that one part of it contains a good quantity of pure metal strongly magnetic, the rest of it being impure or mixed with other substances, it is plain that the impure part can only obstruct the action of the purer part; hence this latter, being separated from the rest, must act more powerfully than the whole together did.

14. The force of a magnet may be variously increased or lessened by the various application of iron, or another magnet, to it. Thus, the holding of a piece of iron of some magnitude to one pole of a magnet, incrases the attraction of the other pole, so as to enable it to lift a greater weight. Also, the attractive power of a magnet may be increased considerably by gradually adding more and more weight to it; for by this means it will be found that the magnet will keep suspended on one day a little more weight than it did the preceding day; which additional weight being added to it on the following day, or some time after, it will be found that the magnet can keep suspended a weight still greater, and so on as far as a certain limit.

On the contrary, by an improper situation, or by putting a very small weight of iron into it, the magnet may gradually lose much of its strength.

Heat weakens the power of a magnet; and a white heat destroys entirely, or at least in a great measure. Hence it appears, that from this cause alone, besides others which may concur, the power of a magnet must be continually varying.

15. A strong magnet at the least distance from a leffer, or a weaker, cannot draw to it a piece of iron adhering actually to such leffer or weaker done; but if it come to touch it, it can draw it from the other; but a weaker magnet, or even a little piece of iron, can draw away or separate a piece of iron contiguous to a greater or stronger load-line.

16. In these northern parts of the world, as various authors have said, the north pole of a magnet generally has an attractive power somewhat stronger than the south pole; but in the southern parts of the earth, the south pole of the magnet is said to poise the greatest attractive power. However, this law has not yet been properly ascertained.

17. Neither the attraction nor the repulsion of magnetism is sensibly affected by the interpolation of bodies of any sort, except iron or ferrous bodies in general. Thus, suppose that when a magnet is placed at an inch distance from a piece of iron, there is required an ounce of force to remove it; or, which is the same thing, suppose that the attraction towards each other is equal to one ounce; it will be found that the same degree of attraction remains costantly unaltered. viz. always equal to one ounce, though a plate of other metal, or of glass, or paper, or other body, be interposed between the magnet and the iron; or though they be included in separate boxes of glass or other matter. Neither the absence or presence of air has any effect upon them. In short, no other substance besides iron, or those bodies which contain that metal in any of its metallic states, does sensibly affect the attraction or repulsion of magnetism. Accordingly, Mr. Boyle found this true in glass, as he felt hermetically; and glass is a body as impervious, as mull are, to any effluvia. The magnetic virtue is sensibly continued through the substance of several contiguous bodies or pieces of iron, as keys, &c. It prevails the pores of the hardest bodies; and equally attracts the iron in vacuo, as in open air.

18. It has frequently been observed, that bars, and other pieces of iron, by having remained a long time in one situation, have become magnetic. Sometimes iron bars, which were not capable of a permanent magnetism on account of their softness, have in time, and by being left exposed to the atmosphere in a due situation, acquired a considerable degree of magnetism; but it has been also remarked,
MAGNET.

acquires either none at all, or a very small degree of magnetism.

For these experiments, the bars or needles must be proportioned to the degree of electric power; otherwise they will not succeed. See Van Maren's account of a very powerful electrical machine, constructed for the Museum of Teyler at Haarlem; and Cavallo's Treatise on Electricity, vol. i. p. 66, and vol. ii. p. 282.

Hence, a stroke of lightning, which is an electrical phenomenon, often renders magnetic pieces of iron, or steel, or those bodies which contain iron, as certain bricks, &c.

If one pole of a magnet, for instance the north, be applied to one end, C, of an oblong piece of iron or steel, like C D (fig. 4) that end, C, will become a south pole; and if the bar, C D, be very long, there will be found a part of it, to far distant from C, which is poleless of the north polarity; and this is followed by another part poleless of the south polarity; and so on alternately, till the power becomes imperceptible; the number of those successive poles depending upon the strength, and principally upon the length of the bar; but if the bar be of a proper length and thickness, which must be likewise proportioned to the strength of the magnet employed, then the bar will have only two poles, its other extremity, D, acquiring the north polarity.

In the latter case, if the pole of the magnet be gradually moved along the surface of the bar from C as far as D, it will afterwards be found, that the polarity of the bar is entirely changed, the extremity, C, being now poleless of the north, and the extremity, D, of the south polarity.

It is evident, that, whilst the magnet is advancing along the surface of the bar, the south polarity of the end C, before it changes into a north polarity, must decrease in strength; and that when the magnet is at a certain point M, the end, C, has no polarity at all; its south polarity being just vanished, and the north polarity just beginning. With respect to the extremity, D, it must be observed, that its north polarity, by the approach of the magnet, is increased as far as a certain limit H; after which, as the magnet comes still nearer to D, the north polarity of this extremity decreases, till it vanishes when the magnet is arrived at a certain point N; after which its north polarity begins to be changed into a south one.

The points, M and N, have been called the points of indifference; because, when the magnet is at M, the extremity, C, of the bar has neither the south nor the north polarity; and when the magnet is at N, the end, D, has no polarity. The point, H, has been called the culminating point, because, when the magnet is at that point, the polarity first acquired by the end, D, of the bar is the strongest.

As the determination of these points, in bars of different sorts of iron, of different lengths, &c. not only shews more evidently the action of the magnet, and points out the advantages and disadvantages attending the practical methods of making artificial magnets, but is besides likely to open the way to further discoveries; there have been no pains spared to investigate the particulars on which their situation depends, and a vast number of accurate experiments have been made for that purpose; but, notwithstanding those endeavours, such is the various nature of magnets, of iron, &c. that the present knowledge of the subject does not allow these points to be determined in a given bar, without actual experiments. The general laws which may be deduced from the various experiments made for this purpose, are the following:

1. The points M, H, and N, do not come always in the order shown by the figure; but though their order is not always the same, yet it is evident that the point, H, can never...
Magnet.

never coincide with, or come after N, c.e. nearer to the end D, than the point N.

2. When the bars differ in length only, every thing else being the same, the longer the bar is, as far as a certain limit, which depends on the strength of the magnet employed, the greater is the distance C M.

3. The stronger the magnet is which is employed, the greater is the distance C M, as far as a certain limit, which depends upon the proportion between the power of the magnet and the length of the bar; and beyond which limit C M will be shorter than if a weaker magnet had been used.

4. When the bars differ in length only, every thing else being the same, the distance, C H, is greater in a longer bar, as far as a certain limit, which depends as has been mentioned above.

5. The stronger the magnet is which is used, the greater is the distance C H, as far as a certain limit, which depends as above.

6. In a longer bar, every thing else being the same, the distance, C N, is greater than in a shorter one, as far as a certain limit, &c.

7. The distance C N, in bars of equal length, is greater when a stronger than when a weaker magnet is used, as far as a certain limit, &c.

8. When the bars differ only in thickness, every thing else being the same, the distance, C M, is greater in thicker than in thinner bars; but the distance, C N, is nearly the same in them all, as far as a limit, which depends as before-mentioned.

9. Lastly, when the bars differ only in hardness, the distances C M, C H, C N, are sometimes equal, sometimes greater, and sometimes shorter, in the harder than in the softer bars.

Besides the points of indifference and culmination, there is another point to be considered, namely, the magnetic centre, which is the point or part between the two poles, where the magnet has no attraction nor repulsion. With respect to this point, we shall briefly observe, that it does not always lie midway between the two poles; and that, when one pole of a magnet is drawn over the surface of an oblong piece of iron, as in the before-mentioned experiment, the magnetic centre moves forwards in proportion as the magnet is advanced; but at a certain limit, both the magnet and the said centre are in the same place, or rather in opposite sides of the thickness of the bar. The motion and place of the magnetic centre are subject to a great deal of variety, arising from the nature, length, and thickness of the bar, as well as from the strength of the magnet, and from the manner of drawing it along the surface of the iron or other ferruginous body.

When any magnet, but especially an oblong one, having two poles, is broke in two, the magnetic centre of each part is at first generally much nearer that end of the piece which is contiguous to the fracture; but in time it advances nearer the centre of the piece.

What has been observed concerning oblong pieces of iron or steel, may serve to explain the phenomena which take place in pieces of an irregular form; the particular enumeration of all which cases would be endless, and of little, if at all of any use.

Every piece of iron or ferruginous body is capable of retaining only a certain degree of magnetic power; so that if a strong magnet be applied to a comparatively small piece of steel, that piece, whilst it remains within the influence of the magnet, will appear to be very powerfully magnetic; but, as soon as it is removed from the vicinity of the magnet, its power begins to decrease, and in a short time comes down to that degree which the piece of steel is capable of, and which may be called its point of saturation. Hence it follows, that if a certain magnet is just sufficient to communicate to a piece of iron or steel the full power of magnetism of which that piece is capable, a stronger magnet will not increase it in the least.

19. The power or virtue of a magnet, and of iron or steel impregnated with the magnetic virtue, may be impaired by long lying in a wrong position, with regard to the earth or with respect to each other. Thus, if two magnets be placed so, that their contrary poles may be contiguous to each other, they will preserve one another’s power; but if the north pole of one be placed near the north pole of the other, and the south near the south, then they will entirely destroy or diminish each other’s magnetism; and if their original powers were very unequal, the polarity of the weaker magnet will be changed by the action of the stronger one.

In general, the same means which facilitate the communication of magnetism, when pieces of iron, &c. are properly situated with respect to the poles of the earth, or of other magnets, will likewise facilitate the loss of magnetism, when the magnets are improperly situated; thus, a red heat destroys in a great measure, or entirely, the power of a magnet. A steel bar, strongly magnetic, will have its power much diminished by being repeatedly thurc between two flumes, especially if it be struck finding in a direction perpendicular to the magnetic meridian. A bar of pretty hard iron, which has acquired some degree of permanent magnetism, by being made red hot, and then cooled in the direction of the magnetic line, will have that power destroyed, or much diminished, by a few small blows on its middle.

20. Some have said that iron or steel has been rendered heavier or lighter by being magnetic; but Gaffendus, Mercenius, and Gilbert maintain the contrary; and it seems to be allowed, upon the whole, that its weight is not thus affected. Mr. Whilton says that he found, by accurate experiments with large needles, that after the touch they weighed less than before. One of 4384/8 grains lost 27 grains by the touch; and another of 5750 grains lost no less than 14 grains. Cavallo suggests, that the vicinity of iron, or of some other ferruginous body, might have some action on the magnetic steel when it was weighed.

21. A piece of iron wire, well touched, will, upon being bent round in a ring, or coiled round on a fliick, &c. generally quite lose its directive virtue; but it will always have it much diminished: and yet if the whole length of the wire was not entirely bent, so that the ends of it, though for the length of one-tenth of an inch, were left straight, the virtue will not be destroyed in those parts: though it will in all the rest. This was first observed by Meffrs. Grimaldi and De la Hire; and is confirmed by the experiments of Dr. Derham; who adds farther, that though coiling or bending the wire as above would always destroy its virtue by day, yet it would not do in the evening. In order to weaken or destroy the magnetism of a wire by bending, let the magnetic power be communicated to an iron or soft steel wire, of about four or five inches in length, and about 1/4 of an inch in diameter: then roll it round a small fliick, so as to make four or five revolutions round the fliick; after which, on straightening the wire again, its magnetism will be generally found to be quite destroyed by the bending, or considerably weakened.

The effect is the same with shorter or longer wires; for
MAGNET.

if they make one revolution round the fick, the effect will take place; which is evidently owing to the fires or derangement of the particles of the wire, as is rendered more evident by the following observation; viz. that if the wire be of such springy nature, as to recover its straight situation, if left to itself, after coiling it round the fick, then its magnetism is either not at all, or little diminished: so that, in order to produce the above-mentioned effect, a train of the parts of the wire is absolutely necessary.

When only the middle of the wire is bent, and its extremities remain straight, then the magnetism is seldom destroyed, or even diminished.

If the magnetic wire be cleft or split lengthwise, the parts will sometimes contrary, and sometimes the same poles as they had when in one piece. When one part is much thinner than the other, then this slender part will generally have its poles reversed.

22. The sphere of the activity of magnets is greater and left at different times: in particular that preferred in the repository of the Royal Society will keep a key or other body suspended to another, sometimes at the height of eight or ten feet; and at others, not above four feet. (See 4 above.)

To which we may add, that the variation of the magnetical needle from the meridian varies at various times of the day, as appears from some experiments of Mr. Graham. See Declination and Variation.

23. The directive power of a magnet is extended to a greater distance than its attractive power; for instance, if a magnet be freely suspended, another magnet properly situated within a certain distance of the former, will turn it out of its wanted direction; yet the degree of attraction exerted by these magnets against each other, is not sensible at that distance; which may be easily tried; by fixing one of the magnets to the fcale of a balance. The reason of this property is, that the directive power depends both upon the attraction of the poles of different names, and on the repulsion of those of the same name; whereas, the attraction takes place only between poles of different names. In order to render this explanation more intelligible, imagine that a magnetic needle is freely suspended, and is placed within the influence, or sphere of action of a magnet. In this disposition, suppose that the north pole of a magnet attracts the south pole of a magnetic needle with a force equal to ten grains; and, as the attraction between poles of different names is nearly equal to the repulsion between poles of the same name, it follows, that the same north pole of the magnet repels the north pole of the magnetic needle with a force equal to ten grains; but these two forces both concur in altering the direction of the needle; therefore, the endeavour of the magnet to turn the needle's direction is equal to 20 grains; whereas the attraction, or the force by which the needle is drawn towards the magnet, is only equal to the difference between the two above-mentioned opposite forces, which difference arises from the pole of the magnet being nearer to one than to the other of the poles of the needle. The same reasoning may be applied to the action between the fourth pole of the magnet and the suspended needle.

24. By twisting a piece of wire touched with a magnet, its virtue is exceedingly diminished, and sometimes so disordered and confused, that in some parts it will attract, and in others repel; and even in some places, one fide of the wire seems to be attracted, and the other side repelled by one and the same pole of the ftone. The effect of magnets on a crooked wire may be shewn in the following manner. Let an iron wire of about a quarter of an inch in diameter, and four or five inches long, be bent somewhat like a Gothic arch; viz. with a sharp corner in the middle, A B C, 1/5; and tie it fast to a crofs bar, or let an affiant hold it with the corner downwards; then apply either pole of the magnet, D E, to one of its extremities A, and whilst the magnet remains in that situation, apply a piece of iron, H, of no great size, to the corner C, and you will find that the iron remains suspended. Now, if another magnet be applied to the other extremity, B, of the crooked wire, fo that the pole, G, may be contrary to the pole E, the iron, H, will immediately fall off; but if the pole, G, be analogous to the pole E, viz. be both south, or both north, then the iron, H, not only will not remain adhering to C, but the faid corner will be capable of supporting a weight fll over which will fupport it. The felfe thing which is, that in the former cafe, the extremities, A, B, of the bent wire being placed of different polarities, the corner, C, was the magnetic centre, where there is no attraction nor repulsion; whereas, in the second cafe, both extremities of the bent wire being posfemed of the fame polarity, the corner, C, was necessitated to acquire the contrary polarity; and in this cafe, the bent wire muft have two magnetic centres, viz. one on each fide. 25. A piece of wire that has been touched, being cleft or cleft lengthwise, in two, the poles are sometimes changed; as in a cleft magnet; the north becoming the fouth, and the fouth the north: and yet sometimes one-half of the wire will retain its former poles, and the other half will have them changed. When one part is much thinner than the other, then the slender part will generally have its poles reversed. (See No. 21 supra.) To which it may be added, that laying one or other fide of the half uppermoft, caufes a great alteration in its tendency or a\viation to the poles of the magnet.

26. A wire being touched from end to end with the fame pole of the magnet, the end at which you begin will always be contrary to the pole which it touched; if it be again touched the fame way with the other pole of the magnet, it will then be turned the contrary way. 27. If a piece of wire be touched in the middle with only one pole of the magnet, without moving it backwards or forwards; in that place will be the pole of the wire, and the two ends will be the other pole. 28. If a magnet be heated red-hot, and again cooled either with its south pole towards the north in a horizontal position, or with its south pole downwards, in a perpendicular position, its poles will be changed. 29. Mr. Boyle (to whom we are indebted for the following magnetic phenomena) found he could probably change the poles of a small fragment of a load-foine, by applying them to the opposite vigorous ones of a large magnet. Dr. Knight discovered a method of changing the dire{tion of the poles in natural magnets, multiplying and variously placing them at pleasure. In the first instance, recorded in the Philosophical Transactions, he inverted the poles of a magnet by a process which required only a minute's time; so that the fame end, which before attracted the south end of the needle, now attracted the north end, and vice verfa; in the fame time he again turned the direction of the polarity of the ftone at right angles, to its former dire{tion; and afterwards inverted this falt direction of the poles. In the second series of experiments, he cut a piece of natural load-foine into the shape of a paralleloiped, 1/5ths of an inch long, 1/5ths of an inch broad, and 1/5ths of an inch in thickness; its weight was three dramis and ten grains. In this ftone he placed the magnetical virtue in fuch a manner, that the two opposite ends became, both of them, fouth poles, and the middle was quite round a north pole. The two opposite ends of another ftone were made both north poles, and the two oppofite sides fouth poles. At one end of another ftone he placed a north pole, surrounded by a fouth; and at the other end a fouth, surrounded by a north pole; fo that the edges of each
Magnet.

each surface had a pole of a different denomination from that which occupied the middle. On another occasion, he inverted the poles at the ends of a piece of magnet, and then transferred them to the sides of the stone. All these changes of the poles are easily produced by steel bars, A B, C D. (Plate VI. Magnetism, fig. 6.) impregnated with a strong magnetic virtue, by which the piece of magnet, E F, placed between them is so affected, that the poles may be changed at pleasure, and excited in places that are touched by the ends of the bars. Mr. Michell has shown the method of doing this both in small and large magnets. If a small and short magnet is to have its poles changed, lay the supporters described under Armed Magnets (6), that the centre of their force shall, at each end, lie at the end of the line designed to be the axis of the magnet, and touch it double in the manner explained under Artificial Magnet, as near as may be in that direction. If the poles are to be converted, and the magnet be long enough, touch it double, according to the directions for converting the poles of an artificial magnet; then support it, and touch it over again with fresher touches: or if the magnet is short, apply bars as supporters only, and change them two or three times; or else make use of the following method, applicable to large magnets. If the poles of such are to be changed, the middle of the end of the piece of iron placed at each end of the magnet (see Armed Magnet) is to be placed against the end of the line designed to be the axis. If the poles are to be converted, it should be done first by touching double, if a sufficient force of magnetic bars can be applied for this purpose: but if, by touching double, the poles will not be converted, place the magnet between two pieces of iron, then keeping them steady at their distance, remove the magnet, and connecting the pieces of iron by wedges of iron, that may not stand in the way of it, when it is to be put in its place again, apply the supporters as before, and putting the magnet in its place, take off the iron wedges. This may be done two or three times, if it be found necessary, re-touching the supporters every time. (See Artificial Magnet.) It is well known, that lightning not only destroys, but reverses, in some cases, the poles of magnetic needles. 30. Hard iron tools, well tempered, when heated by a brisk attrition, as filing, turning, &c. will, while warm, attract thin filings, or chips of iron, steel, &c. though not when cold; though there are not wanting some instances of their retaining the virtue when quite cold. 31. The iron bars of windows, &c. which have flooded a long time in an erect position, grow permanently magnetic; the lower end of such bars being the north pole, and the upper end the southern. 32. A straight bar of soft iron (e.g. one of two or three feet in length, and about 2ths of an inch in diameter), that has not flooded long in an erect posture, if it be only held, in these parts of the world, in a vertical position, will become magnetic; and its lower end the north pole; as appears from its attracting the south pole of a needle; and the upper end the south pole, being capable of repelling the south pole: but then this virtue is transient, and by inverting the bar, the poles will shift their places. An iron bar of four or five feet in length, and above an inch thick, in this situation, will be capable of attracting a small bit of iron, or a common sewing-needle.

The explanation of this curious phenomenon is as follows: since, in these northern parts, the earth is possessed of a fourth magnetic polarity, the lowest part of the iron bar, being nearest to it, must acquire the contrary, viz. the north polarity; the other extremity of the bar becoming a south pole. It follows, likewise, (and it is confirmed by actual experiment), that in the southern parts of the earth, the lowest part of the bar acquires the south polarity; that on the equator the bar must be kept horizontal, in order to let it acquire any magnetism from the earth; and that, even in these parts of the earth, the most advantageous situation of the bar is not the perpendicular, but that a little inclined to the horizon. In short, in every part of the world, it must be placed in the magnetic line, viz. in the direction of the dipping-needle. If the iron bar, instead of being kept in the magnetic line, be placed in a direction perpendicular to it, then it will acquire no magnetism, because, in that situation, the actions of both poles of the earth upon each extremity of the bar are equal. If, instead of the above-mentioned two directions, the bar be placed in any other position, then it will acquire more or less magnetic power, according as it approaches nearer to the former or to the latter of the said two directions.

A bar of hard steel, or of hard iron, does not acquire any magnetism from the earth, like the bar of soft iron, because the magnetic power of the earth is weak, in proportion to that which is required, in order to render a steel bar magnetic. In order, therefore, to render the quality permanent in an iron bar, it must continue a long time in a proper position. But the fire will produce the effect in a short time: for as it will immediately deprive a load-stone of its attracting virtue, so it soon gives a verticity to a bar of iron, if, being heated red-hot, it be cooled in an erect posture, or directly north and south. Nay, tongs and pliers, by being often heated and set to cool again in a posture nearly erect, have frequently gained this magnetic property. It is a well-known proposition, that soft iron, or soft steel, acquires magnetism very easily, and loses it with equal facility; but that hard steel acquires that power with difficulty, and afterwards retains it obstinately. From the consideration of these properties, Mr. Cavallo was led to imagine, that if a piece of steel, whilst red-hot, were placed between magnetic bars, and whilst standing in that situation, cold water were to be suddenly poured upon it, so as to harden it, there might, perhaps, be obtained an artificial magnet much more powerful than what can be produced in the ordinary way; because the magnetic bars employed for such purpose would communicate a great degree of magnetic power to the steel when red-hot, and consequently soft, which power would be fixed upon the steel by the hardening.

In order to put this project to the trial, five magnetic bars were so disposed, in an oblong earthen vessel, that the north poles of three of them might be opposite the south poles of the three others, forming two parcells of bars, lying in the same direction, and about three inches asunder, which was nearly the length of the steel bar which was intended to be rendered magnetic. Things being thus disposed, the steel bar was made quite red-hot, and in that state was placed between the magnetic bars; after which, cold water was immediately poured upon it, which rendered it so hard as not to admit being filed: its magnetism was found to be considerably strong, but by no means extraordinary. From repeated trials with steel bars of different sizes, and by using a greater or less number of magnetic bars, Mr. Cavallo found that short steel bars acquire a proportionally greater degree of magnetism, by this method, than those which were longer; that the magnetism in the longer bars is not proportionally as strong, principally because the artificial magnets, being placed at their extremities, have very little power on those parts of the pieces of steel which are near its centre; and, lastly, that when, in order to remedy the just-mentioned inconvenience, more magnets are placed nearer the middle of the steel bar, then this piece of steel generally acquires many succedaneous magnetic poles.

Upon the whole, it seems that though this method alone be
be not sufficient to communicate to steel bars an extraordinary degree of magnetism, yet it may be of great use in constructing large artificial magnets; for, if these bars, instead of being hardened in the usual way, by plunging them, when red-hot, in water, be hardened whilst flanging between powerful magnets, they will thereby acquire a considerable degree of magnetic power, without any additional trouble to the workman. They may then be polished, after which they may be rendered more strongly magnetic by the usual method of touching them with other magnetic bars; whereas it is a very laborious operation to render magnetic large bars of hardened steel from the very beginning, viz. when they have none of that power.

In the course of performing these trials, Mr. Cavallo frequently observed that the pieces of steel, whilst they were red-hot, seemed not to be attracted by the magnets; so that the leaf shook, and even the pouring of the water, could remove them from the proper situation, which rather forfeited him; because it has been affected by some authors, that the magnet attracts red-hot iron as well as cold. Kircher especially says, that he tried the experiment, (De Magn. lib. i. p. 2, theorem xxxiii.) and found that the piece of iron, heated so as to be hardly discernible from a burning coal, was attracted by the magnet as easily as when cold; and he even ascribes a reason why the power of a magnet is destroyed by a great degree of heat; whereas the red heating of the iron will not prevent its being attracted by the magnet. The reason he gives is, that the fire corrupts and calcines the magnet, but purifies the iron. The following experiments were made in order to ascertain this matter:

"I kept (says Mr. Cavallo) a piece of steel in the fire till it was quite red-hot, and in that state preferred the magnet to it, so as to touch it repeatedly in various places; but no sign of attraction could be perceived before the redness disappeared. I mean, however, such redness as may be evidently seen in the clear daylight; for, as was shown by other experiments, when the magnet begins to attract the heated iron, the redness of the latter can still be seen in the dark.

"Having repeated the experiment with different pieces of iron and of steel, the result was constantly the same, viz. whilst the iron or steel remained quite red-hot, or white-hot, the magnet did not attract it; but the attraction began when the degree of redness which is clearly perceivable in the daylight began to disappear; and it was as strong as ever when the iron was cooled a little more than when the redness quite disappeared in the dark. In regard to this limit, or maximum of attraction, I think I have observed, as well as the nature of the experiment would permit, a difference between steel and iron, which is, that in steel the maximum of attraction follows the disappearance of the red heat sooner than in iron.

"This experiment is subject to two sources of mistake, which, perhaps, misled Kircher, and which is necessary to mention, for the sake of others who wish to repeat it. The first is, that when a piece of iron, of no great extent, is red-hot, or even white-hot, in one place, and below a red heat in other parts, the magnet will frequently attract it, though the red heat be not preserved to it. The second cause of mistake is, that when a small piece of iron or steel, as a common sewing-needle, is made red-hot, and is then presented to the magnet, if the magnet touch it, the contact cools it instantly below the necessary degree of heat, and of course the attraction takes place. It is owing to this last cause, that I have not yet been able to ascertain, whether the attraction between the magnet and the iron be quite an

33. Mr. Boyle found, that by heating a piece of English ochre red-hot, and placing it to cool in a proper posture, it manifestly acquired a magnetic virtue. And an excellent magnet of the fame ingenious gentleman's having lain near a year in an inconvenient posture, had its virtue surprizingly impaired; as if it had been injured by fire. 34. A needle well touched, it is well known, will point north and south; if it have one contrary touch of the same file, it will be deprived of its faculty; and by another such touch, it will have its poles quite changed. 35. If a bar of iron have gained a verticity by being heated red-hot, and cooled again, north and south, and then hammered at the two ends; its virtues will be destroyed by two or three smart blows on the middle. Mr. Martin says, that by a smart stroke of a hammer on the un-touched end of the dipping-needle, he has often caused the whole magnetic virtue to come to that end from the other, so as to make it dip on that side as much as it did on the other before; or, on the contrary, by such a stroke he has sometimes made it dip much more on the touched end than before. Sometimes, by striking it, the needle, which dipped before, will be restored to its equilibriam, as if the virtue had
MAGNET.

had made its escape, or were uniformly diffused all over the needle. 36. By drawing the back of a knife, or long piece of steel wire, &c. leisurely over the pole of a load-stone, carrying the motion from the middle of the stone to the pole; the knife or wire will accordingly attract one end of the needle: but if the knife or wire be paffed from the said pole to the middle of the stone, it will repel that end of the needle which in the other case it attracts. 37. Either a magnet or a piece of iron being laid on a piece of cork, fo as to swim freely in water; it will be found, that whichever of the two is held in the hand, the other will be drawn to it; so that iron attracts the magnet as much as it is attracted by it: a motion and re-action being always equal. In this experiment, if the magnet be set about, it will direct its two poles to the poles of the world. 38. A knife, &c. touched with a magnet, acquires a greater or less degree of virtue, according to the part it is touched on. It receives the strongest touch, when it is drawn leisurely from the handle towards the point over one of the poles: and if the same knife thus touched, and thus in possession of a strong attractive power, be retouched in a contrary direction, viz. by drawing it from the point towards the handle over the same pole, it immediately loses all its virtue.

39. The attraction of iron towards the magnetic needle, or magnet, is increased to a certain degree by the action of vitriolic acid. The experiment, ascertaining this fact, is stated by Mr. Cavallo, who made this discovery of it, as follows: some pieces of iron, as filings, nails, &c. are put into an earthen pot, and the pot is placed laterally near one end of a field of magnetic needle; in consequence of which, that end of the needle will be drawn away from its natural direction, and will approach the pot more or less, according to the quantity of iron and vicinity of the pot. In this situation, if diluted vitriolic acid be poured upon the iron in the pot, so as to occasion a brisk effervescence, the needle will be found to come nearer to the pot during some minutes, after which it will gradually recede. This increased attraction is more or less, according to the quantity, surface, and vicinity of the iron, according to the briskness of the effervescence, &c. but with two or three ounces of iron filings, or with about fix ounces of nails, and a suitable quantity of diluted vitriolic acid, the needle may be expected to make a movement from about 15' to half a degree.

40. When first observed this phenomenon, I naturally supposed (says Mr. Cavallo) that the increased attraction might have been caused by a quantity of iron filings being brought by the violence of the effervescence nearer to that side of the pot which flood towards the needle; and to avoid this source of mistake, I tried the experiment with a single piece of wire instead of filings, and twirled the wire in various directions, so as to be admitted into the pot. This experiment was several times repeated then, and also very lately, and the iron was used in various forms, viz. nails, turnings, pieces of wire, &c. but the result has been invariably the same, namely, an increased attraction." Mr. Bennett has questioned the fact. See Phil. Trans. for 1792, p. 93.

41. Natural magnets may be imitated in the following manner: Take some martial æthiops, or, which is more easily procured, reduce into very fine powder the scales of iron, which fall from red-hot iron when hammered, and which are found abundantly in smith's shops. Mix this powder with drying linseed oil, so as to form it into a very stiff paste, and shape it in a mould so as to give it any form you require, whether of a terrella, a human head, or any other. This done, place it in a warm place for some weeks, and it will dry so as to become very hard. Then render it magnetic, by the proper application of powerful magnets, and it will acquire a considerable power.

We shall here subjoin some additional observations on the subject, extracted from the laws of magnetism, proposed by Mr. Wharton. An inclinatory, or dipping-needle, of six inches radius, and of a prismatic, or cylindrical figure, when it oscillates along the magnetic meridian, performs, according to Mr. W. every mean vibration in about 6' or 560"; and every small oscillation in about 5", or 530"; and the same kind of needle, four feet long, makes every mean oscillation in about 24", and every small one in about 22".

The entire power of magnetism in this country, as it affects needles a foot long, is, as he says, to that of gravity nearly as 1 to 500; and as it affects needles four feet long, as 1 to 600. And the quantity of magnetic power accelerating the same dipping-needle, as it oscillates in different vertical planes, is ever to the cosines of the angles made by those planes, and the magnetic meridian, taken on the horizon.

Thus, if we would estimate the quantity of forces in the horizontal and vertical situations of needles in London, we shall find that the latter, in needles a foot long, is to the entire force along the magnetic meridian, as 96 to 100; and in needles four feet long, as 9657 to 10000: whereas in the former, the entire force in needles a foot long is as 28 to 100; and in those four feet long, as 2595 to 10000. Whence it follows, that the power by which horizontal needles are governed in these parts of the world, is but one quarter of the power by which the dipping needle is moved.

Hence, also, since the horizontal needle is moved only by a part of the power which moves the dipping-needle; and that it only points to a certain place in the horizon, because that place is the nearest its original tendency of any its situation will allow it to tend to; whenever the dipping-needle stands exactly perpendicular to the horizon, the horizontal needle will not deflect one point of the compass more than another, but will wheel about every way uncertainly.

The time of oscillation and vibration, both in dipping and horizontal needles equally good, is as their length directly; and the actual velocity of their points along their arcs is always equal.

Hence magnetic needles are, ceteris paribus, still better, the longer they are; and that in the same proportion with their length.

MAGNET, in Medicine. Some writers of the middle ages have, from a mistaken translation of Theophrastus, been induced to account the load-stone poisons, which the ancients were so far from doing, that they gave it inwardly. Galen ascribes a purgative quality to it, and recommends it in dropsies; and Dioscorides considers it as a good medicine to evacuate gross melancholic humour. It is doubtless possessed of the same virtues with the other ores of iron, though in modern times never used inwardly, having been only made an ingredient in some plasters. To these plasters very extraordinary virtues have been ascribed; such as, that, when applied to wounds, they would extract iron, or even a knife, from the human body. See several familiar stories in Kircher's "De Magnete," who was too wise to give them any credit. The chemists are said to have been able to extract an oil of wonderful efficacy from the magnet, and to have made with it several preparations.

It has been said, that the application of the artificial magnet, or of a magnetic bar, to the teeth, will instantly cure the toothache, that it will ease the pains of parturient women, that it will disperse white swellings, &c.; and, on
on the contrary, that the wounds made with a knife, or other steel instrument, which has been previously rubbed with a magnet, are mortal. It is hardly necessary to add, that none of these pretended medicinal or poisonous qualities in the magnet are warranted by authentic facts: and as magnetism does not affect the fine, the taffy, or any other fibre of the body, it is improbable, to the greatest degree, that it should have any effect upon animal bodies. For though there are, without doubt, particles of iron in almost every part of an animal body, yet these particles are so subdivided and calcined, and bear so small a proportion to the other elements, that, in a natural state, the magnet has no action upon them.

Magnet, in Metallurgy and Chemistry. Iron ores may generally be discovered to be such by the magnet; for almost all of them will be attracted by it either before or after ignition. A strong artificial magnet, well hung, and used as a needle, will serve for this purpose. It will also readily find, and separate any little bits of iron or steel from other things, and particularly iron or steel from those of other metals. It will likewise discover whether tools, &c. are made of steel, or whether they are iron case-hardened; for the steel will receive a strong touch, when the other will hardly receive any. For the use of the magnet, see Needle. According to Neumann, the magnet is almost totally soluble in spirit of nitre, and partially in the vitriolic and marine acids. See Iron, Ores of.

Magnet, Armored, denotes one that is capped, cased, or fet in iron or steel, in order to make it take up a greater weight, and also more readily to distinguish its poles. As both magnetic poles together attract a much greater weight than a single one, and as the two poles of a magnet are generally in opposite parts of its surface, in which situation it is almost impossible to adapt the same piece of iron to them both, at the same time; therefore it has been commonly practiced to adapt two broad pieces of soft iron to the poles of a lead-iron, and to let them project on one side of the magnet, because in that case, the pieces of iron being rendered themselves magnetic, another piece of iron could be conveniently adapted to their projections, so as to let both poles act at the same time. Those pieces of iron are generally held fast upon the magnet by means of a bracket or silver box. The magnet in this case is said to be armored, and the pieces of iron are called the armature.

In fig. 7, Plate VI. AB represents the magnet; CD, CD, represent the armature or pieces of iron, the projections of which are D, D, and to which the piece of iron, F, is made to adhere. The dots ECD represent the iron box, having a ring, E, at its upper part, by which the armed magnet may be supported. Thus the two poles of the magnet, which are at A and B, are made to act at D, D, where the straight piece of iron, F, may be conveniently applied.

For this purpose, and to avoid the armature, artificial magnets have been made in the shape of a horse-shoe, having their poles in the truncated extremities; for which reason they have more power than the straight magnetic bars.

When a piece of natural magnet is required to be armed, the first operation is to find out its poles; then let the magnet be properly shaped, viz. either in the form of a terrella, or in the more usual one of a parallelopipedon, in which latter case care must be had to let the poles fall about the middle of two opposite surfaces, in which direction the magnet ought to have the greatest length possible; it having been often observed, that a natural magnet is weakened in power much more by cutting off a part of its length, in the direction of the poles, viz. so as to make the magnetic axis shorter, than in any other direction.

After having shaped the magnet properly, let two plates of soft iron be made, equal in breadth to those surfaces where the poles stand, and to project a little way on one side of the stone, as shown in the figure. Those projections D, D, must be much narrower than the breadth of the plates. For magnets smaller than one ounce, the lower surfaces of the projections, to which the iron, F, is to be applied, need not be larger than about one-tenth of an inch; and from a quarter to half an inch is sufficient for larger magnets.

The thickness of the plates C, D, must be proportioned to the power of the magnet; there being a certain size which is the properest for any magnet, a larger or smaller thickness than which being not so advantageous. This thickness cannot be easily determined without actual trial; hence the best way is to make them very thick at first: then filing a little off, and examining the power of the magnet alternately: for the power increases gradually till a certain degree, at which limit the filing ought to be discontinued.

It is indifferent whether the armature be kept on by tying, or by a box; whether of metal or of wood; but as the box is the most permanent, this ought to be preferred: and it may be made of any metal excepting iron or steel.

When the magnet is spherical, the armature, or pieces of iron, must be adapted to that surface, and each to cover about a quarter of it.

What has been here said about the natural magnet, is equally applicable to the artificial ones; so that many magnetic bars may be joined together, and may be armed as to form a very powerful compound magnet.

The armature rather strengthens the power of the magnet, for the same reason for which a piece of iron affixed to a magnet tends to render it more powerful.

If the artificial magnets be made in the shape of a horseshoe, or of a semicircle, then there is no need of the armature, it being sufficient to join them together, either by riveting or by a box; and, indeed, even with straight bars, the compound magnet may be made without the armature; but then, as the two magnetic poles cannot act in the same plane, it is proper to have two of those compound magnets, for the purpose of giving more conveniently magnetism to other bodies.

By this means the late Dr. Gowin Knight constructed two very powerful artificial magnets, or magnets of magnetic bars, which are now in the repository of the Royal Society. Each of these magnets consists of 240 bars, disposed in four lengths, so as to form a parallelopipedon, every length containing 64 bars. All these bars are kept together by means of iron braces, and the whole is suspended upon pivots and a proper wooden pedestal or carriage, so as to be easily placed in any required position. For a farther description of these magnetic magnets, see the Phil. Trans. vol. lvi. p. 591.

Mr. Michell directs to increase the power of a natural magnet, if it be small and short, by laying a great number of iron bars at its ends, after the manner of supporters, care being taken to apply the proper poles: if it be pretty long, so as to allow room for it, by touching it also double with several bars, according to its bulk, applying them to all sides at once. To increase the power of a large magnet, instead of placing supporters, he advises to put a large piece of iron, the thickness and breadth of the magnet, at each end of it. This piece of iron should be either three or four times as long as it is thick, or else short, and three or four
foutr times as large at the end not touching the magnet, as at the other: in the former of these ways, there are to be placed on one side, in the other face at the broad end, as many supporters as can conveniently stand there. This, if the magnet be very short, may be sufficient; if it be long, it should besides be touched double. If the magnets to be thus improved be very susceptible of magnetism, they should have much thicker armour than is generally used, because they will thus retain more magnetism; and the armour should be so fastened, that the hoops, &c. used for that purpose may not stand in the way of applying anything to the ends, or the fides; for it is much the best way to make any short magnets magnetic in their armour, because they will retain more power by this means. But Mr. Michell apprehends, that the best way of managing very large magnets, would be to fit them, in a direction parallel to the axis, into several long bars of the length of the future, and having made them magnetically finely, to put them into their armour, in the manner directed for compound artificial magnets. The steel bars used for artificial magnets may be armed and made magnetic, like the natural magnets. Armed compound artificial magnets may be made of several bars, exactly of a length, with armour nicely fitted to them. The bars should have the same proportions as those of single unarmed magnets; they should be touched finely, and put into their armour, as they are touched, with the poles of the same denomination the same way. The armour should be pretty thick, and should have a wedge of iron applied to it, whilst the bars are putting in, and till the whole is bound together and finished; for which reason the cafes, that keeps the armour together at bottom, should be put on before any of the bars are in. The iron wedge should always continue applied to the magnet, but when it is used; for this will be a great preservation to it; though with all this precaution, it will of a great deal of its first strength, in a very little time. Mr. Michell directs an occasional magnet of this kind to be made in the following manner: let there be a small box, about an inch deep, six inches long, and three or four wide; in the bottom of this box fix two bars of iron, at each end one, about 4ths of an inch square, reaching quite across the ends and through holes in one side, and projecting a little way beyond: these projecting ends serve as feet to fit with, like those of the common armed natural magnet: the face of these feet should lie in the plane of each other, and they may be reduced, by taking off the edges, to about half the breadth of the bar, in the flat way of the box. When the magnet is wanted, apply a wedge of iron to the two feet that come through the side of the box; and having made any number of the fix-inch bars as magnetic as may be, place them one by one with their edges against the two iron bars in the box, and with their poles of the same denomination the same way, pressing them close against the side of the box, which will keep them from turning over and lying flat-ways. Having placed as many of the six-inch bars as are required in this manner, lay two or three doubles of flannel, or something else that is soft and flanpny, over them, and press them against the two iron bars with the lid of the box, and flatten it down. Such a magnet as this may be easily taken to pieces and retouched, and let together again, as occasion shall serve. A magnet of this kind, consisting of three dozen of fix-inch bars, will lift fifty pounds avoirdupois.

The following experiment will shew in what circumstances a magnet can lift the greatest weight. Take a magnetic bar, and find by trial an oblong piece of iron, about four inches long, and of a weight a little greater than the magnet will support. It is plain, that if you affix this iron to one pole of the magnet, the moment you remove your hand, the iron will drop; but if, before you remove the hand, you present another larger piece of iron just under the lower extremity of the former, and within half or three-quarters of an inch from it, you will find that the magnet will then support that piece of iron which it could not support before, when a secondary piece of iron was not under it. In short, a magnet can lift a greater weight of iron from another piece of iron, as an anvil, or the like, than from over a table.

The reason of which property is, that in the former case, the iron basis, or inferior piece of iron, becoming itself in some measure magnetic, helps to increase the magnetism of the first piece of iron, and consequently tends to increase the attraction between it and the magnet; which does not take place when the iron is lifted from over a table, or something else which is incapable of acquiring any magnetism.

In order to render this property more intelligible, suppose that a piece of iron be affixed to the north pole of a magnet; it is plain, that by the action of the magnet the part of it that stands next to the magnet has acquired a fourth polarity, and its other, or inferior extremity, has acquired a north polarity, the attraction being a consequence of this acquired magnetism, and being greater or smaller in proportion as that acquired magnetism is more or less powerful; consequently, whatever tends to increase that magnetism in the piece of iron, must likewise increase the attraction. Now, when another piece of iron is under the former, that other piece of iron, being within the sphere of action of the magnetic bar, becomes magnetic, and the part of it which is contiguous to the north pole of the magnet acquires the south polarity; but this is contiguous to the lower end, which is the north pole, of the first piece of iron, therefore it must increase that north polarity, and, of course, the fourth polarity of the upper end of the first piece of iron, which bands next to the magnet.

In fact, if, instead of the secondary piece of iron, you put the south pole of another magnet at a little distance below the lower extremity of the suspended iron, you will produce the same effect, viz. will increase the attraction between it and the north pole of the first magnet; but if you present the north pole of the second magnet under it, then you will produce the contrary effect, viz. will weaken its magnetic power, and, of course, diminish the attraction.

The variable power of a magnet may be shewn by suspending iron to it, in the following manner. Suspend a magnet in a place that is not much hooky, and apply to it as much weight of iron as it will just support. For this purpose, the magnet, either natural or artificial, ought to be armed, or made in the shape of a horse-fly, viz. so as to have the poles in one plane; in this form the effect being more conspicuous. Let a hook or a scale, like those used for a balance, be fastened to this iron. On the following day, you may put a little more weight into the scale, which the magnet will support. One or two days after, a little more weight may be added; and so on; the power of the magnet increasing daily and, though this increase of power is neither unlimited nor very regular, being affected in some measure by the vicissitudes of heat and cold, &c.; yet, upon the whole, the power of a magnet will be considerably increased by this artifice.

It is very remarkable, that if, in the course of the operation, the iron were to drop from the magnet, on replacing it, you will find that the magnet will no longer support as much
Magnet.

much weight as it did a moment before, so that now you must diminish the weight, though in the course of the following days you may increase it gradually; hence, in placing the weights into the scale, or upon the hook, care must be taken not to give it any jerk, so as to cause the iron to fall off; otherwise a great deal of the work will be lost.

The reason of this experiment is, that the iron being rendered magnetic, tends to strengthen the magnetism of the magnet, in the same manner as any other magnet endeavours to render magnetic any ferruginous substance that is placed within its sphere of action. When the iron falls off, the magnet loses part of the acquired power, especially if the magnet had acquired more than its point of saturation, there having been removed the cause which kept it up; and when the iron is replaced, the magnet will not recover the lost power very readily, because there is required a considerable time to communicate a certain degree of magnetic power to a hard ferruginous substance, as the magnet is, especially when that magnetism must be communicated by the action of a proportionably weak magnet, like the iron weight.

According to Epinus's hypothesis of the magnetic fluid, this experiment is explained thus: The magnetic fluid in a magnet is not equally diffused through its substance; but one pole, or half of it, is overcharged, and the other undercharged. There is a strong attraction between the undercharged part and the superfluous quantity of magnetic fluid in the overcharged part, and the restoration of the balance is in great measure prevented by the hardness of some other quality of the magnet. Now, when the iron is affixed to the magnet, it becomes magnetic, viz., that part of it which is contiguous to the overcharged pole of the magnet, becomes undercharged, and the opposite one becomes overcharged. In this situation, the undercharged part of the iron, endeavouring to draw the magnetic fluid of the magnet towards itself, accumulates or draws it still nearer to that overcharged pole of the magnet; and, on the other side, the overcharged part of the iron being contiguous to the undercharged pole of the magnet, tends continually to drive the magnetic fluid away from that undercharged pole of the magnet; but the power of the magnet, according to the hypothesis, depends on the unequal distribution of the magnetic fluid, therefore the action of the iron, by endeavouring continually to increase that unequal distribution, must increase the power of the magnet.

It follows from this experiment, that a magnet is apt to lose much of its power when kept without any iron affixed to it.

Magnet. Arsphenical, Magnet Arsphenical, in Chemisty, denotes a mixture of equal parts of arsenic, fulphur, and antimony, melted together over the fire, and condened in manner of a stone.

It is a very gentle caustic, and was first invented by Alexander Sala. It succeeds very well in taking down fungous flesh in wounds. It has its name magnet, because, being worn during malignant diseases, it is supposed to preserve the wearer from infection, by a magnetic power.

Magnet, Artificial, is a steel or iron bar, impregnated with the magnetic virtue, so as to posses all the properties, and be used instead of the natural load-iron.

Before we proceed to give a particular account of the various methods that have been practiced for making artificial magnets, it may not be improper to premise some general observations on the communication of magnetism. We have already more than once had occasion to remark, that when a piece of iron or steel, or, in short, of any ferruginous body, is presented to a magnet, within a proper distance of one of its poles, it becomes instantly magnetic the part of it which is nearest to the magnet acquiring the contrary polarity, &c.

This acquired magnetism is stronger with soft iron, and weakest with hardened steel, or with the brittle fort of cast iron; the other forts of iron or ferruginous bodies acquiring a stronger or weaker power, according as they approach the hardens of the latter, or the softness of the former. But the permanency of the acquired magnetism follows just the reverse of this rule; so that the hardest steel retains it for many years with little or no diminution; whereas very soft iron lores it entirely the moment it is removed from the influence of the magnet; the other ferruginous bodies preserving it for a longer or shorter time, according as they participate more of the nature of hard steel, or of that of soft iron. Hence it may be deduced, that, in general, the best method of making artificial magnets consists in applying one or more powerful magnets to pieces of the hardest steel, because those pieces will thereby acquire a considerable power, and will retain it for a long time; taking care, in this operation, that the north pole of the magnet or magnets be applied to that extremity of the piece of steel which is required to be made the south pole, and that the south pole of the magnet be applied to the opposite extremity. In the same manner as a piece of steel or iron is rendered magnetic, a weak magnet may be rendered more powerful, or its power may be restored when lost.

It is evident, that in this method the operator should have one or more magnets, by the application of which the steel, or other ferruginous body, may be rendered magnetic; therefore it may be added, by what means is magnetism originally given to such artificial magnets, as are said to have that power imparted without the interference of any magnet? The answer to this question is, that no magnetism at all can be communicated to any ferruginous body whatever, without the action of another magnet; and that, in the method vulgarly called, of giving magnetism to steel, &c. without the aid of a magnet, the beginning of the magnetic power is communicated from the earth, which is a real magnet; and, therefore, there is no magnetism communicated but by the action of another magnet. See art. 52, p. 67.

There are some particular circumstances which demand attention, in order to enable us to ascertain the best method of contriving artificial magnets.

1. The nature of the body must be adapted to the power which is to render it magnetic; remembering, that the soft ferruginous bodies both acquire and lose magnetism easier than those which are harder.

2. The shape of the bodies is to be considered next, experience showing that an oblong one is in general preferable to any other. In case of steel bars, they ought to be quite hard, in order to acquire the greatest possible power, provided one has magnets sufficiently strong for the purpose; and if cylindrical, their diameters ought to be about one-fifteenth of their length; or, if not cylindrical, their thickness ought to be such as nearly to equal the weight of the cylindrical bars of the same length, and the diameter of which may be about one-fifteenth of their lengths.

3. Several magnets are much preferable to a single one, for the purpose of communicating magnetism; in the application of which it must be remembered, that the north pole of the magnet produces a north pole in the part of the ferruginous body to which it is applied, and that the north pole of the magnet produces a south pole in the part, &c.

4. If it were required to construct a strong magnet, when the operator has either no magnet at all, or a very weak one, he must proceed gradually. It being impossible for a hard
Magnet.

and large feel bar to receive any sensible degree of magnetcism from the action of the earth, or of any other weak magnet, the operator must begin with giving magnetism to several small, soft feel bars, impringing one at a time by means of the weak magnet, or, if he have no magnet, by means of one or more iron rods properly situated, which in that case are real, though weak magnets. Then, by joining in a proper manner the small feel bars already made magnetic, he may communicate a stronger power to larger and harder feel bars; which will be capable of impregnating bars still larger; and so on.

It has been affected by various authors, that if a short bar of soft iron be repeatedly froaked iron end to end, in any situation, by a sufficiently long iron bar, likewise kept in any situation the feel bar will thereby acquire a considerable degree of magnetism; from which it might perhaps be inferred, that there is no necessity of deriving the origin of magnetism from the earth. But an accurate investigation of this pretended fact has shown, that the feel bar will not acquire magnetism in every situation. Indeed, as the bar of iron is rendered more or less magnetic by the earth in every situation, except that which is perpendicular to the magnetical line; in a random way of making the experiment, it is almost impossible to keep the bar so near that direction as to acquire no magnetism at all from the earth; but if, in rubbing the feel bar, the iron one be kept in a situation nearly perpendicular to that of the magnetical line, then the feel will acquire no magnetism at all. Besides, when the iron bar is kept in any situation, the degree of magnetism which is communicated to the bar, is greater or less in proportion as the direction of the bar is nearer to or farther from that of the magnetical line; which proves, beyond a doubt, that the communicated magnetism is originally derived from the earth.

In order to make a piece of iron acquire magnetism from the earth, let the following proceed be purified: Take a bar of soft iron, about two or three feet long, and between one-half of an inch and two inches thick, (such as some kitchen pokers,) and place it in the magnetical line, i.e. in the direction of the dipping needle, if this be at hand, or straight up in higher latitudes N. or S. than 40°, but horizontally when nearer to the equator than the above-mentioned degree of latitude. Then place a magnetic needle on a pin, and holding the pin in your hand, present the needle to the various parts of the bar from top to bottom, and you will find, that in this situation the lower half of the bar is posseffed of the north polarity, capable of repelling the north and of attracting the south pole of the needle, and the upper half is possessed of the south polarity, capable of repelling the south and of attracting the north pole of the needle. The attraction is strongest at the very extremities of the bar; it diminishes as it recedes from them, and vanishes about its middle, where no pole of the needle is attracted in preference to the other. In short, in that situation, the iron bar is as much a magnet as any piece of iron that stands within the influence of a magnet.

If you turn the bar top-fleve down, the extremity of it, which was south pole when it stood up, will now become north pole, and the other extremity will become south pole.

In the southern parts of the world, the lower part of the bar is a south pole; or, to be more explicit, when in any part of the world the bar is situated in the magnetic line, the extremeties of the bar will acquire the polarities corresponding to the nearest poles of the earth.

In order to fix in an iron bar the magnetism which the earth has communicated to it, the following circumstances should be regarded. The very soft iron acquires the greatest degree of magnetic power in the shortest time, but looses it with the same quickness; so that, if the preceding experiment be performed with a bar of that sort of iron, the magnetism communicated to it by the earth will not be permanent; but if it be made red-hot, and be left to cool in the magnetic line, or if it be repeatedly struck with a hammer, whilst standing in the magnetic line, it will thereby acquire a small degree of permanent magnetism; which power, however, either by leaving the bar for some time in an improper situation, or by inverting and striking it again, will be soon destroyed.

When the iron is somewhat harder, the acquired magnetism falls much longer; though a longer time, or longer operation, be required in order to render it magnetic.

As the conduction of a weak magnet or a ferrous body continually tends to increase the magnetism of that body, to the iron, bars, which are left in the direction of the magnetic line for a considerable time, become continually more strongly magnetic, and the acquired power becomes more permanent.

The reason why iron, by long standing, by hammering, &c. acquires a permanent magnetism from the earth, whereas by the mere position, in a short time, the power is not at all permanent, seems to be the unequal texture of the iron; suppose, for instance, that a piece of iron is composed of hard and soft particles, or of some, through which the magnetic power moves very easily, and others, through which it moves very slowly. The former then of those particles acquire the magnetism at first from the earth, and lose it very easily; but by continuing in the same position, or by being softened, the hard particles gradually acquire magnetism from the former, and having once acquired it, retain that power for a long time. It is, besides, very probable, and in certain circumstances actually proved, that some sort of iron becomes harder by being kept long exposed to the atmosphere.

The method of making magnets of this kind, by means of a natural magnet, and even without the assistance of any magnet, was figured some years ago by Mr. Servington Savery, and particularly described in the Phil. Trans. N. 414. See also Abrigment, vol. ii. p. 255. &c. But as his method was tedious and operose, though capable of communicating a very considerable virtue, it was little practiced. A more simple method was proposed by Mr. Arnold Marcel, nephew to Mr. Lewinnek, and is described in the Phil. Trans. (See Martyn's Abr. vol. vi. part ii. p. 258.) It is as follows: "In the year 1776," says he, "making several further observations about the magnetical force which I found in great pieces of iron, I made use of a large iron vise, about 30s. weight, in which I fixed a small anvil of about 1/2 lbs. Upon the bright surface of this anvil I had the steel, to which I would give the virtue, in a position of north and south, which happened to lie in a diagonal of the square surface of the anvil; then I took a piece of iron, one inch square, and 53 inches long, of about 3lbs. weight, having at one end the figure here represented (fig. 8;) brightly polished at A, and taper at the other end. Then I held flat down the piece of steel upon the anvil with one hand, and with the other I held the iron bar aforesaid perpendicularly, with its point A, upon the steel, and, pressing hard, I rubbed the steel with the iron bar towards me, from north to south, several strokes, always carrying the bar far enough round about, to begin again at the north, to prevent the drawing back of the magnetical force. Having thus given ten or twelve strokes, I turned the steel upside down, leaving it in the same position as to north and south, and, after
after rubbing it and turning it, till I rubbed it about 400 times, it received by degrees more and more strength, and at last had as much as if it had been touched by a strong load-flone. The place where I began to rub, was always that which pointed to the north when the needle was hung, the end where I had ended the stroke turning to the south. Sometimes it has happened, that in a few strokes I gave the steel its virtue: nay, even in the very first stroke, one may give a great deal to a small needle. This way I have given the magnetical virtue to needles of sea compasses, made of one piece of steel, so strongly, that one of the poles would take up three quarters, and the other a whole ounce of iron. Although these needles were anointed with linseed oil, which made a hard coat, to keep them from rubbing, yet they kept the virtue; but in strengthening these sorts of needles, I rubbed by turns first to the right and then to the left side.

"The same way I brought the virtue into the point of a knife, so that it would detain 15 ounces.

"I brought the said virtue into four small pieces of steel, each one inch long, and 4th of an inch broad, as thin as the string of a watch. These four pieces I joined together, as into an artificial load-flone, weighing 18 grains troy, and then I drew up and fasten an iron nail, which weighed 144 grains troy. This artificial load-flone has now these six years been tumbled about, and been lying among iron and steel, and in any position, and yet it has rather got more than lost any of its virtue.

"The magnetical virtue being thus brought into iron or steel, I have farther observed, that that end where the stroke was begun, would draw to the north, and where the stroke ended, to the south, in whatever situation the steel had been laid upon the anvil to give the virtue. I took a piece of steel, and rubbed it from one end to the middle, and then from the other end to the middle, and found it had two north poles, one at each end, and the middle a south pole.

"Further, beginning to rub from the middle towards each end of another piece of steel, I found it to have at each end a north pole, and in the middle a south pole."

A very easy way of giving magnetism to a small piece of soft steel, is the following: Take two pokers of soft iron, or two iron bars, of about an inch square, and more than three feet in length, keep them in the magnetical line, or if in this island, perpendicularly, as shown in fig. 9. Then let the piece of steel, C B, be either fastened to the edge of a table, or be held by an assistant; and placing the lower extremity of the bar A B, and the upper extremity of the bar C D, both on the same side, and in the middle of the steel, stroke the steel from the middle towards its extremities, moving the end of the bar, C D, from the middle of the piece of steel towards its end C, at the same time that the end of the bar, A B, is moving from the middle of the piece of steel to its other extremity B; and when the bars are arrived to the said extremities, remove them from the steel, and apply them again to the middle, and so on; thus striking the piece of steel about forty or fifty times on every side, will give it a considerable degree of magnetism.

It is evident, that if in this experiment, when the iron bars are arrived to the extremities of the steel, you bring them back to the middle of it, by drawing them along the surface of the steel, the experiment will not succeed, because the magnetical power communicated by their rubbing the steel in one direction, will be destroyed by their contrary motion.

Dr. Gowin Knight was the first who brought this kind of magnets to their present state of perfection, so as to be of much greater efficacy than the natural ones. The result of his method, though the process itself was kept secret, was first published in the Phil. Trans. for 1734, vol. xii. art. 8, and Phil. Trans. for 1745, art. 3. See also vol. xlv. for 1747, art. 2. Mr. Wilson has communicated to the public Dr. Knight's method; who informs us, that having provided himself with 3 large quantities of clean filings of iron, he put them into a large tub, that was more than one-third filled with clean water: he then, with great labour, worked the tub to and fro for many hours together, that the friction between the grains of iron by this treatment, might break off such smaller parts as would remain suspended in the water for some time. The obtaining of these very small particles in sufficient quantity, seemed to him to be one of the principal desiderata in the experiment. The water being thus rendered very muddy, he poured the fame into a clean earthen vessel, leaving the filings behind; and when the water had stood long enough to become clear, he poured it out carefully, without disturbing much of the iron sediment, as fully represented, which now appeared reduced almost to impalpable powder. This powder was afterwards removed into another vessel in order to dry it; and this process was several times repeated. When a sufficient quantity of this fine powder was procured, he made a paste of it with linseed oil; preferring this vehicle, because it contained a considerable quantity of the phlogistic principle. With these two ingredients he made a stiff past, which he well kneaded, before he formed it into convenient shapes, and then upon wood, and sometimes on tiles, in order to bake or dry it before a moderate fire, at about a foot distance from it. In about five or six hours it generally attained a sufficient degree of hardness. When these baked pieces were become old, he gave them their magnetic virtue in any direction he pleased, by placing them between the extreme ends of his large magazine of artificial magnets for a few seconds or more, as he saw occasion. By this method, the virtue they acquired was such, that when any one of these pieces was held between two of his best ten-guinea bars, with its poles purposely inverted, it immediately of itself turned about to recover its natural direction, which the force of those very powerful bars was not sufficient to counteract. (Phil. Trans. vol. xix. part i. for 1779, art. 5.)

However, the method of making artificial magnets was discovered and published by Mr. John Michell, in a Treatise of Artificial Magnets, printed in 1750, and by Mr. John Canton, in the Phil. Trans. for 1751, vol. xlvii. art. 6, p. 31. The process for this purpose was also found out by others, particularly by Mr. U. Temperley, in Natural and Experimental Philosophy, vol. ii. p. 261, and in the Royal Society's Journal for 1750, and 1751.

Mr. Michell's method of making magnets is as follows: prepare a dozen bars of steel, of about 1 1/4 ounce weight each, six inches long, and half an inch broad; let these be hardened with a full, but not too great heat: let one end be nicked all round with a chisel, to distinguish it from the other; and the ends of the bars should be cleaned after hardening, either upon a smooth stone, or razor-grinder's wheel; the size and shape of the bars may be varied at pleasure, provided that the length be proportioned to the thickness. The best sort of steel is that which has no veins of iron in it, and Mr. Michell has found the common blunted steel at least equal to any other. When any magnet does not answer expectation, it will be proper to harden it over again, with a greater or less degree of heat, till it proves better. In order to prepare these bars, contrive a box, that shall have two pieces of iron, about an inch long each.
MAGNET.

Each, fixed upright in the middle of each end, over against each other, at the distance of six inches from outside to outside. These pieces of iron may be about a quarter of an inch square, and should be filed pretty smooth on the sides. Against these are to be placed, with their edges towards them, the twelve magnetic bars, fix one on each, with their south, or north poles one way, and fix on the other side with the same poles the contrary way. It is necessary to observe that these bars must neither be taken out, nor put in, all, or too many on a side at once; for if two only be left, with their poles of the same denomination the same way, without one or more on the other side to counter-balance their effects, they will damage each other: and if two of the same side be taken out together, or laid with their poles of the same denomination together, after they are taken out they will also damage one another: and if this be the case it will be proper to remove them before they are used, after the manner preferred for making of magnets. In order to make the marked ends of these bars south poles, and the other ends north poles, place fix of them in a line north and south, bringing the unmaked end of one, to touch the marked end of the next throughout; the marked ends lying towards the north, which will be some advantage to them. Then take an armed magnet, and placing it with both poles upon one of the bars, the north pole towards the marked end, which is to be a south pole, and the south pole towards the unmaked end, which is to be a north pole, slide it backwards and forwards from end to end of the whole line of bars three or four times, taking care that they all touch. Then taking it off, remove the two endmole bars into the middle, and pass over them again three or four times. Having thus touched the bars, it will not be improper to turn them with the other side uppermost, and to touch them over again on that side as before, omitting the endmole bars, till they are removed into the middle, where they also are to be touched.

If an unarmed magnet, either natural or artificial, be used, lay the bars in a line as before; place the south pole of the magnet upon the marked end of the endmole bar, and slide it over the whole line to the end: then taking that pole off, place the north pole upon the same bar in its room, not at the extremity of the bar, but towards the middle, and slide it back again; then change the poles again, observing to let the magnet on at the middle of the bar, and slide it to the other end, as at first. Having done this four or five times, remove the two endmole bars into the middle, and placing the south pole of the magnet upon the marked end of them, slide it to the unmaked end; and then, placing the north pole upon the unmarked end, slide it to the marked end. Let this be repeated three or four times, and turning the bars with the other side upward, repeat the same process again. When the magnets are weak, it may be necessary to touch the bars, according to the preceding direction, before they are hardened, when they will receive the magnetic virtue more easily; then, making the whole dozen magnetic, in the manner hereafter prescribed, till they are as strongly as they will be in their soft state, harden one half; and having made these again magnetic with the remaining half that are soft, harden those also, and proceed. But if the magnets are too weak to perform properly, even in this case, recourse must be had to smaller bars of steel, which should also be soft; and if these fail, bars of iron must be used. Having communicated a small degree of magnetism to fix the bars, let the other fix, which are unmagnetic, be laid in a line, in the same manner as the former: and let A B, (Plate VI. Magnets, fig. 16.) represent this line, consisting of fix bars, though three only are delineated. The line drawn across at the end of each bar, represents the mark distinguishing that end which is to be made the south pole, from the other. Let C D, E F represent the fix bars already made magnetic; these lean against each other at the top, and are separated by a piece of wood, or other matter except iron, about the tenth of an inch at the bottom. The three magnets in C D have all their south poles downward, and are placed towards the unmaked ends of the bars in the line which are to be north poles; and the three magnets in E F have all their north poles downward, and are placed towards the marked ends of the bars which are to be south poles. Slide these fix magnetic bars thus placed, backward and forward three or four times over the whole length of the line. Then taking them off, having first brought them to touch at the bottom, remove the two endmole bars of the line into the middle, and replacing the magnetic bars upon them, as before, pass over them again. Then taking them off, and turning the bars in the line with the other side upward, go over them again in the same manner, excepting the endmole bars; which, when these in the middle are touched, are to be removed thither, to be touched in their turn. Thus the bars in the line will give a stronger power to that of the other fix, by which they were touched; and, therefore, these latter may now be laid down in a line, and retouched, after the same manner, with the latter: when this is done, lay those down again, and retouch them with the others: repeat this operation a few times, first touching one set, and then the other, till they have acquired as much magnetism as they will retain; or till they will receive no additional force by any farther repetition. The fix-inch bars, made magnetic after this manner, when properly hardened, will firmly lift, by one pole, a piece of iron, weighing a pound or better, if it be of a proper form; and fix such bars will touch a line of fresh bars of the same size, to their full perfection, by three or four times sliding over them; except the endmole, which must always be removed into the middle. As several magnets laid together with their poles of the same denomination the same way, will greatly injure one another, unless they have something to counteract them, it is absolutely necessary not to place two of them, of a side, or together; but singly, one on one side, and one on the other, making them to lean together, that they may rest against one another at the top: at the bottom they are preserved from injuring one another, by being placed upon the bar which is to be made magnetic. In like manner, they must not be taken off two of a side together, but singly, first on one side, and then on the other. But the readiest way of taking them off is first to bring them to touch one another at the bottom, in the same manner as they do at the top, and then they may be removed at once, and upon occasion set on again; only observing not to separate them again at the bottom, till they are placed upon the bar which they are to touch. The reason of removing the two bars at the ends of the line, in order to their receiving a greater virtue, seems to be, that the fix magnets, employed in touching, are endeavouring to make that part of the bar which is not included between them magnetic, in a contrary direction from that which is included between them. As this last is the direction of magnetism designed, the former endeavour would be injurious; and it is prevented by two causes: one of which is the power, whereby the steel refits in a degree every endeavour, either to make it magnetic, or to destroy its magnetism; and the other is the power of the bars already in some measure magnetic, which lie at both ends of the bar that is touched. Now this last power is wanting at one extremity of those bars that are placed at the ends; and consequently not having a sufficient force fully to refit the contrary endeavour,
vour of the magnets employed in touching them, they become less magnetic than the others, which have a sufficient force. Though in the line of bars, when making magnetic, each bar has only one at each end to support it (those magnets that are planted at the ends of the others to preserve them being called supporters) against the contrary endavour of the six, made use of to touch it; and this does very well; yet some will receive an additional force by being supported with larger magnets; or instead of these, two or three of their own size, at each end; those at the marked end all with their north poles touching it, and those at the unmarked end all with their south pole touching it. And because there will be two or three north poles, and as many south poles together amongst the supporters, at the other end from the bar to be touched, that have nothing to counteract them, it will be proper to place the south pole of another magnet among the north poles, and the north pole of another among the south poles, that they may not hurt one another, which they otherwise will do.

The manner above described is called the double touch: and Mr. Michell observes, that two magnets will give more strength to a bar of their own size, when used after this manner, than a single magnet equal to five of the former in strength, when applied after the manner of the simple touch. This ingenious writer has described a frame, contrived for holding several of the six-inch bars, when they are used in touching large bars, and when they cannot be conveniently held in the hand; for an account of which we must refer to his excellent pamphlet, already cited, p. 25, &c. ed. 2. He observes, that the form of magnets is of very little consequence with regard to their receiving the magnetic virtue, provided that they have a sufficient length in proportion to their bulk. The straight bars may be made square, round, or flat; though the flat are most convenient for touching; and probably somewhat stronger. These may also be pointed at the ends, as in fig. 11, in order to render them lighter, and to increase their power of lifting; though pointed bars are not so proper for touching. The magnet may be made in the form of a horse-shoe, as in fig. 12, where a wedge of iron is tipp'd to be applied to the poles of it; and it will thus lie in a narrower compass, a wedge of iron may be applied to its two poles, and it will lift by both poles at once. The magnet may be also made annular, which is a plain flat bar, bent flatways instead of edgways; and a semi-circular magnet may be bent flatways, like the annular, or edgways, like the horse-shoe; and two magnets of this kind may be conveniently placed together, in order to preserve each other.

The poles of a magnet may be converted by placing the bars which are to retouch it, with their north poles towards its north pole, and the south pole towards its south pole. In doing this, they should be placed on at the middle, and slid once or twice backwards and forwards, before it is supported; and then that which was the north pole must be supported as a south pole by north poles; and that which was the south pole, as a north pole by south poles. In order to make a bar magnetic, so that it shall have several poles, support it at the places where the poles are designed to be, with poles of a contrary denomination from those designed; and if any places supported with south poles, the next places on either side must be supported with north poles, and vice versa. Having done this, confider each piece included between any two sets of supporters, as a separate bar, to be made magnetic, with its south pole towards the north set of supports, and its north pole towards the south set, and touch it accordingly. Magnets of this sort will not do well, unless they are very long; and at best they are always weak, and will very soon be injured; so that they should only be made occasionally.

Mr. Michell has also published a method of obtaining magnetifin by means of three iron bars, without the affifance of a natural load-borne, for which we shall refer to his pamphlet, p. 60, &c. and proceed to describe the method described by the ingenious Mr. Canton.

This gentleman has succeed in his attempts to convey a considerable magnetic virtue to bars of hardened steel, as to be able to impregnate such bars with this virtue to as high a degree, at least, as any bars of the same weight and dimensions, which he had seen or heard of; and to an as high a degree, as he apprehends, the same bars, in their present state, are capable of being impregnated. Mr. Canton was able, in about half an hour's time, to communicate to fix bars of hardened steel, at first entirely destitute of any magnetic virtue, the utmost virtue they were capable of receiving; and that without the mediation or affiance of any natural load-borne, or of any artificial magnet. Mr. Canton has published the description of his process with such directions, that any person may readily perform the same. For this purpose procure a dozen bars; fix of stout steel, each three inches long, 5/1 inch broad, and 1/16th of an inch thick, with two pieces of iron, each half the length of one of the bars, but of the same breadth and thickness: and fix of the hard steel, each 3/4 inches long, 5/8 an inch broad, and 1/16ths of an inch thick, with two pieces of iron of half the length, but the whole breadth and thickness of one of the hard bars; and let all the bars be marked with a line quite round them at one end. Then take an iron poker and tongs, or two bars of iron, (Plate VII. Magnetifin, fig. 1.) the larger they are, and the longer they have been used, the better; and fixing the poker upright between the knees, hold to it near the top one of the soft bars, having its marked end downward, by a piece of fewing filk, which must be pulled tight with the left hand, that the bar may not slide; then grasping the tongs with the right hand a little below the middle, and laying them nearly in a vertical position, let the bar be broked by the lower end, from the bottom to the top, about ten times on each fide, which will give it a magnetif power sufficient to lift a small key at the marked end; which end, if the bar was fufpended on a point, would turn towards the north, and is, therefore, called the north pole, and the unmarked end is, for the fame reafon, called the south pole of the bar. Four of the soft bars being impregnated after this manner, lay the other two (fig. 2.) parallel to each other, at the distance of about one-fourth of an inch between the two pieces of iron belonging to them, with a north and a south pole against each piece of iron; then take two of the four bars already made magnetic, and place them together, so as to make a double bar in thickness, the north pole of one being even with the south pole of the other; and the remaining two being put to thefe, one on each fide, fo as to have two north and two south poles together, separate the north from the south poles at one end by a large pin, and place them perpendicularly with that end downward, on the middle of one of the parallel bars, the two north poles towards its south, and the two south poles towards its north end; slide them backward and forward three or four times over the whole length of the bar, and removing them from the middle of this, place them on the middle of the other bar as before directed, and go over that in the same manner; then turn both the bars with the other fide upward, and repeat the former operation; this being done, take the two from between the pieces of iron, and placing the two outermost of the touching bars in their room, let the other two be the outermost of the
the four to touch thefe with; and this process being repeated till each pair of bars has been touched three or four times over, which will give them a confiderable magnetic power, put the half dozen together after the manner of the four (fig. 3), and touch with them two pairs of hard bars, placed between the irons at the dinance of about half an inch from each other; then lay the soft bars aside; and with the four hard ones let the other two be impregnated (fig. 4), holding the touching-bars apart at the lower end near two-tenths of an inch, to which distance let them be separated after they are set on the parallel bar, and brought together again after they are taken off; this being observed, proceed according to the method already described, till each pair has been touched two or three times over. But as this vertical way of touching a bar will not give it quite fo much of the magnetic virtue as it will receive, let each pair be now touched once or twice over, in their parallel position between the irons (fig. 5), with two of the bars held horizontally, or nearly fo, by drawing at the fame time the north of one from the middle over the south end, and the south of the other from the middle over the north end of a parallel bar; then bring them to the middle again without touching the parallel bar, give three or four of these horizontal strokes to each fide. The horizontal touch, after the vertical, will make the bars as strong as they can possibly be made; as appears by their not receiving any additional strength, when the vertical touch is given by a greater number of bars, and the horizontal by thofe of a superior magnetic power. This whole process may be gone through in about half an hour, and each of the larger bars, if well hardened, may be made to lift twenty-eight Troy ounces, and sometimes more. And when these bars are thus impregnated, they will give to a hard bar of the fame fize its full virtue in less than two minutes; and will, therefore, answer all the purpofes of magnetifm in navigation and experimental philofophy, much better than the lead-tons, which is well known not to have fufficient power to impregnate hard bars. The half dozen being put into a cafe (fig. 6), in fuch a manner as that two poles of the fame definition may not be together, and their irons with them as one bar, they will retain the virtue they have received; but if their power fhou’d, by making experiments, be ever fo far impaired, it may be refurred without any foreign affiffance in a few minutes. And if, out of curiofity, a much larger fet of bars fhou’d be required, there will communicate to them a fufficient power to proceed with, and they may in a short time, by the fame method, be brought to their full ftrength. Mr. Canton, by the fame process, communicated magnetic virtue to two large bars, each half an inch square, 104 inches in length, and weighing nearly ten ounces and twelve pennyweights, to fuch a degree, that one of them lifted by one of its ends seventy-nine ounces and nine pennyweights; and a flat femicircular magnet, weighing an ounce and thirteen pennyweights, was made to lift, by applying its two ends together to an iron wedge, ninety Troy ounces. The fame ingenious gentleman could also readily deprive his bars of their virtue; and change the poles of a natural lead-tons, by placing it in an inverted direction, between the contrary poles of his larger bars, laid down at fome distance from each other, in the fame ftraight line continued at the dinance of about a quarter of an inch from either of the poles, without touching the flone with either of the bars.

The method in which the fleep he made use of was hardened as fo follows: having cut a fufficient quantity of the leather of all fkins into very fmall pieces, an iron pan is provided, which a little exceeds the length of a bar, is wide enough to admit of two bars fide by fide without touching each other on the pan, and at leaff an inch deep. This pan is nearly half filled with the bits of leather, upon which are laid the two bars, having falleden to the end of each a fmall wire for taking them out; the pan is then quite filled with the leather, and placed on a gentle flat fire, being covered and furronded with charcoal. The pan, being brought to something more than a red heat, is kept about half an hour, and the bars are suddenly quenched in a large quantity of cold water. Mr. Hare, in his Effays on Iron and Steel, p. 147, claims the merit of directing this process for hardening Mr. Canton’s bars.

In order to communicate the magnetic virtue to a fleep bar, to the needle of a compass, &c. by means of two magnetic bars, place the bar or needle, A B (fig. 7), upon a table, then place the two magnetic bars C D, E F, ftraight up upon A B, at a little and equal distance from the middle of the bar A B, and in fuch manner, as the fouth pole D, of one of the bars may be nearest to that end of the bar, A B, which is required to become the north pole, &c. then these two bars must be flid gradually towards one extremity of the bar, keeping them constantly at the fame distance from each other; and when one of the magnetic bars, for instance, C D, is arriued at A, then they must be flid the contrary way, till E F arrives at B; and thus the bar, A B, must be rubb’d a greater or smaller number of times, till it will be found by trial to have acquired a confiderable power. When the magnetic bars are powerful, and the bar, A B, is of very good fteel, and not very large, a fcore of frokes are fully fufficient. When the magnetic bars are to be removed from the bar A B, care must be had to bring them to the fame situation where they were firft placed, viz. at a little and equal distance from the middle of the bar A B, and then they may be lifhed up.

In this operation, the effect of the bars may be improved feveral ways, which will be found neceffary when the bar, A B, is proportionally large, and it is required to give it the greatest poifible power. This may be effected, firft, by taking the magnetic bars at top, interposing a piece of wood or other fubftance, except iron, to keep them apart, as fhewn in fig. 8; for in this manner, the upper poles of the bars being contiguous, will tend to ftrengthen each other, and, of course, their lower poles will also be ftrengthened. Secondly, by placing the bar, to be rendred magnetic, between two bars of soft iron, or two other magnets, as fhewn in fig. 9, or in the manner before directed. Thirdly, the magnetic bars may be fhined the contrary way, after the manner used by Mr. Alpinus (fig. 10); so that the magnets C D, E F, may make an angle of about fifteen degrees with the bar A B.

The bar, A B, may, in the fame manner, be rendered magnetic by mean of an armed magnet, as fhewn in fig. 11; or by a hufle-magnet, as fhewn in fig. 12, placing both the poles of the magnet in contact with the bar, &c.

In all these methods, the bar to be rendered magnetic must be froke on every fide; and, in order to let the magnetic centres fall just in its middle, care must be had to froke one-half of the bar just as often as the other half.

Whenever a fleep bar, or in general a piece of ferugiouf fubftance, is rendered magnetic by applying two bars, or whenever two magnetic poles are applied to it at the fame time, as used in this and the preceding experiment, the operation is ufually called the double touch, in diftinction from the single touch, which is when only one magnetic pole is applied to it.
MAG

As artificial magnets are frequently made in the shape of a semicircle, or like a horse-shoe, for the sake of bringing both poles in the same plane, the crooked file bars of which they are constructed are made magnetic in the same manner as the straight bars, excepting only, that the magnetic bars which are used are for it must follow the curvature of the file bar; thus, if it be required to render magnetic the piece of steel A B C (fig. 13), place it flat upon a table, and to its extremities apply the magnets D F, E G; joining their extremities F, E, with the conductor or piece of soft iron F G. Then apply the magnetic bars H, I, to the middle of the piece A B C, and stroke it with them, from end to end, following the direction of the best file, so that on one side of it the magnetic bars may stand in the direction indicated by the dotted representation L K. In this manner, when the piece of steel has been rubbed a full ten number of times on one side, turn the other side upwards, and repeat the operation till it has acquired a sufficient degree of magnetism. In this operation, the same precautions must be followed as were recommended for the method of communicating the magnetism to straight bars, viz. the magnets D F, E G, as well as the magnets H, I, must be placed so that their fourth poles must be towards that extremity of the bent file which is required to be made the north pole, and their north poles towards the other extremity. The magnets, H, I, must be first placed on the middle of the bent file; and after having drawn them over one leg of it as often as over the other, in order to let the magnetic centre fall just in the middle of the bent file, they are removed, &c.

If a person has only one magnetic bar, or a terrella, with which he wishes to give magnetism to a needle or other bar, the only way of effecting it is, to apply one pole of the terrella, or magnetic bar, A B (fig. 14.), to one extremity, C, of the needle, and to draw it all along the surface of it till it reaches the other extremity D; then the magnet being removed, must be applied again to the extremity C, and must be drawn over the needle as before. Thus the needle must be rubbed several times, by which means it will acquire a considerable degree of magnetism.

It must be observed, that the extremity of the needle which the pole of the magnet touched last, acquires the contrary polarity. Thus, in the present instance, if B be the north pole of the magnet, the extremity, D, of the needle will afterwards be found to have acquired the south polarity, and the other extremity, C, the north.

In this operation it is evident, that, after the first stroke, when the magnet is applied again to C, this extremity, having acquired the north polarity, will have that power destroyed by the vicinity of the north pole, B, of the magnet; so that it seems that every stroke undone what was done in the preceding. However, the fact is, that by repeating the strokes the power is increased; but, in general, this method will never be so advantageous as when more than one magnetic pole is used; hence it ought not to be used, excepting in case of necessity, viz. when one has only one magnetic bar or terrella.

Artificial magnets are preferable to the natural ones in a variety of respects. Mr. Mitchill mentions particularly, that they may be had at much less expense and trouble, and in greater plenty; that they are much superior to natural magnets in strength, and better able to communicate the magnetic virtue in proportion to their strength; that they are more easily restored to their former strength when they are at any time damaged; that they furnish several poles; and that they may be had in every form. Cavallo's Magnétism. Cavallo's Philosophy, vol. iii.

MAGNETICAL Amplitude, Animath, and Delineation, see the several sublimatives.

MAGNETICAL Island, in Geography, an island in the South Pacific ocean, near the N.E. coast of New Holland, discovered by Capt. Cook in the year 1770, and so named from its seeming to have some effect on the compass. S. lat. 19°. W. long. 213° 22'.

MAGNETICAL Line, is that line in which a needle would place itself, if left at entire liberty to turn itself as well vertically, as horizontally. See Dipping.

MAGNETICAL Meridian. See Meridian.

MAGNETICAL Needle. See Needle. See also Mariner's Compass, Dipping, and the article Magnet.

MAGNETICAL Paradox. Upon the table A B (Plate VI. Magnetism, fig. 15.) place a piece of iron wire, rot a tenth of an inch long. Let the magnetic bar, E F, be held at about four or five inches above the table, with either pole downwards, and in such a place, as that the perpendicular let fall from it to the table may touch the table at G, viz. two or three inches distance from the iron wire; these distances, however, are subject to a good deal of variety, arising from the power of the magnet.

By the action of the magnet the iron wire will elevate one of its ends, as represented by C D, forming with the table an angle, which is larger the nearer the wire comes to the point G, where it stands quite erect.

In this situation, if you give gentle knocks to the table, the wire, C D, will gradually proceed towards G, every knock making it jump up and advance a little way. The reason of which a superficial observer would immediately attribute to the attraction between the magnet and the iron wire, which, being not sufficiently strong to raise the wire from the table, has just power enough to draw it a little nearer to the point G, when the motion of the table lifts it up.

Thus far the experiment shows nothing extraordinary; but if it be repeated with only this variation, viz. that the magnet, instead of being held above the table, be placed below it, viz. at H I, the event will be, that the wire, which will now make an obtuse angle towards G, as represented by K L, on knocking the table, will gradually recede from the point G,lew, as if the magnet repelled it; which has given to this experiment the name of magnetic paradox; for, in fact, the magnet attracts the wire.

This phenomenon results from the directive property of the magnet acting at a greater distance than the attractive.

In order to explain the immediate cause of this phenomenon, it must be considered, that the wire K L, (fig. 16.) being rendered magnetic by the action of the magnet H, is inclined to it according to the above-mentioned laws of the dipping needle; but, on account of its weight, and because it is supported not in its centre, but by one end, namely K, which stands upon the table, it does not incline so much as it ought to do, if it were freely suspended by its centre, the end K, now being a little higher than its proper situation. Let M N be the perpendicular, which passes through the centre of the wire. Now, when by the motion given to the table, the wire is made to jump; this, being remaining in the air, will take its proper inclination, as shown by r Q, its centre remaining in the same perpendicular M N; for the directive power of the magnet, H, acts at a greater distance than its attraction. In this situation it is evident, that a perpendicular P O, let fall from the lower extremity, r, of the wire, touches the table in a point farther from G than the point K; and as the wire after the jump comes down to the table again with the proper inclination, viz. parallel to r Q, it follows, that now its lower end will touch the table at O; and thus every knock will
will force it to recede a little more from the point $C$, which lies just over the magnet $H$.

The same explanation applied to the first part of the experiment, will shew that the wire must in that case, viz. when the magnet is held above the table, approach continually the point $G$.

This experiment may be diversified by using iron filings, instead of the iron wire; for, in the first case, the filings dispersed over the table will be gradually collected about the point $G$; and in the latter case, the filings placed about the point, $G$, will be gradually forced to recede from that point. Cavallo's Magnetism, chap. vii.

MAGNETICAL VARIATION. See VARIATION and DECLINATION.

MAGNETIS LAPIs, in the Natural History of the Ancients, the same given in different ages to two very different substances. The earliest Greek authors expressed it by the load-stone, which became afterwards called Hercleius lapis, (see IRON, Ore of, and Magnet); and then the word magnet was applied to a very different stone brought from the same place, the neighbourhood of Magnesia in Lydia.

This was a fine beautiful and bright substance, of a pure white, and so very bright and glossy, as to bear a resemblance to polished silver. It was dug in large mafles, and was of a texture capable of being wrought into any figure. Accordingly it was in great esteem among the ancients, who had it wrought into vellies for the use of the table.

It seems to be wholly unknown at present among the nations we have commerce with. Hill's Theophilus. p. 70.

MAGNETISM, MAGNETISMUS, that quality or constitution of a body, and its pores, whereby it is rendered magnetic, or a magnet.

Magnetism is found to be a transient power, capable of being produced and destroyed again.

Magnetism of the Earth is that property of the terrestrial globe, from which the magnetism of the ordinary magnets, the direction of the magnetic needle, and other phenomena are derived, and upon which they necessarily depend. This hypothesis is evinced by so many observations, that no philosopher can be sceptical enough to dispute its truth. The principal reason, says Mr. Cavallo, which prove it, almost to a demonstration, are, first, that almost all the phenomena which may be exhibited with a usual magnet, may be also exhibited with the earth, as far as it may be tried; and secondly, that vast mafles of iron, or ferruginous substance, actually magnetic, are dug out of the earth almost in every part of it.

The phenomena of the compass and of the dipping needle, in different parts of the world, and the magnetism naturally acquired by soft iron when properly situated, are exactly imitated by a common magnet, or a terrella; but the only phenomenon, which has not been observed with respect to the earth, and which is the principal property of the usual magnets, is the attraction of a piece of iron, or other ferruginous substance. For instance, if a piece of iron be presented to either of the poles of a common magnet, it will be powerfully attracted by it; but if it be presented to the middle of the magnet, the attraction will be found to be hardly perceptible, or at least incomparably weaker than at the poles; in conformity to which, it might be expected, that a piece of iron should be attracted more powerfully downwards, when near the poles of the earth than when near the equator; which attraction, being combined with the attraction of gravitation, ought to be known by the difference of the weights of the same piece of iron, when weighed near the poles, and when weighed near the equator; for, if the magnetic attraction of the earth upon it be at all sensible, it ought to weigh more in the former case than in the latter. But this difference of weights has not yet been ascertained; however, if it were to be tried with all the accuracy necessary for a nice an experiment, I am inclined to think that it would be found to answer; viz. that the same piece of iron would be found to weigh somewhat more in places nearer to the poles, than it does nearer to the equator: but, even in case no such difference of weights were observed, it would be improper to infer that the earth does not exert any magnetic attraction towards the iron on its surface, and that this attraction is not stronger near the poles than near the equator; because, first, the magnetism of the earth being very weak, the difference of the attraction in different places must be likewise very small, notwithstanding the directive power is considerably strong: for, as was explained under the article MAGNET, the latter of these powers tends to a much greater distance than the former. And, secondly, it must be considered, that the equatorial diameter of the earth is longer than its polar diameter, and that the attraction of gravitation, or the weight of bodies, decreases in proportion to the squares of the distances from the centre of the earth; in consequence of which, if we abstract the magnetic attraction, and consider only the attraction of gravitation, it will appear that the piece of iron must weigh more when weighed near the poles than when weighed near the equator; namely, because when near the poles, it stands actually nearer the centre of the earth than when near the equator.

If the magnetic needle pointed always due north and south, or always within a certain distance of those points, it would shew that the earth has two fixed magnetic poles, either coinciding with its astrononical poles, or at some distance from the same; but the continual variation of the magnetic needle shews, that these magnetic poles of the earth move with respect to the surface of the earth, and, on this account, many suppositions have been offered to the public by divers ingenious persons. It was imagined, that there was a large magnet inclosed within the body of the earth, which being not fixed to the external part, moved with respect to it, and, consequently, occasioned the variation of the needle.

To this purpose, Mr. Whiston alleges that the earth on which we live, includes within it a vast spherical magnet, concentrical thereto, having its own poles, meridians, equators, and parallels; and all much of the same general nature of those with small terrella, or spherical load-stones, in the possession of the curious among us.

The power of a good terrella, or a spherical load-stone, says this author, as it affects a needle a foot long, is equal to the magnetic power of that internal load-stone about two and a half, or three diameters of such load-stone. From which consideration, the quantity of magnetic attraction at all distances from the internal load-stone, for needles a foot long, may be determined; and from the same consideration it appears, that the diameter of this internal load-stone is about eleven hundred and fifty miles. To which we add, that, in regard for Isaac Newton has demonstrated, that the power of gravity diminishes within the earth, and is less there than at its surface, nearly in the proportion of its greater nearness to the centre, the magnetic power, at two thousand nine hundred miles distance from us, and nearly one thousand and sixty from the earth's centre, which is 1/2 of the power of gravity here, will be somewhat greater than the power of gravity there; which limit is worthy our attention, gravity being stronger than magnetism on the one side of it, and weaker on the other; we mean, as it affects needles of one foot diameter. At that limit, therefore, at least
leath near the magnetic poles, iron a foot long will be twice as heavy, and fall twice as fast, as any other natural body, viz. by the union of those two equal powers, gravity and magnetism; and of consequence, above that limit, such an iron will be less than twice as heavy, below it more than twice as heavy, as any other natural body.

The earth's internal load-flone, he says, is not fixed to our upper parts, but is moveable with respect to them, and actually revolves on the earth's axis, from east to west, in a certain long period of time; as appears beyond contradiction, from the constant variation of the horizontal needle westward; as well as the regular increase of inclination of the dipping needle.

The only way to render this motion, i.e., the variation, possible and intelligible (to use Dr. Halley's words), is to suppose it to turn about the centre of a globe, having its centre of gravity fixed and immovable in the same common centre of the earth. This moveable internal surface must likewise be loose, and detached from the external part of the globe, which may be reckoned the shell, and the other the nucleus or inner globe, included within it, with a fluid medium between. Now, from the variation's moving westward, it is plain, that the forefald nucleus has not precisely attained the same degree of velocity with the exterior parts in their diurnal revolution; but so nearly equals it, that in three hundred and sixty-five revolutions, the difference is scarcely sensible: and must probably have arisen from hence, that the impulse, whereby the diurnal motion was impressed on the earth, was given to the external parts, and thence communicated to the internal.

This internal magnet has one central pole northward, in the nature of the poles of our common load-flones; but its southern pole appears not to be central, but rather circular, and that at a great distance from the southern pole of the earth.

The northern magnetic pole is new situate, says Mr. Whiston, about the latitude of 76½ degrees; i.e. 13½ degrees from the north pole of the earth, and about 50 degrees eastward from the meridian of London.

The southern magnetic circular pole has its centre, or central pole, nearly in the parallel of 60 degrees; and, in a meridian passing along the east coast of Borneo, about 117 degrees eastward of London. Its radius is also an arc of a great circle of about 44 degrees.

The respective motion of the internal magnet, or the velocity, v.g. of its north pole, appears to be 27 deg. 0 min. in 144 years, i.e. upwards of one degree in five years; so that it makes an entire revolution in 1920 years. Hence, as the number of degrees in the upper earth's diurnal revolution is to the number of days in the revolution of the internal magnet, i.e., as 81 is to 700,000, so is the respective motion of this magnet from east to west to the real motion of the upper earth from west to east; or, to speak briefly, so is the difference of their motions from west to east to the entire motion of the upper earth the same way. This external fixed earth has therefore communicated almost all its motion already to the internal magnet; and can communicate no more than this difference of their motion, and that only in an infinite term of years; or, in other words, this real internal motion can never be the seven hundred thousandth part swifter than it is at present. This internal motion, therefore, began with the commencement of the diurnal motion of the upper earth; and has gone on still faster and faster by the communication of that motion through the intermediate fluid. Since, therefore, action and re-action are equal, and tend to contrary parts, this internal load-flone, thus accelerated by the upper part, must have all along retarded that upper earth, and made the diurnal rotation still slower and slower. This acceleration on one side, and retardation on the other, must have been very great at the first beginning of the diurnal motion, when the difference of their motion was equal to the entire motion itself, and must have been diminishing ever since. To which cause is probably owing that acceleration of the moon's motion with respect to that of the earth, since the time of the old astronomers, first taken notice of by Dr. Halley, and embraced by Sir Isaac Newton. And the same consideration seems to suggest a method for determining the age of the world: for, were the proportions of the quantity of matter in the upper earth to the internal magnet, with the tenacity of the intermediate fluid, &c., known, one might go back from the known difference of their velocity now, and find those differences and quantities of motion themselves, a priori, in all past ages; or, were the velocity of the first diurnal rotation of the upper earth known, we might geometrically determine, a priori, how long ago that rotation began, or how ancient our earth is.

The variation of magnetic needles from the azimuth of the meridians of the internal magnet is derived, says Mr. Whiston, from the difference of the strength of the several parts of the internal magnet's surface; which as it is only to be known by experience, that variation cannot be determined before-hand, unless where there are good accounts how much it had formerly been; it being probable, that it returns round, and will be the same in any year of the next revolution of the internal magnet, that it has been in the like year of any former revolution, or will itself have a revolution in about 10020 years. Mr. Whiston adds, that the two fixed magnetic poles in our upper earth, first introduced by Dr. Halley, as necessary to solve the irregularity of the variation of the horizontal needle from the meridians of the moveable internal magnet, seem not to have any just foundation in nature, the like irregularities being found in the common tercele, or spherical load-flones, and being best accounted for from the composition of the magnets, which are found to have parts of different degrees of purity, strength, and perfection; so that where the parts are weaker than ordinary, the stronger neighbouring parts prevail, and draw the needle that way: not but Dr. Gilbert's notion of prominent and depressed parts on magnets may have some room, and be allowed to contribute somewhat to such variations. See Variation.

On the supposition above stated, the variation ought to be regular; that is, it ought to move in all parts of the world, as to suffer to the two points of the large internal magnet; which, however, is not the case.

In order to supply the deficiency of this hypothesis, it was farther imagined, that there were four magnetic poles within the earth, which were moveable with respect to each other, and that, therefore, the variation of the needle ought to be derived from all their actions conjointly; which would render the theory of the variation exceedingly intricate; but, notwithstanding this difficulty, a regularity, within certain laws and limits, ought to be still observable respecting the variation; but no such regularity has been yet proved. In short, without detaining our readers any longer on this point, it will suffice to say, that no theory yet offered has been sufficient to foretell, with certainty, the variation of the needle for any future period of time, or for any place distant from those in which observations have been frequently made. See Declination, Compass, and Variation.

Mr. Cavallio is of opinion, that the magnetism of the earth arises from the magnetism of all the magnetic sub-
MAGNETISM.

...fances therein contained, and intermixed with other bodies; that the magnetic poles of the earth may be considered as the centres of the polarities of all the particular aggregates of the magnetic substanties; and that these principal poles must change place, relatively to the surface of the earth, according as the particular aggregates of magnetic sub-
stances within the earth are in some manner or other altered, so as to have their power diminished, increased, approached, or removed from the principal poles.

Although no regularity has been established with respect to the variation of the needle, yet as the different situation of the magnetic poles within the earth occasions a great variety of appearances, and as the right understanding of these varieties may be of great use to those who wish to in-
vestigate this intricate subject, the development of which will be of vast use to mankind; we shall here subjoin the principal cases, as they are drawn up by Mr. Loomer, which seem to be possible, relating to the position of the magnetic poles; conceiving, agreeably to the most natural and most generally received supposition, that they are two, and that they lie on the surface of the earth. These cases are no more than four, viz.

Case 1.—If the magnetic poles of the earth had coincided with the true poles thereof, there could have been no declination or variation of the needle's compass in any part of the world, that is, if the earth be uniformly magnetical; for, in that case, the needle, in pointing to the magnetic poles, would always have pointed to the true poles also; this needle would therefore be necessarily directed along the course of the meridian, or, in other words, it would have no declination or variation either to the east or west thereof.

Case 2.—If the magnetic poles were situated in the same meridian, and in opposite parallels; upon that meridian which passes through the magnetic and true poles, from the one of the magnetic poles to the other, and upon the oppo-
site meridian all along, there could be no declination, for the reason mentioned in the former case. Likewise, upon the equator, there would be no declination; for though if one of the magnetic poles were only to act upon the needle, in passing along the equator to the distance of 90 degrees in longitude east or west, the declination would incrase, so that at 90 degrees distance from the line of no declination it would be equal to the angle contained between the magnetic and true poles; yet, as the other magnetic pole, in this case, is always within the same distance of the earth as the former, upon the opposite end of it with equal force, and consequently, will keep it parallel to itself all round the equator. But in going from the equator north or south, the declina-
tion would increase so as to be 180 degrees on the least arches or spaces of the meridian contained between the true and the magnetic poles, which is the greatest possible de-
clination in all cases whatsoever. It must be farther ob-
erved on this case, that the lines of no declination, includ-
ing those arches of 180, form two great circles of the globe along the meridian and the equator, crossing one another at right angles, and dividing the surface of this globe into four quarters, two in each hemisphere; the one hemisphere having west declination in the north, and east de-
clination in the south half thereof, and in the opposite hemi-
sphere it would be just the reverse; so that each of the arches or semicircles of no declination would have east declination on the one side of them, and west declination on the other. The small arches of 180° declination, which are between the true and magnetic poles, may be reckoned in all cases as a part of the lines of no declination; for there indeed the needle conforms itself to the meridian as well as in the other parts of the circle, though its ends are reversed. In short,
as all the lines of declination do coincide and terminate in the magnetic and true poles, these arches of 180° are a kind of limit, making with each of those lines, as in the present case, a curve line or figure returning into itself; which figures, from 180° between the poles, to 0 declina-
tion upon the equator, do each of them include a space larger than the other, till at last they fill up the whole quar-
ter of the surface of the globe, and confonn themselves, as nearly as possible, to the figure and shape thereof.

As a variety of this case, it may be added, that the mag-
netic poles may be situated in the same meridian, but in parallels which are not opposite. In that case, the only alteration which could happen is, that in the hemisphere in which the magnetic and true poles are nearest to each other, the figures formed by the lines of declination become smaller, and the corresponding figures in the opposite hemisphere, larger. The line of no declination, which, in this case, represents the equator, would also be proportionally nearer to those poles which are nearest to one another.

Case 3.—If the magnetic poles were situated in oppo-
site meridians, and in opposite parallels; upon those meri-
dians which pass through the magnetic and true poles there could be no declinations, for the reasons mentioned in the two former cases. But upon the equator, eastward or westward, to the distance of 90°, the declination would actually increase, so as there to be equal to the angle which measures the distance between the true and the magnetic poles; and from thence it would, in the same manner, de-
crease for the other 90° to the opposite meridian. The de-
clination lines of 10°, 20°, &c. as far as the greatest declina-
tion upon the equator, in this case, become arches or curves, which conform themselves, as nearly as may be, to the course and direction of the lines of no declination, and are called lines of the first order. But the lines of the greatest equatorial declination cross one another at the distance of 90° in longitude from the meridian or circle of no declina-
tion, something in form like the letter X, or like two Gothic arches joined at the vertex. They are called lines of the sec-
ond order, and may very properly be considered as the boundary between the lines of the first and third order, as the lines of no declination are always boundaries between the lines of east and west declination. In this case, those lines of no declination, including the arches of 180°, form only one great circle along the meridian, dividing the surface of this globe into two hemispheres of which one has east declination, and in the other west declination.

From the greatest equatorial declination to the arches of 180°, the declination lines of the third order are curves returning into themselves, and in shape nearly resembling parabolas erected upon those arches of 180°.

As a variety of this case, it may be added, that if the magnetic poles were situated in opposite meridians, but in parallels which are not opposite, then, in that hemisphere in which the true and the magnetic poles approached nearest to one another, the figures formed by the lines of declination would be smaller, and in the opposite hemisphere the cor-
responding figures would be larger in proportion.

Case 4.—This case is a very extensive one, viz. when the magnetic poles are situated neither in the same nor in opposite meridians; and this seems to have been the real position of those poles ever since any observations of the declination of the magnetic needle have been made.

In this case, then, the lines of no declination cannot be either in the direction of a meridian or along the equator, as in the former case, but in a kind of curves, which are variously inclined to both; and they divide the surface of the globe into two parts, but these parts are not hemi-

Magnetism.

Spheres, as in the last cafe, for they may be of a very different extent. If the magnetic poles be situated in meridians nearly opposite, the curvature of those lines will not be so great, that is, they become more like to Cafe 3. But as the magnetic poles approach nearer to the same meridian, the curvature of the lines of no declination becomes greater, till they almost touch one another. Something in form like the figure of the number 8, and at last they complete the two great circles, as in Cafe 2. The lines of the former correspond to the greatest equatorial declination, if the magnetic poles be situated in meridians nearly opposite, have a declination nearly equal to the angle formed between the magnetic and true poles, as in Cafe 3; but as the magnetic poles approach towards the same meridian, this declination decreases, till at last it entirely vanishes, as in Cafe 2. The other declination lines in this cafe are so similar to the former, that they require only to be referred to it. Lastly, it must be observed, that whether the magnetic poles be situated in opposite parallels or not, makes as little difference in this as in the former cafe.

Hitherto the magnetic poles have been considered to lie on the surface of the globe; but if we attentively consider the situation which they may more likely have, it will appear, that in all probability they are not situated near the surface of this globe, but at some depth below it; at least this must be the case with the south pole; for, since the water of the sea is incapable of magnetism, and the southern hemisphere, especially about the south pole, contains a vast deal more sea than land; it is plain that the south magnetic pole must be situated at least near the bottom of the sea; in consequence of which, the variation of the needle in that hemisphere must be different from what it would be if the magnetic pole were situated on the surface of the terraqueous globe. The same may be observed with respect to the situation of the north magnetic pole. Besides this, we must also consider the irregularities arising from the unequal and irregular situation of land and sea; it being natural to conceive, that large tracts of land on one side of the magnetic needle will draw it away from the real meridian, whereas a large ocean can produce no such effect. This, however, is subject to a great deal of variety, arising from the nature of the land, the depth of the sea, the nature of the ground at the bottom of the sea, &c. It appears, therefore, that a great many causes combine to act upon the magnetic needle, occasioning it to decline from the true meridian, and that it is almost impossible to form a useful theory upon it.

Magnetism, Theory of. As for the causes of magnetism, or the manner in which attraction, repulsion, and other magnetic phenomena are produced, we have yet no hypothesis, that will satisfactorily account for them. Plutarch tells us, the magnet attracts iron, by emitting some spiritual effluvia, whereby the contiguous air being opened and driven on either side, does again drive that contiguous to it; and thus the action being communicated round, the iron is thereby protruded; but this is contradicted by the equally vigorous action of the loadstone in vacuo, and in the open air. Others of the ancients ascribe the action of a magnet to a fluid that animates it; and others to an unknown sympathy between the effluvia of the iron and those of the magnet.

An opinion, that has much prevailed among the ancients is that of Des Cartes, maintained by Malebranche, Rohault, Regis, &c. and even admitted and confirmed by Mr. Boyle, &c. In this it is supposed, that there is continually flowing from the poles of the world, a subtle, impalpable, and invisible matter, channelled or flirted, which matter, circulating round the earth, in the planes of the meridians, re-enters at the pole, opposite to that from which it issued, and paffes again through the poles parallel to its axis: that the magnet has two poles answerable to these of the earth; and that out of these there issues a matter like that just mentioned; and that this matter, entering at one of the poles, gives the impulse, whereby iron tends to the magnet, and produces what we call attraction. Now, besides the magnetical matter, entering the poles of the magnet, there is always a certain quantity thereof circulating round the magnet, composing a kind of vortex about it. The space wherein this matter moves, is the sphere of activity of the magnet, within which its attractive faculty is confined.

Dr. Gilbert, in his work "De Magnete," folio, printed 1600, concludes, from some experiments which he made, that the needle is not attracted by the magnet, but turned into its position, by what he calls a direnient virtue; which he supposes to surround the stone, somewhat in form of an atmosphere.

As to its directive faculty, or the inclination of a needle touched with it to the poles of the world, and its dip to a point beneath the horizon, they follow from the same principle; since, were the magnet or needle to have any other situation, the magnetic matter would strike on its other surface in vain; and, not being able to get admission, would, by degrees, change its situation, till such time as its pores corresponded to the course of the magnetic matter; which situation having once acquired, it would cease to move, the magnetical matter then ceasing to disturb it.

The form or essence of a magnet, therefore, is supposed to consist in its being perforated by an infinite number of parallel pores; some of which are disposed to admit the flirted matter from the north pole of the world, others that of the south pole; and thus the north and south poles of the magnet.

Mr. Hartsoeker maintains, that the magnet is no more than a common stone, full of an infinite number of hollow prisms, which, by the diurnal motion of the earth, are ranged parallel to each other, and nearly parallel to the axis of the earth. These prisms have their cavities filled with an extremely subtle matter, which, by the diurnal motion of the earth, is passed from prism to prism; thus making a circulation, and returning into the prisms, where it first began. From these principles he deduces all the phenomena of the magnet; and M. Andry does the same, from the doctrine of alkaline and acid.

As to the directive power of the magnet, Mr. Whiston inclines to think it mechanical; and ascribes it to magnetic effluvia circulating continually round the loadstone; of which circulations, he thinks, there are evident indications in magnetic experiments; as Mr. Boyle thinks there are of the magnetist, or magnetic effluvia of the earth; though these effluvia are never yet rendered sensible, as electric effluvia began to be in his time. But the attractive power Mr. Whiston thinks entirely immechanical, as the power of gravity; not being able to devise any such motion of a subtle fluid belonging to the loadstone, as will account for the attractive power in the sequesteruly proportion of the distances reciprocally; though if he could, yet would that be no more than to remove the immediate power of the Supreme Being one step further; the last resort of all mechanical principles whatever being in the immechanical power and efficacy of the Deity.

Dr. Newton deduces from several experiments the following propositions, which he offers, not so much to explain the nature of the cause of magnetism, as the manner in which it acts; the magnetic matter of a loadstone, he says,
moves in a stream from one pole to the other internally, and is then carried back in a curve line externally, till it arrive again at the pole where it first entered, to be again admitted; the immediate cause why two or more magnetic bodies attract each other, is the flux of one and the familiar stream of magnetic matter through them; and the immediate cause of magnetic repulsion is the conlusion and accumulation of the magnetic matter. His opinion was, that this earth had originally received its magnetism, or rather that its magnetic powers had been brought into action, by a shock, which entered at about the Southern, and passed out at the northern tropic. This, according to his statement, was the course of the magnetic fluid, and he supposed, that the magnetic poles were at first diametrically opposite to each other. But it is this, the case at first, we are led to conclude from Mr. Canton's doctrine, that they would not have continued so for; for, on account of the intense heat of the sun in the torrid zone, according to the principles stated under the article Declination, the north pole must soon have retired to the north-eastward, and the south pole to the south-eastward. (Phil. Trans. vol. xliv. p. 665 &c.) Mr. Michell rejects the hypothesis of a fluid, but though he proposed to establish a theory of magnetism, to explain his experiments, no such theory has appeared. Signor Beccaria, from observing that a sudden stroke of lightning gives polarity to magnets, conjectures, that a regular and constant circulation of the whole mass of the electric fluid from north to south may be the original cause of magnetism in general. This current he would not suppose to arise from one source, but from several, in the northern hemisphere of the earth: the abatement of the common centre of all the currents from the north point, may be the cause of the variation of the needle, the period of this declination of the centre of the currents may be the period of the variation, and the obliquity with which the currents strike into the earth may be the cause of the dipping of the needle, and also why bars of iron more easily receive the magnetic virtue in one particular direction. Lettre dell' Elettricismo, p. 269, or Priestley's Hist. Elec. vol. i. p. 409, &c.

Similar to this last hypothesis is that proposed by the ingenous Apisim, (Tentamen Theoriz Electricitatis et Magnetismi, cap. i. § 3.) which, though labouring under several objections, seems however to be the most plausible.

From the analogy of the elabilihied or more common hypothesis of electricity, which goes under the name of Dr. Franklin's. Mr. Apisim is led to imagine, that there exists a fluid producive of all the magnetic phenomena, and consequently to be called the magnetic fluid; that this fluid is so volatile as to penetrate the pores of all bodies; and that it is of an elastic nature, viz. that its particles are repulsive of each other.

He farther supposes, that there is a mutual attraction between the magnetic fluid and iron, or other ferruginous bodies; but that all other substances have no action on this fluid; they neither attracting nor repelling each other.

He then observes, that there is a great deal of resemblance between ferruginous bodies and electrics, or non-conductors of electricity; for the magnetic fluid passes with difficulty through the pores of the former, as well as the electric fluid passes with difficulty through the pores of the latter. However, there is not a body that has any action on the magnetic fluid, and is, at the same time, analogous to non-electrics; nor, in fact, there is no body, the particles of which attract the magnetic fluid; and yet this fluid can pervade its pores without any obstruction. In iron, instead, a kind of gradation of this sort seems to take place; for, the softer the iron, the more freely does the magnetic fluid pervade its pores; and, on the contrary, the harder it is, the greater opposition it offers to the free passage of that fluid; so that the iron, when soft, seems to be more analogous to non-electrics than when hard.

According to this hypothesis, iron, and all ferruginous substances, contain a quantity of magnetic fluid, which is equally dispersed through their substance, when those bodies are not magnetic; in which state they shew no attraction nor repulsion against each other, because the repulsion between the particles of the magnetic fluid is balanced by the attraction between the matter of those bodies and the fluid, in which case those bodies are said to be in a natural state; but, when in a ferrigenous body, the quantity of magnetic fluid belonging to it is driven to one end, then the body becomes magnetic, one extremity of it being now overcharged with magnetic fluid, and the other extremity undercharged. Bodies thus constituted, viz. rendered magnetic, exert a repulsion between their overcharged extremities, in virtue of the repulsion between the particles of that excess of magnetic fluid, which is more than overbalanced by the attraction of their matter. There is an attraction exerted between the overcharged extremity of one magnetic body, and the undercharged extremity of the other, on account of the attraction between that fluid and the matter of the body; but to explain the repulsion, which takes place between their undercharged extremities, we must either imagine that the matter of ferruginous bodies, which deprived of its magnetic fluid, must be repulsive of its own particles, or that the undercharged extremities appear to repel each other, only because either of them attracts the opposite overcharged extremities; both of which suppositions are embarrassed with difficulties.

A ferruginous body, therefore, is rendered magnetic by having the equable diffusion of magnetic fluid throughout its substance disturbed, so as to have an overplus of it in one or more parts, and a deficiency of it in one or more other parts; and it remains magnetic as long as its impermeability prevents the restitution of the balance between the overcharged and undercharged parts. Moreover, the ferrous iron is rendered magnetic by the fluid of the magnet; because, when the overcharged part or pole of the magnet is presented to it, the overplus of magnetic fluid in that pole repels the magnetic fluid away from the undercharged extremity of the iron, which, therefore, becomes undercharged, or posseffed of the contrary polarity, to the pole remote part of the iron, which consequently becomes overcharged, or posseffed of the same polarity as the presented pole of the magnet. When the piece of iron is rendered magnetic by presenting to it the undercharged extremity or pole of the magnet, the part of the iron which is nearest to it, becomes overcharged, &c. because that part of the magnet, being deprived of its magnetic fluid, attracts the magnetic fluid of the iron to that extremity of the iron which lies nearest to itself.

In consequence of which it appears, that, in order to give magnetism to a body, as a piece of steel, the strength of the magnet employed must be such as to overcome the resistence, which the substance of the steel makes against the free passage of the magnetic fluid; hence, a piece of soft steel is rendered magnetic more easily than a hard one; hence, a stronger magnet will render magnetic such ferruginous bodies, as other smaller magnets have no power upon.

The action of two magnets upon each other is likewise easily explained by this hypothesis. When two equal magnets
MAG or eleftrified philosophers; but certain external power, &c. then the weakest will have its power diminished, destroyed, or changed, in proportion to its fellow, weaknesses of magnetism, and other circumstances, which will easily occur to the intelligent reader.

Our venerable countryman, Mr. Cavendish, had invented a similar theory, and had entered in many respects more minutely into the detail of its consequences without being acquainted with the abovement work of Epines; although the publication of his paper on the subject was 12 years later. Lambart, Meyer, Coulomb, and Robison have also pursued inquiries of a similar nature, both theoretically and experimentally, with great success. See Young’s Philosophy, vol. i. lect. 55.

Magnetism, Law of. See Magnet, supra.

Magnetism and Electricity, Analogy between. The well-known property of amber, by which, after being rubbed, it attracts small bodies, was, in an early period of the science of electricity, described under the appellation of the magnetization of amber; for hence two powers, the electrical and the magnetic, were confounded as the same, or at least not sufficiently distinguished. At a later period these two powers have been regarded as quite distinct from each other, but in several respects exhibiting a mutual resemblance. We shall, therefore, here state some particulars in which they resemble one another, and others in which they differ. The power denominated by philosophers electricity (see that article) is of two sorts, viz. the positive, and the negative electricity. In the science of electricity, it is an invariable law, that bodies possessed of the same sort of electricity repel each other, whereas those which are possessed of different electricity attract each other.

Thus, in magnetism, there is a north and a south pole; those parts of magnetic bodies which are possessed of the same electricity, repel each other; but those which are possessed of different polarities attract each other.

In electricity, whenever a body in a natural state is brought within the sphere of action of an electrified body, it becomes itself electrified, and possessed of the contrary electricity, after which an attraction takes place; so that in truth there is no electric attraction but between bodies possessed of different electricities; for instance, if a piece of paper be brought sufficiently near a glass tube, electrified positively, the paper will acquire the negative electricity, and will then be attracted by the tube; but if the paper be so circumjanced as not to have it in its power to acquire the negative electricity, then no attraction will take place.

Thus, a ferruginous substanse, which is brought within the sphere of action of a magnet, cannot be attracted by either pole of the magnet, unless it acquires a peculiar electricity.

One sort of electricity cannot be produced by itself, but is always accompanied by the other; thus, if a glass tube be electrified positively on its external surface, a negative electricity must exist, either on its internal surface, or on the air contiguous to the tube.

In the same manner, the two magnetic poles are always together; nor was there a piece of ferruginous substanse ever produced, which had one polarity, and not the other.

The electric virtue can be retained and confined by certain bodies, like glass, amber, reifs, and others, called electriæ; but it easily pervades other substances, called conductors, or non-electrics.

The magnetic virtue is retained by ferruginous substances, especially those of a hard nature, like hard steel, and the magnet; but it pervades easily, and without the least perceptible impediment, all other sorts of substances.

On the other hand, the magnetic power differs from the electric, first, in its not affecting our senses with any light, small, taste, or noise; whereas, the electric spark, shock, smell, and taste, are known to every one conversant in electric experiments. Secondly, magnetism attracts only iron, or those bodies which contain that metal in some state or other; whereas, the electric power attracts bodies of every sort. Thirdly, the electric virtue resides on the surface of electrified bodies, whereas the magnetic is quite internal. Lastly, a magnet loses nothing of its power by magnetising other substances; but an electrified body loses part of its electricity by electrifying other substances. Here, however, must be remarked, that an electrified body loses part of its power, when in electrifying another body touches it, and that body acquires then the same electric electricity; but when that other body is electrified by being only brought within the sphere of action of the former, in which case it acquires the contrary electricity, then the former body loses nothing of its power; for instance, suppose that a body, A, possesses a certain quantity of positive electricity, and that another body B, in a natural state, be gradually brought near A; then the body B, when it comes within a certain distance of the electrified body A, acquires a negative electricity, which negative electricity takes away nothing of the power of the body A; but if the two bodies come very near, so as to touch, or as that the electricity of the body, A, may leap from it to the other, then the body, B, will become electrified positively, and A loses thereby part of its power. Indeed, if he be duly considered, this last case does not seem ever to take place with magnetism; for bodies appear to be rendered magnetic merely by the action of their spheres of activity, or by that power which enables magnets to act at some distance from their own bodies; and therefore we may justly say, that electrified and magnetic bodies agree in this, viz., that they lose nothing of their power, when other bodies are electrified or rendered magnetic in virtue of their spheres of activity.

When the aurora borealis, which has been thought to be an electrical phenomenon, forms a luminous arch towards the northern part of the horizon, the most elevated part, or middle of that arch, is generally in the magnetic meridian.

Several other points of analogy, or of difference between magnetism and electricity, will, perhaps, occur to those persons who examine both subjects; but if they be attentively considered, we think they will be found to be comprehended in those which have been enumerated above. Calvillo’s Magnetism, and Priestley’s Electricity, sib supra.

Magnetism, Animal, an appellation given by some designing or self-deceived operators upon the credulity and purée of mankind, to certain practices, by which, under the pretence of curing diseases, various effects were produced on the animal economy, such as faintings, partial and even general convulsions &c. These practices were principally carried on in France, by a portion of the name of Mefiner, and his disciples, and were believed to influence the human body through the medium of the magnetic principle. In consequence, however, of the appointment of a committee of philosophers for the investigation of the matter by the French king, the true nature of the operation was proved, in the most unequivocal manner, and the effects of it traced,
by the clearest experiments, solely to the mind or imagination of the persons magnetized. An ample detail of this able investigation, as well as of several other facts and practices referable to the same source, will be found under the article Imagination.

Magnetism is also used, by some Chemists, to signify a certain virtue, whereby one thing becomes affected at the same time with another, either in the same or in a different manner. This amounts to the same with what they otherwise call sympathy.

It has been observed, that much confusion in the science of magnetism has been occasioned by the application of the term magnetism to other things which had no relation to it. Thus, the chemical affinity between metals has been called the magnetism of metals by some old authors. The vibration occasioned by the found of musical strings or pipes upon others which were tuned in concord with them has been also called the magnetism of music. Some writers also speak of the magnetism of astronomy, the magnetism of water, &c.

Magnicourt, in Geography, a town of France, in the department of the Frâts de Calais, and chief place of a canton, in the district of St. Pol; two leagues S.E. of St. Pol.

Magnifying, among Philosophers, is chiefly used in speaking of microscopes, which are said to magnify objects, that is, to make them appear bigger than they really are, though in reality they do not, nor can, magnify any object, but only seem it nearer, and discover more of its parts than before were taken notice of.

The magnifying power of dense mediums of certain figures was known to the ancients, though they were far from understanding the cause of this effect. Seneca says, that small and obscure letters appear larger and brighter through a glass globe filled with water; and he absurdly accounts for it by saying, that the eye slides in the water, and cannot lay hold of its object. Nat. Quæst. lib. i. c. 6.

Alexander Aphrodienis, the great commentator upon Aristotle, who flourished near two centuries after Seneca, says, that the reason why apples appear large when they are immersed in water is, that the water which is contiguous to any body is affected with the same quality and colour; so that the eye is deceived in imagining the body itself to be larger. But the first distinct account we have of the magnifying power of glasses is in the writings of Alhazen, who flourished in the twelfth century; and he was preceded by our countryman Roger Bacon, who, in his Opus Majus, demonstrates, that if a transparent body, interposed between the eye and an object, be convex towards the eye, the object will appear magnified; nor is it improbable, that from the observations of Alhazen and Bacon the construction of spectacles was derived. See Spectacles.

Magnifying Glass, in Optics, denotes a little spherical convex lens; which, in transmitting the rays of light, increases them, so as that the parallel ones become converging, and those which were diverging become parallel; by means whereof, objects viewed through them appear larger than when viewed by the naked eye. See Microscope.

Magnin, in Geography, a town of Egypt, on the left bank of the Nile; 12 miles S. of Shobur.

Magnisa, an ancient Magnesia, a town of Asiatic Turkey, in the province of Natolia, situated near a mountain, whose top is always covered with snow. The town is large and populous, but has few Christians; 20 leagues N.N.E. of Smyrna. N. lat. 38° 44'. E. long. 27° 18'.

Magnis Dei, a peninsula of Sicily, on the E. coast, in the valley of Noto; six miles N. of Siracusa or Syracuse; formerly the peninsula of Tapus. Opposite to this peninsula are the ruins of a monument, said to have been erected in memory of the victory of Marcellus.

Magnissa, in Mineralogy, a name given by some of the ancients to the white pyrites, called by others lęcolithos and argyrolithos. See Marcasite.

Magnitude, any thing that has parts without (or extra to) parts connected together by some common term. Magnitude is any thing locally extended, or continued; or that has several dimensions.

The origin of all magnitude is a point, which, though void of parts itself, yet its flux forms a line, the flux of that a surface, and of that a body. Magnitude amounts to much the same with what is otherwise called quantity.

Magnitude, Geometrical, may be usually considered as generated or produced by motion. Thus lines may be conceived as generated by the motion of points; surfaces, by the motion of lines; solids, by the motion of surfaces; angles may be supposed to be generated by the rotation of their sides.

Geometrical magnitude is always understood to consist of parts; and to have no parts, or to have no magnitude, are considered as equivalent in this science. There is, however, no necessity for considering magnitude as made up of an infinite number of small parts; it is sufficient that no quantity can be supposed to be so small, but it may be conceived to be farther diminished; and it is obvious, that we are not to eliminate the number of parts that may be conceived in a given magnitude, by those which in particular determinate circumstances may be actually perceived in it by sense, since a greater number of parts become sensible, by varying the circumstances in which it is perceived. See Maclaurin's Fluxions, art. 290, &c.

Many of late have supposed geometrical magnitude to be composed of infinitely small parts, and infinite in number, and hence have raised many paradoxes and mysteries in a science in which there ought to be none. Nay, infinitely small parts of infinitely small parts, &c. ad infinitum, have been introduced without the least necessity. See Maclaurin's Fluxions, in the Introduction, where he makes several remarks on Monseur de Fontenelle's Geometrie de l'Infini. See Extension.

Magnitude, Literal, denotes a magnitude expressed by letters.

Magnitude, Numerical, is that expressed by numbers.

Magnitude, Broken, denotes a fraction.

Magnitude, Complex, is that formed by multiplication.

Magnitude, Incommensurable, is that which has no proportion to unity.

Magnitude, Apparent, of a body, in Optics, is that measured by the optic or visual angle intercepted between rays drawn from its extremes to the centre of the pupil of the eye. It is one of the fundamental maxims in this science, that whatever things are seen under the same or equal angles, appear equal; and vice versa.

The apparent magnitudes of an object at different distances, are in a ratio less than that of their distances reciprocally.

The apparent magnitudes of the two great luminaries, the sun and moon, at rising and setting, are phenomena that have extremely embarrassed the modern philosophers. According to the ordinary laws of vision they should appear the least when nearest the horizon, as being then farthest distant from the eye; and yet we find the contrary to be true in fact.

Thus it is well known, that the mean apparent magnitude of
of the moon is 30° 30', in round numbers 30°, at a full moon in the midst of winter, and when she is in the meridian, and at her greatest northern latitude, and consequently at her utmost elevation above our horizon: it is also as well known that when she is in this situation, being looked upon by the naked eye, she appears to be, accommodating her magnitude to our sensible measures, about a foot broad. But when she is looked upon as the rives, she appears to be three or four feet broad, and yet if we take her diameter with an instrument, both in the one situation and the other, we shall find that she is only 30°.

Ptolemy, in his Almagest, lib. i. cap. 3, has ascribed this appearance to a refraction of the rays by vapours, which actually enlarge the angle under which the moon appears; just as the angle is enlarged by which an object is seen placed under water; and his commentator Theon explains difficulty how the dilatation of the angle in the object immersed in water is caused. But it was afterwards discovered, that there is no alteration in the angle: upon which another solution was first attempted by the Arab Alhazen; and followed and improved by Vitello, Kepler, Peckham, Roger Bacon, and others. According to Alhazen, the light apprehends the circumference of the heavens as flat, and judges of the stars as it would of ordinary visible objects extended upon a wide plain; the eye sees them under equal angles, but at the same time perceives a difference in their distances, and (on account of the direction of the earth, which is interposed in one case and not in the other) it is hence induced to judge those which appear more remote to be greater. Some further improvement was made in this explanation by Mr. Hobbs, though he fell into some mistakes in his application of geometry to this subject. For he observes, that this deception operates gradually from the zenith to the horizon; and that if the apparent arch of the sky be divided into any number of equal parts, those parts, in descending towards the horizon, will gradually subtend a lefs and lefs angle; and he was the first who expressly considered the vaulted appearance of the sky as a real portion of a circle. Des Cartes, and from him Dr. Wallis, and most other authors, account for the appearance of a different distance under the same angle, from the long series of objects intercepted between the eye and the extremity of the sensible horizon; which makes us imagine it more remote than when in the meridian, where the eye sees nothing in the way between the object and itself. This idea of a great dilatation makes us imagine the luminary the bigger; for any object being seen under any certain angle, and believed at the same time very remote, we naturally judge it must be very large, to appear under such an angle, at such a distance. And thus a pure judgment of the mind makes us see the sun, or moon, bigger in the horizon than in the meridian; notwithstanding their images painted on the retina are lefs in the former situation than the latter.

James Gregory, Geom. Par. Univer. p. 141, subscribes to this opinion: Father Malebranche also, in the first book of his "Recherches de la Verité," printed in 1673, has explained this phenomenon almost in the expression of Des Cartes: and Huygens, in his treatise on the Parhelion, translated by Dr. Smith, Optics, art. 536, has approved, and very clearly illustrated the received opinion. The cause of this fallacy, says he, in short is this; that we think the sun or any thing else in the heavens to be remoter from us, when it is near the horizon, than when it approaches towards the vertex, because we imagine every thing in the air that appears near the vertex to be no farther from us than the clouds that fly over our heads; whereas, on the other hand, we are used to observe a large extent of land lying between us and the objects near the horizon, at the farther end of which the convexity of the sky begins to appear; which, therefore, with the objects that appear in it, is usually imagined to be much farther from us. Now when two objects of equal magnitudes appear under the same angle, we always judge that object to be larger which we think is remoter. And this is the true cause of the deception we have been speaking of. It is a wonder that an hypothesis so rational as this should ever lose its credit, after having been maintained by writers of reputation, and for a great number of years. But it was generally imagined, that the actual perception of those objects which divide the space that is intercepted between the eye and the horizon were necessary, in order to its suggesting the idea of its extraordinary dilatation: and thus philosophers were led to form much more objectionable solutions of the phenomenon. Accordingly Gassendus was of opinion, that the pupil of the eye, which is always more open as the place is more dark; being more so in the morning and evening than at other times, because the earth is covered with gross vapours and besides, being obliged to pass through a longer column or series of vapours to reach the horizon; the image of the luminary enters the eye at a greater angle, and is really painted there larger at the former times than the latter. In answer to which it may be said, that notwithstanding this dilatation of the pupil, occurred by the obscurity, if the moon be viewed through a little pin-hole made in a paper, the surface appears les when in the horizon than in the meridian. Nor can any thing be more absurd than the position of Gassendus, who affirrs, that a dilated pupil magnifies an object for the same reason as a convex glass does.

F. Gouye advances another hypothesis, which is, that when the luminaries are in the horizon, the neighbourhood of the earth, and the gross vapours wherewith they then appear enveloped, have the same effect with regard to us, as a wall, or other denser body, placed behind a column; which, in that case, appears bigger than when inflate, and encompassed on all sides with an illumined air. Further, it is observed, that a column, when sunlight, appears bigger than before, when it was plain; the flutes being to many particular objects, which, by their multitude, occasion the mind to imagine the whole object, whereas they are conceived of a larger extent. The same thing may be said of the several objects seen towards the horizon, to which the sun or moon correspond at their rising and setting. And hence it is, that they appear larger still, when they rise or set between trees; the narrow, yet distant, intervals whereof have the same effect with regard to the apparent diameter of the luminaries, as a greater number of flutes with regard to the shaft of a column.

Bishop Berkeley supposes, that the moon appears larger near the horizon, because her appearance is then fainter, and her beams affect the eye less; but this hypothesis is refuted by Dr. Smith. Mr. Robins has recited some other opinions on this subject, Math. Tracts, vol. ii. p. 242. The commonly received opinion has been disputed not only by F. Gouye, who observes, Acad. Par. 1755, p. 11, that the horizontal moon appears equally large across the sea, where there are no objects to produce the effect ascribed to them; but also by Mr. Molyneux, who says, Phil. Trans. abr. vol. i. p. 221, that if this hypothesis be true, we may at any time increase the apparent magnitude of the moon, even in the meridian; for, in order to divide the space between it and the eye, we need only to look at it behind a clutter of chimneys, the ridge of a hill, or the top of a house. He also makes the same observation with F. Gouye, above-mentioned, and farther observes,
MAG

... that when the height of all the intermediate objects is cut off, by looking through a tube, the imagination is not helped, the moon being still conceived to be as large as before. However, Mr. Molyneux advances no hypothesis of his own. Dr. Deltagilus has well illustrated the doctrine of the horizontal moon, Phil. Trans. abr. vol. viii. p. 130, upon the supposition of our imagining the visible heavens to be only a small portion of a spherical surface, and consequently supposing the moon to be farther from us in the horizon than near the zenith. And, on several ingenious contrivances; he demonstrated how liable we are to such deceptions. But the most complete illustration of this curious subject is given us by Dr. Smith. The cavity of the heavens, he says, appears to the eye, which is the only judge of an apparent figure, to be a less portion of a spherical surface than a hemisphere. In other words, the centre of the concavity is much below the eye, and by taking a medium among several observations, he found that the apparent distance of its parts at the horizon was generally between three or four times greater than the apparent distance of its parts over head. This he determined by measuring the actual height of some of the heavenly bodies, when, to his eye, they seemed to be half way between the horizon and the zenith. In this case their real altitude was only twenty-three degrees. When the sun was but 30° high, the upper arch always appeared less than the under, and he thought that it was always greater when the sun was about 18° or 20° high. Mr. Robins, in his Tracts, vol. ii. p. 245. shows how to determine the apparent concavity of the sky in a more accurate and geometrical manner; by which it appears, that if the altitude of any of the heavenly bodies be 20 at the time when it seems to be half way between the horizon and the zenith, the horizontal distance will be hardly less than four times the perpendicular distance; but if that altitude be 28°, it will be little more than two and a half.

Dr. Smith having determined the apparent figure of the sky, is able to give a satisfactory explanation of the phenomenon of the horizontal moon, and other similar appearances in the heavens. For supposing the arc A B C, (Plate X. Optics, fig. 4.) to represent that apparent concavity, he found that the diameter of the sun and moon would seem to be greater in the horizon than at any proposed altitude, measured by the angle A O B, in the proportion of its apparent distances O A, O B. The numbers that express these proportions he reduced into the following table, answering to the corresponding altitudes of the sun or moon, which are also exactly represented to the eye in the figure, in which the figures of the moon, placed in the quadrantare F G, described about the centre O, are all equal to each other, and represent the body of the moon in the heights here noted, and the unequal moons in the concavity A B C are terminated by the vertical rays that come from the circumference of the real moon, at these heights, to the eye, at O. The diameters of these unequal moons at A and B do, therefore, bear the same proportion to each other, as their apparent distances O A, O B; and they must appear in the same proportion that they really have in this concave, because we judge all objects in the heavens to be in this surface; so that the appearance to the eye is exactly the same, as if several moons were painted upon a real surface, A B C, in the proportions here alligned; in which case we should certainly judge the real magnitudes of the larger paintings of the lower moon to be really larger, though the visible magnitudes of them all, answering to their equal images upon the retina, were exactly equal. For the same reason Dr. Smith observes, that all the objects and difficulties of stars in the heavens, as well as the sun and moon, must seem to be greater in the horizon than in higher situations; which is known to be the case. He also observes, that the apparent conceave of the sky being less than an hemisphere, is the cause that the breadth of the colors in the heavens and outward from the horizon, are reduced to the half; and by an ellipso of the apparent breadths of the inward rainbow, at two different heights, made by a friend, he determined the apparent concavity of the sky to be much the same as by the former methods. (See HALO.) This theory of the horizontal moon is also confirmed by the appearances of the tails of comets, which, whatever be their real figure, magnitude, and situation in absolute space, do always appear to be an arc of the concave sky; and in further confirmation of it, he gives us Mr. Cotes's explanation of the optical appearance of a remarkable meteoor seen in the year 1716. Besides the general cause above stated of the appearance of the horizontal moon, Dr. Smith acknowledges, that, at different times, the moon appears of different magnitudes even in the same horizon, and occasionally of an extraordinary large size. This, he is inclined to believe, is chiefly owing to an extraordinary largeness of her picture upon the retina, which, in the preceding general theory, was supposed to be invariable. This, he says, might be best examined by taking the diameter of the moon with a retinanet, or by noting the year and day of the moon, together with the heights of the barometer and thermometer. For if it should appear, by many such observations, that the largest horizontal moons generally happen at her perigee, in the warmest summer evenings, the barometer being low, and the thermometer high; since these causes are independent of one another, and all conspire to enlarge the picture of the moon, we may reasonably conclude that these extraordinary moons are chiefly owing to the concurrence of these circumstances. But since the difference in the apparent magnitude of the moon is not increased th part of the whole in consequence of her being in her perigee, and the enlargement of the image in all the other cases here mentioned is very inconsiderable, it is probable that when the moon is imagined to be so much larger than usual, the imagination is further imposed upon by some circumstances which have not been attended to. Smith's Optics, vol i. p. 85 &c. Remarks, p. 53.

MAGNOL, Peter, in Biography, a celebrated botanist of Montpellier, was born in 1638. He was bred to physic, but, being a Protestant, could not take his degree there. He was therefore obliged to have recourse to some more tolerable and more Christian university, where such exclusive laws were unknown. Such are not the reproach of popery only. A few years ago some members of the university of Oxford proposed that one of their honorary degrees should be conferred on Mr. Kirwan of Dublin; a proposal intended at least as much for their own honour as for his. But this was found to be impracticable, because fo little that illustrious philosopher and distinguished character was a diverter! Wherever Magnol graduated, he practised physic at Montpellier for a long course of years, and at the same time very industriously cultivated Botany, not only as an auxiliary to medicine, but with the most enlarged views to its advancement as a science of itself. He was beloved for his urbanity, and esteemed for his knowledge. Numerous botanists flocked at this time to Montpellier, that neighbourhood being
MAG

being famous for its vegetable riches; and there were all eager to enjoy the society, and to benefit by the guidance and instructions of so able a man. Hence the herborsations around Montpellier have become celebrated in so many books; and the situations of the hortus Dei at l'Espérance, the Mont Celi, Caletelu, wood of Gramont, &c., have become classic spots. Among the pupils of Magnol were Fagon and the illustrious Tournefort, who regularly studied under him, and on many frequent occasions gratefully acknowledged their obligations to him. He was not chosen public professor till long after the years 1679 and 1681; when Tournefort was at Montpellier. He had indeed been one of four persons, nominated, and recommended to the king for the vacant professorship, in 1669; but his religion was an insuperable obstacle to his appointment, as that of King Solomon himself would, in the same case, have been. This difficulty was removed, by his affuming the guise at least of Catholicism, before the year 1694, when he at length obtained the professorial chair.

In 1679, our author published at Lyons his first work, the Botanicon Menfceliense, an octavo volume of 287 pages, with 22 plates. This same edition was republished at Montpellier in 1688, with a new title-page, and 20 pages of appendix. In this book Linnaeus reckons that 1460 plants are enumerated; Haller says 1354; all found wild about Montpellier, and almost entirely gathered there by the author himself. Among many others, very few of the class Cryptogamur were included, but some of them are now acknowledged varieties, and the last four of the appendix are exotics, inferred merely on account of their novelty. The arrangement of the work is alphabetical. The choice of the names is very select, and various criticisms or descriptions are subjoined, with the particular places of growth and medical virtues of each plant. The plates are rude, but original and characteristical. This is in fact one of the most original and authentic works of its kind, being to the Montpellier botanists what Ray's Syrphus is to that of Britain, the basis of all their knowledge. They are necessarily fupposed to be able to give an account of every plant which it contains; but their ideas are by no means as yet correct respecting every one, and an accurate Linnaean Flora Montfeliensis is still a desideratum.

In 1680, Magnol published an octavo volume, entitled Prodrorus Histioris Generalis Plantarum, in which he undertook a scheme of natural arrangement. We have not seen this performance. Haller says the method is that of Ray, deduced from the parts of each plant; and that the vegetable kingdom is disposed in 76 families, subdivided into genera. The author considers the flowers and fruits as of primary importance, but has recourse also to the roots and habit occasionally. Haller indicates a few mistakes. If they are the worst he could discover, the work must rank very high, even at the present day.

In 1697 appeared the Hortus Regius Montfeliensis, an 8vo. volume of 209 pages, with 21 elegant plates. This is an alphabetical catalogue of the garden, in which several new or rare species are described as well as figured. In their generic distribution the author conforms to Tournefort principally, and his preface shews how much he had contemplated this subject and its difficulties. When we consider that Magnol had had the care of the garden only three years previous to the publication of this rich catalogue, and that he found the collection in a very poor state, the book is an honourable monument of his industry as well as knowledge. The Cryptogamur, Saxifraga bifida, and Umbrosa Lathyris Nipponis, and some others, here appear for the first time.

In 1698, Magnol was admitted a member of the Académie des Sciences of Paris, in the place of his distinguished friend Tournefort, who died that year. He continued to prosecute his favourite studies, having prepared some observations upon the Planx of Calpin Bardin, which however he did not live to complete. He communicated to the Académie des Sciences some objections to the opinion of a circulating sap in vegetables, and some remarks on the importance of their medulla or pith. He also gave an account of an easy method of tingring the flowers of the Tulipaefor with a solution of some kind of lake.

Magnol died in 1715, at the age of 77. He left a son, named Anthony, who was professor of physic at Montpellier, but not of Botany. To this son we are indebted for the publication of the Novus Character Plantarum, on which the fame of Magnol as a systematic botanist chiefly rests. This polished work appeared in 1720, making a quarto volume, of 341 pages. The system therein taught is much celebrated by Linnaeus, who in his Clarges Plantarum, 375-493, gives a general view of it, expressing his wonder that so new and singular a system had not made more profestes. It professes to be founded on the calyx; but that term is taken in a very wide, and, at this time of day, unauthorized sense; for it comprehends the pericarp as well as perianth, the former being denominated the internal calyx, the latter the external. It is necessary to observe that Linnaeus, in the work above-mentioned, p. 376, sect. 2, a. 8, by an erroneous transfusion of the words perianthium and pericarpium, has rendered his account quite unintelligible. According to this system, every plant is fupposed to have either an external calyx (enfolding or inflating the flowers); or an internal one, which is the pericarp; or both. It is more natural than most early systems in its detail, but paradoxical in some of its primary characters. That fort of enveloped external calyx, which merely inflates the flower, is often scarcely more than the receptacle of Linnaeus, the real perianth being either paffed over, or taken for a corolla. The calices devoted to trees and shrubs are, as Haller observes, very imperfect; but we can hardly subcribe to his decision, that the work ought, for the fake of its author, to have been configned to oblivion. It is undoubtedly worthy the consideration of those who study natural affinities, and is not the least estimable for being hoftile to the popular methods of its time, founded on the corolla; though that circumstance has probably contributed, more than any thing else, to its neglect. The corolla in this method of Magnol affords subordinate distinctions only, entering into none of those obfervations and considerations which some of the primary characters in the method of Tournefort depend. — Works of Magnol. Hall. Bib. Bot. Devand, Bibl. Linn. Dorethes Recherches sur la Vie et les Observations de Beauval. V. Brouillonet Corona Fl. Montp. S.

Gen. Ch. Cal. Perianth inferior, of three ovaries, equal, concave, petal-like, deciduous leaves. Car. of fix, un; or more oblong, concave, obtuse petals, narrower at the base. Stam. Filaments numeros, incurved, pointed, compressed and two-edged, inserted into the common receptacle of the stigmas below the gernons; anthers terminal, linear, of two cells, burling longitudinally at the inner side. Poll. Germans numerous, ovate-elliptic, imbricated upon a cylindrical

R
'ovate or ovate receptacle; styles recurved, very short; stigmas longitudinal, creamy. 

Peric. Capsules numerous, fife, crowded, coriaceous, compressed, wedge-shaped, of one cell and two valves bursting outwardly, permanent. Seeds one or two in each cell, roundish-oblong, pulpy, coloured, at length hanging by a thread-like stalk, out of the capsule.

Off. For the distinctions between this genus and Liriodendron, see that article.

1. M. grandiflora. Laurel-leaved Magnolia. Andr. Repof. t. 518. (M. maximo floris subtus furci- 

gines; Trew Elriet. t. 33.)—Leaves perennial, coriaceous, oblong. Petals obvate. —Native of North America, from the northern limits of Carolina to the Mississipi. Michaux. It seems by the Hort. Kew. not to have been cultivated in this country before the year 1734. This is a very noble evergreen tree, sufficiently hardy, at least in the southern parts of England, or near the sea, only requiring plenty of water to blossom freely. The leaves are scattered, on short thick flanks, elliptic-oblong, more or less pointed at each end, from four to ten inches long, and two or three broad, veiny, very rigid and coriaceous; smooth, shining, and of a full bright green, above; opaque, and sometimes clothed with rusty down, beneath; their margin entire, thickened and somewhat wavy. Stipulas solitary, convalute, fleathing, downy, foon deciduous. Flowers terminal, solitary, on thick downy flanks, each as large as a pint bason, white, deliciously fragrant like the flavour of cold lemonade. The petals have the texture and aspect of delicate white leather, and thimk very much in drying. These flowers come out in July. The variety with rusty leaves blossoms at an early age, and is therefore most popular; but the great smooth-leaved kind, first brought to this country, of which finer specimens may be seen at Chelsea, Sion house, and other old gardens, is vastly preferable in itself, when it arrives at a sufficient age to produce its much larger flowers.

2. M. Plumeri. West Indian Magnolia. Swartz. Prodr. 87. Fl. Ind. Occ. 907. Plum. Gen. as above. (Talauma; Jaff. 281.)—Leaves perennial, coriaceous, roundish-obvate, smooth on both fides. Flower-flanks smooth. Petals ten or twelve. —Native of the West Indies, observed by Dr. Swartz in St. Lucia, Martinico, and Guadalupe, where the French call it either Bois pin, or Bois Cachiman. This author describes it as one of the largest of trees, often 80 feet high. "Branches round, annulated, scarched where the leaves have fiood, their bark of a greyish-brown. Leaves alternate, filacked, large, roundish inclining to ovate, coriaceous, reticulated with veins, smooth on both fides. Ffowers thick, round, flatish above, smooth and naked. Petals terminal, solitary, very large, white and fragrant, on thick smooth flanks, marked with whitish rings. Calyx of three large, ovate, concave, coriaceous, petal-like, veiny, deciduous leaves, externally glaucous. Petals from to to 12, rather longer than the calyx, oblong, obtuse, concave, thick, contracted at the base." Dr. Swartz never met with the fruit. Plumer describes and figures the latter as hard and knobby, of a blue colour, lodging in its fibres a few oblong nuts, each of which contains a kernel of the same shape. If Jaffieu, who found a specimen in Surinam's collection, with the name of Talauma, describes it as "large and ovate, resembling a Prunus or cone, composed externally of thick, granulated, corky, permanent scales; while the inner part is woody, hard, hollowed out in its circumference into numerous single-fed cells, apparently not bursting, some of them abortive." These are all the materials we have to judge by. Burman's ignorance and misplaced economy induced him to omit publishing a figure of the plant in his Icones of Plumier; see p. 161 of that book. Swartz seems to have had no suspicion that it could be anything but a Magnolia, though his character and description prove it specifically distinct from the grandiflora; to which however it appears to be so very nearly related, that we think it highly improbable there can be any real generic distinctions in the feed-vessil. We find nothing in Plumier or Jaffieu, but what may be referred to a not quite ripe, or an ill-understood, fruit of a genuine Magnolia.

cous beneath. Petals obvate. —Native of swampy ground in North America. "From New Jersey to Florida." Michaux. It appears to have been the first of its genus intro- 

duced into the gardens of England, having been cultivated by Bishop Compton, at Fulham, in 1688. This is a small tree, very desirable on account of its flowers, which come forth, at the ends of the branches, in July, and are cream-coloured, concave, about two inches wide, with a peculiarly rich visous fragrance, to some people rather offensive. The leaves also are beautiful, about three inches long, vary- 

ing in breadth, veiny; bright green above; glaucous and somewhat blaky beneath. In the variety seen in our gardens they are deciduous; in another, of which we have specimens from Carolina, they are evergreen, and of a longer narrower figure.

4. M. conspicua. Lily-flowered Magnolia, or Youlan, 

Ait. n. 3. Salis. Parad. t. 78. (Mokkwiren t; Banks Ic. Kempf. t. 43.)—Leaves obvate, obtuse with a point, apper- 

earing after the flowers are over. —Prefumed to be a native of China, where it has been cultivated for ages, forming a tree 30 or 40 feet high, with zigzag much divided branches, at the end of each of which, in the early spring, before any leaves appear, flounds an elegant white lily-like flower, four inches wide, with some of the cool lemon scent of the first species, at least when brought into a warm room. The leaves expand in May, and are flexible, on flender flanks, of a broad obvate or wedge-like figure, with a small tip, each three or four inches, or more, in length. Sir Joseph Banks procured this fine plant from China in 1785. It is hardy in our climate, and is at an early age covered with flowers from February to April, though the severe east winds of the season often injure its beauty, unless it is protected by a frame, or planted in a conservatory.

5. M. obvata. Purple Magnolia. Thunb. Tr. of Linn. Soc. v. 2. 356. (M. purpurea; Curt. Mag. t. 392. Andr. Repof. t. 324. M. dicolor; Venten. Malmais. t. 24. M. glauca 2; Thunb. Jap. 256. Mokkwiren; Kempf. Amoen. 845. Banks Ic. Kempf. t. 44.)—Leaves obvate, pointed, appearing with the flowers. Petals oblong, ahtupith. —Native of China, from whence the late duke of Portland is said to have obtained it in 1790. It is tolerably hardy, flowering in May and June, but appears to molt advantage in a conservatory. In the shape and habit of its leaves this agrees much with the last, but the flowers are larger, of a fine
MAGNOLIA.

fine purple, dark at the outside, and do not appear till the foliage is fully expanded; they have little or no scent. Willdenow and Thunberg erroneously consider Kämpfer's Lc. t. 43 and 44 as one of the same plant, nor has any one corrected their mistake till now. It is lamentable that Curtiss's appropriate name, purpuria, has not been preferred to that of Thunberg, who confounding the present plant with M. glauca, rather shakes our confidence in his botanical observations and opinions. It must be presumed that his white-flowered variety is our M. confusa; but in neither of these plants are the leaves glaucous beneath. They are both, especially their ribs and veins, more or less clothed with short brown hairs.

6. M. tomentosa. Slender Woolly Magnolia. Thumb. Tr. of Linn. Soc. v. 2. 336. Wild. n. 5. (M. gracilis; Salis. Parad. t. 87. Kobus; Kämpf. Ameen. 845. Lc. t. 43.)—Leaves ovate-oblong, pointed, downy beneath, appearing after the flowers. Petals fix, oblong, obtuse.—Native of Japan and China, from which last country the late Mr. Greville is said to have received a plant, which bloomed with him in the spring. Mr. Salisbury certainly knew the synonym of Kämpfer, from his herbarium and papers in the British Museum, and has well alluded to this to be a distinct species from the last.

7. M. pumila. Dwarf Magnolia. Ait. n. 6. Andr. Repof. t. 226. Sims in Curt. Mag. t. 977. (Gillenia indica; Rottleri MSS. Sampsa Salèa, or Milk Flower, of the Malays.) Leaves elliptic-lanceolate, pointed, smooth. Petals fix, obvate, very blunt, concave. Flower-flalk and calyx smooth, incurved.—Native of China, or rather, as we suspect, of some of the East Indian islands. It is cultivated in China, (from whence the late lady Amelia Hume received a plant about 1786,) as well as at Batavia and Madras, but is never known to produce fruit in any situation in which it has come under the examination of botanists, so that the genus is by no means certain. See what we have already mentioned on this subject under LIRIODENDRON tulipera. The prefent is a humble, smooth, deciduous thorn, kept in the greenhouse, where it blooms at various periods during summer. The foliage has a glaucous tinge, and is wary, and finely reticulated with veins. Flowers terminal, drooping, globoso, cream-coloured, short-lived, very fragrant at night, more like those of M. glauca in shape, but smaller, and with more of a greenish cast. The cells of the antlers are close together, at the inner side, and the whole anther is club-shaped and obtuse, very unlike that of the other species. Mr. Andrews alone has expressed these most important characters.

8. M. fuscata. Brown-flaked Magnolia. Andr. Repof. t. 226. Sims in Curt. Mag. t. 1068. Ait. n. 7. (M. ammonegolia; Salis. Parad. t. 5.)—Leaves elliptic-lanceolate, smooth. Petals fix, elliptical, concave. Flower-flalk erect, hairy, as well as the calyx.—Native of China, from whence it was procured by Mr. J. Banks, for Kew garden, in 1759. We saw and described the plant about the fame time in lady A. Hume's collection. It flowers in the greenhouse from April to July. The stem is of humble growth, with brown hairy branches. Leaves elliptic-lanceolate, sometimes inclining to obvate, about three inches long, smooth, veiny, deciduous except when kept in the flore. Flowers on lateral or axillary hairy silky flanks, of a dark dull purple, smelling strongly like apples, much smaller than those of M. pumila. Antlers with nearly marginal linear cells, opening inwardly, in true Magnolia.

9. M. acuminate. Blue Magnolia. Linn. Sp. Pl. 756. Ait. n. 8. (M. flava also, folio majore acuminate, sub aldantae; Carex Carol. v. 3. 151; with a plate.)—Leaves ovate-oblong, pointed, downy beneath. Petals more than fix, channelled, glaucous.—Native of North America from Pennsylvania to Carolina, upon the loftiest mountains. Michaux. Mr. Collinson first introduced it alive into England, in 1736. His original tree was lately in fine perfection at Mill Hill, and we hope still exists there, having escaped the devastation which that interregling spot underwent on its first fale, when ignorance and bad taste contended which should do the most mischief there. The place is now become a school, and its few remaining treasures must be preferred to be in great jeopardy. (See Collinson, Peter.) The present species forms a large, unbranched, deciduous tree, whose wood is yellow. Leaves clustered at the end of each branch, but on its subfrequent elongation becoming alternate, stalked, pointed at each end, several inches long, and nearly half as broad; green and smooth above; paler, and at first downy, beneath. The flowers appear among the young leaves early in June, standing solitary, each on a short smooth stalk, at the end of the branches. They are neither fragrant nor beautiful, though remarkable for their pale-green very glaucous petals, which vary in shape, but are always concave, or channelled, and nearly about two inches long. The capsules, with its red fruits, hanging by long threads out of their cells, is sometimes ripened in England. We have seen it at Kew, June 30th, 1779.

10. M. virgiana. Magnolia of Virginia. Linn. Sp. Pl. 755. Ait. n. 10. (M. folis ovato-oblongis ad bain et acuminatis, utrinque viridibus; Trew Ehret. t. 62, 63.)—Leaves lanceolate. Petals nine; the three outermost reflexed and dependent.—Native of Carolina; more rarely of Virginia. Miller appears to have had this tree at Chelsea in 1753, nor is it now uncommon in curious collections. It loves a moist strong soil. The leaves are deciduous, oblong, smooth, light green, tapering at each end, of a very large size, usually 18 inches long at an early period, and finally above two feet, spreading in the form of an umbrella at the end of each branch. Among them, early in June, flanks an upright, very large, white flower, remarkable for the three pendulous outer petals, and for its peculiar scent, which Munchaufen commends, but most people find insufferable, from its harsh-like overwhelming faint sweetness. Ehret compares it to a vast quantity of white lilies. The fruit is not known to have been ripened here.

11. M. auriculata. Ear-leaved Magnolia. Michaux Boreal-Amer. v. 1. 328. Wild. n. 8. Ait. n. 12. Andr. Repof. t. 573. Sims in Curt. Mag. t. 1206. (M. Fraferi; Wall. Carol. 159, t. 1. M. auricularis; Salis. Parad. t. 45.)—Leaves spatulate-ovate, acute; heart-shaped at the base; smooth beneath. Petals obovate.—Native of lofty mountains in Carolina, from whence it was first brought to England alive by the late Mr. Frazer in 1786. This, like the last, is a tree that flowers at an early age, and their habits are similar. The prominent rounded lobes at the base of the leaves mark the present species. The flowers appear in July, and are large, of a yellowish-white, and delightfully fragrant. Willdenow seems to have taken from the figure in Mr. Walter's book his character of "claws to the petals," for which there is no just foundation, that figure having been fealtly drawn, from a dried specimen.

12. M. macrophylla. Long-leaved Magnolia. Michaux Boreal-Amer. v. 1. 327. Ait. n. 9.—Leaves spatulate-ovate; heart-shaped at the base; glaucous and downy beneath.—Native of North America, to the west of the river Tennessee. Michaux. Brought by Mr. Frazer and his son, in 1800, "from the wilderness in Kentucky, on
the banks of the south fork of the Cumberland river."—

It flowers in June and July. We have seen but a leaf, which has a round, downy, fringed *fimbriate*, full of pith, as Michaux describes all the branches to be. The leaf itself is near 18 inches long, and nine broad, somewhat panduriform, being contracted above the dilated heart-shaped base, and then again extended: the upper surface is green and smooth; the under singularly glaucous, or nearly white, and finely downy; both are minutely reticulated with numerable veins. Michaux says the petals are *fix*, white, the lower ones purple at their bases.

17. *M. cordata*. Heart-leaved Magnolia. Michaux Bor- real—Am. v. i. 328. Ait. n. t. — 4. Leaves heart-shaped, somewhat downy beneath.—Native of dry open hills in Georgia and North Carolina. Michaux. Meefs. Frazer are recorded as having brought it to Kew in 1821, but it has not yet bloomed. Michaux says it is allied to *M. acuminata*, and that the flowers are yellow. We have never seen a specimen. S.

*Magnolia* in Gardening, contains plants of the evergreen and deciduous tree kinds, of which the species usually cultivated are, the laurel-leaved magnolia (*M. grandiflora*); the swamp deciduous magnolia (*M. glauca*); the blue magnolia (*M. acuminata*); and the umbrella magnolia, or umbrella tree (*M. tripetala*).

The first fort has varieties with broad leaves, and with narrow leaves.

And in the second kind there is a variety with long leaves, which is evergreen.

**Method of Culture.**—All these plants may be increased by seed, layers, and cuttings of the shoots.

With regard to the first mode, the seed, which is received annually early in the spring from America, preferred in sand, should be sown, as soon as possible, in pots of light rich earth, half an inch deep, plunging them in a moderate hot-bed, to bring up the plants an inch or two in height, or in the common earth under a warm wall or hedge, or in a frame, in the full sun, till the middle or latter end of April, then replanting them in an eyther border open to the morning sun, giving moderate sprinklings of water in dry weather. The plants will rise the same year; those in the hot-bed, probably in April, and the others in May, inuring those in the first situation timely to the full air. The plants should, all summer, be regularly supplied with water, and at the approach of winter be removed into a greenhouse, or, rather, under a garden-frame, to be sheltered from frost all winter, induding them with the open air in mild weather. If the pots be plunged in a bark hot-bed, &c. about March, under a frame, two or three months, it will forward the plants greatly; being careful to give water and having them to the open air gradually, so as to be removed into their pots fully in June, to remain till the autumn, when they should be allowed shelter in winter, as before. The following spring, they should be planted into separate pots, and plunged into a hot-bed, as before, to set them forward, giving water, occasional shade, and the benefit of free air; and in June removing the pots to a shady border for the remainder of the summer. In winter they should have shelter as before, from severe frost, but have the full air in all open weather. They require the same care for two or three winters, when some of them may be turned out of the pots with balls of earth about their roots, into the full ground, in a warm sheltered situation, particularly the deciduous kinds; but the first, or evergreen kind, should not be too soon exposed to the winter's cold, but be continued in occasional shelter in the above manner four or five years, till two, three, or more feet high; and when turned out, matted occasionally in severe winters, retaining some in pots to be managed as greenhouse plants of the more hardy kind.

In the layering mode, the layers should be laid down in autumn or spring, choosing the young pliable shoots for the purpose, giving them a gentle twist, or a slit in the part laid into the earth. Some will be well rooted in one year, others probably not in less than two; then take them off, and plant each in a pot in the early spring, plunging them in a moderate hot-bed for a month or two, to promote their growth freely at first, and they will generally form good strong plants by the following autumn, allowing them shelter in winter for a year or two, when they may be planted out.

In the cutting plan, the cuttings should be made from the young shoots of the preceding year, and be planted in pots of good earth, plunging them to the rims in the common or close hot-bed, giving water and occasional shade; some of them will be rooted the same year, when they must beinsured by degrees to the open air, after which they may be managed as the layers.

It may be noticed that the first, or evergreen kind, is one of the most beautiful trees in nature, both in its growth, and in the luxuriance of its noble leaves, which render it singularly conspicuous at all seasons. And the deciduous kinds are also highly ornamental trees, and may be introduced into clumps and shrubberies, where, by their fine foliage, they exhibit an elegant variety.

In common, all the different species are cultivated in the nurseries, for sale, from which they may be taken up and planted out in the early spring or autumn months; but the former is the better in moist places.

With regard to their disposition in the shrubbybery, as they are rather tender in their early growth, they should have a sheltered sunny situation, in a rather dry soil, being planted in the most conspicuous places, and not too closely crowded with other shrubs. But they have a good effect even when driped singly in different parts, as in open spaces of short grass-ground, in sheltered situations; especially the first kind, from its evergreen nature.

*Magnol.iae*, in Botany, a natural order of plants, so called from the genus *Magnolia*, which makes a principal figure among them, is the seventy-fifth in the system of Jullien, and the sixteenth of his thirteenth classes. See Ge-

**Rania.**

The *Magnolia* are thus characterized. *Calyx* of a definite number of leaves, sometimes bracted. *Petals* generally of a definite number, truly invested below the germens. *Stamens* numerous, distinct, with the same insertion; anders coalescing with the filaments. *Germens* several, either definite or indefinite in number, placed on a common receptacle; styles either one to each germens, or wanting; filaments one to each germens. *Capsules* or *berries* as many as there are germens, of one cell, containing one or many seeds; sometimes the pericarps coalesce into one single fruit. *Embryo* of the seed straight, destitute of albumen. *Stem* shrubby or arborescent. *Leaves* alternate, mostly undivided, the younger ones sheathed by *flapules* which embrace the branch, being convoluted in the form of a horn, as in the Fig genus, and protecting the bud, which is terminal. These *flapules*, however, soon fall off, leaving a circular scar. The *flowers* are either terminal or axillary.

The genera referred by Jullien to this order are *Eury-
andra* of Forster, which following the authors, Schrader makes a *Tetraecia*, see Euryandria; *Decins* of Forster, the *Wintera* of Schrader; *Illicnum, Niichla*, and *Magnolia of Linneus*; *Talouma* of Jullien, which is the original Magnolia of Plinmeri; *Libi-
dendron*
MAGNUM Os, in Anatomy, a name of one of the bones of the corpus. See its description in the article Extremities.

MAGNUS, John, in Biography, archbishop of Upsal, in Sweden, was born in 1488. He opposed most strenuously the Reformation in Sweden, and finding his efforts unsuccessful, he retired to Rome, where he died in 1544. He wrote a History of Sweden, and lives of the archbishops of Upsal: he had a brother Olaus, who was one of the persons at the council of Trent, where he displayed considerable talents for business. He died at Rome in 1590. His greatest work is a History of the Northern Nations.

MAGNUS, organist of the church of St. Giles-in-the-Fields, who flourished about the year 1729, was esteemed by his contemporaries, a great master of harmony, and an admirable extempore player on the organ; of whose great abilities many years after his decease we have often heard. Roxburghe and Dr. Arne speak with rapture. Before Kelway and Stanley were arrived at great renown, which they afterwards acquired by their voluntary playing, Magnus drew crowds of young organsists to St. Giles's every Sunday to hear him on the full organ, on which, deploring single folio tubs, he had attained to such command, as able to conduct four parts in fugue, with as much correctness and facility, as others could two parts, without fugue or imitation. Excessive fluidity and application brought on a disorder in his intellects, which put an end to his excellence, at an early period of his life.

MAGNY, in Geography, a town of France, in the department of the Seine-et-Oise, and chief place of a canton, in the district of Mantes; 12 miles N. of Mantes. The place contains 1402, and the canton 11,145 inhabitants, on a territory of 2223 kilometres, in 20 communes.

MAGO, a town of the island of Ceylon, near the S.E. coast; 98 miles S.S.E. of Candy.

MAGOAR, a town of France, in the department of the North Coasts; 10 miles S. of Guingamp.

MAGODUS, among the Romans, a name given to those players who sometimes acted the part of men, and sometimes of women: the word is derived from magus, magician, and sēntor, and properly denotes those players who performed extraordinary feats and puerilities.

MAGOLSHEIM, in Geography, a town of Germany, in the kingdom of Wurttemberg; 30 miles S. of Stuttgart.

MAGÓN, a town of the island of Minorca, said to have been founded by the Carthaginians.

MAGONA, in Ornithology, the name given by Buffon to the Macareus of Marcgrave, Ray, &c. and the great Tinamou of Latham. See Tetrao Major.

MAGOPHONIA, formed from magus, magician, and sēntor, or shouts, the name of a feast among the ancient Persians, held in memory of the expulsion of the Magi.

The Magus Smethiis having usurped the throne of Persia, upon the death of Cambyses, 521 years before Jesus Christ, seven of the principal lords of the court conspired to drive him out of it. Their design was executed with good success: Smerdis, and his brother, another Magus, called Patizethes, were killed. Upon which the people also rose, and put all the Magi to the sword; insomuch that there would not have one escaped, had not night come upon them. Darius, son of Hystasipes, was then elected king: and, in memory of this massacre of the Magi, a feast was instituted, says Herodotus, called Magophonia. See Magi.

MAGORA, in Geography, a town of Walachia; 14 miles S.E. of Bucșe.—Alfo, a sea-port of Arabia, in the Red Sea; 150 miles N.W. of Loheia. N. lat. 17° 40'.

MAGOT, in Zoology, the name given by Buffon to the Barbary ape of Pennant, or the Simia immi; which see.

MAGOTTY COVE, in Geography, a bay on the N. coast of Jamaica; one mile W. of Mulliketto cove.

MAGPIE RIVER, a river of Canada, which runs into the gulf of St. Lawrence, about six miles W. from the mouth of the river St. John.

MAGPYE, in Ornithology, a well-known species of the Corvus, or the corvus pica, in the Linnean Syllis, it is a crafty, reticent, noisy bird, called by Ovid nemoras convivis pica. See Corvus Pica.

MAGRA, in Geography, barren mountains of Africa, on the road from Tripoli to Egypt; 150 miles W. of Cairo.

MAGRA, or MAGAR, a river of Italy, which rises in the Apennines, and falling through a valley, called the "valley of Magra," runs into the sea, five miles S. of Sarzana.

MAGRACOTTA, a town of Hindooftan, five miles W. of Palcaucherry.

MAGRE, a town of Hindooftan, in the Myfory country, deemed by the Hindoes a place of peculiar sanctity, and abounding in pagodas and choutries; six miles from Savindour.

MAGREBIANS. See Murgabians.

MAGUA, a town of Hindooftan, in Dowlatabad; five miles S. of Bedar.

MAGUALDE, or Rio das Galines, a river of Africa, in Guinea, which runs into the Atlantic, N. lat. 7°.

MAGUANA, St. John, 60 miles a canton and town on the S. side of the island of St. Domingo, on the left side of the river Neybe. The capital of the ancient kingdom of Maguana flood where the town St. John of Maguana is now situated. This canton was pillaged by the English privateers in 1543. In 1764, the district of the new parish contained 3600 persons, of whom 350 were capable of bearing...
ing arms. Its population now amounts to more than 5000 persons.

MAIRANA. See MAHAYANA.

MAGUARI, in Ornithology. See CICONIA AMERICANA.

MAGUARIS, a name by which Dioscorides calls the Siphium.

MAGUELONE, in Geography, a lake of France, in the department of the Gard, near the Mediterranean, communicating with it, and extending from Catte to Peccas. Its name is derived from that of an ancient town, which was a bishop's see, transferred in 1338 to Montpellier. Charles Martel destroyed the town, because it was an asylum for Saracen invaders. It was rebuilt in the year 1569, but is now a small place, situated on a neck of land between the lake and the sea; five miles S. of Montpellier. N. lat. 43° 30'. E. long. 3° 5'.

MAGUIBA, a river of Africa, that runs into the sea, E. of cape Monte.

MAGULLACONDA, a town of Hindoostan, in Myfore; 30 miles from Changa Balabaram.

MAGUMBA, a province of Africa, in the N.W. part of the kingdom of Loango.

MAGYDARIS, in Botany, a name used by Theophrastus, and other of the old authors, for the laferiptum or laferwort.

MA-HA, or MA-COUFA, in Geography, a city of Chira, of the second rank, in Koetschou. N. lat. 26° 26'. E. long. 107°.

MAHABARAT, an epic poem in the Sanskrit language, by an author very celebrated among all sects of Hindoos, named Vyasa, to whom also is ascribed the sacred romances, the Puranas. (See VYASA and PURANA.) The subject of the Mahabarata is the heroic adventures of the five sons of Pandu, called hence the Pandavas. (See PANDU.) It is a work of great extent, amounting it is said to upwards of a hundred thousand metrical lines, of which more than a third have been translated by Dr. Wilkins, librarian to the East India Company. This learned gentleman published in 1785, an episode of the great poem, under the title of "Bhagavat Gita, or Dialogues of Krishna and Arjun." An extract from that very curious work is given under the article KRISHNA. The Mahabarata contains the genealogy and general history of the house of Bhuvarat, so named from Bharat its founder, the epithet Maha, or great, being prefixed in token of distinction; but its more particular object is to relate the disaffections and wars of the two great collateral branches of it, called from their ancestors the Kurus and Pandus (see KURU), both lineally descended in the feudal degree from Vichitravirya, their common ancestor, by their respective fathers Dritarastra and Pandu. In the dedication of the Bhagavat Gita, Mr. Warren Hastings, under whose superintendence the translation was made, after noticing the banishment of the Pandus, says, "The exiles, after a series of adventures, worked up with a wonderful fertility of genius and pomp of language into a thousand sublime descriptions, returned with a powerful army to avenge their wrongs, and to assert their pretensions to the empire in right of their father. In this state the episode opens." Without allowing the antiquity of four or five thousand years as claimed by the Hindoo literati for their juftly admired Mahabarata, its great age is unquestionable. In general estimation it ranks next to the Ramayana, if it be not superior to it, in reputation for holiness: the Vedas and Puranas only precede these works in the estimation of a great portion of the Hindoos. See RAMAYANA.

Mr. Moor, in his Hindoo Pantheon, after noticing the allegorical character of Oriental mythology, says, "This may serve as a farther specimen of the endless allegories in which the poetical fabilities have veiled the moral, scientifical, and theological knowledge of the Hindoos; all of which, as well as history, and even arts, if not buried in solitude, are obscured by, and intimately connected with, their wild and bold mythology. Thus, again, the Mahabarata is a continued allegory of the conflicts between man's virtues and his vices: the former personified under the names of the five sons of Pandu; of whom Bhima, Yudhishthira, and Arjuna, said to represent Justice, Fortitude, and Prudence, were by one mother, Koonti; and the other two, Nakula and Sahadeva, personifications of Temperance and Wisdom, were by Maderi. (See KOONTI and MADERI.) Other legends attribute the virtues of Modesty and Tenderness to Yudhishthira; Strength to Bhima; and Skill or Courage to Arjuna; to Nakula, Beauty or Harmony; and to Sahadeva, Wisdom and Penetration. The two last brothers are by some said to be the twin virtues of Temperance and Chastity. Man's manifold virtues are consecrated by the hundred sons of Kuru, the brother of Pandu; hence a near relationship exists between Vices and Virtue." P. 92.

MAHABELL, a name in Hindoo mythical legends of a monarch who, although reasonably virtuous on other points, was still so elated by his grandeur, that he omitted the essential ceremonies and offerings to the deities; and Vishnu found it necessary to check the influence of such an example, by revolving to become, for that purpose, incarnated in the person of a wretched Brahman dwarf. This incarnation, or avatar, is one of the ten principal deities of Vishnu, and is called Vaman, or the dwarf. (See VAMANA and VISHNU.) Sir William Jones furnishes the Belus of western history, to be the name of the Bels of this article, for the epithet of Maha prefixed, merely means great in the Sanskrit language.

MAHABUTPOUR, in Geography, a town of Bengal; 33 miles S. of Dacca.

MAHACKACKMACK, a river of America, which falls into the Delaware from the N.E. at the N.W. corner of New Jersey.

MAHA CONDAPALLY, a town of Hindoostan, in Myore; 15 miles S. of Osafloor.

MAHADEO, a temple of Thibet, situated on the lake Manfarooor.

MAHA DEVA, in Hindoo Mythology, is a name given to the god Siva, one of the perious in their divine triad. (See SIVA.) In Sanskrit it means literally the great god; and although we might expect to find this name thus applied by the sect only, who exclusively worship Siva, indicating the pre-eminence of their deity, yet it is said to be commonly given to him by other sects, as well as by his own.

MAHAKALA, a name of Siva, the destructive attribute of the deity. The name seems to be the same as Kal or Kala (which see), with an epithet prefixed, meaning great. Mr. Paterson, in the eighth volume of the Asiatic Researches, thus describes this personification. "Mahal Kal, as represented in the caverns of Elephants, had eight arms. In one he holds a human figure, in another a sword, or sacrificial axe; in a third he holds a basin of blood, and with a fourth he rings over it the sacrificial bell. Two other arms are broken off; with the two remaining he is drawing behind him a veil, which extingutishes the sun, and involves the whole universe in one undistinguished ruin. One of the titles of this tremendous deity is Bhairava, the Terrific; but his principal
The principal designation is Kal-Agni-Rudra." These three words, as we are told in the Hindoo Pantheon, are especially descriptive of Siva, and may be rendered Time, Fire, Fate. See Kal.

Niebuhr gives a print in his Indian Travels of the sculpture above described, which Maurice has copied into his sixth volume of Indian Antiquities. In the Hindoo Pantheon, the following description is given of this subject from the personal examination of the author. "Having lately been in the Elephanta cavern, and when there made some memoranda, I will hence extract what relates to the subject of Mahakala. — The compartment containing the group, of which Siva in this character makes the principal figure, is on the right of the entrance, facing a compartment of like size, containing what is another part of this work, I have supposed to be a marriage ceremony. The figure is of Siva Vinayak, fourteen feet high, but the lower extremities broken off; his attention is from his attitude turned to his left, his aspect is terrific, indicating the immediate execution of some avenging act, — he had eight arms; the superior right and left stretched upwards, and either supporting a cloth or curtain, or putting it over the terrible event he threatens — the fingers grasp the cloth. The left upstretched arm is finely executed; the right is broken at the elbow: the right hand is broken off at the wrist; the corresponding left holds a bell, in good preservation, over a cup in the palm of the next, having a serpent twining near the elbow. A third right hand grasps a long straight sword, uplifted, perfect; the two inferior hands, right and left, are broken off above the elbow: they were in hollowed relief, and the left appears to have supported, or to have grasped, the leg of a kneeling figure, the trunk only of which remains; its legs, arms, and head being broken off. This kneeling figure may have been between five and six feet in height; its back is toward the threatener, and leaning to his direction, as to drop its blood, if spilled, into the cup before noticed. The head of the principal figure has a highly ornamented cap; a scull and serpents are among its frontal ornaments. It has also a pendent necklace, and a chaplet, if it may be so called, of human heads, of which only two or three are plainly discernible, flowing over the left shoulder to the right thigh, in which it is broken off: the Zennar, or holy thread (see Zennar), and a broader belt, run in nearly a like direction. On all the wrists are bracelets, and above the elbows of three of the arms is the ornament called Bazbadan. No figures remain in any preservation to the right of the principal, or under him. On the left, near the suppurated victim, are two bearded faces, expressive of Pity; a compassionate female is just above them, leaning forward over the victim; she holds her hair in her hands, and is an elegant person; below the bearded men are two or three females with pouting aspects: the same emotion, intermingled with terror, is evident in every face of this compartment, where features can be traced.

"Over the subjects just described, is a row of males and females of rather diminutive size; in the middle of the row, nearly over the head of Siva, is a thing like a mitre, with a crozier cut deep in it, and surmounted with a crofs; but the limbs of the crofs not exactly at right angles; two aged and emaciated figures are on the right (the spectator's right) of the mitre, holding up their hands betokening pity and pain; on the other side of the mitre are two similar figures; in front of each pair is a prone, disfigured male child, their heads near the mitre: beyond the hill mentioned pair, on the spectator's left, are a male and female in great anxiety and disrefs, holding tears in their hands.

The subject, supposed to resemble a mitre, crozier, and crofs, appears also in another compartment of this cavern. Fancy may, perhaps, have had some share in making this resemblance; but it is really curious, and I think striking, although, I believe, heretofore not remarked." Hin. Pan. p. 51.

The great antiquity of the cavern wherein is this curious piece of sculpture is unquestionable, although no period approaching to exactness can be assigned for its origin. The Hindoos, and their Brahmins, with their accustomed proneness to hyperbole, throw it back into very remote ages; and some of our missionaries and other European travellers, as if unwilling to be outdone in extravagance, have imagined the figure here described of Mahakala destroying a human being, typical perhaps of Time and the human race, to be a representation of the judgment of Solomon! Without stopping here to discuss such ill-judged speculations, similar instances of which will be found under our article KRISHNA: it may be sufficient to notice the proofs that the art of sculpture had made in India in times certainly very remote in reference to art and science. The compartment described in the preceding extracts is elaborate in figures powerfully expressing one emotion of the mind; a precision strongly indicating great refinement and skill. It may be reasonably questioned if any specimen equal in age and execution can be elsewhere pointed out. Of the cavern temples of India, some account is given under the articles ELEPHANTA, ELORA, and KARLY.

MAHAKALI, a name of Parvati, the comfort of Siva, in his character of Mahakala, under which articles, Kal and Kali, farther information may be sought. MAHA-LAKSHMI, a name given by certain sects of Hindoos to Lakshmi, the comfort of Vishnu. See those articles. Under this name she is worshipped at a pretty temple on the western sea-shore of the island of Bombay, which is much referred to at the annual jatara, or fair.

MAHALEH, in the Materia Medica, the name of the fruit of a tree of wild cherry, called cerasus fiesbrius amara, or the wild bitter cherry, by Baillie. The wood of the tree is of a greyish grey, and fine grain, with a mixture of red in the veins, and is very firm, and of a sweet smell, and used by the French in making cabinets; the leaves and flower carry a rude resemblance of theh of the common cherry; the fruit is round, black, and resembles a cherry, having the same fort of stone in it, the kernel of which is like the bitter almond in taste. It is commended in external applications, and the perfumers of France use it in their washballs. It is to be eaten fresh and sweet; for it very often has an intolerable lingering smell, like that of bugs. See Prunus. MAHALOULE CASSIA, in Geography, a town of Afirica, in the kingdom of Tunis; 9 miles E. of Zunghar. MAHAMALL, a town of Algiers; 27 miles W.S.W. of Tipfa.

MAHAMMA, a town of Arabia, in the province of Yemen; 24 miles S.E. of Chamir. MAHAMUNDALA, a town of Hindooftan, in the Carnatic; 10 miles S. of Chittoor. MAHAN, a town of Peria, in the province of Kerman; 60 miles N.E. of Sirjgan. MAHANADA, or MAHLA-NUDDY, a river of Hindooftan, which rises in the mountains of Berar, in the country of Ruttunpaur, traverses the country of Orissa, falls by Cuttack, where it is sometimes called the Cuttack rive, and discharges itself by several mouths into the bay of Bengal; 40 miles E.S.E. of Cuttack. The farther point to which it is navigable from the sea is Arung. Near this river is the fort called Bond, and a town called Biriagar, which feeds.
see respectively. The mouths of the river, which form an
afflamation of low woody islands, like the Ganges, and many
other rivers, have never been traced, but are described mere-
ly from report. At the mouth of the principal channel, near
Falls point, is a fortified island, named Cojung, or Codjung.
Ptolemy's Adamas river answers perfectly to the Mahanuddy;
and the district "Sabare," on its banks, is said to abound in
diamonds.

MAHANEDA, a river of Hindoostan, which rises on the
borders of Boottan, and runs into the Ganges: 20 miles
N. of Mowrthbadn.

MAHANAGORE, a town of Bengal; 20 miles N. of
Ismamabad.

MAHAIM, or MAHAIM, in Ancient Geography, a
city of Palestine, belonging to the Levites, of the family
of Merari, in the tribe of Gad, on the brook Jakob. (Joh. xxi.
38, xii. 29, 30. 1 Chron. vi. 80.) Jacob gave it this
name, because he had here a vision of angels. (Gen. xxxii.
2.) In the Vulgate it is sometimes called simply "Cafran,"
or the camp. Gen. xxxii. 2. 2 Sam. ii. 8. 12. 29. xvii. 24.
xii. 32.

MAHASAN, in Geography, a city of Perofia, in the
province of Mazanderan, composed of three towns joined to-
ether. In 1392 it was taken, pillaged, and destroyed by
Timur Bec; 12 miles N.E. of Amol.

MAHAPOUR, a town of Hindoostan, in the cir-
car of Chandere; 38 miles W. of Chandere.

MAHANGANO, a province of Africa, in the king-
dom of Angola, having a capital of the same name.

MAHANY, a river of Hindoostan, in Bahar, which
runs into the Ganges, about 25 miles below Bar.

MAHAPRA YAMA, in Metaphysics, is considered among
Hindo philosophers as the grand conglomeration of all things:
the great destruction, as the word appears to mean. See
hereon under KAli.

MAHARSHIS, an appellation applied in Hindo books
to departed sages or saints. The terms Devarshi, Rajar-
shis, and Maharshi, seem nearly synonymous with Rihi,
mixed, feeling; daint, faint great, saint, or great sage. There
are differences doubtless, for Narada is reckoned the chief of
the Devarshis. Kritha in the Bhagavat Gita (see MAH-
ARAT) speaks of his "holy servants the Brahmanis and the
Rajarshis," and says "I am Brigha among the Maharshis,
and of all the Devarshis I am Narad," p. 86. (See NAR-
ADA.) Narada and Brigha are generally called sons of Bra-
mis. The term Maharshi occurring in the sixth section of
the first book of the Ramayan, the learned translators suppos
the following note—"There are four kinds of sages or
Rihis; the Rajarshi, or royal sage; the Maharshi, or great
sage; the Brahmanis, or learned sage; and the Devarshi,
or divine sage; of these the first is exalted the lowest,
and the last the highest." Hindoo Pantheon, p. 95. (See
RISHI.) The names of these sages, and allusions to them,
occur frequently in the writings of the Hindoes.

MAHA-RUDRA, in Hindoo Mythology, a name of
Siva. It means the great Rudra. See Siva and Rudra.

MAHAUP BAY, in Geography, a bay on the W. coast
of the island of St. Vincent, S. of Cumberland bay.

MAHAWA GAUT, a mountain of Bahar; 24 miles
W. of Safarnar.

MAHIBROOK, a town of Africa, in the Sahara; 100
miles W.N.W. of Tombatoo. N. lat. 19° 10'. E. long.
0 15'.

MAHIBUB, in Commerce, a Turkish gold coin. See
SIBUN.

MAHDIA, in Geography. See MADIBI.

MAHE', a town and fortresses of Hindoostan, on the
coast of Malabar. Mount Dilla, which is a remarkable
promontory, situated in N. lat. 12° 14'. E. long. 75° 2'.
or 1° W. of Cochin, appears to be W. 33° 15', or
nearly N.W. by W. from Mahé, distant from it 284 geo-
ographical miles. N. lat. 11° 45'. E. long. 75° 30'.
—Also, a small island in the Indian sea. S. lat. 4° 45'.
E. long. 57° 30'.

MAHENDRA, a name of the Hindoo deity Indra,
which see.

MAHERNIA, in Botany, is of uncertain derivation,
unless, as professor Martyn says, it be fancifully considered
as an anagrammatic inversion of Hermainia; the two genera
being very nearly allied, or rather, in reality, scarcely to be
ed. 2 v. 2. 198. Juff. 290. Lamark Illust. t. 218—
Claws and order, Pedantia Pentagynia. Nat. Ord. Colum-
nera, Linn. Illust., Juff.

Gen. Ch. Cal. Perianth of one leaf, bell-shaped, perma-
nant, cut into five, awl-shaped, longish teeth. Cor. Petals
five, heart-shaped, oblong, spreading, twice as long as the
calyx. Nectaries five, obcordate, on flanks, surrounding
the germen, shorter than the calyx. Stem. Filaments five,
capillary, placed upon the nectaries, shorter than the calyx;
anthers oblong; joined, erect. Ptl. Germen on a short
flank, ovate, five-sided; styles five, bristle-shaped, erect,
the length of the petals; stigma simple. Port. Capule
toate, of five cells, and five valves. Seeds few, kidney-
shaped. Eff. Ch. Calyx five-toothed. Petals five. Nectaries five,
joined to the base, obcordate, placed under the filaments.
Capule of five cells.

The following examples will be sufficient for the illu-
tration of this dubious genus.

324. t. 176. f. 1. (Hermannia ciliaria; Linn. Suppl. 302.)—
Leaves in whorls, linear and pinnatifid. Flowers in
pairs, on long flanks.—A native of the Cape of Good
Hope.—Linnaeus describes this plant in these words.
"Stem shrubby, diffinfe. Branches thread-shaped. Leaves
frequently from eight to ten in a whorl, linear, fljighly
divided or pinnatifid. Inflorescence the fame as in Her-
mania, terminal, the flanks generally two-flowered. Corolla
yellow.—Take away the nectaries from the petals, and
add them to the flamenis, and you will have a Hermannis,
(paradoxical as it may seem) with whorled leaves. What a
strange generic metamorphosis!"

t. 277.—Leaves three-parted, pinnatifid.—A native of the
Cape, whence it was introduced by M. P. Miller, in 1752.
It flowers from June to August.—Stem shrubby, nearly three
feet in height. Branches slender and delicate, with a reddish
 bark. Flowers in clusters, lateral, of a lively red colour
when first expanded, drooping like little bells, mostly two
 together. Linneaus originally esteemed this a species of
Hermannia.

Hort. Schomb. v. 1. 28. t. 54.—Stem erect, rough. Leaves
pinnatifid, cut and hairy. —A native of the Cape, flowering
through the summer and autumn.—Nearly allied to the lat-
in size and habit, but differs in the spurious hairiness of its
flanks, form of its leaves, and colour of its flowers. Stem,
when viewed with a magnifying glass, beft with little protrude-
rances from whose ito tufts of pellucid hairs. Leaves
deply jagged at their edges. Flowers, when in bud, of a
rich crimson colour, but, when expanded, of a deep orange,
becoming yellow as they fade.

M. glabrata.
MAH

M. glabrata. Wild. n. 6. Ait. Hort. Kew. ed. 2. n. 4. (M. odorata; Andr. Bot. Rep. 1. 85.)—Leaves lanceolate, pinnatifid and toothed. Stalks very long, bearing two flowers. Found also at the Cape. It blooms in the summer.—This species was first sent to England about 1792.—

Stem twiggy, and branched. Leaves dark green, the upper ones simple and opposite. Flowers yellow, fragrant like the longipal

The remaining species of Mahernia, enumerated by Willdenow, are, pulchella, dipfia, heterophylla and biflora.

Mahernia, in Gardening, comprises plants of the shrubby exotic kind, for the greenhouse, of which the species cultivated are, the wing-leaved mahernia (M. pinnata); and the cut-leaved mahernia (M. incisa.)

Method of Culture.—These different plants may be increased by planting cuttings of the young branches in the summer season finely, in pots of light mould, watering, and plunging them in a hot-bed till they have frisked root. When they have been well rooted, they may be removed into the greenhouse for protection during the winter season; being managed as the f1s tender plants of this description.

All of them afford scarcity among other potted plants of a similar kind in green-house collections.

Mahesa and Maheswar, in Mythology, names of the Hindoo god Siva; the same, indeed, as Ishu and Isuvara (which see) with the epithet Mahes, or great, prefixed. These names and allusions to them occur perpetually in Hindoo books. The following example from the Gita Govinda of Jayadeva. (see Jayadeva,) as translated by sir William Jones, shews their prevalence, and is descriptive also of the appearance and attributes of Mahesa, or Mahadeva, and of Krishna. (See Kishna.) The last-named deity, agonized by the jealous anger of Radha, exclaims—“Grant me but a fight of thee, O lovely Radhika! for my passion torments me. I am not the terrible Mahesa; a garland of water lilies, with subtile threads, decks my shoulders, not fetters with twisted folds; the blue petals of the lotoes glitter on my neck, not the azure gleam of poison; powdered sandal wood is sprinkled on my limbs; not pale athes. O god of love, mitigate me not for Mahadeva; wound me not again (see the fable here alluded to, under article Kama); approach me not in anger; hold not in thy hand the shaft barred with an amra flower. My heart is already pierced by arrows from Radha’s eyes, black and keen as those of an antelope; yet mine eyes are not gratified by her presence. Her’s are full of shafts; her eyebrows are bows, and the tips of her ears are silken strings: thus armed by Anga (or Kama) the god of desire, the marches, herself a goddess, to enure his triumph over the vanquished universe. I meditate on her delightful embrace; on the ravishing glances darts from the fragrant lotoes of her mouth; on her nectar-dropping speech, on her lips, ruddy as the berries of the bimbli.” See Radha.

Mahesira, in Geography, a town of Hindoo-land, in Mewar; 15 miles S.W. of Cottila.

Maheswar, in Hindu Mythology, a name of Parvati, as the Sakti, or consort of Siva, in his character of Mahesa, which see. She is represented, like her lord, four armed, holding a trident, with a vatt serpent for a ring, a crescent for a gem, and riding on a bull. She is reckoned one of the Matris, or divine mothers of the celestial.

See Matli.

Mahira, in Geography, a district of Arabia, included by the Arabians within the province of Hadramant. This district feems, like Teftan, to be a sandy plain, extending in breadth from the shores of the ocean, backward to the part in which the hilly country commences. These plains have probably been once covered by the sea.

Mahideser, a town of Perlia, in the province of Irak; 78 miles S.W. of Hamadan.

Mahie, the name given by the inhabitants of Otahite, or George’s island, to their bread-fruit when made into a kind of four paties, which, in consequence of having undergone a fermentation, will keep a considerable time, and supply them with food when no ripe fruit is to be had. When, therefore, they see a green tree of new fruit on the trees, they ripen them all at once of their former crop, of which they make mahie. This succedaneum for ripe bread fruit is thus made. They gather the fruit before it be perfectly ripe, and laying it in heaps cover it closely with leaves. In this state it ferments, and becomes disagreeably sweet; the core is then taken out entire, and the rest of the fruit thrown into a hole in their houses, dug on purpose, and neatly lined in the bottom and sides with gralls. The whole is then covered with leaves, and heavy stones are laid upon it. In this state it undergoes a second fermentation, and becomes fourth, after which it will suffer no change for many months. It is taken out of this hole, as it is wanted for use, and being made into balls, it is wrapped up into leaves and baked, and thus dressed it will keep for five or six weeks. It is eaten, both cold and hot, and the natives of those countries seldom makes a meal without it; but to captain Cook and his company the tale was as disagreeable as that of a pickled olive generally is, the first time it is eaten. Hawkinsworth’s Account, &c. vol. ii. p. 145, 193.

Mahim, in Geography, a town of Hindoo-land, in the northern part of the island of Bombay, with a cufom house; 17 miles N. of Bombay.

Mahim, Maham, Mabem, or Mayhem, in Law, a mainy, or corporal hurt, whereby a man lofeth the use of any member, that is, or may be, of defence to him in battle; as, beside arms and legs, the eye, hand, foot, scalp of the head, fore-tooth; or, as some fey, a finger or toe; but the cutting off his ear or nose, or loss of his jaw-teeth, are not held to be mayhems at common law, because they do not weaken but only disfigure him. (Finch L. 204. 1 Hawk. P. C. 111.) The word comes from the French main, of mehainier, to mutilate; the canoyns call it membre mutilatoire; and all agree it confils in the loss of a member, or of the ufe thereof.

By the ancient law of England, he that maimed any man was fentence to lofe the like part, (membrum pro membro) which is ftil the law in Sweden; but this was diffused, and mayhem, by the common law. (1 Hawk. P. C. 112.) was only punnishable by fine and imprisonment, unless perhaps the offence of mayhem be califration, which all our old writers held to be felony. But by fubfequent fituations the crime and pnnishment of mayhem were put more out of doubt. By 5 Hen. IV. cap. 5, cutting out the tongue, or putting out the eyes of a man, to prevent him being an evidence against those who beat, wounded, or robbed him, was an offence declared to be felony, if done of malice prepence, that is, as Sir Edward Coke explains it, voluntarily, and of a fat purpose, though done upon sudden occasion. The fituation 37 Hen. VIII. c. 6. directs, that if a man shall maliciously and unlawfully cut off the ear of any of the king’s subjects, he shall not only forfeit treble damages to the party grieved, to be recovered by aaron of trephais at common law, as a civil satisfaction; but also it by way of fine to the king, which was his criminal amerceament; and by 22 and 23 Car. II. c. 1, called the Coventry Act, it is enacted, that if any one shall of malice aforethought, or by lying in wait, cut out
out or disable the tongue, put out an eye, slit the nose, cut off the nose or lip, or cut off or dabl any limb or member of another person, with intention to doing to main or disfigure him, it is felony without benefit of clergy. In such offenders, his counselors, aids and abettors; and, when the case is difficult to judge whether it be a maim, or not, the judges commonly view the party wounded, and sometimes take the opinion of the surgeons. 2 Roll. Abr. 578.

(See Examination.) By analogy to this, in an action of trespass for mayhem, the court (upon view of such maim as the plaintiff has had in his declaration, or which is certified by the judges who tried the cause to be the same as was given in evidence to the jury) may increase the damages at their own discretion. 1 Sid. 108.

A person who maims himself, for the purpose of begging, and also a person who disfigures himself, that he may not be impressed for a soldier, may be indicted and fined. The offence of willfully and maliciously shooting at any person, which may endanger either killing or maiming him, though no inconsiderable evil confluence ensues, is made felony, without benefit of clergy, by 9 Geo. 1. c. 32.

A horrible practice having of late years prevailed among pickpockets and others, of lacerating those who are the objects of depredation or roflation, and the laws being found inadequate to reach and efficiently correct the evil, the legislature interfered, and by the 43 G. Ill. c. 53, (commonly called lord Ellennborough’s act) which recites that divers cruel and barbarous outrages had been of late wickedly and wantonly committed upon the persons of his majesty’s subjects, either with intent to murder, to rob, or to maim, disfigure or disable, or to do other grievous bodily harm to such subjects; and that the provisions by law made for the prevention of such offences had been found ineffectual for that purpose, it is enacted that if any person or persons shall willfully, maliciously, and unlawfully stab or cut any of his majesty’s subjects, with intent in so doing, or by means thereof to murder, or to rob, or to maim, disfigure, or disable such subject or subjects, or with intent to do some other grievous bodily harm, or to obstruct, retell, or prevent the lawful apprehension and detainer of the person or persons so stabbing or cutting, or of any of his, her, or their accomplices, for any offences for which he, she, or they may respectively be liable by law to be apprehended, imprisoned, or detained; such persons so offending, their counsellors, aids, and abettors, knowing of or privy to such offence, shall be felons, and suffer death without benefit of clergy. Provided, that if it appear on the trial, that such acts of stabbing or cutting were committed under such circumstances as that, if death had ensued thence, the fame would not have amounted to murder, in such cases, the person or persons so indicted shall be deemed not guilty of the felonies whereof they shall be so indicted, but be thereof acquitted.

If the main come not within any of the descriptions in either of these acts, yet it is indictable at the common law, and may be punished by fine and imprisonment; or an appeal may be brought for it at the common law; in which the party injured shall recover his damages; or he may bring an action of trespass; which kind of action hath now generally succeeded to the place of appeals in smaller offences not capital.

2 Haws. c. 23.

Malicious maiming of cattle in the night time incurs a forfeiture of treble damages, by action of trespass, or upon the theft, 22 & 23 Car. II. c. 7.

Mahlberg. See Appeal.

MAHLBERG, in Geography, a town of Baden, with an annexed lordship; 16 miles S.S.E. of Strasbourg. N. lat. 48° 19’; E. long. 7° 15’. Mahlendorf, a town of Silifke, in the province of Neuffe; 9 miles N.W. of Neuffe.

MAHMOOARABAD, an ancient town of Hidooftan, formerly the capital of Guzerat, and founded by sultan Mahmood, in the 11th century. The Ayin Aabaree describes the walls of it, as including a vast extent of ground, and speaks of it, in the latter part of the 16th century, rather as an existing city, than as a place in ruins; 17 miles S.S.E. of Amedabad. N. lat. 22° 47’; E. long. 72° 52’.

MAHMORA, or MAMORA, a sea-port town of Fez, situated near the mouth of the river Seboo, which falls into the Atlantic. The fort of Mamora, which is to the south of the Soobo, is the first inhabited place in the province of Ben-hallen. It was begun by the Portuguez in 1515, and destroyed in the same year by the Moors. It was re-built in 1624 by the Spaniards, from whom it was taken by Muly Ismael in 1681. This fortress, which was originally built at the mouth of the river Seboo, is now two miles below from the confines of the drifted sand-banks and bars, which have rendered the entrance of this river very difficult and dangerous, as to be no longer of any use to commerce or navigation. At this fort there are about 35 or 40 families, which gain a wretched subsistence by the profits of their ferry, and fishing for fish; and mills, which they take such numbers as to be able to supply the whole neighbouring country between November and the end of March. Masa is distant about five leagues N.N.E. from Sallee, and about twenty leagues by land S. of Laracha. Between these two last places the country is variegated by lakes, forests, and vallies, which were formerly tolerably populous. Some of the lakes are nearly eight leagues in extent, and supply great numbers of ducks and water-fowls, and affo of eels. The boats used by the fishermen are a kind of rafts, made of reeds and rushes, about six feet long, and two broad, and will scarcely hold a single person. The fishermen guides them with a pole, and pierces the eels when he has them on the water, with a sort of dart. On the banks of these lakes are several factuaries of the Marnsbouts, who all have a great estimation for their formed holibuts, and a number of camps of the Moors, who cultivate the adjacent lands, which are but moderately productive. This Valley is very pleasant in winter and spring, but in summer it is parched and disagreeable. At the southern extremity is a factuary, on an eminence, appertaining to which are habitations and gardens. N. lat. 34° 25’; W. long. 6° 25’.

MAHMOUD, in Biography, first sultan of the Gazette dynasty, and a great conqueror, was son of the governor of Chorafan, and sovereign of Gazza. He was sixteen years of age when his father died in 997, and soon displayed a vigour of mind which announced his future greatness. Having secured himself upon the throne of Gazza, he marched to Chorafan, which had been seized by the king of Turkestan, drove him out, and took possession of the province. In 1001, this heroic prince carried his arms into Hindooftan, and captured Gebal, a powerful prince in that country, who, in consequence, reduced his crown to his son, and threw himself into the flames. In the following year, Mahmoud reduced Kholf, the revolted governor of Sefallan, and assumed the title of sultan. He repeated his invasion of India, but was soon recalled by the irruption of Ilek Khan, king of Turkestan, into Chorafan. Ilek was soon expelled; but he called to his assistance Ider Khan, who joined him with 50,000 horse. This combined and very powerful army advanced to the city of Balk, where they were met by Mahmoud,
M A H

Mahloud, when a battle ensued, which was fought with great obstinacy, but Mahomad was victorious, and the greatest part of the Turkish army perished on the field. Mahomad now extended his conquests far and wide, and acquired immense treasures. The emperor of Hindustan, who had till now assumed the title of king of kings, dreading his arms, sent to demand peace from him, which was granted, on the condition of the payment of a large tribute. In 1029, he added to his other extensive dominions the great province of Persia, and, settling his son Maffoud, whom he deigned for his successor. He died in 1030, after a prosperous reign of thirty-one years. This great conqueror, who subdued so many neighbouring sovereignties of their territories, is extolled by Mahometan writers for his regard to justice, and for his zeal in the propagation of his religion, which he spread in India by the extermination of a vast number of idolaters, and the demolition of their temples. Several anecdotes are given of him which do honour to his forbearance, and his regard to justice. In one instance a widow preferred a complaint against some persons who had murdered her son; the sultan replied, that the great distance of Iran from Gazzara rendered it very difficult for him to prevent such disorders: "Why then," said the disconsolate woman, "do you conquer more territory than you can govern, and of which you can render no account at the day of judgment?" The reproof awakened such impressions in the mind of the monarch, that he caused it to be proclaimed throughout Iran, that he would be responsible for the lives and properties of all who should, in future, travel thence to India in caravans. MAHOMET, or Mahommed, in Biography, the founder of that system of religious imposture which is called Mahometanism (which see), descended from the tribe of Koreih, and the family of Hethem, the most illustrious of the Arabs, the prince of Mecca, and the hereditary guardians of the caravans; he was the grandson of Abdallah (which see), and the only son of Abdallah (which see), and Amina; and he was born at Mecca, four months after the death of Juli-nian, and two months after the defeat of the Abyssinians, whose victory would have introduced into the Caravans the religion of the Christians, in the year 569 of the Christian era. As he was deprived of his grandfather, father, and mother in his infancy, and his inheritance contested only of five camels and one Ethiopian female slave, the care and conduct of his youth devolved upon Abu Taleb, the most respectable of his uncles, by whom he was inducted in the occupation of a merchant, and with this view he was taken with him into Syria at the age of thirteen years. In his 25th year he was recommended to Khaled, a noble and rich widow, as her factor, who soon rewarded his fidelity with the gift of her hand and fortune, and thus raised him to an equality with the richest persons in Mecca. In his marriage contract he is described as the most accomplished of the tribe of Koreih, and his dowry is stipulated at twelve ounces of gold and twenty camels, which was supplied by the liberality of his uncle. In consequence of this connection, he was restored to the flation of his ancestors; and he passed many years in the habits of domestic life, until at length, in the 40th year of his age, he assumed the title of a prophet, and proclaimed the religion of the Koran. According to the tradition of his companions, Mahomet was distinguished by the graces of his person and manners, so that before he spoke he engaged in attachment and interest the affections of a public or private audience. His attendants applauded his commanding presence, his majestic aspect, his piercing eye, his gracious smile, his flowing beard, his countenance that painted every emotion of the soul, and each gesture that expressed every expression of his tongue. In the intercourse of private life he blended, with respectful attention to the affluent and powerful, condescension and accessibility to the poorest citizens of Mecca; the frankness of his manner concealed the artifice of his views; and the habits of courtly were imputed to personal friendship or personal benevolence. His memory was capacious and retentive; his wit easy and social; his imagination sublime; his judgment clear, rapid, and decisive. He possessed, says one of his biographers, the courage both of thought and action; and although his designs might probably expand with his successes, the first idea which he entertained of his divine mission bears the stamp of an original and superior genius. Educated amidst the nobility race, he acquired a fluency of speech in the purest dialect of Arabia; and he had the art, on proper occasions, of observing a difficult silence. Notwithstanding all these accomplishments in the art of diplomacy, there was something of the barbarian in him, which his youth had never been instructed in the arts of reading and writing. Some, indeed, have questioned this fact, among whom we may reckon Mr. White (see his Sermons, p. 203, 204;) but his incredulity, founded more on conjecture and reasoning, than authentic testimony, is contradicted by numerous and unquestionable authorities. Availing himself of the character of the age in which he lived, and the promptitude of the people among whom his lot was cast, his sagacity led him to improve even his want of literature as a means of more successfully gaining profyelytes and propagating his imposture. In his two journeys to Syria, he refrained his attention to commercial transactions at the fairs of Bostrra and Damascus; and at the early age in which he made these journeys, he could derive no great advantage with regard to the purposes of his pretended mission from such bafity and superficial excursions: nor could he have indulged his curiosity to any considerable degree on account of his ignorance of the Syriac languages. Whatever knowledge he acquired must have been the result of his intercourse with those pilgrims who annually returned to Mecca from various regions, with views of devotion, or of commerce; and from this source he derived that acquaintance with the political state and character of the several Arabian tribes, as well as the theology and ceremonial institutions of Jews and Chriftians. Besides, from his early youth, Mahomet was addicted to religious contemplation; and he was accustomed, during the month of Ramadan, to retire from the world to the cave of Hera, about three miles from Mecca, where he probably formed his system of imposture; or, as Mr. Gibbon expresses it, where he confuted the spirit of fraud or enthusiasm, whole abode is not in the heavens, but in the mind of the prophet. The faith, as the historian adds, which, under the name of Isla
“I am,” he preached to his family and nation, is compounded of an eternal truth, and a necessary fiction, “That there is only one God, and that Mahomet is the apostle of God.” It is impossible, at this distance of time, and amongst the variety of opinions that have been held on the subject, to determine with certainty at what period of his life the idea of framing a new system of religion occurred to his mind; nor can it be ascertained by what kind of reflection he was led among idolaters to form his idea of the unity of God, nor to what degree he blended the ambition of personal grandeur with that of the prophetic character. History furnishes examples of persons whose conviction of truth and ardour in the prosecution and diffamation of it have terminated in the licentiousness of enthusiasm, the rage of conquest, and the violence of tyranny. Perhaps this might, in a degree, have been the case with Mahomet; and he might have proceeded from the honesty of enthusiasm to the extreme of imposture and deception, and with a view of extending the influence of his system, he might find it necessary or expedient to accommodate it to the passions and prejudices of his countrymen, to enforce it by the terrors of the sword, and to unite the character of a conqueror with that of an impostor. It was, however, in the year 609, and about the 40th year of his age, called “the year of his mission.” that he opened his pretended mission. His first convert was his wife Khadijah, to whom he communicated an interview, with which he had been favoured by the angel Gabriel, who had told him, that he was appointed the apostle of God; and to whom he also repeated a psalm, which he pretended to have had revealed to him by the ministry of the angel, together with some other circumstances of this first appearance, which are related by Mahomet writers. Khadijah received the news with great joy, and hastened to impart it to her cousin Warahah, who, being a Chrlitian, was well acquainted with the Scriptures, and who immediately became a profylete. Cautious in announcing to the public the high and honourable office with which he was entrusted, he determined to strengthen his interest by the conversion of the other branches of his family. His next profylete was Zeid, a confidential servant, to whom on this occasion he gave his freedom; and this circumstance established a precedent for his followers. The conversion of Zeid was succeeded by that of his cousin Ali, the son of Abu Taleb, who has been commonly dyled, probably on account of his rank and zeal in the cause, “the first of believers.” But the principal accession to his cause, with regard to reputeability and influence, was that of Abubeker, a person of great authority in the tribe of Koreiz, who prevailed on ten other principal inhabitants of Mecca to follow his example. During three years Mahomet proceeded without exciting public attention; but in the fourth year of his mission, he openly assumed the prophetic office, and announced his having received a divine appointment for the illumination and conversion of his near relations. With this view he directed Ali to prepare an entertainment, and to invite the sons and descendants of Abdalmossilab to a participation of it. When about 40 of the race of Hashem were assembled, Mahomet addressed them with the offer of happiness both in this life and in that which is to come, for which he pleaded a divine authority and command; and he then asked them who would be his companion and vizir? Whilt a general silence prevailed, Ali exclaimed, “I am the man; I will be thy vizir; and I will inherit vengeance on those who oppose thee.” Upon this declaration of attachment and furious zeal in his service, Mahomet commanded all that were present to obey Ali as his deputy: the company, however, treated the order with contempt, and ironically exhorted Abu Taleb to respect the superior dignity of his son. In a more sonorous tone, the father of Ali advised him to abandon his impracticable, romantic, and dangerous delusion. Mahomet, however, was not intimidated, but resolutely told his uncle, that if they set the fan against him on his right hand, and the moon on his left, he would not relinquish his enterprise. When Abu Taleb perceived that he was determined to proceed, he urged no further arguments to dissuade him, but promised to stand by him against all his enemies. The Koreiz, finding that reasoning and military treaty were ineffectual, had recourse to threats and violence; so that the followers of Mahomet could not continue any longer at Mecca with safety; upon which Mahomet, unable to protect them, gave them leave to depart and seek refuge wherever they could find it. Accordingly, in the fifth year of the prophet’s mission, sixteen, of whom four were women, flew into Ethiopia; and these were afterwards followed by others, amounting to the number of 85 men and 18 women, besides children. The king of Ethiopia received them with kindness, and refused to deliver them up when the Koreiz sent to demand them; and, as the Arab writers unanimously attest, became himself a profylete to the Mahometan religion. Persecution, instead of retarding, accelerated the progress of this impollure. In the seventh year of the mission of the pretended prophet, his friends had become more numerous and powerful, by the conversion of his uncle Hamza, and of the indefatigable Omar, who had been once his most violent opponent; and the Koreiz having formed a league against the Hashemites occasioned a division of their tribe into two factions; one of which adhered to the prophet and the other combined against him. For three years this variance continued, but in the tenth year of his mission, Mahomet told his uncle Abu Taleb, that God had signally manifested his disapprobation of the league, which the Koreiz had formed against them, by sending a worm to eat every word of the instrument, except the name of God. When a deputation had examined the league, that had been laid up in the Caaba, and found that Mahomet’s declaration was true, it was declared void. In this year Mahomet left two very important and useful friends, viz. his wife Khadijah, and his uncle Abu Taleb; and for this reason this year was called “the year of mourning.” Upon the death of these two persons the Koreiz became more violent than ever, and determined on the death of the prophet; but being warned of their purpose by an angel or jay, he retired hastily, and in the dead of the night, with his friend Abubeker, to the distance of a league from Mecca, where he concealed himself for three days in the cave of Thor, and where he and his friend received a supply of food and of intelligence from the son and daughter of Abubeker. The Koreiz made diligent search for the fugitives, but being at the entrance of the cavern in which they were hidden, their attention was diverted, as it is said, by a spider’s web, and a pigeon’s nest, which led them to imagine that the place was solitary and inviolate. “We are only two,” said the trembling Abubeker: “there is a third,” replied the prophet, “it is God himself.” As soon as they had opportunity for escape, they mounted their camels; but on the road to Medina, they were overtaken by the emissaries of the Koreiz, from whose hands they rescued themselves by the influence of prayers and promises. The flight of the prophet from Mecca to Medina has fixed the memorable era of the Hegira, which see. At Medina the two fugitives found an asylum. Some of the noblest citizens had previously, in a pilgrimage to the Caaba at Mecca, been converted by the preaching of Mahomet, and on their return they had diffused the belief of God and his prophet; and the new alliance was ratified by their depu-
ties in two secret and nocturnal interviews on a hill called Al Akaba, in the suburbs of Mecca, when they pretended in the name of their wives, children, and absent brethren, that they would for ever profest the creed, and observe the precepts of the Koran. The second was a political allocation, the first vital spark, says Gibbon, of the empire of the Saracens. Seventy-three men and two women of Medina held a solemn conference with Mahomet, his kinsmen, and disciples, in the thirteenth year of his mission, and pledged themselves to each other by an oath of mutual fidelity. After reciprocal engagements to each other, they reiterated the oath of allegiance and fidelity, and their treaty was ratified by the people, who unanimously embraced the profession of Islam. Such were their circumstances, when they impatiently expected the arrival of the prophet, at the same time trembling for his safety. After a perilous and rapid journey along the sea-coast, he halted at Koba, two miles from the city, and made his public entry into Medina, 16 days after his flight from Mecca. He was met by 500 of the citizens, and received with acclamations of loyalty and devotion. His brave disciples assembled round his person; and his followers were distinguished into two classes, the fugitives of Mecca and the auxiliaries of Medina, under the denominations of "Mohajers," or "Refugees," and "Ansars," or "Supporters." When Mahomet was established at Medina, he assumed the exercise of the regal and sacerdotal office; and having acquired either by gift or purchase a piece of ground, he built upon it a temple of worship, and a residence for himself. After a reign of six years, 1500 Moslem, in arms and in the field, renewed their oath of allegiance; and their chief repeated the assurance of protection till the death of the last combatant; or the final dissolution of the party. Being now exalted by the choice of an independent people to the rank of a sovereign, he was invested with the prerogative of forming alliances and of waging offensive or defensive war, and accordingly assumed a fiercer and more fangous tone, than he had been accustomed to take, when his moderation was the effect of his weaknesses. In announcing his revelations, he pretended to have received commands for propagating his religion by the sword, for destroying the monuments of idolatry, and with regard to the sanctity of days or months, for purifying the unbelieving nations of the earth. In the first months of his reign, he trained his followers for the warfare to which he intended to conduct them, and displayed his white banner before the walls of Medina, but in the progress of his undertaking he fought in person at nine battles or sieges; and fifty military enterprises were achieved in ten years by himself or his lieutenants. Uniting the professions of a merchant and robber, his petty excursions for the attack of a caravan, gradually prepared his troops for the conquest of Arabia. The distribution of the spoil was regulated, as he pretended, by a divine law; a fifth of the gold and silver, the prisners, and the cattle, the moveables and immovable, was referred by the prophet for pious and charitable uses: the remainder was shared in adequate portions by the soldiers who had obtained the victory or guarded the camp; the remittance of the slain devoted to their widows and orphans; and the inercate of cavalry was encouraged by the allotment of a double share to the horse and the man. From all sides, says the historian, the roving Arabs were allured to the standard of religion and plunder; the prophet indulged the disposition of his countrymen by facilitating the licence of embracing the female captives as their wives or concubines; and the enjoyment of wealth and beauty was a feeble type of the joys of paradise prepared for the valiant martyrs of the faith. "The sword," says Mahomet, "is the key of heaven and of hell; a drop of blood shed in the cause of God, a night spent in arms, is of more avail than two months of fasting or prayer; whoever falls in battle, his sins are forgiven: at the day of judgment, his wounds shall be replenished as vermitious and odorous as scald; and the lofs of his limbs shall be supplied by the wings of angels and cherubins." By such declarations and prospects, the intrepid fous of the Arabs were fired with enthusiasm; the picture of the invisible world was strongly painted on their imagination; and the death which they had always deplored, became an object of hope and desire. The prophet, with a fagacity which distinguished every part of his project, inculcated in the Koran the tenets of fate and predestination, which have ever in every age to exalt the courage of the Saracen and Turks. The first companions of Mahomet advanced to battle with a fearless confidence; where there is no chance, there is no danger; they were ordained to perifh in their beds, or they were safe and invulnerable amidst the darts of the enemy.

The first military expedition of any importance, and which in the event served to establish the reputation of the prophet, was directed against the Kureifs. This was the battle of Beder, which was fought in the second year of the Hegira; for in accordance with Mahomet's fay's, a second battle was followed by a second battle, A. D. 622, they met on the mount Ohrid, six miles to the north of Medina. On this occasion the Korish fielded a force of 3000 men, 700 of whom were armed with curials, and 200 mounted on horseback. Three thousand camels attended their march; and Henda, the wife of Abu Sophian, the chief of the branch of Om-miyah, who had succeded to the principality of the republic of Mecca, with 15 camels of this city, incessantly found their timbrels to animate the troops, and to magnify the greatness of Hobal, the most popular deity of Caaba. The standard of God and Mahomet was upheld by only 550 believers. The Korish advanced in the form of a crescent, and the right wing of the cavalry was led by Caled, the fiercest and the most successful of the Arabian warriors. The troops of Mahomet were skillfully posted on the declivity of a hill; and their rear was guarded by a detachment of 50 archers. The contest was vigorously maintained on both sides; it was severe and fanguinary; Mahomet was wounded, and 70 martyrs, as well as 900 prisoners, were killed. Their bodies were mangled by the inhuman females of Mecca; and the wife of Abu Sophian talied the entrails of Hamza, the uncle of Mahomet. The Muffulmans railed in the field; and the Korish wanted strength and courage to undertake the siege of Medina. In the year 625 the city was attacked by an army of 10,000 enemies; and this third expedition is named from the "nations" which marched under the banner of Abu Sophian, and from the "ditch" which was drawn before the city and a camp of 3000 Muffulmans, the battle of the "Nations" or "Ditch." Mahomet prudently declined a general engagement; and though the contest was protracted for 20 days, the confederates were at length obliged to separate. A tempest of wind, rain, and hail, overthrew their tents; private quarrels were fomented by an insidious adversary; and the Korish, dejected by their allies, no longer hoped to subvert the throne, or to check the conquests, of their invincible exile. As soon as the "nations" had retired from the "ditch," Mahomet, without laying aside his armour, marched against the Jewish tribe of Kozorah, who had incurred his resentment by exciting and joining the war of the Korish; and after a resistance of 25 days, they surrendered at discretion. It was in vain that they appealed to the judgment of a venerable elder; he pronounced the sentence of their death; 700 of them were dragged in chains to the market place of the city; and having
ing been compelled to defend alive into the grave prepared for their execution and burial, the prophet beheld the savage frenzy without emotion. Plunder and cruelty marked his future footsteps; and the town of Chalbar, which was the seat of the Jewish power in Arabia, and its numerous castles, were speedily reduced. It is somewhat singular, that a hatred of the Jews, to whose Scriptures he was indebted for the best parts of his religion, formed so distin-
guishing a feature in the character of the Arabian prophet. Under the subjequent reign of Omar, the Jews of Chalbar were transplanted to Syria; and the caliph alleged the in-
noculation of his dying master, that one and the true religion should be professed in his native land of Arabia. Such was the spirit of persecution and intolerance which actuated this impostor. In the year 629 Mahomet directed his march, accompanied by 1,400 men, towards Mecca; his views were peaceable; 70 camels, choven and bedecked for facricie, preceded the van; the sacred territory was respected, and the captives were defiled, without ransom, to proclaim his elemency and devotion. But on his approach to the city, the Korish opposed his progress, and he determined to at-
tack it; but on their being for peace, he concluded with them and with their allies a truce of 10 years, engaging to restore the fugitives of Mecca who should embrace his religion, and repudiating merely, for the ensuing year, the pri-
ivilege of entering the city as a friend, and of remaining three days to accomplish the rites of the pilgrimage. After the eulomary facricie, Mahomet evacuated the city on the fourth day. The people edified by the devotion of the pro-
phet, who on this occasion acted the part of a crafty politi-
tician; the hostile chiefs were awed, or divided, or subdued; and both Caled and Amrou, the future conquerors of Sy-
ria and Egypt, more feasonably deserted the finking caufe of idolatry. The Arabian tribes submitted and thus in-
creased the power of Mahomet; 15,000 soldiers assembled for the conquest of Mecca, and the idolaters, being the weaker party, were eafily convinced of violating the truce. The feeet was preferved till 15,000 fires proclaimed to the abominatd Korish the defign, the approach, and the irre-
fitable force of the enemy. The haughty Abu Sophian prefented the keys of the city, observed that the fan of Abdullah had acquired a mighty kingdom, and confessed, under the feeyentar of Omar, that he was the apolite of the true God. Mahomet, instead of indulging his own puffion of revenge or that of his followers, forgave the guilt, and united the facfions of Mecca. His troops, in three divi-
ions, marched into the city and took pofeffion of it; the chief of the Korish fell prostrate at his feet; the people of Mecca merited their pardon by the profefion of Islam, and after an exile of seven years, the fugitive miliitaryian was enthroned as the prince and prophet of his native country. But the 360 idols of the Cabba were ignominously demo-
nilished; the house of God was purified and adorned; and a perpetual war was enacted, that no unbeliever should dare to set his foot on the territory of the holy city. The conquest of Mecca determined the faith and obedience of the Ara-
bian tribes; but an obilinate remnant still adhered to the re-
ligion and liberty of their anclesors; and the war of Honain derived its appellation from the "idols," whom Mahomet had vowed to destroy, and whom the confederates of Tayef had sworn to defend. Four thousand pagans advanced with secrecy and speed to surprife the confederate; the banners of Mecca and Medina were defplayed by the prophet; and 42,000 Moflumen entertained a raft and sinful presumption of their invincible strength. They defended without pre-
caution into the valley of Honain; but their number was apprelled by the archers and flings of the confederates who had occupied the heights, their discipline was confounded, their courage was appalled, and the Korish anticipated with faitfaction their impending dejection. The prophet, on his white mule, was accompanied by the enemies; of ten 
faithful companions, who attempted to ward off from him the spears of the affillants, three fell dead at his feet; and in this moment of danger, he called on his brethren and on the Almichty for succour, whilst his uncle Abbas joined in the acclamations of his followers. At length the fugitive Moflumen rallied; the battle was renewed by the exhorta-
tion and example of the prophet; and he animated his vic-
torious troops to inflict a mertreds revenge on the authors of their disgrace. From the field of Honain he halted to the siege of Tayef, 60 miles S.E. of Mecca; but after an ineffectual attack of 20 days, he was obliged to retreat. The spoils of this expedition amounted to 6,000 captives, 24,000 camels, 500,000 sheep, and 40,000 touns of silver. Instead of chafftting the disaffection of the Korish, he en-
downed to secure their attachment by extraordinary libe-
rality; Abu Sophian was prefented with 300 camels and 20 touns of silver; and Mecca was more fincerely converted to the profitable religion of the Koran. The temples and idols of Arabia were every where demolished, and the ambassadors who proflrated themselves before the throne of Medina were as numerous, according to an Arabian proverb, as the dates that fall from the maturify of a palm-tree. Hence this year was called "the year of embasies." The nation submitted to the God and the sceptre of Mahomet; and 114,000 Moflems accompanied the last pilgrimage of the pope. On this occasion he took with him all his wives, with a great number of camels intended for victims; and the ceremonial which he observed at the facred city has served as a model to the Moflems of succeeding ages.

It was in the 7th year of the Hegira that Mahomet began to think of propagating his religion beyond the boundaries of Arabia, and deputed messengers to invite the neighbouring princes to embrace Mahometanism. The Persians with their koveign after some hesitation avowed themselves proflytes. The emperor Herachius at firft treated Mahomet with refpect; and some have said, that he would have profen the new faith, if he had not been afraid of losing his crown. Mahomet prepared for effecting by conquest what he bad failed to ac-
complish by a peaceful message; but he was obliged to defit from the undertaking, as too hazardous, and indeed imprac-
tical. The firft conflict between the trooves of Mahomet and the emperor Herachius took place in the eighth year of the Hegira. A body under the command of Zeid advanced to the attack of Muta, a town of Pageline, the governor of which had affifinated one of the Moflem envoy. In the sharp conflict that ensued, Zeid with the two next in com-
mand was slain, and the death of Zeid was much lamented by Mahomet, his miler and friend. However, the active and intrepid Caled, denominated "the Sword of God" spread around the terror of his name; and the prophet re-
ceived the submission of the tribes and cities from the Eu-
phrates to Alibh, at the head of the Red sea. Mahomet, in the confidence of his power, had declared war against Herachius; and with an army of 20,000 foot and 10,000 horfe, he marched towards the Syrian frontier, and his un-
willng followers suffered extremely from the heat of the sumer and the drought of the defert. At Tabue, a fer-
tile spot in the midway between Medina and Damasacus, they pitched their camp. The confequence of this toflome expedition was the submission of some Arabian princes, who became tributaries; but as the Imperial heirs had retired to a diftance, without appearing to have any delign of making an attack upon Arabia, Mahomet satisfied himself by writ-

6
ing a letter to Heraclius urging his conversion, and then returned back to Medina. After his return he promulgated a new chapter of the Koran, revoking all former edicts in favour of the idolaters, and annulling all treaties that had been made with them. To his Chritic subjects, Mahomet readily granted the security of their persons, the freedom of their trade, the property of their goods, and the toleration of their worship. In this respect he pursued a conduct highly political, as it was the interest of a conqueror to pro-

pole a fair capitulation to the most powerful religion of the earth; and the same wise policy has ever since accompanied the Mahometan jurisdiction. Till the age of 63 years, Mahomet retained a vigour of constitution which enabled him to endure the corporeal and spiritual fatigues of his mission. The last conspicuous act of his life was his pilgrimage to Mecca, already mentioned. His health had been declining for four years previous to his death; and he abjured this change not to the access of epileptic fits which some writers have erroneously reported to have been the remote cause of his growing infirmities, but to pafon administered to him at Chitihar by a Jewish female, from a motive of revenge, as some have said, or according to others, from a desire of putting his prophetic character to the test. However this be, his mortal disease was a fever of fourteen days, which at inter-val deprived him of the use of his reason. During the interruptions of his disorder he employed himself in haran-
guing his disciples from the pulpit, and performing other religious duties of his function, and in giving instructions with regard to the measures that were fit to be pursued after his decease. He beheld, it is said, with firmness the approach of death, satisfied the demands of his creditors, enfranchised his slaves, directed the order of his funeral, moderated the grief of his weeping friends, on whom he bestowed the benediction of peace, and regularly performed the exercise of public prayer till the third day before his departure; from all which circumstances it has been inferred, that he really believed the truth of his mission, and that he derived consolation from the contemplation of having conferred great benefits on mankind. This may be easily accounted for by the consideration that enthusiasm was bound to a very considerable degree with his impatience. The choice of Abu-
bekar to supply his place indicated his respect for this ancient and faithful friend, as he seems to have thought him a fit successor in the facerdotal and regal office. When his faculties were perceptibly impaired he wished to dictate a di-
vine book, which should contain the form and substance of all his revelations; but a dispute arising in his chamber, whether he should be allowed to supercede the authority of the Koran, he was under a necessity of reproving the in-
decent vehemence of his disciples. If any credit may be given to the traditions of his wives and companions, he main-
tained to the last moments of his life and in confidential intercource with his family, the dignity of an apostle and the faith of an enthusiast; describing the visits of Gabriel, and expressing his lively confidence, not only in the mercy, but the favour, of the Supreme Being. In a familiar dif-
course he had mentioned his special prerogative, That the second of death was not allowed to take his place till he had respectfully asked the permission of the prophet. The request being granted, Mahomet fell into the agony of dissolusion, and expired in the arms or on a carpet near the feet of his favourite wife Ayefha, the daughter of Abubeker, in the month of June, A.D. 632, Hegira 11, at the age of 63. Some of his followers would not for a time believe the reality or possibility of his death, till Abubeker calmly reasoned them out of their delusion. He was interred at Medina, in a grave dug beneath the bed on which he lay in the apartment of Ayefha, over which a magnificent building was erected by one of the succeeding caliphs. It is hardly necessary to mention, unless with a view of exposing it, the vulgar and ridiculous story invented and propagated by the Greeks and Latins, that Mahomet's tomb is suspended in the air at Mecca, by the action of equal and potent load-stones: for he was not buried at Mecca, and his tomb at Medina, which has been visited by millions, is placed on the ground. The number of his wives, all of whom except Ayefha were widows, was at least fifteen: by Khadijah he had four children, one of whom, Fatima, the belt beloved of his daughters, and married to Ali, survived him; and he had also a son, by his Egyptian concubine, Mary, whose name was Ibrahim, and who died not long before him. However Mahomet might restrict the in
cumincx of his disciples by the precepts of his religion, he claimed a special exemption for himself, and pretended a special revelation which dispelled with his observance of the laws which he imposed upon his nation. During the life of Khadijah, who laid the foundation of his future fortune, and in the course of 24 years, he seems to have restrained his ruling passion within due bounds; but as he advanced in years and authority, this passion gained strength, and he made his religion subservient to the illicit indulgence of it. Besides his numerous wives, he allowed himself in a variety of amours, which were prohibited by his own laws. His connection with Zeinah, the wife of his enfranchised ser-
vant and adopted son, Zeid, gave great offence to some of his friends. Zeid, in order to gratify his master, confented to her being divorced; and the prophet, whose religion was easily accommodated to his passions and interest, feigned a revelation from heaven, recorded in a chapter of the Koran, which authorized him to marry her, notwithstanding a degree of affinity that had been always regarded by the Arabs as an absolute prohibition. Hafiza, the daughter of Omar, who was one of his wives, discovered him in an improper connexion with Mary, an Egyptian captive; but in order to silence her reproaches, he promised never to repudiate the offence. Finding, however, that the circumstance was divulged to his other wives, and that they concurred in rejecting it, he withdrew from them all for a month, and spent the time in company with Mary; and in order to justify his infidelity and violation of an oath, he recurred to his usual practice of producing a new chapter of the Koran, containing a special dispensation. We may indeed be allo-

sumed that successive forgeries of this kind, intended to answer purposes of personal and licentious gratification, should not have excited a prejudice in the minds of his fol-

lowers and of his countrymen in general, which would have defeated all his efforts for propagating his imposture. But we should recollect the disposition and character of the Arabs, whose luidious complexion has been noticed by the writers of antiquity. (Ammian Marcell. l. xiv. c. 4.) Much has been said by Mahometan writers in praise of the corporeal and mental endowments of the Arabian prophet; and though we cannot allow the very extraordinary qualities which have been ascribed to him, it must be acknowledged that he possessed various accomplishments, few of which have already been noticed, and a verity of talents and character, that served to raise him above his contemporaries, and to qualify him for the undertaking in which he embarked. "Could I truly delineate," says Gibbon, "the portrait of an hero, the fleeting resemblance would not equally apply to the holiness of mount Hera, to the preacher of Mecca, and to the conqueror of Arabia. The author of a mighty revolution appears to have been endowed with a pious and contemplative disposition: so soon as marriage had
MAHOMET.

had raised him above the purfuit of want, he avoided the
paths of ambition and avarice; and till the age of 40, he
lived with innocence, and would have died without a name.
The unity of God is an idea most congenial to nature and
reason; and a flight conversation with the Jews and Chris-
tians would teach him to define and deteft the idolatry of
Mecca." Indeed, for every thing that is valuable in his
religious syftem he was indebted to Judaism and Christianity:
but his rude and barbarous civil policy, being rendered im-
mutable by its alliance with religion, an alliance that is in-
congruous and unnatural, has prevented every kind of mo-
toration and improvement in thofe countries where his
laws are received. " It was the duty of a man and a citizen
to refcue his country from fin and error. The energy of a
mind ineffantly bent on the fame object would convert a
general obligation into a particular call; the warm fugg-
teions of the understanding or the fancy would be felt as
the inspirations of heaven; the labour of thought would ex-
pire in rapture and vifion; and the inward fervation, the in-
vifible monitor, would be defcribed with the form and attri-
butes of an angel of God. From enthufiafm to impoffure
the step is perilous and slippery; the defton of Socrates
(see DEMON) affords a memorable inftance how a wife man
may deceive himself, how a good man may deceive others,
how the confcience may flumber in a mixed and middle flate
between felf-flation and voluntary fraud. Charity may be-
lieve that the original motions of Mahomet were thofe of
pure and genuine benevolence but a human millinary is
incapable of cherifhing the obfolute unbelievers who reject
his claims, defpire his arguments, and perfeque his life;"—
hence "the pallions of pride and revenge were kindled
in the bosom of Mahomet."—" The injuflice of Mecca, and
the choice of Medina, transformed the citizen into a prince,
the humble preacher into the leader of armies."—" In the
exercife of political government, he was compell'd to abate
of the ftren vigour of fanaticifm, to comply in fome mea-
Sure with the prejudices and pallions of his followers, and
to employ even the vices of mankind as the instruments of
their falvation: theufe of fraud and perfidy, of cruelty and
injuftice, was often subfervient to the propagation of the
faith; and Mahomet commanded and approved the affiffia-
nation of the Jews and idolaters, who had escaped from the
field of battle. By the repetition of fuch acts, the character
of Mahomet muft have been gradually flained; and the in-
fluence of fuch pernicious habits would be poorly com-
penfated by the practice of the personal and facial virtues
which are neceffary to maintain the reputation of a prophet
among his feftaries and friends. Of his latf years, ambition
was the ruling pallion; and a polifhan will fufpeft, that he
fecretly fmeled (the victorous impoffur!) at the enthufiafm
of his youth and the credulity of his profeflaries." Maho-
met, in his private and domestic life, feemes to have de-
fpized the pomp of royalty, and to have submitted to the
menial offices of the family. The interdiftion of wine was
confirmed by his example, and his ordinary food conftituted
of barley-bread, milk and honey, dates and water. Although
he indulg'd himfelf in fenfual gratifications; the incontinence
of his countrymen was regulated by the civil and religious laws
of the Koran: their incestuous alliances were blamed; the
Boundless licence of polygamy was reduced to four legitimate
wives or concubines; their rights both of bed and of dowry
were equitably determined; the freedom of divorce was
difcouraged; adultery was condemned as a capital ofence;
and fornication, in either sex, was punished with an hun-
dred fhripes.
It is a natural inquiry how Mahomet, without literature,
without pretending to the power of working miracles, and
without a charader that entitled him to veneration among
perfons who made any pretence to religion and virtue, fe-
cured the fuccefs of a fyltem of doctrine and practice, which
must have appeared to all but his prejudiced followers to
have origiuated in enthufiafm and impoffure—h a fyltem
which restricted the boundless licence of Arabian idolatry;
which impofed obligations of prayer, purificition, and alms-
giving, that were burthenfome; and which undermined the
interfet and influence of fome of the moft powerful and
affluent of his countrymen? The basis of his doctrine, we
have already faid, was the truth of the unity and spiritual
nature of the deity: this truth muft have approved itself to
the minds of the thoughtful; and the vulgar would be al-
ured by the prospects which he held out to them of a future
happiness, adapted to their groffer apprehensions and pal-
fions. Whilft we admit that, in the early period of his
pretended milion, he might have been actuated by a fincer
defire of ameliorating the faith and manners of his country-
men, and allow his charader to have pofterfied fome traits of
the patriot and reformer, pride and ambition were his ruling
principles; and his discriminating charader muft be that of
an ufurper and impoffur, who owed his fuccesfs more to the
accommodating nature of his doctrine, and to the power of
the fword, than to any other caufe. "Are we surprised,"
fays Mr. Gibbon, "that a multitude of profeflaries should
embrace the doctrine and the pallions of an eloquent fanatic?
In the hiftories of the church, the fame fuccefs has been
tried and repeated from the time of the a[p[plies to that of
the reformers. Does it feem incredible that a private citizen
should grab the fword and the fceptre, fubdue his native
country, and erect a monarchy by his victorious arms? In
the moving picture of the dynafies of the latl one hundred
fortunate ufurpers, none have arisen from a bafer origin,
surmounted more formidable obftacles, and filled a larger
scope of empire and conquest. Mahomet was alike inftucted
to preach and to fight; and the union of thofe oppofite
qualities, while it enhanced his merit, contributed to his
fuccesfs: the operation of force and perfuafion, of enthufiafm
and fear, continually acted on each other, till every barrier
yielded to their irrefifible power. His voice invited the
Arabs to freedom and victory, to arms and rapine, to the
indulgence of their daring pallions in this world and the
other. The restraints which he impofed were requisite to
etablfih the credit of the prophet, and to exercife the
obedience of the people: and the only objection to his fuc-
cesfs was his rational credul of the unity and perfedions of
God. It is not the propagation, but the permanency of his
religion that deferves our wonder: the fame pure and perfed
imperfion, which he engraved at Mecca and Medina, is pre-
served, after the revolutions of 12 centuries, by the Indian,
the African, and the Turkifh profeflaries of the Koran."—
The Turkifh dome of St. Sophia, with an increafe of
ft pandeur and fize, reprefents the humble tabernacle erected
at Medina by the hands of Mahomet. The Mahometans
have uniformly withiheld the temptation of reducing the
object of their faith and devotion to a level with the fenes
and imagination of man. "I believe in one God, and Ma-
omet the apostle of God," is the fimple and invariable pro-
fefion of Islam. The intellectual image of the Deity has
never been degraded by any visible idol, &c. "From the
Atlantic to the Ganges, the Koran is acknowledged as
the fundamental code, not only of theology but of civil and
criminal jurisprudence; and the laws which regulate the
actions and the property of mankind are guarded by the
infallible and immutable fa[tiion of the will of God."—

MAHOMET.

MAHOMET I., sultan of the Turks, born about the year
1373, was one of the sons of Bajazet, who was dethroned by
Tamerlane. After his brother Solymans had lost his
life in the war with Mufa, he declared himself his avenger,
and being allowed by the Greek emperor Manuel, defeated
Mufa, who was killed in the field, or made captive and put
to death by Mahomet's orders. The victor was proclaimed
sultan at Adrianopole in 1413, when he entered the
lands of his empire. Soon after his accession, he raised over it
an army into Lefier Asia, and did much mischief there.
After having subdued Servia, part of Schorvan, and Macedon,
and reduced to obedience the provinces of Lefier Asia,
he died in the year 1421, having reigned eight years
with distinction and success, and leaving behind him a char-
Gibbon.

MAHOMET II., emperor of the Turks, named "The Great,"
and "The Victorious," son of sultan Amurath, or Morat II.,
was born at Adrianople in 1430, and received an
education very superior to that generally bestowed on the
princes of the Turkish empire. He was well skilled in
five languages, and was conversant in history and geography.
During the life of his father, he twice assumed the
omage, and twice renounced it, at the command of his
parent. He made no opposition to his father's will, but
never forgave the minions who were the advisers of the
measure. One of his first acts, after the death of his father,
was to repel the forces of Constantine, which remained in the
land of Mahometanism, when thus established, and of its
exile. During the preceding times, various
causes might be assigned, whole joint operation would be
full of the effect; without having recourse to any miraculous
or particular interposition of
providence. Of these causes we shall satisfy ourselves with
mentioning only one, which appears to be of peculiar force
and importance. In almost all those countries, which
acknowledge the authority of Mahomet, so intimate is the
connection, to absolve the dependence of the civil government
on religion, that any change in the latter must necessarily
and inevitably involve the ruin and overthrow of the former.
The Koran is not, like the gospel, to be considered merely
the standard by which the religious opinions, the worship,
and the practice of its followers are regulated; but it is a
political
; on this foundation the
erected; from hence every law of the
is derived; and
by
authority every question of life and of property is
finally decided. It is obvious, therefore, that in every
country where Mahometanism had been once received
and
the circumstance now mentioned must have
operated with uncommon weight to crush any important
innovation in religion; since from this inseparable connection

Vol. XXII.
He subdued Caramania, the sovereigns of which had long been the most inveterate enemies of the Turkish sultans. He conquered Negropont, the ancient Euboea, and wrested Kaffa in Crim Tartary from the Genoese. One of his latest attempts was the siege of Rhodes, in which he was rendered unsuccessful by the valour of the knights. He, however, as a compensation for this disaster, captured Otranto in Italy, which gave him a footing in that country; but to him this was of little use; his end was hourly approaching; he died in the month of May 1481, at the age of fifty-one, after a reign of thirty years. The vigour of mind and body, and the lustre of enterprise by which this conqueror was characterized, raised him swiftly above the mere posefiers of an hereditary throne. His successes, however, were chiefly obtained by the force of numbers, urged on by an unshaken desperation, and it has been asserted that he generally failed in the contest with combined skill and valor. The evils which he brought upon Chirillendom have caused his moral qualities to be pointed in the darkest colours by its writers. He has been accused of irreligion, perhaps chiefly from the tolerant spirit which directed his conduct towards the vanquished of different religions; yet he displayed the usual zeal of princes in founding splendid edifices for the public worship of the established faith. Univer. Hist. Gibbon.

Mahomet III., emperor of the Turks, son of Amurath III., was born in 1564, and succeeded to the throne on the death of his father in 1596. The first act of his infamous reign was the murder of nineteen brothers, and ten of his father's wives from whom offspring might be apprehended. Having thus secured his throne, he gave himself up to indolence and sensuality, little attentive to the affairs of the empire, which were seldom more prosperous than in this reign. In his contests with neighbouring powers he was commonly unsuccessful. A series of disasters excited against him a conspiracy, to quell which, he was under the necessity of sacrificing some of his officers, and banishing the queen mother from his counsels. Mahomet died in 1603, at the age of thirty-nine, after an inglorious reign of about eight years.

Mahomet IV., emperor of the Turks, was born in 1642, and succeeded his deposed father in 1649. During his minority the government was administered by his mother, assisted by a council of baihaws. He found his country at war with the Venetians, which was continued with various success. The empire at home was speedily recovered by the revolt of the bashaw of Aleppo, who at first gained great advantages over the grand vizier, but in the end lost his life. In the year 1665, war was rekindled with great vigour in Hungary, and the Turkish arms were at first successful. A great victory gained by Montecuccoli, the imperial general at Raab, in 1664, inclined the Ottoman court to a peace, which was soon after concluded. The conquest of the island of Candia from the Venetians in 1669, after a siege of 25 years, was one of the most memorable events of this reign. A war with Poland in 1672, was terminated with a peace very humiliating to the Poles, but the nation refused to ratify it, and John Sobieski in the following year gave the Turks a complete defeat at Choczwim, which circumstance was the means of raising him to the Polish throne. After this, for several years, the tide set in strongly against the Turks. A career of all fortune excited defections among them, and the army broke out into a fierce mutiny. Out of their camp near Bregade, they marched for Constantinople, and sent before them a demand of the grand vizier's head; which was granted. They next upbraided the sultan with his neglect of public affairs, and entreated him to reign a government which he had proved himself unfit to conduct. Mahomet, as a measure of self-defence, determined to put his brothers to death, but being apprised of his intention, they took methods of saving themselves from the threatened danger. At length Mahomet submitted to pronounce the decree of his own renunciation. He quitted the throne in 1687, and was confined to his apartments, where he resided till the year 1691. He left two sons, who afterwards came to the throne of the empire. Mahomet IV. is described as distinguished for justice, clemency, and valor, though the history of his reign is that of his generals and minions; his own activity was shown chiefly, if not wholly, in the pursuits of the chase. Univer. Hist.

Mahomet Pigeon, in Ornithology, the common English name of a species of pigeon, called by Moore the columba Numidica alba. It is of the same shape and size with the Barbary pigeon, and has all the characters of that species, but is always perfectly white, which gives the red circle about the eyes a more lively look. See COLUMBA.

MAHOMETANISM, MAHOMETISM, or MOHAMMEDANISM; the sylllem of religion broached by Mahomet, and still adhered to by his followers. See MAHOMET.

Mahometanism is embraced by the Turks, Persians, and several nations among the Africans, and many among the East Indians.

Browne says, that if we divide the known countries of the earth into thirty equal parts five of them are Christians, six Mahometans, and nineteen Pagans.

The system of Mahometanism is contained in the Koran, commonly called the Alcoran; which see.

The first and chief article of the Mahometan creed is, that there is no other God but one God; which they have from the Koran, where these words are repeated incessantly: there is no other God but he. Tour God is the only God. I am God, and there is no other God but I. This grand axiom of their theology seems to have been taken from the Jews, who were continually rehearsing those words of Deuteronomy, Hear, O Israel; the Lord our God is One.

For this reason, the Mahometans account all fiats as own any thing of number in the divinity, to be infidels or idolaters. And accordingly, one of the first lessons they teach their children is, that God is neither male nor female, and, consequently, can have no children. (See the 2d, 57th, and 5th chapters of the Koran.) Hence, the profyltes of Mahomet, from Moslem to Moroccon, are distinguished by the name of "Unarians," and the danger of idolatry has been prevented by the interdiction of images.

The second article of Mahometanism consists in this, that Mahomet was sent from God. By which they exclude all other religions; under pretence that their prophet was the last and greatest of all the prophets that God would ever send, and that as the Jewish religion ceased with the coming of the Meduslah, so likewise the Christian religion was to be abrogated with the coming of Mahomet. Not but they own Moses and Jesus Christ to have been great prophets; but Mahomet they hold to be "The Prophet," by way of excellence, commemorated to purge the by corrupt origin of the Old and New Testament, which they allow, from the corruption introduced in them by Jews and Christians, and to restore the law of God to its original purity; and the paraclete or comforter promised in the prophecies.

The Mahometans call their religion Islam, denoting, as some say, submission or submission to the service and commands of God; but, according to others, formed from the root yslam, signifying to be saved, and, therefore, the same with the religion of faith or salvation; and they divide it into two distinct parts, viz. Islam, i. e. faith or theory; and Islam, i.e.
MAHOMETANISM.

i. e. religion or practice: and teach that it is built on five fundamental points, one belonging to faith and the other four to practice.

Under the confession of faith already recited, they comprehend six distinct branches, viz. belief in God; in his angels; in his scriptures; in his prophets; in the resurrection and day of judgment; and in God's absolute decree and predetermination both of good and evil. The four points relating to practice, are prayer, under which are comprehended those washings or purifications which are necessary preparations required before prayer; alms, fasting, and the pilgrimage to Mecca. Their faith in God has been already mentioned: with respect to their opinion of angels, they believe them to have pure and subtle bodies, created of fire, and that they are differently employed, in writing down the actions of men, or in carrying the throne of God, and other services. The four angels, whom they regard as most distinguished by God's favour, and on account of the offices assigned them, are Gabriel, called the holy spirit, and the angel of revelations, and faprophied to be honoured with the peculiar confidence of God, and employed in writing down the divine decrees; Michael, the friend and protector of the Jews; Azrael, the angel of death, who separates man's souls from their bodies; and Iraffil, whose office it will be to sound the trumpet at the resurrection. They also believe that two guardian angels, changed every day, attend on every man, to observe and write down his actions. Their whole doctrine concerning angels they have borrowed from the Jews, who learned the names and offices of those beings from the Persians. The devil, called by Mahomet "Elhiz," from his desirous, was one of those angels, who are nearest to God's presence, called Azazil, and fell, according to the doctrine of the Koran, for refusing to pay homage to Adam at the command of God. They also admit an intermediate order of beings, called genii, some of which are good, and others bad; and capable of future salvation or condemnation, as men are, whence Mahomet pretended, that he was sent for the conversion of genii as well as of men.

As to the scriptures, the Mahometans are taught by the Koran, that God, in divers ages of the world, gave revelations of his will in writing to several prophets, the whole, and every word of which, it is absolutely necessary for every good Muslim to believe. Mahomet acknowledges the divine authority of the Pentateuch, Psalms, and Gospel, and often appeals to the confonnacy of the Koran with those writings, and to the prophecies, which he pretended, were contained concerning himself, which the Jews and Christians have faprophied.

Besides these books, the Mahometans take notice of the writings of Daniel and several other prophets, and even cite them, but they do not believe them to be divine scripture, or of any authority in matters of religion. Among the prophets, in number 224,200 according to some, and 124,000 according to others, they reckon 313 apostles, hearing special commission to reclaim mankind from infidelity and superstition; six of whom were entrusted with new laws or dispensations, successively abrogating the preceding; these were Adam, Noah, Abraham, Moises, Jefus, and Mahomet.

At death, they maintain, that the bodies of those, who believe the unity of God, and the mission of Mahomet, rest in peace, and are refreshed with the air of paradise; otherswise they are grievously tormented. The souls of the former are conveyed to heaven, where a place is assigned them according to their merit and degree; those of the wicked are tormented, till they are rejoined to their bodies at the resurrection; the approach of which will be known by certain signs that precede it: these are the lesser and the greater signs: the latter of which are the fun's rising in the west; the appearance of a monstrous beast, which shall rise out of the earth in the temple of Mecca; war with the Greeks and the taking of Constantinople; the coming of Anti-Christ; the defeat of Jefus on earth; war with the Jews; the eruption of Gog and Magog; a smoke which shall fill the whole earth; an eclipse of the moon; the return of the Arabs to the worship of their ancient idols; the discovery of a vast heap of gold and silver by the retreat of the Euphrates; the demolition of the temple of Mecca by the Ethiopians; the speaking of beasts and inanimate things; the breaking out of fire in the province of Hejaz or Yemen; the appearance of a man, who shall drive men before him with his hand; the advent of the Moli, or director, a person of the family of Mahomet, to govern the Arabs, and fill the world with righteousness; and a wind that shall sweep away the souls of all who have but a grain of faith in their hearts. But the immediate sign of the resurrection will be the first blast of the trumpet, which will be sounded three times. The day of judgment will continue, as the Koran says in one place, 1,000 years, but according to another passage, 50,000 years: the resurrection, say they, will be general, extended to all creatures, angels, genii, men, and animals; who will be assembled on the earth, give an account of their actions, and receive retribution. On this occasion each person will have the book, wherein all the actions of his life are written, delivered to him, and their works will be weighed in a balance, which they minutely deserve. When the examination is finished mutual retaliation will follow; which will be executed by taking away a proportionable part of the good works of him who offered injury to another, and adding it to him who suffered it. Brutes will be changed into dust; and the believing genii be assigned a place near the confines of paradise, and the unbelieving punished eternally and cut into hell, with the infidels of mortal race. After this process, the good and wicked are conducted to a bridge, called Alfrat; over which the former shall safely pass, while Mahomet and his Moslems lead the way, but the latter will fall down headlong into hell; where there are seven different apartments, adapted to as many distinct classes of the damned, who will suffer both from intense heat and excessive cold. In this state infidels only will be liable to eternal punishment; but the Moslems or believers will be delivered thence, after they have expiated their crimes by their sufferings. This place of punishment is separated from paradise by a wall, called "Al dri," in small in breadth as to admit the blest of heaven and damned to converse together. The righteous, after having passed the bridge above-mentioned, will be refreshed by drinking at the pond of their prophet, and then admitted into paradise, situated in the seventh heaven, and next to the throne of God; where they will feed on the most delicious fruits, be clothed in the most splendid filken garments, refreshed with rivers of water, wine, milk, and honey, and entertained with the most delightful music; and the virgins of paradise with black eyes, the enjoyment of whose company will be a principal felicity of the faithful.

It appears from the Koran, that women as well as men will not only be punished for their evil actions, but also receive the reward of their good deeds, and that both will enjoy a perpetual youth.

Hence it appears, that the vulgar opinion, which charges the Mahometans with maintaining that women have no souls, or if they have any, that they will perish like the brutes,
brutes, without any future recompense, are criminals. It is, however, a general notion, that they will not be admitted into the same abode as the men, because their places will be supplied by the paradisical females already mentioned. One circumstance relating to these beautiful females, conformable to what Mahomet had ordered of the men, he acquainted his followers with in the reply which he made to an old woman; who directing him to intercede with God, that she might be admitted into paradise, was told by him, that no old women would enter that place; which curing the aged female to flight and shed tears, he explained himself by saying, that God would then make her young again.

"Further, the orthodox doctrine with respect to predetermination is, that every thing which happens in this world proceeds entirely from the divine will, and is irrevocably fixed from all eternity in the preferred table; God having secretly predetermined not only the adverse and prosperous fortune of every person in this world, in the most minute particulars, but also his faith or infidelity, his obedience or disobedience, and consequently his everlasting happiness or misery after death; which fate or predetermination it is not possible for any forfear or wisdom to avoid. Of this doctrine Mahomet makes great use in his Koran for the advancement of his designs, encouraging his followers to fight without fear, and even desperately, for the propagation of their faith, representing to them that no caution on their part could avert their inevitable death, or prolong their lives for a moment. In regard to the four fundamental points of religious practice; Mahomet is Saul to have declared, that the practice of religion is founded on cleanliness, which is one-half of the faith, and the key of prayer, without which it will not be heard by God. Such is the opinion which the Mahometans entertain of cleanliness, that it is purely on this account they seem to have adopted circumcision, though it be not mentioned in the Koran. Mahomet has obliged his followers to pray five times every twenty-four hours at certain fixed hours, turning their faces towards the temple of Mecca, which is pointed to by a niche in their mosques; the life and spirit of prayer, they hold, are the inward disposition of the heart; nor do they ever perform this duty in unclean apparel, nor suffer their women to attend on these occasions, lest their preference should inspire a different kind of devotion from that which is requisite in a place dedicated to the worship of God.

The Mahometans, are legal and voluntary; the gaws of which is frequently insinuated in the Koran. Hafiz, or Hufein, the son of Ali, and grandson of Mahomet, is said to have three in his life divided his substance equally between himself and the poor, and twice to have given away all he had; and the generality of Mahometans are so addicted to acts of benevolence, that they extend their charity even to brutes. Fasting is called by Mahomet the gate of religion; and his followers are expressly required to fast during the month of Ramadan; which they observe by abstaining from meat, drink, and women, from day-break till sun-set. Besides this, they have several other voluntary fasts. The pilgrimage to Mecca is a necessary part of the practice; that, according to a tradition of Mahomet, he who dies without performing it may as well die a Jew or a Christian; and it is expressly commanded in the Koran. The various ceremonies prescribed to those who perform this pilgrimage are extremely absurd and ridiculous, and appear to be relics of idolatrous superstition.

Besides the fundamental points of faith and practice above received, the Mahometans are required by the Koran, to abstain from wine, gaming, usury, drinking by arrows, the eating of blood and dwine's flesh, and whatever dies of itself, or is slain in honour of any idol, or strangled, or killed by accident, or by any other beast. The Koran allows polygamy within certain limits; forbidding any man to have more than four, whether wives or concubines; but Mahomet had the privilege of marrying as many wives, and keeping as many concubines as he pleased. It allows also of divorce; but severely punishes fornication and adultery.

Wilful murder, though forbidden by the Koran under the severest penalties to be inflicted in the next life, is neverthelefs by the same book allowed to be compounded for, on payment of a fine to the family of the deceased, and freeing a Meden from captivity; but this commutation depends on the choice of the next of kin, who may either accept or refuse it. Manslaughter was redeemed by fine, and the freeing of a captive; and if a man were not able to do this, he was required to fast two months together, by way of penance. The fine for a man's blood was set in the "Soma" at 100 camels, and was distributed among the relations of the deceased. Theft was ordered to be punished by cutting off the hand. As to injuries done to men in their perfons, the law of retaliation, which was ordained by the law of Moses, is also approved by the Koran; but it was seldom executed; the punishment being generally turned into a waxlet or fine, paid to the party injured. In the punishment of lecherous crimes, not provided for by the Koran, the Mahometans have commonly recourse to stripes or dubbing, according to the usual practice of the East. Under the head of the civil laws of the Mahometans, we may comprehend the injunction of waging against infidels, which is repeated in several passages of the Koran, and declared to be very meritorious in the fight of God; those who are slain fighting in defence of the faith, being reckoned martyrs, and promoted immediate admission into paradise.

The months which the ancient Arabs held sacred were al Moharran, Rajej, Dhu'kaada, and Dhu'kijja, the 1st, the 7th, the 11th, and the 15th in the year Mahomet by the Koran confirmed the observance of these months.

The day of the week which Mahomet has set apart for public worship is Friday; besides which they have two annual feasts called Bican.

After the death of Mahomet, a schism arose among his followers, which divided them into two great factions, whose separation not only gave rise to a variety of opinions and rite, but also excited the most implacable hatred, and the most deadly animosities. Of these factions the one acknowledged Ali, the father-in-law of Mahomet, as his successor, or the true Caliph, and its adherents were distinguished by the name of Sunnites; while the other adhered to Ali's son-in-law, and were known by the title of Shiites. Both, however, adhered to the Koran as a divine law, and the rule of faith and manners; to which indeed the former added, by way of interpretation, the Soma, i.e., a certain law, which they looked upon as defended from Mahomet by oral tradition, and which the Shiites refused to admit. Among the Sunnites we are to reckon the Turks, Tartars, Armenians, Africans, and the greatest part of the Indian Mahometans; whereas the Persians, and the inhabitants of the grand Mogul, are generally confederated with the followers of Ali, though the latter indeed seem rather to observe a strict strictness in this contile. Besides these two grand factions, there are other subordinate sects among the Mahometans, which differ with warmth concerning several points of religion, though without violating the rules of mutual toleration. Of these sects there are four, which far surpass the rest in point of reputation and importance, viz., the Hanefites, the sect of Malee, the sect of Al Shirazi, and that of Ebn Hanbal, which are
are called the orthodox Mahometans. Sale's Preliminary Discourse. See ALCORAN.

The rapid successes which attended the propagation of this new religion, was owing to causes that are plain and evident, and must remove, or rather prevent, our surprise, when they are attentively considered. We have enumerated the principal under the biographical article MAHOMET. But the subject is of importance, and we shall therefore here resume it. The terror of Mahomet's arms, and the repeated victories which were gained by him and his successors, were, no doubt, the irresistible arguments that persuaded such multitudes to embrace his religion, and submit to his dominion. Besides, his law was artificially and marvelously adapted to the corrupt nature of man; and, in a more particular manner, to the manners and opinions of the eastern nations, and the vices to which they were naturally addicted: for the articles of faith which it propounded were few in number, and extremely simple; and the duties it required were neither many nor difficult, nor such as were incompatible with the empire of appetites and passions.

It is to be observed farther, that the gross ignorance under which the Arabians, Syrians, Persians, and the greatest part of the eastern nations, laboured at this time, rendered many of their people ready to the artifice and eloquence of this bold adventurer. To these causes of the progress of Mahometanism, we may add the bitter discriminations and cruel animosities that reigned among the Christian sects, particularly the Greeks, Nestorians, Eutychians, and Monophysites; distinctions that filled a great part of the East with carnage, assassinations, and such detestable enormities, as rendered the very name of Christianity odious to many. We might add here that the Monophysites and Nestorians, full of resentment against the Greeks, from whom they had suffered the bitterest and most injurious treatment, affliited the Arabians in the conquest of several provinces, in which, of consequence, the religion of Mahomet was afterwards introduced. Other causes of the sudden progress of that religion will naturally occur to such as consider attentively its spirit and genius and the state of the world at this time. Mollien's Ecc. Hist.

MAHON, in Geography. See PORT MAHON.

MAHON, a river of Ireland, in the county of Waterford, which runs into the sea; 11 miles E. of Dungarvan.

MAHONE BAY, a bay on the coast of Nova Scotia, separated from Margarets Bay by the promontory, on which is the high land of Apscotogen.

MAHONING, a township of America, in Pennsylvania, situated on Susquehanna river.

MAHONY, a township of Susquehanna river, in Pennsylvania, having 1103 inhabitants.

MAHONY, a town of Hindoostan, in the cirec of Sohagpoor; 20 miles N. of Sohagpoor.

MAHOU, a city of China, of the first rank, in the province of Szechuan, seated on the Kichiu; comprehending, within its district, only one city of the third class, but a great trade. N. lat. 28° 32'. E. long. 103° 51'.

MAHOWLY, a town of Hindoostan, in Orude; 25 miles N.W. of Koubad.

MAIR, Hanna, a town of Syria, where the Greek Catholics live a convent and a printing-office; 18 miles N.E. of Bairoun.

MAHARABUT. See MARAHABUT.

MAHARAJEGUNGE, a town of Hindoostan, in Barbar; 11 miles E. of Haipour. - Also, a town of Bengal; 30 miles N.E. of Purman. - Also, a town of Hindoostan, 20 miles W. of Benares.

MAHRAS, EL, a town of Tunisia; 60 miles S. of Chairoan.

MAHRATTAS, a powerful people of Hindoostan, who derived their name, as some say, from "Marhat," a province of the Deccan, mentioned by Ferishta, and comprehending Baglana, or Baglians, and other districts, which at present form the most central part of the Mahratta dominions. The original meaning of the term Marhat is unknown; but there is no doubt that the name of the nation is a derivative from it; for we may depend upon the testimony of Ferishta, who wrote at a period, when the inhabitants of the province of Marhat did not exist as an independent nation: but were blended with the other subject Hindoos of the Deccan. We learn also from an earlier authority than that of Ferishta, viz., from Nizam-ul-Deen, an officer in the court of Achar, who wrote a general history of Hindoostan, brought down to the 40th year of that emperor, that one of the kings of Delhi made an excursion from Deogur, or Dowlatabad, into the neighbouring province of "Marhat." This relation occurs also in Ferishta's history of Hindoostan. It was in the reign of Alla I. A.D. 1312. From a paper published in the "Aristic Researches," (vol. ix.) we learn that it is asserted in India, that the "Maharattas" are foreigners, and that they acknowledge this to be their origin. A tribe called Ranas, related to the Mahrattas, say, that they were descended from Nuthirvan; and the Paris, in India, fix the time of their emigration in the reign of Abu-Deer, which lasted only two years from 632 and 633. Some of these emigrants left Peria at different periods, in consequence of the fanatic zeal of the Mussulmen, and their perfecuting spirit; but the emigration of the children of Nuthirvan is the most ancient. These emigrants, some retained their ancient religion, and were called Paris; others termed Hindoos, and are called Ranas and Mahrattas. The Mahrattas are called "Maharatrias" in Sanscrit: "Marha" is great and illustrious, and "Rahtri," synonymous with Raja-putra, implies their royal descent; and their name also indicates, that they were acknowledged to belong to the second class on their arrival in India, and of course that they were not Brahmins. When the new adventurers obtained power and influence, they assumed the title of Maharatrias, and by driving out such others as became useless, when brought to the standard of the dharma in life, they became considered by the name of Mahrata, Mahrata, and Mahar. The founder of the Mahratta empire may be considered as Sevajee, who was born in 1658, and attaining the condition of a subject, embraced the early opportunity of becoming independent. The progress of his conquests was so rapid, that he became formidable to the armies of the Mogul empire, before Aurungzebe's accession to power; having seated on the principal part of the province of Baglana, and the country of Cocean, situated between it and the western sea. He had also taken possession of other places of strength. In the Carnatic he had possession of Gingee, together with an extensive district round it; and this, perhaps, may be regarded rather as an usurpation of one of the Viziapoor conquests, than as an acquisition made from the original sovereign of the Carnatic; for the king of Viziapoor appears to have possessed the southern part of the Carnatic, including Tanjaore. At the death of Sevajee, in 1682, his domains extended from the northern part of Baglana, near Surat, to the neighbourhoov of the Portuguese districts of Goa, along the sea-coast. His conquests had been the fruits of hardy and persevering valor; partly acquired in defiance of Aurungzebe, then in the zenith of his power. Sevajee had left plundered Surat and Golconda, and even attacked
attacked Goa when the Portuguese power was at its height. His son Sambajee fell a sacrifice to his debauchery, having been seized on treacherously, in one of his licentious excursions, and cruelly put to death by Aurungzebe in 1740. The Mahrattas, however, remained unfi...
within their extensive empire, which extends from sea to sea, across the widest part of the peninsula; and from the confines of Agra northward, to the Kistna southward; forming a tract of about one thousand British miles long, by seven hundred wide. To the western flat, which is divided among a number of chiefs or princes, whose obedience to the padishah, or head, resembles that of the German princes to the emperor, being merely nominal, and whose confederacy never takes place except for mutual defence, belong several "jagirdars," or holders of "jaghires," one on the north of Poonam, and two on the south. The revenue of this state is not easily aforesaid; but it has been rated by a native of India at 12 crores of rupees, or 12 millions sterling; and the net receipts, jaghires deducted, at five crores. The same account makes the military establishment in the field at 200,000 troops, foot and horse; besides an equal number in garrison. Another account of the revenue gives five crores for the net revenue. Major Russell observes that if the provinces possessed by this state were to be rated in the same proportion as in the time of Aurungzebe, the net revenue would be about eight crores of rupees, or eight millions sterling. The most powerful jagirdar within this state is that of Sindia, who, since the Mahratta peace in 1783, has extended his frontier from Malwa towards the Jumna, occupying most of the petty states that theretofore existed there, and particularly that of Gohurd. He also extended his arms southward to Delhi, and into the provinces of Mewat and Jynagur; reducing many fortresses and a considerable tract of country, which had been possessed by the Jats and Nadijai Cawn. The revenue of his paternal, or original dominions, in Malwa, &c. has been estimated at one crore of rupees per annum. Among his new acquisitions, Gohurd has been supposed to possess 800,000 rupees per annum; Holkar has been supposed to possess 100,000 rupees per annum; and Indian and Holkar's capital is Indore, about 20 coffies S. or S.E. of of Cegein. For an account of Berar, see there; and for further particulars relating to the Mahratta states, see Hindostan. Rennell's Introduction to his Memoir, paffim, and his Map.

MHDRAUZEDURGAM, a town of Hindoostan, in Myore; six months N.E. of Killaagheri.

MAHRENBERG, or Mahrenberg, a town of the duchy of Sirea; nine miles N. of Windtich Gratz.

MAHSENA, in Ithystology, See SELERA.

MAHU, in Geography, a town of Sweden, in Sudermanland; 28 miles N.W. of Nykioping.

MAHUDGEE, a town of Hindoostan, in Oude; 12 miles N. of Fyzabad.

MAHUNWAH, a town of Hindoostan, in Guzerat; 31 miles S.E. of Puttan Sumaut.

MAHUR, a cairn of Hindoostan, in Berar, on the N. side of the Godavery river, E. of Ellichpourt, and N. of Tellangan. The chief towns are Mahur and Nerumul. — Also, a town, the capital of the above cairn, 112 miles E. of Ellichpourt. N. lat. 19° 24'; E. long. 78° 3'.

Also, a town of Hindooostan, in the cairn of Gurrah; 90 miles S.S.W. of Allahabad. N. lat. 124° 18'; E. long. 81° 2'.

MAHUREA, of Aublet and Jaffieu, in Botany. See Bonnetia.

MAHURRY, in Geography, a town of Hindooostan, in the cairn of Surgoonga; 35 miles N.W. of Surgoonga.

MAI, a town of Persia, in the province of Larifian; 41 miles W. of Lar.

MAIA, a river of Russiæ, which, rising in N. lat. 59° 50', E. long. 139° 10', pursues a S.W. course to N. lat. 57° 40', and then uniting with the Maimakan, changes its course to N.N.W. and runs into the Aldan, N. lat. 60° 20'; E. long. 133° 40'.

MAJAH, in Ornithology, the name of a bird described by Nieremberg as very common in the island of Cuba, and frequenting the fields of rice in large flocks. It is described to be a small bird of a yellowish colour, very delicate, and well tinted, and remarkable for having a flambe on the back or outside of the neck. See PINCELLA MAJA.

MAJAH, or Majan of Buffon, a species of Loxia; which see.

MAJAGUE, the name of a Brazilian bird of the web-footed kind, but having its hinder toe loose. It is of the size of the common goose; its head is large and round; its neck long; and it always carries it crooked like a swan; its beak is strong and hooked at the end; it is all over of a brownish-black colour, except that its throat is yellow. It is found about the mouths of rivers, and feeds on fish; it builds on the ground; it is very nimble in running, flying, and diving, and is not easily taken, but it is a very well-tailed foul. It is the Brazilian parrot of Latham. See Procellaria Brasiliensia.

MAIKA, in Geography, an outport of Russia, on the coast of the Frozen ocean. N. lat. 71° 16'; E. long. 169° 14'.

MAIKAHAR, a town of Russia, in the government of Perim; 16 miles N. of Obrinik.

MAIYAN, a town of Peria, in Farifian; 18 miles S. of Iftihan.

MAJAH, a town of Algiers, in the province of Constantiata, at the entrance of an extensive plain, to which it gives name; 50 miles S.S.W. of Bouiejan.

MAIANTHEMUM, in Botany, from Max., the month of May, and xipheus, a flower, a name given by some authors to the Lir. of the Valley. See CONVALLARIA.

MAIJAR, in Geography, a town of Peria, in Chouftian; 12 miles N. of Konlan.

MAIJARES, a town of Transylvania, in the Maros; 17 miles E. of Bihrz.

MAIDA, a town of Naples, in Calabria Ultra; 9 miles W.N.W. of Squallace.

MAIDEN, an edged instrument used in some countries, and formerly in Scotland, for the bebving of criminals. The maiden is a broad piece of iron, of a foot square, sharp on the lower part, and leaded above with lead, so fiercely to be lifted; at the time of execution, it is pulled up to the top of a narrow wooden frame ten feet high, with a groove on each side for the maiden to slide in. The prisoner's neck being fastened to a bar underneath, on a flint given, the maiden is let loose, and the head in an instant separated from the body. It has been lately much used in France as an instrument of decollation, under the name of Guillotine.

MAIDEN is also the name of a machine first used in Yorkshire, and since introduced into other places, for washing of linen; consisting of a tub nineteen inches high, and twenty-seven in diameter at the top, in which the linen is put, with hot water and soap, to which is adapted a cover, fitting it very closely, and fastened to the tub by two wedges, through a hole in the middle of the cover passes an upright piece of wood, kept at a proper height by a peg above, and furnished with two handles, by which it is turned backward and forward; to the lower end of this upright piece is fastened a round piece of wood, in which are fixed several pieces, like cogs of a wheel. The operation of this machine is to make the linen pass and repair quick through the water. Gent. Mag. vol. xxii. p. 32.
MAI

MAIDEN-AFFEET, are those where no person is condemned to die.
MAIDEN-HAIR, Atlantic, in Botany and Medicine. See Adiantum, and Asplenium.
MAIDEN-HAIR, Black, a name sometimes given to the dwarf fern. See Asplenium.
MAIDEN-HAIR, English. See Trichomanes, and Asplenium.
MAIDEN-HAIR, White, or Wall-Rue. See Asplenium.
MAIDEN-Islets, in Geography, a cluster of small islands in the Bay of Isaac-harbour, near the W. coast of the island of Antigua.
MAIDEN PAPA, a mountain of Scotland, in the county of Roxburgh: 8 miles from Hawick.
MAIDEN PLUM, in Botany. See Plum.
MAIDEN-RUTS, in our Old Writers, a noble paid by the tenant of some mansions on their marriage. This was laid to be given to the lord, for his omitting the custom of marriage, whereby he was to have the first night's lodging with his tenant's wife; but it seems more probable to have been a fine for a licence to marry a daughter.
MAIDEN ROCKS, in Geography, a chain of rocks in the E. coast of the island of Java. S. lat 7° 43'. E. long. 114° 30'.

MAIDENHEAD, anciently called South Ealington, a market-town in the hundred of Cookham, Berkshire, England, is situated 26 miles from London, on the borders of the Thames, in the parishes of Bray and Cookham. It consists principally of one long paved street; and derives its chief importance from the bridge, by means of which the great western road was carried through the town. Previously the road passed through Burnham, and travellers usually crossed the river at a ferry called Bambam's End, about two miles north of Maidenhead. The original bridge, which was of wood, Camden says, was erected about the year 1400; but there is sufficient evidence of its being of greater antiquity, and that, in 1597, it had been built long enough to need repair; for which purpose, a toll for three years was then granted. The present bridge, which is a work of considerate merit, was constructed from the designs of Sir Robert Taylor; and its foundation was laid in 1772. It consists of seven large semi-circular arches of stone, and three smaller, at each end, of brick. The expense of building it was 19,000l., independent of some contiguous lands, which were purchased to render the work complete. The approach to this structure is grand and spacious, the ends being formed with curves outwards: along the sides is a broad pavement, fenced with a balustrade. Maidenhead was originally incorporated in the 25th year of Edward III., under the name of the guild or fraternity of the brethren and gilders of Maydeneth, or Maidenhithe. After the Reformation, a fresh incorporation was granted, in the name of the warden and burgesses of Maidenhead. King James II. granted another charter with the style of mayor, bridge-masters, and burgesses, who are empowered to choose a high steward. Two of the burgesses, who are eleven in number, are annually elected bridge-masters. The high-steward, the recorder, the mayor, and his immediate predecessor, are justices of the peace. The mayor is clerk of the market, coroner, and judge of a court, which is held once in three weeks. The market, which was granted in 1452, is still kept on Wednesdays, and is a considerable mart for corn. Here are three annual fairs. The revenues of the corporation consist chiefly of the tolls of the market and bridge. The principal trade of the town is in malt, meal, and timber; and the inhabitants derive additional livelihood from the constant passage of travelers, for whole accommodation several inns have been opened. In that part of the town which lies within the parish of Cookham is a chapel, exempt from episcopal jurisdiction; the minister is appointed by the mayor and bridge-masters. In this division of the town is also an almshouse for eight poor men and their wives, founded and endowed in 1659, by James Smith, esq., citizen of London. The number of inhabitants in Maidenhead, as returned to parliament in 1801, was 919, occupying 160 houses: but either some mistake was made in that enumeration, or the population has been rapidly on the increase, for, in the year 1806, it amounted to 1100. At the western extremity of the town is a large brick manufactory, the seat of Sir Isaac Pococke, bart. Lylyson's Magna Britannia, vol. 1. 401. 1866.

MAIDENHEAD, a small neat village of America, in Huntington county, New York, situated on the road between Princeton and Trenton; 6 miles from each, and having a Presbyterian church; the township contained, in 1793, 1032 inhabitants.

MAIDEN-LAND, a name given by Sir Richard Hawkins, in 1594, to land which he discovered in steering towards the straits of Magellan, in honour of queen Elizabeth, and which, as he says, lies "some three-score leagues from the nearest part of South America". This land was afterwards found to be two large islands by captain John Strong, of the Farewell, from London, who, in 1629, passed through the strait which divides the eastern from the western of these islands. To this strait he gave the name of Falkland's Sound, in honour of his patron, lord Falkland; and the name has since extended, through inadvertency, to the two islands that are separated by it. See Falkland's Islands.

MAIDHAT, a town of Persia, in the province of Isfik, 55 miles S.S.W. of Dairen.

MAIDSTONE, a borough and market-town in the hundred of that name, lathe of Aylesford, and county of Kent, England. It is beautifully situated on the banks of the river Medway, whence it is supposed to have derived its name. The origin of this place is wholly uncertain. Camden, and some others, have considered it as the Vagnisca of Antoninus, though upon very insufficient evidence. A few writers have also conjectured it to be the Caer Megnadi, or Megwad, mentioned in Nennius's Catalogue of British Cities; but this opinion is equally doubtful with the former. The Saxons named it Medwegelum, and it occurs in Domesday-book, by the appellation Meddeleone, of which terms its present name is an easy and obvious corruption.

This town is a borough by prescription, and the capital of the county of Kent. In ancient times it was governed by a portreeve and twelve brethren. Edward VI., in the third year of his reign, formed it into a charted corporation, by the style of the "mayor, jurats, and commonly", and about the same time members were first returned from hence to serve in parliament. The charter granted by this monarch was either renewed, or confirmed with additional privileges, by several successive kings. By the last charter, dated in 1748, the government was vested in a mayor, twelve jurats, forty common council-men, a recorder, two sergeants at mace, and other inferior officers. Freemen, not receiving arms, have the right of electing the burgesses to parliament.

Maidstone extends about a mile in length, from north to south, and somewhat more than three quarters in breadth, from east to west. The principal portion of its buildings stands on the eastern bank of the river, by which it is watered, rising gradually from its brink. It comprises chiefly four principal streets, which intersect each other; with some lesser ones branching off from them at right angles.
angles. The high street, in particular, is very spacious, and
magnificently well-built. Every part of the town has been con-
siderably improved within these few years. In 1791, an act
of parliament was obtained for the purpose of having it new
lined and lighted, and its different market-places repaired;
which act has been carried into execution with great effi-
cacy and judgment. The church, one of the largest parochial
edifices in the kingdom, is a very handsome embattled build-
ing, containing a nave, aisles, and chancel. It is adorned
with a lofty embattled tower, which formerly supported a
spire, but the latter was destroyed by lightning in November,
1730. The windows are large, and ornamented with rich
tracery, particularly that facing the hall. By whom this
church was first constructed, is uncertain; but it is well
ascertained to have been rebuilt by archbishop Courtney
in the time of Richard II., from whom the estate to
render it collegiate, for the use of the warden, chaplains,
and other members of the new college, then building close
to the southern side of the cemetery. This prelate
was buried in the centre of the chancel,—a grave about five
feet deep, whence his bones were discovered in 1704; but
his monument has been long since destroyed. On the north
side of the chancel stands a very ancient defaced tomb,
raised in honour of one of the Woodvilles, ancestors to king
Edward IV. th’s queen; and in the vaults within the com-
omnial-rails several of the ennobled families of Aitley and
Marham lie buried. At the corner of East-lane is the
priory, or priory, so called from having been anciently the
house of a convent of Franciscans, or Grey Friars, founded
here by Edward III., but which was afterwards removed to
Waltham, in Norfolk. Faith’s chapel, in the northern
district of the town, appears to have been long used as a
place of worship, but its history is very little known. The
free grammar-school is a foundation of considerable repute,
some of the most notable characters in this country having
been educated here. The school-room, and part of the
adjoining buildings, originally formed the chapel and lodg-
ings of the “Fraternity of Corpus Christi,” which was
founded by a few of the inhabitants professing the rule of
St. Benedict. Before the free-school, there are two charity
schools, established through the interest of the Rev. Dr.
John Woodward; two ranges of alm-houses, and a poor’s-
house, erected in 1720. The shire-hall, a good modern
edifice, is appropriated to public business. The affixes for
the county are held here, as are also the quarterly secessions,
and other county courts. Adjoining to this place is a
prison, called the Brambles, which anciently belonged to the
archbishops of Canterbury, but now to the corporation.
The gaol, in East-lane, erected in 1741, has since been
much enlarged and improved. At the upper end of High-
street is a conduit, which forms the chief reservoir for sup-
plying the inhabitants with water. Another building, of
the same kind, also stood in the middle of this street previous
to the year 1793, when it was pulled down. A new octagon
structure, in the lower part of the town, contains a third
reservoir. The water which supplies these reservoirs is
brought by pipes laid under the Medway, from an inclosed
spring, called Rocky-hill, in the Weald-borough. The
theatre, situated on the west side of High-street, is a neat
small building. In Earl’s-court is Earl’s-place, a curious
ancient stone mansion, having a large Oriel window, filled
with painted glass, and at a short distance beyond Week-
street are very extensive barracks, both for infantry and ca-
valry, the erection of which has greatly increased the popu-
lation of the town.

Maidstone has been long celebrated as the first hop-market
in the kingdom. Some manufacturers, however, are likewise
Vol. XXII.
carried on here. The linen trade, first established by a few
refugees from the Netherlands, in the reign of Queen Eliza-
thel, still continues to flourish. There are besides many
paper-mills in the immediate neighbourhood, and an extensive
distillery of English spirits, or Maidstone Geneva, and some
very considerable beer and porter breweries. The circum-
stance of the tide rendering the Medway navigable for vessels
of fifty or sixty tons, contributes much to facilitate and
encourage the trade of this town in all its departments.

The principal events of historical importance immediately
connected with Maidstone, are the rebellion of Sir Thomas
Wyatt, and the battle fought here in 1643, between the
Cavalier loyalists and the parliamentary forces under general
Fairfax, in which the former were defeated after a most
futile and sanguinary contest. The plague has at different periods
made great ravages here. A sudden thaw, in January 1795,
also occasioned considerable damage, not only in the town but
in the adjacent country. Here was a palace belonging to the
archbishop of Canterbury, now demolished.

The population of this town, according to the para-
mountary returns of 1801, was estimated at 8027, viz. 3835
males, and 4192 females, of whom 5196 were returned as
employed in various branches of trade, and 306 in agri-
culture. The market days are Thursday in every week
and the second Tuesday of every month, when supplies of all kinds
are abundant. The neighbourhood is adorned by a number of
gentlemen’s seats, spread throughout a fertile vale, where
meadows, woodlands, rich orchards, and flourishing hop-
grounds combine to exhibit a most extensive variety of pic-
tureque and romantic scenery. Gibraltar-house, on the
opposite side of the river from the town, forms an agreeable
place of resort during the summer season. The Mote, the
seat of the earl of Romney, lying about a mile to the S.E.,
of the town, was anciently the residence of the Wyatt fa-
mily, and forfeited upon the attainder of Sir Thomas by
queen Mary. In the park, which is extensive, is erected a
pavilion, on the spot where his majesty was entertained after
the review of the Kent volunteers in 1799. Allington-castle,
on the west side of the river, is still as interesting ruin.
It is said to have been originally erected in the time of the
Saxons by the noble family of the Columbus, but being
razed by the Danes, was rebuilt by the great Earl Wor-
rage. It was some time after the property of the Wyatts,
and afterwards the Aitleys. The chapel, a small gloomy
edifice, contains several monuments in honour of the latter
family. Newton’s History and Antiquities of Maidstone,

Maidstone, a township of America, in Essex county,
Vermont, on Connecticut river, containing 152 inhabitants.
—Alfo, a township of Upper Canada, between Sandwich
and Rochester, upon lake Erie.

MAJESTY, MAJESTAS, a title or quality given to kings;
and which frequently serves as an appellation to distinguish
them by.

The word seems composed of the two Latin words, major,
greater, and flatus, slight.

The emperor is called, his Cæsarian or Imperial majesty;
the king of Spain, his Catholic majesty; the king of France,
formerly, his most Christian majesty; the king of Great
Britain, his Britannic majesty, &c. Some have also extended
this title to the pope, and even to the archbishops of
Palatine.

Psalms observe, that our forefathers used this quality
very sparingly; and that the frequent use of the word,
which now obtains, had not its beginning before the reign
of their Henry II. He influence several letters of St. GREG-
ory, U
Mai, who, writing to king Theodoret and Theodoric, only compliments them with excellence.

Till the time of Charles V. the king of Spain had no title, but that of highness; Louis XI. was the first in France who assumed this title; and before our king Henry VIII. the kings of England were only addressed under the titles of grace, which began in the time of Henry IV., and excellent grace, under Henry VI., and highness. See King.

At the peace of Munster, there was a great contest between the ministers of the emperor and those of France; the first would not allow the title of serenity to the king of France, and the latter would not give that of majesty to the emperor. As last it was agreed, that whenever the French king should write with his own hand to the emperor, he should give him the title of imperial majesty; and reciprocally, when the emperor should write to the king, he should give him that of royal majesty.

Under the Roman republic, the title majesty, majestas, belonged to the whole body of the people, and to the principal magistrates; so that to diminish or wound the majesty of the commonwealth, was to be wanting in respect to the late, or to its ministers. But the power afterwards passing into the hands of a single person, the appellation of majesty was transferred to the emperor, and the imperial family.

Pliney compliments Trajan on his being contented with the title of greatnaces; and speaks very invidiously of those who affected that of majesty. And yet majesty seems to be the most modest and just title that can be attributed to sovereigns, since it signifies no more than the royalty, or sovereign power.

Maieur, St., Regular Clerks of. See Fathers of Somaqua.

Mai, in Geography, a river of Ireland, in the county of Limerick, which rises in the Galtees, crosses the county, and falls into the Shannon, some miles below Limerick.

Mailhan, Emanuel, in Biography, an able philosopher and mathematician, was born at Toulouse in the year 1601. He gave early indications of an inquisitive disposition, and an inclination for learning. He went through a course of grammar-learning at the college of the Jesuits; here he spent his vacant hours in improving his mind, and at eighteen years of age he determined to renounce the world, and was admitted into the fraternity of the Minims. In studying philosophy, he became dissatisfied with the principles of Aristotle, and took every opportunity of exposing them to contempt. He took delight in inventing and solving geometrical problems, which he could do with ease and accuracy, though at this time he had never seen the Elements of Euclid, nor any other book written with the same view. When his mathematical acquirements were discovered, he was immediately appointed by his superiors to the mathematical chair, which he filled with such address and judgment, that his reputation soon spread beyond the boundaries of his own country. He obtained higher preferment, and rendered himself distinguished by his mathematical discoveries and physical experiments, which extorted the applause and admiration of those who were most conversant in these sciences. A circumstance that contributed to extend the fame of his learning, was a contest which arose between him and father Kircher concerning an invention in optics. In 1643, Mailhan printed at Rome his treatise "De Perspective Hierarhis," which met with a very favourable reception, and which contains a method of making telescopes, invented by himself, which he fully explains without any attempt at mystery or difguise. In the year 1650, Mailhan returned from Rome to Toulouse, and was created provincial, and in 1652 he published, in Latin, his "Courie of Philosophy," in four volumes, octavo, by which he might be considered as the refoter of it. When this work appeared, the adherents to the Aristotelian system inferred that it was impossible to reconcile the author's opinions with the truths of Religion. This objection Mailhan undertook to refute, in a work entitled "Philosophia Sacra." In 1657 he was chosen to supply the place of father Merfenne, in a society of learned men, who held their meetings at the house of Henry Lewis de Montmort, master of the requests. In 1663, when Lewis XIV. passed through Toulouse on his return from his marriage, he visited the cell of father Mailhan as one of the most curious objects in the province. The monarch was so struck with what he saw, that he was defirous of transplanting the venerable father to his capital, but he had higher objects in view than to shine in courts; he was seeking after truth, and endeavouring to enlarge the boundaries of science, and preferred the obliquity of a cloister to the splendour attached to a palace. In 1662, father Mailhan published the first volume of his "Philosophia Sacra," which drew him into a long controversy with several learned opponents, of which a full account is given by Bayle. In 1674 he published replies to all his antagonists, and in the same year he gave the world the second volume of his "Philosophia Sacra," which was followed by a dissertation "De usu lectioi Petronii." Thee literary labours did not prevent him from reading lectures to his pupils, and superintending the instruction of the younger members of his order. Besides this he was engaged in an extensive correspondence with the principal philosophers of his own age. Scarcely was any man more indulgent than Mailhan; to use the expression of one of our countrymen, it might be said, that "Leisure and he had taken leave of one another" from an early period of his life. He is said to have studied in his sleep; for in his dreams he was often employed on some theorems, the deductions of which he pursued till he arrived at their demonstration; and he was often suddenly awakened by the excitement which he felt in such discoveries. He died at Toulouse in 1676, in the seventy-fifth year of his age. The innocence of his life, the simplicity of his manners, and his amiable virtues, rendered him no les the object of esteem, than he was of respect, on account of his genius and learning. Bayle. Moreri.

Maiherga, in Geography, a town of Africa, in Sahara; 100 miles S.S.E. of Algiers.

Mai Inductio, in Antiquity, denotes an ancient custom for the priest and people of country villages to go in procession to some adjoining wood on a May-day morning; and return with a May-pole, boughs, flowers, garlands, and other tokens of the spring. This May-game, or rejoicing at the coming of the spring, was for a long time observed, and still is in some parts of England; but it was condemned and prohibited in the diocese of Lincoln by bishop Grotthend.

Majir, in Geography, a town of Africa, in Biledulgerid. N. lat. 33° 30'. E. long. 6° 29'.

Mail, Maille, is primarily applied to the meshes or holes in net-work.

This term in heraldry originally expressed the mesh of a net, and is derived from maclusa, Lat. or mafele, Fr. signifying the same. Richet says, maille is used as a verb neuter, to express the art of netting. Some derive it from the Irish word mala, said to signify armour; or the word mail, which in Welsh properly means fleec, and metaphorically handkerchiefs and armour. (See Rowland's Mona Antiqua.) Buyer in his French Dictionary translates the word maille, a little iron ring.
MAIL, Black. See Black Mail.

MAIL, Coat of. See Coat of Mail.

It is called also an Holbergan; which fee.

Anciently they also wore shirts of mail under the waistcoat, to serve as a defence against swords and poniards. We also read of gloves of mail.

Of mail there are two forts, viz. chain and plate mail. Chain mail is formed by a number of iron rings, each ring having four others inserted into it; the whole exhibiting a kind of net-work, with circular meshes, every ring separately riveted. This kind of mail answers to that worn on the ancient breast-plates; whence they were denominated "loricæ hamatae," from the rings being hooked together. Thus, "Loricam confirmatum hamis, auoque trilecim," Virg. Æn. i. iii. v. 67.

Plate mail consisted of a number of small laminæ of metal, commonly iron, laid one over the other, like the scales of fish, and fewed down to a strong linen or leathern jacket, by thread paffing through a small hole in each plate. This was exactly the form of the ancient "lorica quammoda." Similar to this is the Sarmatian cuirass (see Cuirass), described by Paufanias, as quoted by Lipsius and Montfaucon. They take the hoofs of their horses, which they cleanse and poliſh, and then cut in little pieces like dragon's scales; which done, they bore the scales, and afterwards few them with the fins of an ox or horse: the dragon's scales resemble the diviſions in a pine-apple when it is green. Thus they make their cuirasses, which, for beauty and strength, are not inferior to those of the Gauls, for they very well futfain both dillant and clofe blows; whereas the cuirasses of linen are not so fure, nor proof againſt iron. The linen ones are commodious for hunters, as the lions and lepers cannot penetrate them with their teeth. The cuirass covered the body before and behind: it consisted of two parts, a breast and back piece of iron, faftened together by means of fraps and buckles, and other familiar contrivances. They were originally, as the name imports, made of leather, but afterwards of metal, both bras and iron. To the cuirass was buckled the armour for the Shoulders and arms: the firlt called "poul-drons," the second "brasſarts," "garde bras," les avant bras, and corruptly in English "vambraces." At the joint or bending of the arm, the vambraces were cut obliquely; the vambraces on the inside, when the arms were ftraightened, were covered by pieces of mail called "gouffets," and afterwards by a contrivance of plates refemblying hearts. Cuirasses with entire sleeves of mail are mentioned by different military writers. A defence for the arms, called "fplints," constituted part of the fuit denominated an "almagne ryvet." The hands were defended by gauntlets, sometimes of chain mail, but more frequently of small plates of iron, riveted together; in imitation of the lobofer's tail, fo as to yield to every motion of the hand. Some gauntlets included the whole hand, as in a box or cafe; others were divided into fingers, each finger confiting of eight or ten separate pieces, the fide being glazed with buf leather: some of these reached no higher than the writ, others to the elbow; the latter were fyled long-armed gauntlets, many of which are to be seen in the Tower of London. The thighs of the cavalry were defended by small trips of iron plate, laid horizontally over each other, and riveted together, forming what were called "cuifarts," or thigh pieces; of these fome entirely enclosed the thighs, and others only covered the front of them, the ifide next the horse being unarmed. They were made flexible at the knees by joints, like thofe in the tail of a lobofer, and were called "gemonilleres," or knee-pieces. Taffets, or shirts, hooked on to the front of the cuiraffe, were used by the infantry.

For the defence of the legs were worn a fort of iron-boots, called "greves." Plates of iron covering the front of the leg were also frequently worn over the focking of mail. The greves commonly covered the whole leg, as in the armour of John of Gaunt, and that of Henry VIII.; with these they had broad-toed iron shoes, with joints at the ankle; sometimes they had ftabous of mail. Boots of jack-leather, called curbouly (cuir bouille), were also worn by horfemen; these are mentioned by Chaucer. The "hauberk" was a complete covering of mail from head to foot. It confined of a hood, joined to a jacket with sleeves, breeches, focking, and shoes, of double chain mail, to which were added gauntlets of the fame construction. Some of these haubersks opened before like a modern coat; others were clofed like a firt. In France only perfons poſsessed of a certain eflate, called "un fief de hauberk," were permitted to wear a hauberk, which was the armour of a knight; efiures might only wear a fimple coat of mail, without the hood and fhoes. The "hauberſeon" was a coat compofed either of plate or chain mail, without sleeves; the firt of mail was much in the form of the firts now worn, except that it had no sleeves: it was always of chain mail. Grofe's Mil. Antiq. vol. ii. See Armour.

MAIL, or Mail, also signifies a round ring of iron; whence the play of paff-mall, from palla, a ball, and maille, the round ring on which it is to pafs.

Mail is likewise used for the leathern bag in which letters are carried by the poft.

MAIL-Coach, a carriage particularly and expressly appropriated for the conveyance of letters to all parts of Great Britain. It is distinguished for its expedition and security; two most important considerations in a populous, commercial, and wealthy country. Previous to the year 1784, letters were conveyed from the metropolis to distant parts of the kingdom, and vico verſa, by carts with a fingle horse to each, or by boys on horfback; in confquence of which, many robberies were committed, delays occafioned, and lofes sustained. John Palmer, efq. afterwards comptroller-general of the poft-office, devifed a new plan, which he recommended to government, as calculated to increase the revenue, accommodate the public, and be highly advantageous to all parties. His propofal was acceſsed to, and the inventor has been rewarded with a large annual income. His plan was to provide a certain number of coaches, of light construction, and each to be adapted to carry the various bags or packets of letters, which were defined for a particular part of the country, or line of road. All the coaches were to leave London precisely at 8 o'clock in the evening, and to arrive at and leave certain poft-towns at specific times. Each coach is drawn by four horses, travels at the rate of eight miles an hour, including the time allowed for change of horses, &c.; and each coach is provided with a coachman, a guard with fire-arms, and allowed to carry four passengers inside, and two outside. The present fare (1812) is about 6d. per mile for each of the former passengers, and 4d. for the latter. The fystematic regularity, punctuality, superior safety, and expedition of the mail-coaches of England render them peculiarly eligible and convenient for travellers. The property and profits of the poft, or conveyance of letters, are vested in government, which contrachts with the proprietors of coaches for the carriage of the mail; but thec proprietors derive their chief profit from the hire of passengers, and carriage of small packets. The mail-coach establishment is under the superintendence of T. Halter, efq. For further particulars, see Post Office. The mail-coaches run above 13,000 miles daily. There is a similar establishment in Ireland.
MAILAH, in Geography, a river of Africa, which rises in the Sahara, and discharges itself into the Shott.

MAILCOTTA, or MILCOTTA, a town of Hindooftan, in the Myfors; where the Mahatta chiefs met lord Cornwallis in the year 1791; 15 miles N. of Seringapatam.

MAILED, implies a thing speckled, or full of specks; as the feathers of hawks, partridges, &c. or the fur of some wild beasts.

MAILLA, Joseph-Anne-Mary de Moyric de, in Biography, a Jefuit miffionary, was born at Maillac, and, having been educated by thefeociety, was fent on the miffion to China in 1703. He was employed by the emperor K'uan-hi, with the view of making the map of China and thefe Tartary, which was engraved at Paris. He afterwards made particular maps of several of the provinces. Being fixed at the imperial court, he had access to the "Great Annals of China," which he translated into French, and sent over his MS. to France, where it was partly printed, and intended to make 12 volumes 40. This work forms the mott complete history of the Chinese empire. Mailla died at Pekin in 1748, in his 75th year, after a residence of 45 years in China. His remains were interred at the expence of the emperor Kien-Long.

MAILLE, in the French Coinage, denotes a small weight used for gold and filver, 40 of which are equal to the ounce, or one-eighth of the mark = 3778 English grains.

MAILLE, in our Old Writers, a small kind of money. Silver half-pence were likewise termed mailles, 0 Hen. V. By indenture in the mint, a pound weight of old sterling filver was to be coined into three hundred and sixty farthings, or pennies, or four hundred and twenty mailles, or half-pennies, or one thousand four hundred and forty farthings. Hence the word mailles was derived, which is now vulgarly used in Scotland to signify an annual rent. Hence white maille, white rents, (vulgarly called quit-rents,) were rents made in filver; and black maille denoted properly rents paid in cattle, otherwise called neat-gelt; but more largely it was used to signify all rents not paid in filver. See Black Maille.

MAILLET, Benedict de, in Biography, born of a good family of Lorraine in 1659, was nominated, at the age of thirty-three, confu of the French nation in Egypt; after which, he obtained the confu of Leghorn. In 1712 he was appointed to visit all the factories of Barbary and the Levant; and executed his commission so much to the satisfaction of the government, that he obtained leave to retire with a pension. He died at Mafelle in the year 1738. He had, during his whole life, been a diligent student of natural history, which his lively fancy turned into fyllum, which for some time interested the public. He maintained that all the land of this earth, and its vegetable and animal inhabitants, rose from the bottom of the sea, on the fuccifive contractions of the waters: that men had originally been tritons with tails; and that they, as well as other animals, had left their marine, and acquired terrestrial forms, by their agitation when left on dry ground. The work was published after the death of its author, by La Mafrier, who also published, in 1743, "A Description of Egypt," drawn up from the papers of De Maillet.

MAILLEZALIS, in Geography, a town of France, in the department of the Vends, and chief place of a canton, in the diocofe of Fontenay-le-Comte; 6 miles S. of Fontenay. This was once the see of a bishop, since removed to Rochele. The place contains 1355, and the canton 12,652 inhabitants, on a territory of 200 kilometres, in 13 communes.
man are delineated. In this temple there are no altars; it is open only on festivals, and strangers cannot see it without a special order. The great pagoda, which is larger and more magnificent than the former, is accessible to all strangers, under the conduct of a priest. We cannot here describe in detail the various parts of this structure; the temple, which is an elegant Chinese building, and richly decorated, contains five idols of a colossal stature, filling the whole northern aisle. The principal idol is denominated "Gheffur," or "Gheffur Chan;" his size is gigantic, and his face glitters like burnished gold; on his head he has a crown, and his garments are made of the richest silk; in his hand is a tablet, to which he directs a steady attention. Two small female figures, refembling girls about 14 years of age, stand on each side of the idol. The other idols are of an enormous size, though less in magnitude than Gheffur Chan. Tapers and lamps are kept burning day and night before the idols. There are various utensils in the temple, marked with Chinese devices and inscriptions; and, among others, a hollow wooden black lacquered helmet, which all devout persons strike with a wooden hammer, whenever they enter the temple. The first day of the new and full moon is appointed for the celebration of worship, upon each of which days no Chinese ever fails to make his appearance once in the temple. Their principal festivals are held in the first month of the year, called the white month, and answering to our February. Mr. Fallas has given us the following description of their superstitious behaviour during an eclipse of the moon. At the close of the evening in which it appeared, all the inhabitants were employed in raising an uproar, by hideous shrieks, knocking wood, and beating cymbals; which noise was heightened by striking the bell and beating the kettle drums of the great pagoda. The Chinese supposes, that during an eclipse the wicked spirit of the air is attacking the moon, and that he is frightened away by these hideous shrieks and noises. When a fire occurred at Maimat'chin, none of the inhabitants attempted to extinguish it, but allowed it to rage in idle conflagration, occasionally sprinkling water on the flames, in order to fan the fire god, who, as they imagined, had chosen these houses for a sacrifice.

The merchants of Maimat'chin come from the northern provinces of China, chiefly from Peking, Nanking, Sandchu, and other principal towns. They come hither without their wives and families; for there is not one woman at Maimat'chin. This circumstance is owing to the policy of the Chinese government, which totally prohibits women from having the slightest intercourse with foreigners. For the mode of carrying on commerce between the Chinese and Russians, and the principal articles which they mutually exchange, we refer to the article KIAKTA.

MAIMBOURG, Lewis, in Biography, an ecclesiastical historian, was born at Nancy, in France, in the year 1610. When sixteen years of age he was entered in the society of Jesuits, and soon became a teacher of the classics in their schools. He was much celebrated afterwards as a preacher, though he had been generally charged with introducing into the pulpits low and vulgar descriptions, and falling of wit, or even buffoonery, highly unbecoming his sacred office. As a writer, as well as a preacher, he was perpetually attacking the Jansenists, and in 1682 he wrote a treatise against the pretensions of the church of Rome, and in support of the liberties of the Gallican church: on account of this he was ordered by pope Innocent X. to be expelled the society. For this disgrace, the king made him ample recompence by the grant of a pension, on which he retired to the abbey of St. Victor at Paris, where he died in 1686, at the age of seventy-fix. He was a very voluminous writer; his historical productions originally formed sixteen volumes, in 4to.; they consist of "The History of the Crusades;" "The History of the League;" "The History of the Decline of the Empire after Charlemagne;" "The History of the Pontificates of St. Gregory the Great, and of Leo;" "The History of the Schism of the Greeks;" and of the Schism in the East;" "The History of Ariana;" of the heresy of the Iconoclasts; of Lutheranism; and of Calvinism." Bayle, Menur.

MAIMONIDES, Moses, or Mofes the son of Maimon, a Jewish rabi, was born at Cordova, in Spain, in 1135. He has, by way of eminence, been called "The Doctor," and "The Eagle of the Doctors." He was, in every sense of the term, descended from illustrious ancestors, fix of his ancestors having been distinguished by the title of wise. The early part of his education was undertaken by his father; who, in due time provided him tutors from the most learned men of his age. He possessed very superior abilities, and made a rapid progress in all the branches of knowledge to which his attention was directed. He was perfectly skilled in the Hebrew, Arabic, Chaldee, Turkifh, Median, and other languages. With all the branches of philosophy and the mathematics he was intimately acquainted, and also with Jewish jurisprudence, as is evident, not only by the comments with which he illustrated the whole body of laws of the Hebrews, but by the ability and judgment with which, from a confused and most intricate mafs, clothed in corrupt and varying dialects, he reduced them to a regular system, written in pure Hebrew, and in an easy and elegant style. He likewise acquired a profound knowledge of the medical art, in the practice of which he attained the highest reputation. His very extraordinary talents and accomplishments in almost every species of learning excited the jealousy of his contemporaries; to avoid the ill effects of this, he resolved to quit Spain, and remove into Egypt, before he was thirty years of age. From this circumstance, and from his residing in that country during the remainder of his life, he is, by some writers, called "Moses Egyptian;" by others he is named "Moses Cordubensis," from the place of his birth. In Egypt he opened a school, to which a number of pupils reforted from all parts, and particularly from Alexandria and Damascns, who made such improvement under his instruction, that they proved the means of spreading his fame throughout the world. He was appointed physician to Saladin, sultan of Egypt, who entertained him the highest respect. His reputation was so great that he was applied to for advice and counsel by persons of the very first rank. Among others, the rabbi Aben Tybbon, wishing for a solution of some serious difficulties, on important points, proposed to pay him a visit, that they might confer on the matters at length in conversation. To which Maimonides replied, that nothing would afford him greater pleasure than such an interview; yet he could not encourage him to undertake so long a voyage, because his own time was so fully occupied, that he could scarcely promise him his company for a single hour, either in the day or at night; "I live," said the learned doctor, "in Egypt, at the distance of nearly two fables;" his journey from Al-Cairo, where the king resides. On him the duties of my appointment require a very regular attendance. I generally visit him every morning; but when either himself, or any of his children, or of his concubines, are sick, I am not allowed to flir from the palace, so that I very often spend the whole day at court; if I find nothing amusing at court, I return home towards noon, but when arrived at my house, almost famished for want of food, I find all the approaches to it crowded with
with Gentiles and Jews, men of all ranks who have been impatiently waiting my return. No sooner have I alighted from my horse, and washed my hands, than I humbly request the indulgence of the multitude till I have appeased my craving appetite. As soon as I have dined, I examine the cates of my patients, and prescribe for them. This employment commonly lasts till night, when I am so overcome with the fatigue of hearing, speaking, and prescribing, that I can scarcely speak any longer or even keep myself awake. Maimonides, after having spent a long and most useful life, died at the age of seventy, in the 1204th year of the Christian era, and was interred, with the highest funeral honours, in the land of Canaan. For three whole years did the people at large bewail his death, and they called the year in which it took place, "Lamentum Lamentabile;" and in speaking of him, they used to say, that, from the time of Moses the prophet, no one approached so nearly to him in wisdom and found learning, as Moses the son of Maimon. He is frequently designated in the writings of the Jews by the name of Rambam, the confounders of which are the initials of the words Rabbi Mofes Ben Maimon. Notwithstanding his avocations as a physician, he devoted much of his time to the composition of learned works, a few of which may be mentioned: the first, in the order of time, was his "Pirush Hemianah," or, a commentary on the Mishnah, which he began in Spain, when he was in the twenty-third year of his age, and finished in Egypt, when he was about thirty. It was written in the Hebrew language, and translated into Hebrew by Rabbi Aben Tybbon. The best edition of this work is published with the Mishnah, at Amsterdam, in 1698, in 16 volumes, folio. The prefaces were published in Arabic, but in the Hebrew characters by our countryman Dr. E. Pococke, under the title of "Porta Mosis," in the year 1655. The next work to be noticed is entitled "Jad Chazekeh," or Strong Hand, which is also named "Mishna Hathora," or The Reception of the Laws; it consists of a cumpendium of the Talmud, which fee, and presents a complete code of Jewish, civil, and canon law, with a commentary. The best edition is that of Amsterdam, in 1702, in 4 volumes, folio. The principal work of this great man is entitled "More Nevochim," or Guide to the Perplexed, which is partly critical, partly philosophical, and partly theological; its design being to illustrate and explain the meaning of the fercpures. It was translated from the Arabic into Hebrew by R. Aben Tybbon, in the year 1551, and published at Venice: Buxtorf the younger gave an excellent version in the Latin tongue, the which was published at Basil in 1629. Another important work of Maimonides is his "Sefer Hamitzoth," or Book of Commandments, containing an exposition of the precepts of the Mosaic law. The titles of the other pieces of Maimonides may be seen in W. liii Biblioth. Heb.

MAIN, East, or Slade river, in Geography, a river of Canada, which runs into James bay, N. lat. 52° 18'. W. long. 78° 45'. On the east of this river is Esl Main House, a station for the Indian trade in Canada. N. lat. 52° 15'. W. long. 78° 42'. Main, a town of Persia, in the province of Farfallan; 14 leagues N. of Schiras; the inhabitants of which being descendants of the ancient Spartans, have never yet been conquered by the Turks.

Main, Chief, or Principal. Thus the main-mast is denominated, in contradistinction to the fore or mizen-mast; the main-keel, main-wales, main-hatchways, main-breath, &c., are thus distinguished from the false-keel, channel-wales, and the fore and after hatchways. The main-breadth is the broadest part of the ship, and is contained between the upper and lower heights of the breadth lines.

Main-body of an army, is the body of troops that marches between the advance and the rear guard. In a camp it is that part of an army which is encamped between the right and left wings.

Main-guard. See Great and Main Guard.

Main Harmonique, Fr. See Harmonic-Hand, Hexachords, and Solmization.

Maine, in Geography, a sea-port town of the Morea, near the W. coast; 30 miles S. of Mitra.

Mainbay, a town of Aca; 15 miles N. of Prome.

Mainburg, a town of Germany, in the circle of Bavaria, on the Ambs; 32 miles N. of Munich.

Maine, a division of France, before the Revolution, which was divided into Upper and Lower Maine; about 18 miles long and 20 broad. It now chiefly forms the departments of the Mayenne and Sarthe.—Allo, a river of Germany, which rises in the marquisate of Culmbach, on the confines of Bohemia, and after passing by a number of principal towns, joins the Rhine, a little above Mentz.

Maine, a district or province of the United States of America, belonging to the Massachusetts, bounded on the N. by Lower Canada, E. by the province of New Brunswick, S. by the Atlantic ocean, W. by New Hampshire, from which it is partly separated by the Piscataqua river, and situated between N. lat. 43° 48', and between W. long. 54° 54' and 70 39'. Its average length and breadth are each 200 miles; and it contains 40,000,000 square miles, or 25,000,000 acres. The district of Maine is divided into seven counties, as in the following table.

The chief rivers of this district are Penobscot, Kennebeck, Sac, Androscoggin, St. Croix, &c. The most noted lakes are those between N. lat. 45° and 41° 30'; and between W. long. 65° 54' and 70 39'. Its most remarkable capes are those at Nuddock, Porpoise, Elizabeth, Small Point, Pemiquid, and Petit Manan. Almost the whole coast N.E. of Portland is lined with ilafs, among which vesels may generally anchor with safety. This district, though an elevated country, cannot properly be denominated mountainous. The soil is generally arable and very fertile, more especially between Penobscot and Kennebeck rivers. On some parts of the sea-coast the lands are but indifferent; but they might be much improved by manuring them with the rock-weed, which grows on the rocks between high and low water mark, in very large abundance. The swamps and funken lands might be easily drained, and afford a rich fat soil. The soil of the interior country is represented as being excellent, and well adapted both for tillage and pasture. Where the soil is properly prepared for receiving the feed, it is said to be favourable for the growth of wheat, rye, barley, oats, peas, hemp, and flax, and for the production of almost all kinds of culinary roots and plants, Eng-
MAI

hiae of maize, and also for Indian corn of short stalk. Kennebeck is much improving in apple- orchards. Hops are the spontaneous growth of the country. Peaches are scarcely known; but plums, small cherries, small pears, grapes, raphberries, gooseberries, currants, blackberries, and cranberries, are among the wild fruits of Maine. This country is uncommonly good for grazing, and large flocks of neat cattle may be fed in it both summer and winter. It abounds in white pine and spruce trees, suitable for masts, boards, or shingles; and maple, beech, red, white, and grey oak, and yellow birch, may be considered as the principal productions of the country. The moifit land produces fir, which yields a balsam that is much prized. Here are also elms, poplars, and ash trees; also haws, horn-beam, butter-nut, balm of Gilead, and hemlock trees. Upon the whole, the district of Maine may be regarded in the three following divisions of it; the first, comprehending the tract lying E. of Penobscot river; the second, and belt tract, lying between Penobscot and Kennebeck rivers; and the third, first settled, and at present most popular, W. of Kennebeck river. The climate in this district, as well as in every part of North America, is colder than is the same degree of latitude on the eastern side of the Atlantic. The weather is more regular here in the winter than it is in the southern states. Frosts commence sometimes in September, and always before the middle of October: the severe cold begins about the middle of December, and lasts open, and close of March. Of late the winters in this country are more moderate, and less snow has fallen than twenty years ago.

From the different rivers of this country water may be drawn for mills and all water works; and its rivers furnish plenty and variety of fish. The salmon fishery, in the bays and around the islands, has of late years become a considerable object to the inhabitants. The animals of this district were formerly deer, and moose of a large size; but there are now few to be seen. The fox, hare, wolf, beaver, &c. are found here. Cattle and horses are easily reared in this country; and the sheep, on the Kennebeck river, are larger than those in Massachusetts proper, the mutton is of higher flavour, and the fleeces are much heavier. The rattlesnake is the only poisonous serpent in this district, and is rarely seen. Birds, though increasing, are not numerous.

The manufactures and commerce of this country are in an improving state. From the first settlement of Maine till the year 1774 or 1775, and even in some places to a later period, the inhabitants neglected agriculture and generally followed the lumber trade; but when they found that Indian corn, rye, potatoes, and flax grew in their fields, and afforded an abundant profit, they applied to the cultivation of the soil; and they now raise a sufficient quantity of corn and other grain for their own consumption; and they export from the Kennebeck, either in cattle or other articles, more than they import. Their wool and flax are very good; hemp has been lately cultivated with success: and almost every family manufacture wool and flax into cloth, and makeatiens of flax and linen sufficient for their own use. The principal exports of this country consist of various kinds of lumber, such as pine-boards, ship-timber, and almost every species of split timber manufactured from pine and oak, which are exported from the various harbours in large quantities. Dried fish also furnishes an article of export, and also pickled fish, such as salmon, haddock, &c. Mountain and bog-iron ore are found in some parts, and works have been erected for its manufacture. A spirit of literary improvement has been lately excited in this district. Bowdoin college in Brunswick is in a prosperous state. (See College.) Academies have been incorporated by the legislative in Hallowell, Berwick, Fryeburg, Bath, Hamden, and Machias, and endowed with grants of the public lands; and another has been instituted at Portland. Town schools are also maintained in most of the towns and in many of the plantations.

The people of this district are distinguished by no peculiar features from their neighbours in New Hampshire and Vermont; but they are, like them, a brave, hardy, enterprising, industrious, hospitable people. The prevailing religious denominations are Congregationalists and Baptists; and there are a few Quakers, Methodists, Episcopalian, and Roman Catholics. The remains of the Penobscot tribe are the only Indians who reside in this district: they consist of about 100 families, and live together in regular society, at Indian Old Town, which is situated on an island of about 200 acres, on Penobscot river, just above the Great Falls. They are Roman Catholics, and conduct their worship in an orderly manner and without molestation. The constitution of Maine is the same with that of the Massachusetts, both being incorporated under one government. In the district of Maine are large tracts of land belonging to the state, called the Eastern lands. Of these lands the commonwealth have sold as much as has brought into the treasury a net balance of 269,057 $; the price of these lands, that have been sold, are for the encouragement of literature and other useful and humane purposes have been granted to the amount of 431,000 acres.

The first attempt to settle this country was made in 1607, on the W. side of Kennebeck river, near the sea; but this proved unsuccessful, attempts for this purpose were not renewed till between the years 1620 and 1630. In 1653 Sir Ferdinando Gorges obtained a grant from the council of Plymouth of the tract of country between the rivers Piscataqua and Sagadahoc or Kennebeck, and up Kennebeck as far as to form a square of 120 miles; and Sir Ferdinando is supposed to have furnished government in this province. In 1639 Gorges obtained from the crown a charter of the soil and jurisdiction, containing as ample powers as were ever granted by the king of England to any subject. In this year he appointed a governor and council; and government was administered in this form until the year 1652, when the inhabitants submitted to the Massachusetts, and in 1691, by a charter from William and Mary, the province of Maine, and the large territory eastward, extending to Nova Scotia, was incorporated with the Massachusetts Bay; since which time it has been governed and courts held as in other parts of Massachusetts. Several proposals have been made for separating this district from the Massachusetts; the last was made in 1802; but the legislature have not interfered in the business. Such, however, are the rapid settlement and growth of this country, that the period when this contemplated separation will take place, is probably not far distant. Morse's Geog.

MAINE-PORT, in Ecclesiastical Antiquity, a small tribute, commonly of loaves of bread, which in some places the parishioners pay to the rector of their church, in recompence for certain titles. Cowell.

MAINISI, in Ichthyology, a name used by Aristotle, Athenaeus, and others of the old Greek writers, for the fish now called the maena, menura, and mengla. It is a species of the genus, and is distinguished from all the other species of that genus, by having four large teeth, and a large homed body, ornamented with a black spot in the middle of the sides. This is the fish the Narbonese call jaule. See Species.

MAINLAND of Shetland, or Zetland, in Geography, the principal of the Shetland islands, situated in the Northern ocean.
MAINLAND.

It extends about sixty miles in length from north to south, and in some places is upwards of twelve in breadth. The whole of this island may justly be regarded as a series of promontories, every part of it being intersected by small arms of the sea. Hence scarcely a spot is to be found more than three miles distant from the shore. The coast is generally bold and rocky, but the numerous bays with which it abounds form safe and commodious harbours for the shipping which have occasion to frequent it. The interior presents to the view many interesting features, pattering both of the tranquil and of the wild. The latter, however, chiefly predominates; and while spots of cultivated retirement are comparatively few, the romantic beauties of simple nature are displayed in abundance and variety. Numerous hills diversify the face of the country, and traverse it in different directions. Of these the most lofty is called the Needle, an elevation of some 1,000 feet, and it is seated in the north of North Haven. The flattish work of Sir John Sinclair, it is flated to rise 3,044 feet perpendicularly above the level of the sea, but Dr. Edmonston seems to think its height does not exceed 2,000 feet, if indeed it is actually so much. The view from the summit of this hill in clear weather is splendid and magnificent in the extreme. The cluster of islands scattered beneath, and curiously divided by the ocean, afford a prospect infinitely diversified and agreeable. On the highest eminence there is a house constructed of four large upright stones, and two which serve as a covering for the roof. It is called a watch-house, and was probably used in remote ages to give notice of any approaching danger. A pyramidal tower of small stones is erected on the top of this hill, which is a landmark to the fisheries all round the country, and generally the first land defrayed by ships if they fall to the west of the island, as they approach it from the north.

The climate of the Mainland is extremely variable and damp, although by no means generally wholofeme to the inhabitants. Spring can scarcely be said to commence until April, and there is but little natural warmth before the middle of June. The summer usually terminates with August. Autumn is a very uncertain season, and winter commences as early as the beginning of October. The soil of Mainland is no less various than the climate. The arable land lies chiefly on the coast, and bears a small proportion to the waste and uncultivated parts, though its productiveness might be greatly increased by labour and exertion. The only grains grown are a species of barley, known by the name of beer or big, and a small kind of black or grey oats. Potatoes are raised in considerable quantity. The manure chiefly in use is sea weed, sometimes alone, but oftener mixed with earth or dung from the byres, or cow-houses. Though lime-flone is sufficiently abundant as well as the means of burning it, it is seldom employed. This is a matter of deep regret, as on those spots where it has been tried, the increase of fertility has much exceeded expectation. In consequence of this inattention of the natives to the management of their grounds, the vegetable products of the island are far from being adequate to its consumption. Hence the necessity of importing considerable quantities of grain from other more prolific districts. Carts are fearfully known here, for the belt of all reason, that there are no roads made by art in any part of the country. The construction of their ploughs is extremely rude, being in all probability of the same description with those used in ancient times over the whole of Europe. They consist of a crooked piece of wood bent (naturally) almost to a right angle, forming the beam, to which is fixed an oak flail about seven feet long, which is very pliable, and yields to the pressure of the driver's hand when he wishes to deepen the furrow. The counterflanks almost even up and down, and is never of sufficient length. A square hole is cut through the lower end of the beam, wherein the merchal, a piece of oak about twenty-two inches long is introduced. The furrow is rendered deep or shallow by driving a wedge below or above the merchal, on the outside of the beam. The man who holds or governs the plough walks by its side, and directs it by a bit or handle. The driver, or guide, precedes the oxen, usually four in number, and draws them along by means of a rope fastened to their horns. The other agricultural implements correspond to the mean construction of the plough. Owing to the limited extent of many farms the ground is very often dug with spades. Seeding time commonly begins here about the middle of March, but it varies in different parts of the country. It is earliest in the parishes of Tingwall, Whitenees, Weefdale, and Dunrossness, where the soil is drier than in most other places, and has a limedom bottom. With respect to the period of harvest, the feasons are so various, as to render it impossible to lay any thing precise concerning it, being sometime over by the middle of September, and at other times scarcely finished in November. When it has to be thus late, the crop affords little subsistence to man, and is only valuable as fodder for the cattle. The whole lands of the island nearly remain without inclosures. The cultivated lands are divided, but the extensive hill pastures remain in common. For the division of these many proposals have been offered, but the attempt has hitherto proved abortive, and indeed it must be confessed, that upon the present Shetland system of agriculture such an event would be attended with very little advantage, unless proper fences were constructed, or shepherds appointed to confine the sheep or cattle within any preferred boundaries. It is somewhat remarkable that not a single tree is to be seen in the whole island, and still more extraordinary that no proper attempt has been made to ascertain whether the climate will permit their growth. Certain it is, however, that in early ages they must have reached considerable perfection here, as many decayed stumps of large trees are often found among the bogs and moors.

With respect to the domestic animals of the Mainland of Shetland, it is well known they are the smallest of any in the British dominions; a circumstance doubtless the consequence of their scanty supply of food, and the total disregard manifested by the inhabitants for the improvement of their native breed. Some attempts have indeed been made by a few individuals to introduce breeds from more southern countries, but the climate of this northern region has been found unfavorable to the animals of warmer latitudes. The number of horses reared here is very considerable. They are generally about nine or ten hands high, full of spirit, and better calculated to endure fatigue than much larger horses. They are usually denominated Shetland ponies, and are evidently sprung from the Norway horse. These animals are never put into a house, either in summer or winter, nor do they receive any food but what they gather from the ground. The horned cattle are greatly inferior in every point of view to those of Orkney or the Watern islands of Scotland. The cows give very little milk; but as a great portion of the rents was of old paid in butter, now converted into money, it seems reasonable to conclude either that cows were formerly more numerous here, or produced greater quantities of milk than at present. Cheefe is seldom made, and indeed a great many of the farmers are yeat ignorant how to manufacture it. Their method of making butter is peculiar to the Shetland islands: Red-hot stones are thrown into the churn just at the time when the butter is about to separate from the serum, after which the churning is continued till the butter separates,
separates, and rises to the surface. The number of cattle
in the whole island is estimated at about 40,000 head. Swine
are bred in great plenty, and are particularly remarkable for
the extreme shortness of their backs. The sheep are of dif-
ter breeds, two of which produce a very fine wool, man-
ufactured by the inhabitants into fockings. These animals
feed at large on the hills, each proprietor having a peculiar
mark upon them, to distinguish whose property they are.
The alrernuts of the inhabitants, and the fagacity of their
dogs, in tracing and separating their own flocks from the
general flock, are subjects of wonder to every stranger who
visits the Mainland.

In this island there are very few goats, and no hares or
foxes; and in general few wild or ravenous quadrupeds of
any kind. Tame and wild hawks, however, exist here in
great abundance, particularly the latter; some of which are
extremely destructive to the young lambs. By the police of
the country, every person who kills an "ern" is entitled to
a reward of 3l. 4d.: for a corbie or raven he receives 3d.;
and for a crow 2d. These rewards are paid by the commis-
sioners of the land-tax, upon seeing the heads of the hawks
that have been killed. The number of migratory birds
which frequent the coasts is immense, and, though they build
their nests on the brink of precipices, they are usually inac-
cessible, the inhabitants, disregarding the dan-
ger of the attempt, plunder them both of their eggs and
young.

The mineralogy of this island, though of little importance
for the purposes of common life, presents many interesting
objects of contemplation to the geologist. Rocks of primary
and secondary formation can be distinctly traced in many
places, and offer a variety of satisfactory illustrations of the
Neptunian theory. Volcanic appearances are extremely un-
common, and purely adventitious. The hills chiefly run in
ridges, or appear conical and detached. Except in the parish
of North Main, there are few of them of the rugged or
abrupt kind. Sunnaburgh-head, a bold and lofty rock at the
southern extremity, is composed entirely of indurated sand-
stone, and the fame material appears to form the coast along
the greater part of the peninsula of Unstroofs. The cliffs of
Coomingburgh are composed chiefly of micaceous schists, as
are likewise the hills which bound the valley of Ochter,
which form the coast of North Main, and are immense in
height. Amongst the natural beauties, the rocks affording a variety of curious
forms from the excavations of the sea. Ronas-hill, on the
northern portion of this parish, is an immense mountain of
granite, and all the rocks on its western boundary are com-
poied of the fame foffil. About a hundred and fifty feet
from the shore, here itands a very lofty rock or holm, the
fides of which are perfectly murlal. It is called Maiden Sher-
rice, and has never yet been trod by human foot, the black
gulls maintaining it in exclusive and unmolested possession.
Near Lerwick, the rocks are a mixture of sandstone and
breccia. Limefcone is found in considerable abundance near
Coomingburgh. Beds of the fame mineral stretch along
Weefdale, as well as throughout the whole valley of Ting-
wall; in all which places it is wrought, and forms an
article of exportation. Some strata of iron ore have like-
wise been discovered in different parts of the country, and
attempts have been made to open mines, but none of them
have yet proved successful.

The only remains of antiquity worthy of notice are the
what are called Peirs-houses, and the abode in every
district of the island. They are usually about fourteen feet
high, but differ in the extent of their circumference at the
base. The interior consists of several cells or apartments,
one of which, situated in the centre, is of much larger di-
mensions than any of the others. All of them are construc-
ted of large flat stones, without any cement or mortar.

The only villages in the Mainland are Lerwick and Scall-
away. The latter is the more ancient of the two, but the
former the more considerable. Lerwick is situated on the
Dreiky found, long the general rendezvous of the Dutch
fishing-vessels; and, being the seat of the courts of justice,
is esteemed the capital of the Shetland islands. See Ler-
wick and Scallaway.

As to the inhabitants of this island, the inferior classes are
usuallv represented as depressed and miserable. Both the
men and women are, generally speaking, well proportioned,
of fair complexion, and an agreeable expression of coun-
tenance. Great attention is paid by them to the growth of
the hair, which is valued in proportion to its length. The
prefedy are noted for their curiosity and acuteness; but the
acquisition of useful knowledge is seldom the object of their
inquiries. Some of them, however, however, have excelled in the me-
chanical arts by the mere force of natural genius alone, un-
aided by education or example. Dr. Edmonston mentions
a blacksmith, who was completely master of clock and
watch-making in all its branches, although he had probably never witnessed any part of that delicate manufacture. Small as the country is, a considerable variety of manufac-
tures is discernible in different districts; the inhabitants of
some parishes being remarkable for their gaiety, and others
no less for the gravity and sobriety of their deportment.
Suffocation, indolence, and fertility are qualities too generally
diffused among them, the consequence, no doubt, of the in-
memorial opposition of feudalism. Belief in witchcraft,
fairies, and the efficacy of alms, is still prevalent over
the whole island, and freemasonry is universally considered
as conferring upon its votaries the rare faculty of detecting
theft.

The manufactures carried on here are but few, and thefe
in general imperfectly conducted. The knitting of worsted
flockings, caps, and gloves by the women, is among the most
ancient. Shetland hollies has long been held in high repute,
and formed a considerable article of exportation. The de-
mand for it has been large; however, considerably diminished
even in the British isles, and scarcely any of it now reaches
the continent. A fort of coarse cloth or cloth is woven
here by the individual weavers, as well as blankets for home
consumption. Kelp is now a stable manufacture, and at Ler-
wick there is both a dry and a rope manufactory. The
chief employment of the inhabitants, however, and the princi-
al source of their wealth, are the fisheries established
on their coasts, which abound with herring, cod, taff, and
lin. The Dutch formerly owed to their Shetland fisheries in
no small degree the elevated station their country held during
the two last centuries, among the nations of Europe. Al-
motl all the land proprietors here are engaged in this traffic,
and as more profit arises from it than from their estates, their
lands are made subervient to its prosecution. Hence in
some measure proceeds the low condition of husbandry, and
the dependent obsequiousness of the common people. Every
laid endeavours to establish on his estate a large number of
persons as he possibly can, as he thereby obtains a greater
number of fishermen. Tents are therefore divided and sub-
divided, and waste lands allotted to all who are willing to set-
tle on them. The facility of obtaining petitions encourages
marriage, and as a consequence, the population of the island
is much greater than it can support. The young men being
burdened with more numerous families then they can well
support, find themselves speedily involved in difficulties.
Having no leas of their positions, and all the in that they
x

Vol. XXII.
ject dependence on their superiors may be reasonably con-
cluded to exist; and it actually does exist over the whole of
Shetland. The chief exports from the island are, fish, oil,
butter, beef, hides, tallow, flax, salt, and rabbits.
The imports consist of the luxuries, and even ne-
cessaries of life, particularly cloth and corn; the whole island,
as already hinted at, not producing grain sufficient to supply
the inhabitants more than eight months in the year. For
a more particular account of the Mainland, and a view of its
general history, see the article SHEETLAND ISLANDS, also "A
View of the ancient and present State of the Zetland Islands,"
by Arthur Edmonston, M.D., 2 vols. 8vo. 1829.

MAIN-MORTE. A term in some ancient customs, still
obtaining in Burgundy, signifying a right which the lord
has, on the death of a chief of a family that is main-zero,
of taking the belt movable in the house; or, in default of
that, the right hand of the deceased was offered him,
in token that he could serve him no longer. See MONT-
MAIN.

MAINNO JASON, Del. in Biography, an eminent Italian
lawyer, born at Pederot in 1465, was sent to Pavia to study
the law, having received the elements of a good education
in his native place. Free from the constraint of parental
observation, he applied himself more to the gaming table than
to those pursuits which were intended to fit him for future
life. By this line of conduct he was soon reduced to a state of
almost abject indigence. The ambition and love of his father,
together with his own sufferings, effected such a change in
his mode of living, that he became the admiration of his
superiors on account of his learned acquisitions. In 1467
he was elected a professor at the university of Pavis, and
continued there with high reputation till the year 1485,
when he accepted a professorship at Padua. In 1488 he re-
moved to the university of Pisa, to which the republic of
Florence invited him, on a very liberal salary. After this
he returned the professor's chair at Padua, where his reputa-
tion was so high, that he is said to have had three thousand
auditors. Besides the duties of his office as teacher, he
transacted much public and important business with accuracy
and fidelity. In 1492 he was sent by the duke of Milan to
do homage to the Emperor Alexander VI., on which occasion he
pronounced an oration that was afterwards printed. He
was, in 1494, sent to compliment the emperor Maximilian on
his marriage, and on this occasion he was rewarded with the
title of cavalier and count-palatine: and next from Ludovico,
duke of Milan, he obtained the rank of patrician, and ho-
norary poll of senator. Lewis XII. of France, attended
by five cardinals, paid a visit to his school; Jason, in in-
ducing his majesty, humbly requested him to enter, to the
grave of which he replied, "I am no king here," and obliged
the professor to precede, he being entitled to the chief re-
spect among his scholars. After the lecture the king em-
braced Jason with the utmost cordiality, and in the course of
a familiar conversation, he hinted to his majesty, that he
might favour him, by mentioning his name to the pope as
not disfigured to wear a cardinal's hat. He was, how-
ever, unable to attain to the object of his ambition, and
continued to hold his office as professor till the year 1511;
after this he fell into a state of dotage, in which he continued
till he died in 1519. This gentle-man was esteemed one of the
greatest masters of jurisprudence in his time, and is men-
tioned by Alciatus among the five jurists who alone deserve
to be read. Gen. Bioy.

MAINOUR, Manour, or Minor, Fr. Mainvewvre, a
manu, in Law, signifies the thing that a thief takes away, or
feals. Thus, to be taken with mainour, is to be taken with the
thing stolen about him. If the defendant were taken with
the mainour, and so carried to court, in ancient times they
would arraign him on the mainour, without any appeal or
indictment. But this proceeding was taken away by several
statutes in the reign of Edward III., though in Scotland
a similar process remains to this day. See ATTACHMENT
of the Forest.

MAINPERNORS. See MAINPREN.

MAINPRISE. compound of the French main, band,
and pris, or prints, taken, the taking or receiving a man into
friendly custody, who otherwise might be committed to
prison; upon security given for his forthcoming, at a day
affigned.

They who thus undertake for any one, are called main-
pernors, because they receive the person into their hands;
whence also comes the word mainpernable, denoting the per-
son who may be thus bailed. P. N. B. 25o. 1 Hat. P. C.
14. See MAINPRISE.

The writ of mainprise is a writ directed to the sheriff,
(either generally, when any man is imprisoned for a bailable
offence, and bail hath been refused; or specially, when the
offence or cause of commitment is not properly bailable be-
law), commanding him to take secureties for the prisoner's ap-
pearance, and to let him at large. Mainpernors differ from
bail, in that a man's bail may imprison or surrender him up
before the stipulated day of appearance. Mainpernors can
do neither, but are barely secureties for his appearance at
the day: bail are only secureties, that the party be answerable
for the special matter which they stipulate: mainpernors are
bound to produce him to answer all charges whatsoever.
Coke, ab supra, c. 3. 4 Inft. 179.

MAINMAINTAINERS, are those that maintain or secound a
cause depending between others, by disburming money, or
making friends for either party, &c. not being interested in
the suit, or attorneys employed therein. Stat. 19 Hen. VII.
cap. 14. See MAIN-MAINTAINERS.

MAINTENANCE, MAIN-MAINTENEMENT, an unlawful
maintaining, or officious meddlesome in a suit between others,
by affilling either party with money or otherwise, to prosecute
or defend it. Hawk. P. C. 249.

The word is metaphorically taken from the succouring a
young child, that learns to go by one's hand; but it is used
in the bad sense in some of our statutes.

By the Roman law, it was a species of the crimen fals
enter to anyone in any confederacy, or to do any act, to support
another's law-suit, by money, wittness, and the like. A
man may, however, maintain the suit of his near kindman,
servant, or poor neighbour, out of charity and compasion,
with impunity; otherwise the punishment by common law is
fine and imprisonment; and by Law. 32 Hen. VIII. cap. 9.
a forfeit of 10s. See BARATRY and CHAMPIARTY.

There lies a writ against a maintainer, called a writ of
maintenances.

MAINTENNON, Frances D'Aubigné, in Biography,
celebrated in the history of France as well for her great ac-
complishments, as for the singularity of her fortunes, was
born in a prison at Niort in the year 1635. In this solitary
abode her father, Constans D'Aubigné, was confined for
some political offence. Here he and his infant daughter re-
mained during the first three years of her life, at which time
her father, having obtained his liberation, carried her with his
wife and son to Martignac. She was indebted to her mother
for an excellent education, that was unquestionably the base
of her future elevation. On the death of her father, in 1647,
the family returned to France, when the young lady was
taken under the care and protection of Madame de Villette,
who infused into her mind those principles of the Calvinistic
faith
...faith to which her father had been zealously attached. Her mother, who was a strict Catholic, took great pains in converting her to her own opinions, which she effected. They removed to Paris, where the mother very soon died, leaving her children in the greatest indigence. Frances, from this circumstance, and from the severity of some other near relations, was induced to give her hand to the famous Scarron, who was not young, and who from difeafe was in a state of decrepitude. She accepted this union, it is said, rather than the other alternative which he offered her, of paying her portion to be received into a nunnery. The house of her husband was frequented by many men of rank and wit, and the young wife attracted general admiration by the graces of her person, and the elegant charms of her conversation. In this dangerous situation she conducted herself in such a manner, that her virtue was unfelted and unsuspected. Her intimacy with the celebrated Ninon de l'Enclos did not in the least injure her reputation, and the testimony of her friends, in favour of her morals, has been admitted as good evidence. Scarron died in 1660, and his widow was again left in a state of indigence: for a short time, and after much solicitation, she obtained from the queen-mother the pension which her late husband had enjoyed, but at the death of the queen, she was again destitute. At this time a proposal was made to her to go to Lisbon to undertake the education of the children of a Portuguese prince. She gladly listened to the proposd, and, just before her intended departure she waited upon the king's mistref, Madame de Montespan, who, struck with the elegance of her manners, and the graces of her conversation, told her she must not think of quitting France. She immediately applied to Lewis XIV. for a pension to be settled on the forlorn widow, to which the monarch angrily replied, "Fhall I never hear of any thing but the widow Scarron." Indeed, fire, replied the favourite, "you ought long since to have ceased to hear of her." The pension was, however, granted, and she remained in France. Madame de Montespan, who had now strong claims to her gratitude, conceived such an affection for her, that she entrusted her with the secret of the children which she had by the king, and placed them under her care. At first she had the mortification to find that Lewis was not friendly to her. Her talents, however, were such as time would bring into notice, and she gradually rose into favour, and was chosen by the monarch himself to attend his eldest son, by Madame de Montespan, the duke of Maine, to Bar, for the recovery of his health. This situation engaged her in a direct correspondence with the king, a circumstance that operated very strongly in her favour: she augmented her pension, and made her liberal presents. Her serene and equal temper, and rational conversation, gradually gained upon Lewis, till at length she became his confidential friend. Her age, which exceeded that of the king, the moderate share of personal attractions which she retained, and the strictness of her religious principles, seem to have been sufficient assurances of the innocence of their connexion. Madame de Maintenon has been charged with ingratitude towards her benefactors, who was now discarded from the court, but she has found advocates who have fully vindicated her from the suspicion. Her situation with Lewis was, for some years, equivocal: she was an acknowledged favourite, but to what extent was not known; there was a singular mixture of devotion and gallantry in the correspondence carried on between the king and her female friend, and in allusion to this, Voltaire observes: "This fire and commerce of tenderness and female on the part of the king, of ambition and devotion on that of the new mistress, seem to have lapsed from 1681 to 1686, which was the epoch of their marriage. This union was never doubted, though never openly acknowledged at court, and Madame de Maintenon preferred that name while she was regarded and honoured as a queen. She always conducted herself with extreme good sense and moderation; she was very referred in asking favours for herself and family, and in these respects she formed a striking contrast to preceding favourites. Excessive caution, amounting to timidity, which appeared to extinguish every warm and generous emotion, was a characteristic feature of her conduct. She devoted herself entirely to the king, which she found to be a task that rendered her elevated situation most painful and joyless." "What a punishment!" said she, to a near relation, "to be obliged to amuse a man who is no longer amiable." That her feelings on this subject were extremely acute, is evident from an extract of a letter to an intimate friend: "Why," says she, "cannot I give you my experience? why cannot I make you sensible of the wearisomeness to which the great are a constant prey, and the labour they undergo to fill up their days? Do not yee see that I am consumed with melancholy, in a condition which it was barely conceivable that I should ever have attained." She attempted to supply the void which she felt by the practices of a minute and scrupulous devotion, and the infirmary the king with a similar tale; but, at the same time, she was not insensible to the ambition of ruling, and often exerted her influence when she was not suspected of having an opinion. But she found it necessary to use the utmost circumspection, for the king would not hear a rival; and if he suspected any design to control his will, he was apt to determine on the contrary. As his infirmities increased, she became more and more necessary to his existence, and is said to have shared with his confessor the possession of his mind to the last hour. She employed a considerable portion of a scanty income in deeds of charity and benevolence, but her most splendid work was the establishment at St. Cyr, near Verfailles, including a religious community, and an institution for the gratuitous education of 500 young ladies of quality. For this she engaged Racine to compose the sacred drama of Either and Athaliah, in which the young ladies acted their parts to well, in the first representation, that she determined they should not appear in the characters again. On the death of the monarch in 1715, Madame de Maintenon retreated to the peaceful mansion, thenceforth remaining all concern with the great and perilous world, acting in the laudable duties of the directs of the institution, and instructors of the young people educated in it. She was occasionally visited by a few particular friends; among whom her former pupil, the duke of Maine, was always received with the expressions of truly maternal affection. She lived to the great age of eighty-four, and died at St. Cyr in 1719. She is known in the literary world by a collection of letters in nine vols. 12mo. which were published in 1756; these are well written, and contain many things worthy of attention. Gen. Biog.

MAIENON, in Geography, a town of France, in the department of the Eure and Loire, and chief place of a canton, in the district of Chartres; nine miles N. of Chartres. The place contains 1605, and the canton 13,369 inhabitants, on a territory of 205 kilometres, in 21 communes.

MAJO, FRANCIS, or CICCO DE MAJO, in Biography, a Neapolitan composer of the first class, who flourished from about the middle of the last century to 1774: his works are few, as longevity was not allowed him. Metastasio's Artis Artes in 1765, Antigono in 1769, a Didone Abbandonato, and Alessandro nell' Indie, both these last in 1774, are all his dramatic works with which we are acquainted. He was in very high favour at Naples and Rome in the year 1770,
when natives as well as foreigners were eagerly collecting his opera airs composed for great singers; of which airs the style was noble, the accompaniments elegant and interesting, without disturbing or overpowering the voice, and each air is a more complete whole, perhaps when detached for occasional use at concerts, than those of any other great opera composer with whose productions we are acquainted.

M. Laborde's character of this charming composer is very just; but his dates are far from accurate. Artaxerxes was not the first opera which he composed, but Rosciemero, for the theatre Delle Dame at Rome in 1759; and in 1765 his Demolouette was performed at the Argentina theatre in the same city.

M. Laborde tells us, that though he had often gone the rounds of the great theatres in Italy, he never would quit his country; but in 1794, we find by Metastasio's letters to Farinelli, that he was at Vienna in his way to Mannheim, where he was engaged to compose an opera.

Farinelli seems to have given him a letter of recommendation to the imperial laureat, in the answer to which we may form some judgment of the private character of this gifted man.

Metastasio, in his first letter to Farinelli, in which Ciccio de Majo is mentioned, says, "Our dear Majo has been arrived some time, but I have seen him but once, and then only for a short time. I received him with all that affection which I cannot help bellowing on persons beloved by you, and whose merit is universally known. Nor shall I neglect any opportunity of serving him, as far as the Auguft circumference of my limited faculties shall extend. The best of it is, that he not only never comes near me, but leaves me in perfect ignorance of the hiding place where he has hitherto amused himself here, during the leisures in which he has hitherto lived. Perhaps some ancient sparks have rekindled the extinguished conflagration, and the poor soul will be involved in the flames and smoke which formerly, as I am informed, foreclosed and confounded him."

In another letter of the same date, Metastasio says, "Your most amiable de Majo generously gives me credit for wishing to serve him, but hitherto has absolutely avoided putting my zeal to the test. A man of his merit, and your friend, would have a right to dispence of me at his pleasure. But he, who is no fool, knowing perhaps the little extent of my power, is unwilling to expose me to the flame of confiding it. I am unable to inform you whether he has been caught in the old net. I never frequent the woods which expose him to such danger, and have never been able to examine him; as during his long residence on the banks of the Tiber, I have only had the pleasure of seeing him two or three times, at most. Indeed his continuing so constantly invisible, and remaining here so long, without any apparent motive, seems to favour your conjectures. If he is at sea, I wish him a prosperous gale; if such a wish is not inconsiderable; as the felicity of a navigation depends much on the caufe for which we embark; and I never wish my friends to be perplexed of such an inconsiderable care."

And in a third letter, he says, "Our ardent and laudable Majo, flirinated by his friends and by his duty, is at length set off for Mannheim, where he is engaged to compose an opera for the elector palatine. With what heart he has left the banks of the Tiber, enamoured turtles say!"

This exquisite composer and tender hearted swan, who had been puffed of the world, would have left it all for love, with as good a grace as Mark Antony, died in 1771. The last opera he composed, was Dudone Abbanio, for Venice, in 1770.

Majo Bamba, in Geography, a town of Peru, in the jurisdiction of Chacapoyas.

Majo, John, in Biography, was born at North Berwick, in Scotland; he laid the foundation of a learned education in his own country, and afterwards studied some time at Cambridge and Oxford. In 1593 he went to Paris, where he prosecuted his studies at different colleges; in 1595 he was made doctor of the Sorbonne, and in 1599 he returned to his native country, and was elected professor of divinity at St. Andrews, where the celebrated Knox was one of his pupils. He afterwards attained to the office of provost of that university, where he died at the age of seventy-eight, in the year 1547. He was a voluminous writer in metaphysics and logic, but his works on these subjects have long been forgotten, and he is now remembered and quoted only as the historian of his own country. His main work is entitled "De Gestis Scotorum," in 8 books, first published at Paris in 1521, which bring down the history from the earliest periods to the year 1495. He rejects the fictions of antiquarians relative to the remote history of the nation, and reduces the life of its early kings. He is a fervent advocate for the independence of his country, and speaks freely of the power of the people and the prerogatives of parliament; he is an enemy to public abuses, and speaks with decision of the acts of the kings whose conduct he never scruples to condemn. Bishopp Lefiis says of his history: "Veritas ubiqui quam eloquentia studior." Gen. Biog.
MAJ

were, petrifications or soliths, renal calculi, transfusion, anatomy, botany, artificial medicated baths, &c. Eloy Diet.

Major's Bay, in Geography, a bay of the island of St. Christopher. N. lat. 17° 20'. E. long. 62° 22'.

Major, in Law, a person who is of age to manage his own affairs. See Age.

By the civil law, a man is not a major till the age of twenty-five years; in England, he is a major at twenty-one, and in Normandy at twenty.

Major, in Logic, is understood of the first proposition of a regular syllogism.

It is called major, because it has a more extensive sense than the minor proposition, as containing the principal term. See Proposition.

Major, in the Art of War, a name given to several officers of different qualities and functions.

Major-general. See General, Major.

Major of a Brigade, either of horse or foot, is he who receives orders, and the word, from the major-general; and gives them to the particular majors of each regiment. See Brigade-major.

Major of a Regiment is an officer, whose business is to convey all orders to a regiment, to draw it up, and exercise it, to see it march in good order, to look to its quarters, and to rally it, if it happen to be broken in an engagement, &c.

The major is next in subordination to the lieutenant-colonel, and generally promoted from the eldést captain. He is the only officer of a regiment of foot, who is allowed to be on horseback in the time of service; but he always rides, that he may quickly get from place to place, as occasion requires.

The major of a regiment, either of foot or of horse, ought to be a man of honour, integrity, understanding, courage, activity, experience, and address; he should be skilled in arithmetic; that he may keep a detail of the regiment in every particular, and also in horsemanship; and he should be well acquainted with all military evolutions, that he may be competent to the exercise of his duty in the instruction of others.

Major of Artillery is the next officer to the lieutenant-colonel. In the field he receives daily orders from the brigade-major, and communicates them, with the parole, to the colonel, and then dictates them to the adjutant.

The whole detail of the corps rests with this officer; to him all the non-commissioned officers are subordi-

Major of Engineers. See Engineer.

Major, Serjeant, is a non-commissioned officer, subordi-

Major, Tows, is the third officer in order in a garrison, being next to the deputy-governor.

He ought to understand fortification, and hath charge of the guards, rounds, patrols, and sentinels.

There are also aids-major, drum-major, and other officers, so called, on account of some seniority or prerogative that they have over the rest. See Aid-major, and Drum-major.

Major, Fife, has the same authority over the fifers as the drum-major has over the drummers. He teaches them their duty, appoints them for guards, &c.

Major Helice, in Anatomy, a name given by Albinus to one of the muselles of the eye, called by Santorini and others, helice mutuus. This author distinguishes it under the name major, from another muselle which he calls the minor helica, and which Santorini calls only fibra muculures in plana helicis facieb, though it be a true and proper muselle.

Major and Minor, in Music. See Magister.
The kingdom of Majorca, comprehending the ancient Iberian islands, or the Balearic and Pitutey, lost much of its ancient population in the year 1229 by the defeat of the Moors, and the carnage made by the Christians, in order to revenge the death of the celebrated venturer de Bein, William of Mon- cado, and his brother. In the year 1301 the Jews, who had been driven from Spain on account of their excursions and fury and settled here, were banished from the island. About the beginning of the 15th century, Majorca was afflicted with famine for 10 years, and its commerce declined with its population. In 1403 the river Rierra carried away 1600 houses, and drowned 5500 persons. A similar catastrophe occurred in 1408 and 1411. These disasters were succeeded by a civil war. In 1475 the island suffered great devastation from the plague. By these and other occurrences the population of Majorca was much diminished; but in this state it furnished troops for a militia, raised in order to defend the coast against the incursions of the Barbarians. The nobility of Majorca was formerly confederate; and in the middle of the 16th century they engaged against the Africans, who endeavoured to invade the island. But after this epoch it enjoyed much internal tranquillity, though it never rose to that eminence, which it is said to have attained under the Moors. The number of inhabitants is now estimated at about 136,000 persons, among whom are reckoned 1500 secular priests, 1000 monks and hermits, 600 cloistered nuns, and 600 women voluntarily engaged in charitable institutions. The agriculture of Majorca is in a flourishing condition. The mildness of the climate, and the fertility of the country, has given to the islands of this kingdom the name of the "Fortunate Islands." (Strabo, lib. iii.) The groves of orange trees produce excellent fruit, and the vines are loaded with grapes. The mountains in general are covered with trees of various kinds, as firs and holm-oaks, fit for carpenters and ship-builders; and the wild olives are abundant. The plains and valleys, which are well watered, exhibit the appearance of meadow ground. The flocks furnish a great quantity of the finest wool; and by the culture of mulberry trees, they feed a number of silk worms, whose produce serves not only for domestic use, but promises to afford an article of exportation. In some territories they cultivate several kinds of corn, and delicious figs, which are dried; in others they graze cattle. The plain between Felonice, Monturrat, San Juan, and Petra is considered as the granary of the island. Corn, wine, oil, fish and dried figs, and brandy, supply the wants of the interior. The eastern valley of Alcudia is very fruitful and rich. Grains of different species, honeycombs, olives, carobs, hemp, and every variety of fruits and herbs, are abundant. The valley of Soler is famous for its beauty and fertility, and is the pride of the islanders; and the canto of the mountains of Banusbur ante abounds in wine and flax, which are also produced in many other parts of the island. The Majorcans, however, are reproached with a latitude injurious to their prosperity. They import as much as 50,000 fannas of wheat to supply the consumption of 130,000 inhabitants, who pollute a territory of 1254 square miles, which are supposed to be the extent of the island. The Majorcans manufacture a sort of coarse strong cloth for their own use, and a large quantity of corded woollen stuff, which is exported into Catalonia and the kingdom of Valencia. They have also looms for tapestry, blankets, and fabrics, all in wool, exported to Malta, Sar--dina, Valencia, and even to America. They manufacture silk in the island, and make several stuffs used by the inhabitants, as well as linen cloths, none of which are very fine. The coarse canvas, which they fabricate for the use of the marine, is exported. They make brooms, paniers, and haf_kets, out of the leaves of the palm-tree, which are transported into Spain. These islanders have been famous for their inland work, and this branch of commerce is profitable. The wines of Majorca are excellent. The lightest and finest, though frisky and delicate, are Muscadel, Mal--vaia, Pampot Roda, and Montona. The oxen are small and feeble; the sheep large, with beautiful and heavy fleeces. The pigs are large and fat; game is very plentiful, and confisols of hares, rabbits, snipes, partridges, quails, &c. Poultry is very common. Their cheese is made of goats' and sheep's milk, and some of it is very good. Their exports, consisting of wines, oils, brandy, oranges and lemons, almonds, cheeses, capers and beans, amount in value to about 306,729l. 1s. 4d. This sum is augmented by the produce of some articles of manufacture. The inhabitants receive, in return, corn, salt provisions, sugar, coffee, rice, different sorts of flax, cloth, silk linens, linens of different qualities, livery, hardware, medical drugs, planks and building wood, powder and shot for sporting, &c. which may amount to the value of 124,535l. (a. Sd) sterling. Hence it appears, that the balance of trade is annually: to Majorca 385,690l. 11s. 6d. sterling.

The island of Majorca is not only delightful of navigable rivers, but its highways are inconvenient for travelling, and very much out of repair; so that all the articles of land carriage, from the interior to the sea, are conveyed on the backs of mules, or by carts of very clumsy construction. It has been said, that mines of gold and silver and precious stones were formerly found in this island; but of this there now remains no evidence. Its quarries of various sorts of marble and of stone are, however, numerous. In the marlstone of Campos a quantity of natural salt is discovered, but for want of being worked it turns to little account: near the fame town is a spring of sulphureous water, called the holy, or St. John's fountain, which is reckoned salutary in various complaints. In this island are some birds of prey, particularly the hawk; but venomous animals are very little known. The coral fishery is carried on in the bay of Alcudia during the months of July and August. The manners of the Majorcans are at the same time with those of the Syrians, and most strikingly resemble the Catalans; they are both excellent soldiers and sailors. The drets of the peasants is a cap, which covers their short hair, a jacket down to the waist, large breeches, and shoes tied with a string; above the breeches they have a sort of frock. The neat and simple head,dres of the females is called "rebosillo;" it consists of a double handkerchief, the upper part of which covers the head, and is hid under the chin, leaving only the face exposed, then extending over the shoulders, and falling down half of the back, the two ends meet, crofs, and are tied before. Among the wealthy the rebosillo is an expensive article of dres, on account of the embroidery and lace. The women are in general fond of ornaments; those of fortune having a gold chain hanging along the petticoat, and sometimes a chain of the same metal from the corset, to which is fixed a valuable medalion: they have also all their fingers covered with rings, and make use of watches, bracelets, and other trinkets. When they get abroad, they wear a mantle like those in Spain, and carry in their hands a fan and a long chaplet, ornamented with gold beads, and a crofs of the same metal. The Majorcans value themselves on their fidelity to their sovereign; they are devout without bigotry, and their manners are soft and pious; the women have a great degree of natural elegance.

12
MAI

Perfections of distinction, men of business, and merchants speak Catalan; but the language spoken among the rest of the islanders is a kind of mixed jargon, the origin of which it would not be easy to trace. The authors, who have written on the Balearic islands, say, that the Limousine tongue is used, but this language is merely a dialect differently pronounced, and spoken in the southern provinces of France. The Balearic conists of Greek, Latin, Arabic, Catalanian, Languedocian, and Catalan, intermixed with Syriac, Carthaginian, and Vandal or Gothic words, or rather it is a strange medley of all. De Laborde's View of Spain, vol. iii. See Baleares Infibs.

MAJORCA. See PALMA.

MAJOR-DOMO, an Italian term, frequently used to signify a steward or master of the household.

The title of major-domo was formerly given in the courts of princes to three different kinds of officers. 1. To him who took care of what related to the prince's table, or eating; otherwise called thaler, presedus menae, architecum, dajifer, and princeps coquorum. 2. Major-domo was also applied to the steward of the household. 3. The title of major-domo was also given to the chief minister, or him to whom the prince deputed the administration of his affairs foreign and domestic, relating to war as well as peace. Instances of major-donos in the two first senses are frequent in the English, French, and Norman affairs.

MAJORIANUS, Julius Valerius, in Biography, an emperor of the western Roman empire, was called to the throne in the year 457, having served with much reputation in the army. His address to the senate on this occasion spoke the language of one fully sensible of the duties incumbent on him. He appears to have possessed many excellent qualities both of the heart and head. The laws which he caused to be enacted, and which are extant at the end of the Theodosian code, are proofs of his attention to the happiness of his subjects, and the welfare of the empire. He granted a discharge to the inhabitants of the provinces from all arrears of tribute, and removed many exactions in the collections of the taxes. He enjoined severe penalties against the dilapidation of the public edifices of Rome, and made many wholesome regulations to encourage marriage, and restrain adultery. He rendered himself illustrious by his victories over the Vandals and Moors, who invaded his territories. He was at length the victim to the ambition of some of his chiefs, and compelled to abdicate his throne and authority in the year 461, after a reign of little more than three years; and in a few days after he was massacred by Ricimer, one of his generals. His character was that of an active, virtuous, and humane emperor. Univer. Hist. Gibbon.

MAIRAN, John James d'Ortois de, an eminent French philosopher, who flourished in the eighteenth century, was born at Beziers in the year 1678. He devoted himself from a very early period to the study of literature and science, and obtained seats in the Academy of Sciences, and the French Academy. To the former he was chosen perpetual secretary, after the death of Fontenelle in 1741. While he continued in that office, he was punctual and diligent in performing its duties, and possest the happy art of placing the most abstruse subjects in a clear and intelligible light. In his eulogies he nearly equalled his predecessor in the faculty of characterizing the subjects of them, and of impartially appreciating their merits. He died in 1771: he was author of a great number of publications on interesting topics, of which the following may be mentioned, "A Differtation on Ice?" "A Differtation on the Cauze of Light of phosphoric Bodies and Glowworms?" "An historical and phyical Treatise on the Aurora Borealis?" "A Letter to Father Paremsin, containing several Questions relating to China," which is said to be a very curious work, and full of that philosophical spirit which characterizes the other works of the same author: some "Memoirs" published among those of the Academy of Sciences: "Difertations," and "Eulogies" on deceased academicians, were printed in 1747.

For further information relative to Mairan, see Mem. de l'Acad. des Sciences, in which there are many curious articles concerning Harmonics and the philosophy of Euclid. He accounts for the medicinal powers of music in the following manner. "It is from the mechanical and involuntary connection between the organ of hearing, and the concomitances excited in the outward air, joined to the rapid communication of the vibrations of this organ to the whole nervous system, that we owe the cure of spasmodic disorders, and of fevers attended with a delirium and convulsions, of which our Memoirs furnish many examples."

MAIER, JOHN LE, a French poet, was born at Hainault in 1473, and died in 1524. He wrote among other pieces an allegorical poem, called the "Tales of Cupids, and of Atropos."

MAIER, James LE, a Dutch navigator, who failed from the Texel in 1615 with two ships, and in the following year he discovered the straits, which bear his name in South America. After visiting New Guinea, he failed to Batavia, where he was made prisoner, and his vessel sacrificed, under the pretense of his having infringed on the rights of the Dutch East India company. He died on his passage to Europe in 1617.

MAIER, LE, a French musician of the 17th century, is generally allowed the honour of having invented, or at least brought into use, in France, the syllable fi, to express the 7th of the key of C, instead of repeating the mi in diminution, by which students in singing escape the pernicious difficulty of the mutations. The title to the invention, small as it seems, has been often disputed; but having taken great pains to trace the first use of this syllable in singing, we have never been able to discover any musician to whom it is to justly due as Le Maier. With respect to the utility of this invention, we think it would be much extended if the sharp 7th of every major key, as well as that of ut, were called fi.

MAIER, LE, Straight of, in Geography, a narrow passage from the Atlantic to the Pacific ocean, between Terra del Fuego on the west, and the westward of Staten Land on the east, about five leagues long and as many broad; so called from Le Mair's, who, with his companion Schouten, failed from the Texel on the 14th of June 1615, discovered this passage; and they were the first who ever entered the Pacific ocean by the way of Cape Horn. In the account of lord Anson's voyage it is said, that it is difficult to determine exactly where this strait lies, though the appearance of Terra del Fuego be well known, without knowing also the appearance of Staten Land; and that some navigators have been deceived by three hills on Staten Land, which have been mistaken for the Three Brothers in Terra del Fuego, and so over-shot the freight. But no ship, says lieutenant Cook, who passed this strait in January 1769, can possibly miss it: the coasts Terra del Fuego within sight of land: for it will then, of itself, be sufficiently conspicuous: and Staten Land, which forms the east side, will be fill more manifestly distinguished, for there is no land in Terra del Fuego like it. The freight of Le Mair can be missed only by flanding too far to the eastward, without keeping the land of Terra del Fuego
Fuego in sight: if this is done, it may be missed, however accurately the appearance of the coast of Staten Land may have been exhibited; and if this is not done, it cannot be missed, though the appearance of that coast be not known. The entrance of the freight should not be attempted but with a fair wind and moderate weather, and upon the very beginning of the tide of flood, which happens here, at the full and change of the moon, about one or two o'clock: it is also best to keep as near as to the Terra del Fuego shore as the winds will admit. By attending to these particulars, a ship may be got quite through the freight in one tide; or, at least, to the southward of Success Bay, into which it will be more prudent to put, if the wind should be unfavourable, than to attempt the weathering of Staten Land with a lee-wind and a current, which may endanger her being driven on that island. The bay of Good Success lies about the middle of the freight, on the Terra del Fuego side, and is discovered immediately upon entering the freight from the northward; and the south head of it may be distinguished by a mark on the land, that has the appearance of a broad road leading up from the sea into the country: at the entrance it is half a league wide, and runs in wellward about two miles and a half. There is good anchorage in every part of it, in from ten to seventeen fathom, clear ground; and it affords plenty of exceeding good wood and water. The tides flow in the bay, at the full and change of the moon, about four or five o'clock, and rise about five or six feet perpendicular. But the flood was two or three hours longer in the freight than in the bay; and the ebb, or northerly current, was with nearly double the strength of the flood. On the W. side of the Cape of Good Success, which forms the S.W. entrance of the freight, lies Valentine's Bay, from which the land trends away to the W.S.W. for twenty or thirty leagues; it appears to be high and mountainous, and forms several bays and inlets. At the distance of fourteen leagues from the bay of Good Success, in the direction of S.W. ½ W. and between two and three leagues from the shore, lies New Island; about two leagues in length from N.E. to S.W., and terminates to the N.E. in a remarkable hillock. At the distance of seven leagues from New Island, in the direction of S.W., lies the Isle Exouts, and a little to the W. of the S. of this island lie Barnevelt's two small flat islands close to each other; they are partly surrounded with rocks, which rise to different heights above the water, and lie twenty-four leagues from the freight of Le Maire: at the distance of three leagues from Barnevelt's islands, in the direction of S.W. by S. lies the S.E. point of Hermit's islands, which from most points of view may be taken for one island, or a part of the main. From the S.E. point of Hermit's islands to Cape Horn, the course is S.W. by S. distance three leagues. Cook observes, that between freight Le Maire and Cape Horn, they found a current setting, generally very strong, to the N.E. when they were in with the shore; but they left it when they were at the distance of fifteen or twenty leagues.

Though the doubling of Cape Horn, says Cook, is so much dreaded, that is the general opinion it is more eligible to pass through the freight of Magellan, we were not once brought under our clove refed top-fails after we left the freight of Le Maire. But supposing it more eligible to go round the Cape than through the freight of Magellan, it may be questioned, whether it is better to go through the freight of Le Maire, or land to the eastward, and go round Staten Land. In the account of lord Anfow's voyage the advice is, that all ships bound to the South seas, shall ad of passing through the freight of Le Maire, should consantly pass to the eastward of Staten Land, and should be invariably bent on running to the southward as far as the latitude of 61 or 62 degrees, before they endeavour to land to the westward. "But, in my opinion," says captain Cook, "different circumstances may at one time render it eligible to pass through the freight, and to keep to the eastward of Staten Land at another. If the land is fallen in with to the westward of the freight, and the wind is favourable for going through, I think it would be very injudicious to lose time by going round Staten Land, and I am confident, that by attending to the directions I have given, the freight may be passed with the utmost safety and convenience; but if, on the contrary, the land is fallen in with to the eastward of the freight, and the wind should prove tempestuous or unfavourable, I think it would be best to go round Staten Land. But I cannot, in any case, concur in recommending the running into the latitude of 61 or 62°, before any endeavour is made to land to the westward. We found neither the current nor the streams which the running so far to the southward is supposed necessary to avoid; and, indeed, as the winds almost constantly blow from that quarter, it is scarcely possible to pursue the advice. The navigator has no choice, but to land to the southward, close upon a wind, and by keeping upon that tack, he will not only make southerly, but weering, and, if the wind varies towards the north of the coast, his weering will be considerable. It will, indeed, be highly proper to make sure of a prevailing sufficient to double all the lands, before an attempt is made to land to the northward, and to this every man's own prudence will, of necessity, direct him." Hawkesworth's Voyages, vol. ii.

MAIRE, a small island in the Mediterranean, near the coast of France. N. lat. 43° 14'. E. long. 6° 24'.

MAISBINNI, a town of Abyssinia; six miles W. of Axum.

MAISERRY, a town of Bengal; 10 miles S. of Ghideor.

MAISEY, a town of Hindoostan, in Bahar; 45 miles N. of Patna. N. lat. 26° 22'. E. long. 85° 18'.

MAISNAH, a town of Bengal; seven miles N.N.W. of Goragot.

MAISTRE, ANTONY DE, in Biography, a French writer, was born at Paris in 1668; he was brought up to the bar, but quitted the profession, and entered into the society of Port Royal, where he died in 1678. The greater part of his life he spent in acts of the severest mortification, in writing various works, and in the study of theological subjects. His principal pieces are "Pleadings," which have been repeatedly reprinted; a French translation of the treatise "On the Priesthood by St. John Chrysostom;" a translation of the works of St. Bernard: he had employed himself on a French version of the Old and New Testament. Moreri.

MAISTRE, LOUIS ISAAC LE, better known by the name of Sacy, brother of the preceding, was born at Paris in the year 1613. He was brought up for the church, and was ordained priest in 1648. The persecution of the Jesuits, in which the members of Port Royal were involved, obliged him to conceal himself in the year 1661, but being discovered in the place of his retreat in 1660, he was sent to the Bastile. Here he was confined more than two years and a half, during which time he employed himself on the translation of the Bible, and finished the whole of the Old Testament. After his liberation he completed his version of the New Testament, which he went over thrice, before he could pronounce it finished. His works are extremely numerous, and the topics very various. He was a perfect matter
MAI I

matter of the French language, and wrote it elegantly, Moréri.

MAITÉA, in Geography. See Osnarburg Island.

MAITED, a town of Peridia, in the province of Kerman; 16 miles N.E. of Serigan.

MAITLAND, John, in Biography, lord Thylitane, and chancellor of Scotland, was born in 1545. He accompanied king James VI. to Norway, where his comfort, the princes of Denmark, was detained by contrary winds. He died in 1595. He was author of "Epigrammata Latina," published in the "Deliciae Poetarum Scotiorum." Gen. Biog. Diet.

Maitland, William, a topographical and antiquarian writer, was born at Brechin, in Scotland, in 1693. His business as a hair merchant led him to travel, and he visited Sweden, Denmark, and Germany, and finally settled in London. Here he began to apply himself to the study of antiquities; and in 1739 published the first fruit of his labours, which was his "History of London." The work, which was an improvement upon that of Stowe, became popular, and has since been several times reprinted, with considerable additions: it has likewise furnished materials for many smaller and more modern publications. Soon after the publication of this work, the author is supposed to have retired to his native country, for the purpose of purifying enquiries into its historical antiquities; and, in 1753, he published "A History of Edinburgh." Success in this instance led him to extend his researches to a much wider compass, and he employed himself in writing "The History and Antiquities of Scotland, from the Earliest Account of Time to the Death of James; continued by another Hand to the Aedification of James VI. to the Crown of England." This work was published in two volumes folio in 1777; the same year the author died at Montrose. Mr. Maitland deserves great applause for his industry, but he was not reckoned competent for such a task, either with regard to learning or critical acumen.

Maitland, Henry, a surgeon, is worthy of notice, principally as being the first person who performed the operation of inoculating the small-pox in England. Mr. Maitland refided at Constantinople, in the early part of the 18th century, with the Hon. Wortley Montague, then ambassador at the Ottoman court, where the only son of that gentleman was inoculated, at the age of six years, in 1717: and, on their return to England, Mr. Maitland inoculated the infant gentleman, in April, 1721. He published a detail of these cafes, and of those of some condemned criminals in Newgate, in February, 1722, in a pamphlet, entitled "An Account of Inoculating the Small-Pox;" and subsequently, a second pamphlet in "Vindication" of the former, in reply to the attack of Dr. Waghaffe. See Inoculation.

MAITRE A CHANTER, Fr., a singing-master. Roufeau has so well pointed out the functions of a singing-master in teaching the elements of the vocal art, that we shall translate the chief part of his article on the subject. He includes the master's task in two principal objects. The first regards the cultivating and forming the voice, by making it capable of all that belongs to singing, with respect to compass, truth of intonation, clearness and sweetness of tone, execution, swelling and diminishing the notes, hitting distances with precision, and acquiring a free and open voice.

The second object regards the study of the musical characters; that is, acquiring a facility in reading music at sight, as accurately and readily as a printed book, in the student's own language.

Vol. XXII.

M A I I

A third part of a master's business is to enforce the duty of pronouncing and articulating the words with accuracy and energy; because defects in pronunciation are much more offensive in speaking than speaking; as the finger is expected to tune and soften the harsh syllables, and render the flow fill more sweet.

Milles used to say, that a voice should be so cultivated and exercised in folefegia, as to resemble a ball of wax, so long tempered in the hand that it can receive any impression.

Roufeau says nothing of expression, but that must come from the heart as well as the voice. It is perhaps only to be learned by imitation, and taught by example. There are many clear and powerful voices which give the hearer no pleasure, however accurately they may execute the notes, while a feeble voice has often the undefinable power of affecting us by a natural pathos and interesting expression that touches and delights us the instant it is heard. See CANTARE, SOLEFEGIA, and EXPRESSION.

Maitre-Jean, Anthony, in Biography, an oculist and surgeon, was educated at Paris, and practised at Mery on the Seine, with great reputation, at the beginning of the eighteenth century. He was particularly distinguished for his success in the treatment of diseases of the eyes, both the healthy and morbid structure of which he had investigated with great industry and accuracy, as his work, entitled "Traité des Maladies de l'Oeil, et des Remèdes propres pour leur Guérison," 1707, sufficiently proves. This treatise, which was several times reprinted and translated, was long a standard, and is still entitled to election. It contained the first satisfactory proofs that the seat of cataract was exclusively in the crystalline lens, and treated copiously on all the varieties of the operation of c Koching. He likewise published, "Observations sur la Formation du Poulet," Paris 1732, with figures, drawn by himself; a work which contains many original experiments and remarks, and which, according to Haller, is not sufficiently esteemed. Maitre-Jean was a corresponding member of the Academy of Sciences at Paris, and some of his papers were printed in the Memoirs of that learned body. Eby Diet. Hilk. de la Méd. Gen. Biog.

MAITS, in Geography, a lake of Prussia, in Narangien; 20 miles S. of Radenburg.

Maittaire, Michael, in Biography, an eminent bibliographer and philogist, was born about the year 1668. The place of his birth has not been ascertained, but it has been inferred from the name that he was descended from parents, refugees from France. He was educated at Chriftchurch, Oxford, and took his degree of M.A. in 1696; previously to this, he had been nominated second master of Weltinginder-school, a post which he occupied till 1699. He was intended for the church, and wrote some controversial pieces, but it does not appear that he took orders. He was patronized by the first earl of Oxford, and enjoyed the favour of the second earl, and was afterwards appointed tutor to lord Chelmsfield's natural son, Mr. Stanhope. He was deeply skilled in classical learning, and was author of many works, which fill bear a good reputation. His first piece was entitled "Grecis et Latinis Dialectis," which was succeeded by an "English Grammar." Typographical antiquities were his study and delight, and he gave the public, in connection with these subjects, the following works: "Stephanorum Historiac, vita ipsum ac libros complectens;" "Historia Typographiarum aliquot Pariensium;" "Annales Typographici ab artis Inventione." In the first volume, the history of printing was brought down to the year 1500: the second continued it till 1536;
1725. Aspucc, the nor. "But the kind of food port given and not the same of Latin poems under the title of "Sanilia."

MAJUMA, or New Gaza, in Geography, a sea-port town of Palestine, near Gaza; which see.

MAIXENT, St., a town of France, in the department of the Two Sevres, and chief place of a canton, in the district of Niort; 6 miles N.E. of Niort. The place contains 5000, and the two cantons 19,757 inhabitants, on a territory of 230 kilometres, in 14 communes.—Also, a town of France, in the department of the Sarthe, seated on the Sevre; badly built, surrounded with walls, and containing an ancient castle with two faubourgs, and about 5000 inhabitants; 6 miles S. of La Ferte Bernard.

MAIZ, in Agriculture, a provincial term applied to a large light fort of hay bale, in some districts.

MAIZE, or Indian Corn, in Botany. See Zea.

MAIZE, in Agriculture, a species of grain much used for food in America, under the name of Indian corn. It is very productive; the size of its ears, where it is cultivated on good warm soils, being, on a medium, nearly a span long, having commonly eight or more rows of grain, each of which usually contains about thirty seeds of various colours, as red, white, yellow, blue, olive, greenish, blackish, speckled, striped, &c. sometimes in the same field and same ear; but the white and yellow are the most common; nor does this diversity of colours ever reach beyond the outside of the grain, the flower of which is always white, with a little tinge of yellow. The seeds, which are as big as large peas, are round at the outer surface, very smooth, and yet extremely close in straight lines. The ear is clothed and armed with several thick hairs, which defend it not only from unoin宜able rains, and the cold of the night (for it does not ripen fully in some places till towards the latter end of September), but also from birds. In the northern districts, the flalk of this plant, which contains a remarkable sweet pith, and is jointed like the sugar-cane, does not grow near so high as in the southern parts. It has long leaves, almost like the flag at every joint, and at the top a bunch of flowers of various colours. Its culture upon any extensive scale has not hitherto been attempted in this climate.

Soil, Preparation, and Method of sowing or planting.—This kind of crop may be grown on most fertile of soils. On a light, poor, sandy soil, in Miller's trials, the method of preparation for it was to have the land ploughed up deep before winter, and laid up in high ridges till the spring, when it was broken fine with the harrow. It was ploughed again in April, laid level, harrowed smooth, and then sowed in drills, four feet asunder, into which the seeds were dropped at the distance of about eight or nine inches from each other. When the plants were about three inches high, they were thinned with a hand-hoe, by cutting up some of them where they grew too close, and the intervals between the rows ploughed shallow, to destroy the young weeds; but when the items were advanced, the ground in the intervals was ploughed deep, and the earth laid up to the plants on both sides; and when the weeds began to grow again, a third ploughing was given, to destroy them. This kept the ground pretty clean from weeds till the corn was ripe, as the seafon did not prove wet; otherwise a fourth ploughing would have been necessary.

In Ireland, in the experiments of Sir Richard Bulkeley, the greens were kept a foot under, in rows about a yard distant from each other. In the latter of these cases there were from each flalk from three to six spikes of grain, and in the latter from three to six flaks, and upon each flak three spikes, or ears of corn, with two hundred and forty grains on each spike, which was an amazing increase.

In M. Duhamel's attempts to raise this fort of grain, he found it to thrive better in a light and sandy soil, than in stiff and clayey land. It did not answer without dung; and the ground intended for it received two good ploughings in March. A third ploughing, given towards the end of April, made the furrows for the feed; and what clods remained after this were either broken by hand or the roller.

And a fine clear day was chosen in May for fowing the feed, which was done by making at the bottom of the furrows, with a flack or other instrument, small holes, into each of which two grains of maize were dropped. The furrows were a foot and a half asunder, and the holes at the same distance, dipped in such a manner, as to form a kind of square. When the corn-plants appeared, the weakest of the two were plucked up, where both feeds had figured; and where neither of them had grown, two new grains were planted. Towards the middle of June the ground was hand-hoed round each plant; and as they flourished, the mould which crumbles down from time to time, laid fresh earth to their roots, and helped to support them. About the end of July, a flight hoing was again given them, which was the half; and the earth laid towards the roots of the plants.

It is suggested, that the panicles of the male flowers, which grow at the top of each plant, and are well known not to contain any grain, should be cut off about the middle of August, but care must be taken that the grain be impregnated before this is done, which may be known by the turgid appearance of the outward covering of the ears: and they should not be cut off from all the plants at the same time, as some of the ears are not impregnated till a fortnight after others. These panicles are excellent food for cattle. When they are cut, or shortly after, all the leaves should be stripped off the flalks, together with all the blighted and smutty ears; for it is said, that the good ears would not grow fo large, nor the grains be so well nourished, if they should be left upon the flalks. All these leaves and ears are given as fodder to oxen.

The proper time for reaping maize is towards the end of September. The ears are then gathered by hand, and put into baleks, in which they are carried, and laid in heaps, from space to space, in the field, after which they are loaded in carts, carried home, and spread upon an even floor prepared for that purpose. They are then taken out of their sheath, or hood, and dried in the sun, before they are laid up in the granary, or else the grain is taken out at that time. Maize, which has been well dried in the sun, will keep several years, and not be the less fit for fowing. The granary should be very dry, and the corn laid up in it should be turned at least every three months, to prevent its growing molly, or being attacked by insects. There are two ways of taking out the grain; the first, which is the most expedient, is by thrash-
ing it with a flail; but in this method a deal of the corn is broken or bruised. The zd, and more common, is by rubbing the ears hard against the edge of a flat piece of iron; this easily separates the grains from the spike, or cob, without hurting them, and this remainder of the ear is very good food for oxen. As soon as the ears are gathered, the flaks remaining in the ground are plucked up, and laid by for winter fodder for oxen or other cattle. The field is afterwards ploughed up as soon as possible, it being the general opinion of farmers, that the roots of the maize would otherwise continue to suck up the rich particles of the earth; whether this be true or not, their notion is, that if this ploughing should be deferred, the next year's crop would certainly suffer by it.

When maize is planted only for fodder, particularly for cows and oxen, it is sowed very thick, and harrowed in, or covered with a rake, in a good soil which has been ploughed twice, and well dunged; but it is observed, that in these thick sowings, all the female flowers are barren, and produce no grain: and it likewise is so great an improverisher of land, that though the ground be dunged every time it is planted, wheat never does so well where this corn has grown, as in the neighbouring fields where it never was grown.

In M. Amien's trials it was found of importance to sow maize rather in the beginning than at the latter end of May, because, if it be fown early, the plants will have acquired sufficient strength, before the great heats, to shoot out their leaves, with vigour, and the ears be not liable to that barrenness to which they are subject when fown late; besides, the stalks will be stronger, and their ears larger and fuller of grain; the ears of maize also are greatly hurt by cutting the panicles too late, which ought to be done before the hoods are open. By leaving a plant with its male flowers at every twenty feet distance, all the female ears may be impregnated.

In order to ascertain whether it is best to fow maize thick or thin, he planted three different spots of ground with this corn in April; the seed used for the first, where the grains were placed about a foot and a half asunder, according to the common practice of the country, weighed one ounce and one penny-weight; the second, in which the grains were only a foot asunder, was fowed with two ounces and two pennyweights of seed; and the third, in which they were but fix inches apart, was fowed with four ounces and a half. The first of these spots produced eighteen pounds and four ounces of grain; the second fifteen pounds seven ounces; and the third eleven pounds two ounces. A manifest proof, M. Amien thinks, that some sorts of grain do not thrive unless they are fown very thin, and that for want of this precaution, a great deal of corn is often lost, and the crops considerably diminished.

It is found that this plant, when cut green, affords a good cattle food: the grain is likewise highly useful for feeding poultry and hogs, and, when ground into flour, for various purposes.

But in America, according to a late writer, the common method to prepare land for Indian corn, is in the fall (Autumn) to plough it, or what is termed flaying it. The soil is raised in a rough manner by ploughing broad furrows; it being so thin, that it is not turned over, but stands very much on the edge: the ploughs are of a bad construction. In the latter end of April, or beginning of May, the plan is to lift it out, that is, crossing the field five or six feet asunder, setting two furrows back to back, then the like the other way, which forms a sort of hill where these furrows cross each other. The practice is then to go with a large hoe, such as that its weight will break the clods in the same manner as mulls (beetles) for that use, and make the mould very fine, something in the manner that gardeners do for cucumbers in the field-gardens in this country. In these hills are put four or five corns, and this is generally done in the frizt of May.

Reckoning four corns to one hill, four thousand only will be required to plant an acre containing a thousand hills. When the corn is come up, the culprit is to go with their hoes, and draw a little mould to the plants, destroy any weeds that may appear, and plant fresh corn, if any be wanting, which often happens; that done, to plough from those hills both ways, then to go with the hoes, and work the hills again, and to draw the plants of an inferior kind out, leaving two of the beit on each hill, or if the land be good, three and sometimes four, and to transplant those drawn out where any are wanting. However, when more than two plants are left on one hill, there will be little corn, but much tops and blades. Then to plough all the land towards the plants one way; after this it is necessary to what they term fucker them, that is, to take off any young sprouts that have tillered, otherwise the corn will not grow in the ear to its proper length or fize, but grow short, what they call cobbing; this done, just before it goes into flisk, they plough the land to the corn the contrary way, which is five times in all. The expense would be about seven pounds per acre, if the work were done by hired labourers, and horses for ploughing.

After the last time of ploughing, which is during the latter end of August, some of them low wheat under furrow, for which the Indian corn crop is a preparation, but which is harrowed in by others in September; the ploughing is done in a skimming manner, very thin.

It is found that "'the raising of Indian corn is an absolute preparation for wheat, rye, or winter barley, and perhaps better for the land in that hot country, than if nothing was grown, coiling little more than the feed wheat. It is a general practice to cut the tops, and pull the blades, before they lay the wheat; the topping and blading is done by cutting the tops off with a knife, just above the uppermost ear, as there are or ought to be two ears on each stalk, which are thrown out about four feet above the ground; the writer has had from five to seven ears put out, but they never came to perfection.'"}

The writer, however, in his own practice, put the corn into the ground in drills, at different distances from three to fix
MAK

six feet, harrowing the seed in, and found on actual trials, that a better crop of Indian corn may be raised by planting at six feet apart, and eighteen inches in the drills, than by any other mode which he has attempted, where the land is rich. Upon very poor land he does not, however, doubt but that the hill method may be superior, as by hoeing and ploughing there may be rather more of the bell earth added to the roots of the corn. This sort of drilling was found the lightest and cleanest method, as well as probably the cheapest.

It is further stated, that "good Indian corn will be from twelve to fourteen feet high, and that the white corn is much higher than the yellow; but the yellow is by far the sweetest, although the tops and blades are not so abundant. There are several kinds or varieties, both of yellow and white corn; the yellow is earlier than the white by one month." And, that, "the tops are set up in bunches or shocks; the blades are pulled off, tied up in small bundles, about one pound each, and hung on one of the corn italks by the tie or band, and in two or three days it is ready to carry." It is added, that "the usual method of preparing them for the winter is to make what is termed a fodder-hoofe, by setting up long grained pofts, and laying a rail upon the top, then placing other rails upon the ground, leaning against what may be termed the ridge-tree, they then lay the tops on like thatch, the blades are flored within the house; the husks are put into the house after the corn is gathered and husked, and given in the winter to the cattle. The white corn generally hangs on till frothy weather, as it takes a great deal of curing or hardening, having a very thick husk and a large cob. One leaf hangs over another, and the ear hangs downwards, and would not take harm all the winter, were not the ear to drop off the stalk. It is generally gathered in frothy weather, and sometimes when snow is on the ground. One reason for this may be, that it does les injury to the wheat, as they are obliged to cart upon the land where the wheat grows. The corn is taken from the cob by hand, as it cannot be threshed as grain is. The farmers have generally a husking seat, when all the neighbours come and help to hufe."

It may be noticed that this sort of crop was formerly introduced in rotation with other sorts of grains, so as to greatly injure the ground, as well as be less productive; and the practice still prevails in many places; but in the more improved methods of cultivation, and where the better sorts of husbandry prevail, it is now the custom to grow this kind of grain in courses with crops of the green ameliorating sort, such as those below, and in that manner.

Courses of Crops.

1. Old American Maize Course.

1. Maize,
2. Wheat or rye,
3. Lay, or mean pasture; or,
   1. Maize,
   2. Naked fallow,
   3. Wheat,
   4. Lay, or mean pasture.

This is not a beneficial crop, and from calculation it cannot; yet it must be a useful one, as it is the whole support of the American population. They begin to eat it as soon as it is formed in what is termed roasting cars; they boil them, and eat the corn in the same manner as we do green peas, with drawn butter, and no bacon, ham, beef, mutton, or any other kind of meat. The blades and tops feed the horses, cattle, and sheep; the corn feeds both man and beast, and is very excellent food for fowls, hogs, &c. The people eat it in hominy, mush and bread, or cakes; the hominy is made in like manner to our cred wheat buttered, by knocking the husk off in a wooden mortar; the mush is made of the flour as our hasty pudding, and eaten with milk or treacle. The better sort of people make a very nice cake, with eggs and milk, about the thickness of pyxsters, or what are called crumpets in London; the lower classes of people mix the flour with water, make a sort of paffe, and lay it before the fire on a board or shingle to bake, and generally eat it hot, as it is but very indifferent food when cold; it is called Johnny cake.

MAIZIERES, in Geography, a town of France, in the department of the Upper Marine, and chief place of a canton, in the district of Joinville; four miles N.W. of Joinville.

MAKADAMA, in Mythology, a name of the Hindoo god of love, Kama; which see.

MAKALLA, in Geography, a fia-port town of Arabia, in the province of Hadramaut; 60 miles S.S.W. of Hadramaut.

MAKANNA, a kingdom of Africa, situated between the rivers Senegal and Gambia; 300 miles from the Atlantic ocean.

MAKARA, a fabulous marine monster, frequently mentioned and alluded to by Indian authors. It is borne in the banner of Kama, the Hindoo god of love, as noticed under that article; one of whose names is hence Makara-ketu. It is also the sign Capricorn in the Indian zodiacs, and some writers deem it the horned shark. A combination of the goats and fish in that sign is not unfreqently seen on the zodiac of several nations, both eudrom and weodern, of which notice is taken under the article CAPRICORN.

MAKAREV, in Geography, a town of Russia, in the government of Nizni-Novgorod, on the Volga; 24 miles E.N.E. of Nizni-Novgorod. N. lat. 56° 25'. E. long. 44° 44'. Alfо, a town of Russia, in the government of Koltrom, on the Oua; 80 miles E. of Koltrum. N. lat. 58° 50'. E. long. 44° 14'.

MAKAYA, a town of Africa, in the kingdom of Kayor, about 21 miles from the Atlantic ocean. N. lat. 15° 20'. W. long. 16° 24'.

MAKE, in Laws, signifies to perform and execute. Thus, to make his law, is to perform that law to which a man had formerly bound himself; v. gr. to clear himself of action commenced against him by his own oath, and the oath of his neighbours, otherwise called to wage law. See WAGER of Law.

So, to make services or customs, is nothing else but to perform what belongs to them.

MAKE.
M A K

Make, To, in Sea Language, is variously applied: c. g. to make a board. See Board.

To make the land, is to discover it from a distant situation, in consequence of approaching it after a sea voyage; to make fall is to increase the quantity of fall already extended, either by letting out the reefs, and by hoisting an additional number of small fairs, or by either of these operations separately; to make flern way, is to retreat or move with the flern foremost: to make water casually signifies to leak; but a ship is said to make foul water, when running in shallow water, her keel dilurbs the mud or ooze, lying at its bottom.

MAKEN Kur-Assay, in Geography, one of the Kurile islands, about 20 versts in length, and ten in breadth. It is covered with rocks, especially about the shores, and many meadow grounds and moil places. It has no standing wood, but a few shrubs; its red foxes are few; sea-beavers and seals lie about its shores. It has neither lake nor stream, though it abounds with springs; it is altogether uninhabited.

MAKEFIELD, Upper and Lower, townships of America, in Berks county, Pennsylvania, the former containing 1101, and the latter 635 inhabitants.

MAKENABAD, a town of Peria, in Segellan; 90 miles S.S.E. of Zareeg.

MAKER, a village of England, in the county of Devon, on the Cornish side of the Tamar, near Plymouth found: the church tower of which is a sea mark. [N. lat. 50° 20'. W. long. 4° 11'.

MAKER-DUR, a town of Hindeodan, in the circuit of Kitchwrara; 22 miles N. of Budawar.

MAKERRA, a river of Algiers, that rives about 26 miles E. from Tremecen, and after a course of about 30 miles changes its name to Sig.

MAKESIN, a town of Asiatic Turkey, in the province of Diarbekir, on the Khabur; 105 miles S.W. of Mosul.

MAKIAN. See Mackian.

MAKINBOY, a name given by the people of Ireland to a kind of spurge, or titylame, common there: this is a very violent purge, as all the other spurges are; but the Irish have an opinion that it will produce this effect only by being carried in the pocket. This opinion, which had been universally believed for many ages, was proved to be false by Dr. Mullen, who carried a large quantity of it about him many days together, on purpose to give a fair trial; but it had not any the least effect on him.

MAKING-UP, a term used by distillers to express the bringing spirits to a certain standard of strength by the addition of water. See Lowering.

It is used principally in the distilling spirits, after their first drawing, either by way of rectifying them, or of giving them the virtues of aromatic ingredients, in order to make the compound waters; such as cinnamon, aniseed, and the like. See Distillation.

In the making of these compounds, some use an alcohol, or totally inflammable spirit, which is much the better method; others use ordinary proof spirit of malt, or molasses. If the latter be used, it is best not to put any water with it into the still; but if the former, so much water is to be added as will reduce it to the proof strength, which is just an equal quantity. When this is done, there should be drawn off three-fifths of the whole by distillation; and the farther better way would be to keep this liquor in this very state, which is just the strength of the trans-eques brandy of the French: but as people require these waters to be kept for drinking, in such a state as not to exceed at the utmost the strength of proof spirit, generally to fall much short of, it is necessary to reduce this three-fifths to the whole, or more than the whole quantity of the proof spirit put into the still. The apothecaries, to this end, usually let the still continue to work without changing the receiver, till an equal quantity is produced to the spirit put in, or one-fourth more; it being the usual standard in these waters to have five quarts made from a gallon of the spirit. By the method of doing this, by letting the still run, the fants are taken into the water, and give it a rapid and digestible taste. Instead of this, the distiller, when he has drawn off his three-fifths of the quantity of proof, makes up the whole of the delimited quantity, by adding the two other fifths, or more than that, if required, of common water, in which it is also customary to dissolve some fine sugar, and this gives a fulness in the mouth to the water, and makes it mellow, or late the fiery taint of the still much sooner. If it be only made up to the strength of proof, it will mellow much sooner than if reduced one-fifth below that standard, as the oil is much more perfectly dissolved in spirit of a standard proof strength, than in such as is weaker. The water employed in the making up, should be either soft and clear river-water, or else spring-water rendered soft by distillation, otherwise it is apt to turn the water thick, and precipitate a sediment, especially if the water be drawn lower than proof, or if the spirit, originally employed, partake of an alkaline nature from the salts used in its rectification, as is usually the case in the malt spirits; the gross oil of which requires to be separated by mixing falt of tartar or pot-ash with it in the still in the rectification.

When it is necessary to make up waters lower than proof, they are generally cloudy; but this may be remedied, and they may be fined down in a day or two with a small quantity of alum, or with whites of eggs, or the jelly of stingles beat up to a froth, and mixed in the same manner as is usually done in the refining of wines.

The fugar, added to these cordial waters, has not only the advantages of mellowing and filling the mouth, but it unites the oil to the spirit in a manner that it could never be united in without it. Shaw's Essay on Distillery.

MAKKEDAH, in Ancient Geography, a royal city of the tribe of Judah, in Palestine, near which the five kings of the Amorites were put to death by Jospha. It was once a very strong city, and placed by Eusebius about eight miles from Eleutheropolis.

MAKO, PAUL, in Biography, canon of the cathedral of Waizen, a learned Hungarian, descended from a noble family, was born at Jaffa-apatin in the year 1724; he entered the order of the Jesuits, and made such progress in his studies, that he was soon appointed teacher of logic and metaphysics at Tymau, and afterwards professor in the university of Vienna. He filled the same department afterwards in the Theresianum, where he procured, by his amiable disposition, the love and esteem of all the young nobility who frequented that seminary from almost every part of Europe; and when the Hungarian high school of Tymau was afterwards transferred to Olcen, the emperors, Mary Therese, appointed him a member of the academic senate. He exerted himself with great zeal and ability to introduce a table for scientific pursuits into Hungary; and during his moments of leisure, he purified, with unabating ardour, the belles lettres. He died in 1793. The principal works which he left behind him are: "Descritpo Provinciæ Moxtarum in regno Pe-tran, quam scripsit Episcopus Franc-Xav. Eder e Soc. Jes. Annis XV. facie apud colcem curiosum digereit, copulavit et adiutatam illustravit, P. Mak:; " Difertato PhyZ. de natura et remedii Fulminum;" " Elementa Mathesis.
MAL

MARAONDA, in Geography, a town of Africa, in Loango, on the sea-coast; 40 miles N.W. of Loango.

MARAONDA, a town of Hindooftan, in the country of Allahabad; 60 miles S. of Allahabad. N. lat. 24° 33'. E. long. 84° 37'.

MAKOVITZE, a town of Hungary; 16 miles S.E. of Palotza.

MAKOWSKI, in Geography, a town of Russia, in the government of Tobolsk, on the Ket; 48 miles W. of Enufelk.

MAKOW, a town of Persian Armenia; 81 miles S. of Erivan—Allo, a town of the duchy of Warsaw; 40 miles N.N.E. of Warsaw.

MAKRAN. See MECRAN.

MAKRAN, a town of Arabia, in the province of Hedjias, the residence of a feechie.

MARCHOU, a town of Arabia, in the highlands of Hedjias, the residence of an independent foreign seechie, whose domain contains several towns and villages. This seechie is of the tribe of Harb, and he is so powerful that on occasion he can bring 2000 men into the field. During the months favourable for pasturage, the most distinguished persons of this tribe live in tents; during the residue of the year, they inhabit the towns and villages. The lower clans live commonly through the whole year in huts thatched with grafs. Their principality is situated upon the mountains between Mecca and Medina. The chief of the tribe of Harb is the person who principally harasses the caravans, and lays them under contribution. Unless the Syrics and Egyptians pay the tribute he demands, for permission to pass through his territories, he murders up an army of his own subjects and his neighbours, all of whom are very willing to pillage a caravan.

MAKSENOKVA, an oitrog of Russia, in the government of Irkutsk, on the coast of the Frozen sea. N. lat. 72°. E. long. 134° 24'.

MAKSIMA, St., a small island of Russia, in the Frozen sea. N. lat. 71° 20'. E. long. 133° 34'.

MARSUBECH, a town of Perlia, in Farfistan; eight miles S. of Komhia.

MAKSYEN, a town of Bulgaria; 50 miles W.S.W. of Ismael.

MAKTHIN, a town of Beftarabia; 34 miles S.S.W. of Akerman.

MAKU, or St. Thaddeus, a town of Perlian Armenia, on the Akfai, a river which runs into the Aras; 60 miles S. of Erivan.

MAL DES AHENDS, or Morbus ardeantium, in Medicine, terms which have been applied by some medical writers to two or three different epidemic diseases, in an acceptation nearly synonymous with the ignis Siti, Antonii, and ignis fæcræ of others. See Ignis fæcræ, and Ergot.

MALA, or DEMAUL, in Geography, a town of European Turkey, in the Morea; 45 miles S.E. of Argos.

MALA, a river of Peru, which runs into the Pacific ocean, S. lat. 12° 40'.

MALA, a river in Botany, a name by which some authors have called the poma amoris, or fruit of the lycopepericon.

MALAAC, in Geography, a town of Meckley, 12 miles S.S.E. of Munnypour.

MALABAR, a name given to the western coast of Hindooftan, from Cape Comorin to about 100 miles S. of Goa.

The name of Malabar is said to be derived from the Malabar word "Malayalam," denoting "mountainous;" the terminations ar, tar, and bar, signifyng, in that language, a people or nation; consequently "Malevar" or "Malebar" would denote as much as "mountaineers," or "inhabitants of the mountains." The syllable lat, when uttered with rapidity, takes the sound of la, and the name of Malabar was applied to the people, from the hilly country, who defended from the mountains, and settled upon the coast. That tract of country which is properly called the Malabar, lies nearly in the direction of N.W. and S.E. from Cape Comorin to Canara, between the 18th and 14th degrees of north latitude; to the east, it is divided from the coast of Coromandel, by a high range of mountains, called the "Ghauts," and to the south-west it is washed by the Arabian sea. The principal kingdoms which it comprehends are those of Travancore, Cochin, Cranganore, and Calicut; of which the first has become the principal and the most powerful. The Malabar, or rather the forts of Coylang, Cali Coylang, Cranganore and Cananore, established by the Portuguese on that coast, were conquered by the Dutch in the years 1662 and 1663, and they long retained the possession of all, except Cananore. The extent of the Dutch company's possessions from Coylang to Chittus, Cananore not being under their dominion, comprised, from S.E. to N.W. a distance of 32 leagues; but if we except Paponettty, (which fee) and some small districts interfaced along the coast, the company possessed no other actual property on the soil than that upon which their fortifications were constructed. The land is every where low, intersected by many rivers, which descend from the interior mountains; it abounds in plantations of trees, and more especially of the cocoa-nut tree, and affords a very pleasant prospect. The rivers render it extremely fertile, particularly in rice; the sea furnishes a copious supply of fish, and provisions are cheap. The seasons are distinguished into the dry and rainy, called the bad and good monsoon; the former being reckoned from October to April, and the latter comprehending the other months. This division is occasioned by the mountains of the Ghauts; for upon the coast of Coromandel, the reverse takes place with respect to the monsoons.

The first and principal article of trade produced upon the coast of Malabar is pepper, which is very abundant, and reckoned the best in Asia. The Areca nut is the second production of the country; and this is conveyed by land to all parts of the peninsula, and likewise by sea, to the coast of Coromandel, and to Bengal. A third production is the wild Cinnamon (Caffia lignea), of which it is said that a quantity of one million of pounds is yearly exported to the gulf of Peria, and to the Red sea; and a small proportion is sent to Europe, where it is principally used to adulterate the genuine, or Ceylon, cinnamon. Coarse cotton cloths are also made in the southern parts, in the Travancore country, which, without forming a considerable object of trade, were mostly
MA L

mostly disposed of to the English at Anjengo. Capok forms
also an article of trade, and is exported to Bengal, to the
coast of Coromandel, and to China.

The native inhabitants of the country are inclined to
be lean; they are usually of the same size and stature as the
Gentoos at Surat and in Bengal; but they are much blacker,
early as black as the African negroes, though with better
formed countenances. Their religion is that of the Hind-1
doos, but many of them have been converted by missionaries
to the Roman Catholic persuasion, and they have many Ro-
mans Catholic churches. Here are also many Christians, of
those denominated Christians of St. Thomas. Among the
Malabars, the "Nairs" are the nobles and warriors of the
land, who are distinguished by the feymetar which they al-
ways wear, and who possess many privileges above the com-
mon people. Their princes possess almost an absolute au-
thority over their subjects. Besides the original Malabars,
many other people have been allured to settle here, by the
profits of trade; such as Moors, Arjubans, Pefrians, and a
 colony of Jews, who, as they pretend, are the potteries of
the ten tribes carried away into captivity by Shalmanefer.
There dwell in a separate town, in which are three syna-
gogues. The towns, or villages, which they inhabit, and
where they are employed in trade, has received the appella-
tion of "Makwan-Sierry." 

Cochin was sold by the Dutch to the king of Travanc-
core, taken from him by Hyder Ali, and re-taken by the Eng-
lish in 1792. Cochim, Quilon, Quilla-Quilon, and the other
settlements of the Dutch, on the coast of Malabar, have
shared the fate of the greater part of their Indian polfife-
sions, and are actually in the hands of the Englih.

MALABAR, Cape, or Sandy Point, a narrow strip of land,
projecting from the S.E. part of cape Cod, in the Massa-
achusetts, eight miles S. by W. N. lat. 41° 33'; W. long.
70° 3'.

MALABAR Nut, in Botany, a species of the juglicia; which
see.

MALABATHRUM, among the Ancients, an excellent
sweet-temented ointment.

MALABATHRUM, Indian leaf, in Botany. See TAMAL-
PATRA.

MALABRIGO, in Geography, a harbour on the coast
of Peru, in the South sea.

MALACATLAN, a town of Mexico, in the province
of Mechoacan; 16 miles S.E. of Colima.

MALACCA, or MALAYA, a peninsula of Asia, at the
extremity of the kingdom of Siam, surrounded by the sea,
except at its junction with this kingdom. The northern
limits are not firmly defined; but the peninsula is reckoned
to be about 80°, or 870 British miles in length, and in me-
dial breadth about 150 miles. It derives its name from the
Malays, who are mostly Malayans, and in a considerable
degree civilized; but the inland parts seem to be poftified
by a more rude native race, of which our knowledge is very
imperfect. In the east century Mandelil, or rather Ola-
rius, who published his voyage, describes Malacca as divided
into two kingdoms, that of "Patam" in the north, and that
of "Johor" in the south. The former was inhabited by
Malays and Siamefe; who were by profession Malayans,
and tributary to Siam. The town is built of reeds and
wood, but the moque of brick; and the commerce was
conducted by the Chinefe and Portuguese fellers, while the
native Malays were chiefly employed in fishing and agriculture.
From this traveller we learn, that in Malacca there are
continued rains with a N.E. wind during the months of
November, December, and January. Agriculture was con-
ducted with oxen and buffaloes, the chief product being rice.
Game and fruits were abundant, and the forests swarmed
with monkeys, tiger, wild boars, and wild elephants. Be-
side the tiger and elegant, Malacca produces the civet-cat,
and Sumatran says that wild men are found here, meaning
perhaps orang-outangs. Some singular birds are also found;
and it likewife produces a delicious fruit called the Mangof-
ten. The Portuguese were accustomed to purchase annually
from Patani about 1500 cattle for their settlement at Ma-
lacca. The kingdom of Johor comprehended the southern
extremity of the Cheronefe, and its chief towns were
Linga, Bintam, Carimon, and Betufabae, the last of which
was the capital, situated in a marshy situation, on the river
Johor, about fix leagues from the sea, and confiffing of
houtes elevated about eight feet from the ground. The
whole of this country belonged to the king, who alligned
lands to those who demanded them; but the indolence of
the Malay left it to the wild luxuriance of nature. Ac-
ccording to the account of Valentin, the peninsula of Ma-
lacca is bounded on the north by the river Riadang, which
runs by Lings to the eafe, and by a small range of hills
that separate it from the kingdom of Siam; and it contained
five provinces, which derive their names from their capitals.
On the easterm coast are those of Patani and Pahang, followed
by the most southern kingdom of Djohor or Johor; and on
the western coast are those of Keidah, or Quehad, and Perah,
followed by another province called the Malay coast, and
of which the capital is Malacca. The inland part of the penin-
insula seems to remain full of extensive and original forests,
without towns or villages; but the country, though not suffi-
ciently explored, is now known to produce pepper and
other spices, with some precious gums and woods. The
chief mineral is tin, in which Quehad and Perah, as Hamil-
ton denominates them, are rich; and a high mountain N. E. of
Malacca supplies rivers that afford small quantities of gold
dust. In the river Pahuang, flowing near the town of Ma-
lacca, lumps of gold about five or fix ounces in weight have
been found at the depth of from three to ten fathoms. Of the
government of Malacca we may form an idea from the account
which Mr. Marsten has given of that of the Malays in Sumatra.
See Menangaeaw.

From an account of the ancient history of this coun-
try, cited by Valentin in his " Description of the Dutch
Settlements in the East Indies," 1726, from a Malay MS.
written in the Arabian character, we are led to believe,
that the Malays were first settled on the eastern coast of
Sumatra, in the kingdom of Palambang, opposite to the
isle of Banca, at the river Malajee, which encircles the
mountain Mahamirar, and afterwards joins the river
Tatang. Some have supposed that the river derives its
name from the Malays; but Valentin is of opinion that they
derived their name from the river, and communicated it to their
present peninsula, which formerly belonged to the king of
Siam, and was inhabited by fishermen. This MS being re-
cent, we can only infer from it that the Malays came from
the west. The traditions founded on this and other simi-
lar MSS. report, that the Malays, during their residence
in Sumatra, chose a king, who reigned 48 years, and pre-
tended to be a descendant of Alexander the Great. This
happened about the year 1160 of the Chirilian era. Dur-
ing this reign, it is said, the Malays proceeded to the oppo-
site coast and settled on the N.E. corner, whence they gra-
dually spread, and the country assumed the name " Tanah
Malacca," or Malay land, extending from 3 to 11 N. lat.
After a residence of some years, the Malays built their first
town " Singapour," which gave its name to the southern
fleet.
The last king of Singapora was compelled by a hostile sovereign of a district in the isle of Java to retire northward, where, in the year 1523, he built a new capital, called Malacca, as it is said, from the name of a tree, the Mirabolon, under which he had taken shelter, while he was hunting. Having established salutary laws, he died in the year 1274. As this king had adopted the appellations "Shah" and "Sultan," it furnishes a presumption that Mahometanism was now introduced. The second in succession after this prince, who is said to be the first Mahometan sovereign, reigned 57 years. He extended more widely the name of Malacca, and having acquired by marriage the kingdom of Aracan, he died in 1333. In process of time, the commercial town of Malacca was regarded, with Madjapte and Po6, as the third celebrated city in these regions. Sultan Mahomet Shah, who ascended the throne in 1374, and in the course of his long reign of 73 years, annexed by marriage the kingdom of Andragin on the E. side of Sumatra, to Malacca, became so powerful that he was styled emperor. In consequence of an alliance with the emperor of China, whose daughter he married, he subdued the kingdom of Pahang. Malacca was now exalted the chief city in these parts of the eastern world. Mansoer died in 1447. During an inglorious reign of his son and successor, the 11th king of the Malays, the 6th of Malacca, and the 5th who professed the Mahometan religion, Malacca became subject to Siam; but at his death, in 1477, he was succeeded by a prince, under whose government, in the year 1509, the Malys threw off the yoke of Siam. It was in this year that the Portuguese discovered Malacca, to which they were led by the vain idea of finding the golden Chersonese of the ancients.

With this view Emanuel, king of Portugal, sent out a fleet of 16 ships under the command of Sequeira. Among the officers of this fleet was Magalhaens or Magellan, who afterwards became the first circumnavigator of the globe. Many attempts were made to affiliate Sequeira, and finding it impossible to make a commercial arrangement advantageous to his country, he returned to Portugal. At this time Albuquerque (see his article) was the Portuguese viceroy in the East Indies. On the 1st of August, 1511, he arrived before Malacca with a powerful fleet, while the king of Pahang was in the town on occasion of celebrating his nuptials with the daughter of sultan Mahumud Shah, the sovereign of the peninsula. Malacca was taken by storm; and the king fled to Johor, where he founded a new town and kingdom. The Portuguese, having gained complete possession of Malacca, formed an alliance with Siam. The king of Johor died in 1513, and was succeeded by his son Sultan Ahmad Shah, who afterwards made a treaty with the Portuguese. Among the Portuguese governors of Malacca was Peter Macarena in 1526, from whom it is said, derived the name anciently given to the isle of Bourbon. During the reign of a sovereign, called Alavoodin, who took possession of the throne in 1591, the Dutch arrived, and formed an alliance with this prince against the Portuguese. In 1566 the Dutch, in conjunction with the king of Johor, attacked Malacca; and they made various attempts in succeeding years to gain possession of the country. But they were obliged to content themselves with a factory in Johor. At length Anthony Van Diemen, the famous governor-general of the Dutch settlements in the East Indies, finding a favourable opportunity for the execution of his purpose, dispatched in June 1640, a fleet of 12 ships and five sloops to blockade Malacca; and these were joined by about 20 small vessels of Johor. The Dutch soon erected a battery, and the siege was accompanied with famine and pestilence. In January, 1541, the famine was so severe, that the inhabitants were obliged to expel their women and children. The Dutch also suffered much from heat and fatigue; and at length impatience and desperation produced a general affright, which was executed on the 14th of January; and the governor capitulated. Valentina reports, that during the siege more than 7000 died in the town, and a greater number found means to escape. The Dutch lost about 1500, chiefly by the plague. Thus the Portuguese, after a possession of nearly 130 years, lost this valuable settlement, then cleared, after Goa, the richest in the East Indies. Malacca, which is represented as a strong place, was taken possession of by the English in August 1795. The Malay empire is now added to the dominions of Great Britain in the East by the capture of Java, in consequence of which Britain is become the mistress of the whole of the Malay Archipelago.

The Malys, whose origin is not satisfactorily ascertained, are in general a well made people, somewhat below the middle stature. Their limbs are small, but well shaped, and they are particularly slender at the wrists and ankles. Their complexion is tawny, their eyes large, their noses seem to be flattened more by art than nature; and their hair is very long, black, and shining. They are reckoned the most ingenious, sagacious, and polished people in the East Indies. As the Malys resemble the Chinese and Tartars in their features, it has been conjectured as probable that they are descended from those nations. Their progenitors from Malacca, across the narrow strait of that name, to Sumatra, thence to Java, and from Java to all Polynesia, was so easy, even in the most frail vessels, that there is no difficulty in accounting for their being found, as they really are, in possession of the sea-coasts almost every island. Mr. Marden, in the last edition of his valuable work, seems to have reiterated the opinion which he once held of Malacca being the original country of the Malys, and to think that they puffed thither from Sumatra. Not only their physical appearance, but their manners and customs, as well as language, have undergone a considerable change by the overwhelming influence of the Arabs, who from the 9th to the 14th century, appear to have enjoyed the exclusive commerce and dominion of the oriental isles, the greater part of which has received the religion of Mahomet. These people in former times possessed great powers, and made a very considerable figure on the theatre of Asia; and their country was well cultivated and populous. The sea was covered with their ships, and their commerce was very extensive. At different times they sent out various colonies, which in succession peopled a great part of Sumatra, Java, Borneo, Celebes, and Macalcar, the Moluccas, the Philippines, and those innumerable islands of the Archipelago, which bound Asia on the E. and which occupy an extent of 700 leagues in longitude from E. to W., and about 600 in latitude from N. to S. Every where the people seem to be the same. They speak almost the same language, and they have the same laws and the same manners. To this purpose Kamper says in his 'History of Japan,' that the Malayans had in former times the greatest trade in the East Indies, in which their merchant ships are not only all the coasts of Asia, but ventured even to the coasts of Africa, particularly to the great island of Madagascar. That the Malayan people have not only frequented Madagascar, but that they have been the progenitors of some of the present race of inhabitants, is confirmed by the testimony of M. de Pages, who visited that island so late as 1774. The title which the king of the Malayans affumed to himself, says Kempfer, of 'Lord of the Winds and Seas.
MALACCA.

to the East and West, is an evident proof of their extensive migration; but much more the Malay language, which spread almost all over the East, much after the same manner as formerly the Latin, and of late the French, did all over Europe.

M. le Poivre, cited by Mr. Pennant in his "Outlines of the Globe," says, that travellers, who make observations on the Malays, are all sworn to find in the centre of Asia, under the scorching climate of the line, the laws, the manners, the customs, and the prejudices of the ancient inhabitants of the north of Europe. The Malays are governed by feudal laws, "that capricious & flem, conceived for the defense of the liberty of a few against the tyranny of one, whilst the multitude is subject to slavery and oppression." Thus have we a chief, who has the title of king or sultan, affixing his commands to his great vessels, who obey when they think proper; these have inferior vessels whose conduct is similar to that of their superiors. The "Oroman," or noble, forming a small part of the nation, live independent, and sell their services to those who are disposed or able to give them the belt price; whilst the body of the nation is composed of slaves, and lives in perpetual servitude. With these laws, says M. le Poivre, the Malays are reftles's, fond of navigation, war, plunder, emigrations, colonies, desperate enterprises, adventures, and gallantry. They talk incessantly of their honour and bravery, whilst they are universally considered by those with whom they have intercourse as the most treacherous and ferocious people on the face of the globe; and yet, which appears extremely singular, they speak the most refined language of Asia. The ferocity of the Macassars is the reigning characteristic of all the Malay nations, and as an evidence of their faithfulness and treachery, it is alleged, that their treaties of peace and friendship never subsist beyond that self-interest by which they were induced to make them; and they are almost always armed, and either at war among themselves, or employed in pillaging their neighbours. Their ferocity, misnamed courage by the Malay, is so well known to the Europeans who have settlements in the Indies, that they have universally agreed in prohibiting the captains of their ships, who may put into the Malay islands, from taking on board any kajen of that nation, except in the greatest extremities of necessity. But it appears not uncommon for a few of these horrid savages suddenly to embark, attack a vessel by forrige, poignard in hand, massacre the people, and make themselves masters of her. Malay barks, with 25 or 30 men, have been known to board European ships of 30 or 40 guns, in order to take possession of them, and murder with their poignards great part of the crew. These Malay who are not slaves always go armed; and they would think themselves disgraced if they went abroad without their poignards, or crifes.

The attire of the males consists of pantaloons with a wide robe of blue, red, or green; the neck is bare, but the head is covered with a turban. The female dresses, like that generally used in the East Indies, is a long narrow petticoat, reaching from the breast to the feet, whilst the other parts are naked, and the hair is commonly tied. The women are reckoned more intelligent than most others in the East, and their conversation is of course sensible and agreeable.

The other inhabitants of Malacca are Portuguese, Moors, and Chinese, and some settlers from Bengal and Guzerat. The chief articles of commerce areazel wood and camphor from the kingdom of Pahang; tin, gold, pepper, pedra de porco, and ivory. The manufacturers are various articles of drefs, worn here and in Hindoostan, cottons, chintz, &c. and some articles of copper. When Malacca came into the possession of the Dutch, the Dutch East India Company appointed the governor, under whose control were several factories, one in the peninsula, and others on the coast of Sumatra. The factories are those of Pernambuco, Perah, on the Malay coast, for the tin trade; of Keulah, or Qualah, on the same coast, for carrying on commerce with the petty king of Xeelah, for tin, gold, and ivory; of Oedjan-Salang, for tin and ivory; of Andirigiri, on the coast of Sumatra, for pepper and gold. The Dutch also traded with Ligur and Tannerven, in the dominions of Siem, for tin; and with Bangkobio, for gold and pedra de porco before the English established themselves there. The island Dending was also considered as a dependence of Malacca.

The language of the Malays, which is original in the peninsula, has been called the Italian of the east, on account of the melody of its frequent vowels and liquids, and the infrequency of any harsh combination of mute consonants. Their character is the Arabic. Mr. Marfden could never discover that the Malays have any original written characters peculiar to themselves, before they acquired those now in use; though it is possible that such may have been lost.

The adoption of the Mahometan religion has occasioned an influx of Arabic words into their language; the Portuguese have also furnished them with many new terms. They write on paper with ink of their own composition, and pens made of the twigs of a tree. The purest Malay is supposed to be spoken in the peninsula, and it has no inflexions of nouns or verbs; and, consequently, no cafes, declensions, moods, or conjunctions; all which inflexions are performed by the use of certain words expressive of a determinate meaning. The Malay language, or that which may be considered as its radix or foundation, has branched out into various dialects, that have been extended to all the islands of the eastern sea; from Madagascar to the remotest of Capt. Cook's discoveries, comprehending a wider extent than the Roman or any other tongue has yet boasted.

Of the connection and similitude of these various languages, Mr. Marfden has exhibited indubitable examples in a paper addressed to the Society of Antiquaries, and published in the "Archaeologia," (vol. vi.) In different places it has been more or less mixed and corrupted, but between the most dissimilar branches, an evident sameness of many radical words is apparent; and in some, very distant from each other in point of situation, e.g. the Philippine and Malagasy, the deviation of the words is scarcely greater than is observable in the dialects of neighbouring provinces of the same kingdom. See Marfden's History of Sumatra, and Dictionary.

In the third volume of the "Africall Researches" (p. 11 and 12.) Sir William Jones has pointed out, in a clear and decided manner, the connection between the Malayan and Sanritan languages; and Mr. Marfden (1d. vol. iv. p. 217.) observes, that the Malayan is indebted to the Sanritan for a considerable number of its terms. This ingenious writer conceives, that the intercourse by which this communication was effected must have taken place in times anterior, probably by many centuries, to the conversion of those people to the Mahometan religion; and before a great number of Arabic words, borrowed from the Koran and its commentaries, were introduced into the language. Our author, however, does not imagine, that the affinity between these languages is radical, or that the names for the common objects of life are borrowed from the Sanritan. The Malayan, as we have already said, is a branch or dialect of the widely extended language prevailing throughout the islands of the Archipelago, called the "Malay-archipelag," and comprehending the Sunda, Philippine, and Molucca islands, in the maritime parts of which the Malayan is used.
MALACCA, Strait of, the narrow sea between the island of Sumatra, and the peninsula of Malacca, extending from the equinoctial line to about 5° N. lat. This strait presents favourable opportunities for commerce, has been maintained for a long time, and in a considerable degree, with Bragal, Coromandel, Surat, Perla, Ceylon, Java, Sumatra, Siam, Tonquin, China, and other places. This was a convenient station for the vessels passing through the strait from Japan to Hindostan, and borne chose this route to Batavia. In this strait provisions are scarce, except fish and a few fruits.

MALACCA Stones, a name given by many authors to the pedr del porco, or hog-bezoar.

MALACHE, formed of μαλαχη, I often, a term used by authors in a different sense; sometimes expressing such medicines as gently soften the belly, and sometimes such ointments as relax and mollify.

MALACHI, the Prophecy of, is one of the canonical books of the Old Testament, written by Malachi, who, according to a tradition among the ancients, was of the tribe of Zebulon, and born at Sapha, after the return of the captivity from Babylon, and who died young. He was probably contemporary with Nehemiah, and must have lived after the time of Haggai and Zechariah, because his prophecy supposes the temple to be rebuilt, and the worship of God established in it. Usher places him in the year 416, and Blair in 436 B.C. Some have doubted whether Malachi was a proper name, or a general appellation, signifying the angel or messenger of the Lord. Malachi, 2:6,7,2, denotes “my angel;” but the LXX have rendered the word, his angel, and not my angel, as the original expresses it; and several of the fathers have quoted Malachi under the name of “the Angel of the Lord.” It is the opinion of the ancient Hebrews, of the Chaldean Paraphrast, and of St. Jerome, that Malachi was Ezra. The chief eruptions which he charges upon the Jews are the same with those for which they were reproved by Nehemiah; he forbids them to expect any farther succession of prophets, exalts them to observe the law of Moses, and predicts the coming of Elias, or John the Baptilst, as the forerunner of the Messiah.

Bishop Lowth, in his “Prælectiones,” says, that this book is written in a kind of middle style, which seems to indicate that the Hebrew poetry, from the time of the Babylonish captivity, was in a declining state, and being past its prime and vigour, was then fast verging towards the debility of age.

MALACHITES See COPPER, Ore of.

MALACHODENDRUM, in Botany, so called by Mitchell and Cavannites, from μαλακος, soft, and δενδρον, tree, on account of its soft or downy leaves. Hence also the origin of μαλακη, a mallock. This supposèd genus differs in nothing from Sturtia, to which we refer the reader, except in the separation of its five styles, which in the other

S, which is more considerable, called Palmaur. The shape of the town, which presents many broad straight streets, is that of a crescent.

Before the conquest of the Portuguese, Malacca was a fishing town; it afterwards contained 11,000 inhabitants; but in the time of Valentyn, the number had decreased to between two and three hundred Dutch, Portuguese, and some Malays in huts at the extremities of the town, who posseffed some plantations in the vicinity. Around the town are woods infested with wild beasts, especially tigers; and elephants are very numerous. This city was founded by the Mahometans in the 15th century, and held by the Portuguese till 1641, when it was feized by the Dutch. It gained great importance from its advantageous position for Indian and Chinese commerce. See the preceding article.

MALACCA Stone, a name given by many authors to the pedr del porco, or hog-bezoar.

MALACHE, formed of μαλαχη, I often, a term used by authors in a different sense; sometimes expressing such medicines as gently soften the belly, and sometimes such ointments as relax and mollify.

MALACHI, the Prophecy of, is one of the canonical books of the Old Testament, written by Malachi, who, according to a tradition among the ancients, was of the tribe of Zebulon, and born at Sapha, after the return of the captivity from Babylon, and who died young. He was probably contemporary with Nehemiah, and must have lived after the time of Haggai and Zechariah, because his prophecy supposes the temple to be rebuilt, and the worship of God established in it. Usher places him in the year 416, and Blair in 436 B.C. Some have doubted whether Malachi was a proper name, or a general appellation, signifying the angel or messenger of the Lord. MALACHITES See COPPER, Ore of.

MALACHODENDRUM, in Botany, so called by Mitchell and Cavannites, from μαλακος, soft, and δενδρον, tree, on account of its soft or downy leaves. Hence also the origin of μαλακη, a mallock. This supposed genus differs in nothing from Sturtia, to which we refer the reader, except in the separation of its five styles, which in the other
MALACHRRRA, like Malborough, and other genera, owes its derivation to 

Gen. Ch. Cal. Common Perianth large, bearing about five flowers, divided into three or five, heart-shaped, acute, permanent leaves. Flower of one leaf, bell-shaped, small, five-leaf, permanent, set round with bristle-shaped scales. Cor Petals five, ciliate, entire, adhering below to the tube of the flower. Stam. Filaments numerous, united below into a tube, gaping and looie above, over the whole surface of the cylinder; anthers kidney-shaped. Fil. German orbicular; style cylindrical, ten-cleft; stigma glos- bofe. \textit{P. ric}. Capsules five, aggregate, roundish, comprefsed on one side, gibbous on the other. Seeds solitary, roundish, angular.

Obf. Cavanilles has remarked, that, in \textit{Malachra}, the divisions of the style and the stigmas are twice as many as the capsules.

Leaves 
filifh, furnished with awl-shaped Ripples. 
Flowers \textit{aggregate}, small, yellow.

Leaves on long, hairy filifh-talks, the lower ones five-lobev at the margin, the upper ones three-lobed. 

Flowers axill- ary, small, biffh-coloured on the outside; white, with purple flecks, within.

Leaves alternate, heart-shaped at the bale, veiny, widely spreading, obtusely ferated or notched. 
Flowers axillary, rather small, of a deep yellow colour.

Leaves palmate. — Found at St. Domingo. — Stem fix feet in height, tender, round, whitifh-green, hairy. 

Leaves crenate, hairy, bright green. 

Flowers small, yellow.

5. \textit{M. brachyta}. Willd. n. 5. Cavan. Diff. t. 34. f. 2. — Flowers many in a head, bracved. Leaves palmate.

— Native of America. — Stem, like the whole plant, very hairy. 

Leaves crenate, with few deep, acuminate lobes. 

Flowers about fourteen in each head, white, streaked with red at the bottom.

6. \textit{M. plumosa}. Willd. n. 6. (Sida plumosa; Cavan. Diff. t. 12. f. 4.) — Flowers many in a head. 
Leaves undi- 
vid- d, elliptical, toothed. — A native of the Brazils. 

Leaves truncated. 

\textit{Malacocarpus} of many leaves, the outer ones ellipti- 

cal and toothed, the inner linear and fringed.

MALACIA, \textit{parasara}, nearly lynnornous with \textit{pica}, and \textit{cit}a, signifies a depraved appetite, which induces the patient to desire to eat things which are indigfeible, and not capable of affording nutrient; or that fort of deprivation of appetite, which was formerly deemed a fort of privilege attached to the state of pregnancy in women, which induced them to long for some particular food, with extraordinary earnefthens, and eat of it to excess. While the danger of refusing indulgence to the long, was held as an axiom, they appear to have occurred perpetually; but they are now generally treated with ridicule, and therefore are seldom heard of. See \textit{Pica}.

MALACODERMATA, formed of \textit{malaco}, fof, and \textit{derma}, skin, in \textit{Natural History}, a term used to express such animals as have only soft skin for their covering; in oppo- 
sition to the \textit{ftracodermata}, which have hard matters for their covering, such as crabs, lobsters, &c.

MALACOIDES, in \textit{Botany}. See \textit{Malope}.

MALACOLITE, in \textit{Mineralogy}. See \textit{Sahlite}.

MALACOPTERIGII, in \textit{Ichthyography}, the name of a large order of fishes, which have not prickly fins.

The term is derived from the Greek \textit{malaco}, fof, and \textit{ptera}, a fin. The fith of this order, are those which have bony fins, with all their extremities not pointed or thary, but soft and harmef. Of this order are the carp, &c.

MALACOSTEON, (from \textit{malaco}, fof, and \textit{osteum}, a bone) in \textit{Surgery}, a morbid fofness of the bones. See \textit{Mollities Ossium}.

MALACOSTOMOUS, in \textit{Ichthyography}, the name of a large genus of fishes, called in English the leather-mouthed kind. These fishes are wholly deliu te of teeth in their jaws, and have them placed in their throats, near the orifice of the flomach.

The word is derived from the Greek \textit{malaco}, fof, and \textit{os}, mouth. All the fith of this genus have their twinning, or arc-bladder, divided into two parts, and of this genus are the carp, tench, bream, chub, and like.

MALACOSTRACA, in \textit{Natural History}, a term used by some, as Airilottio, to distinguish what we call \textit{ftracous} animals of the sea, &c. From those which he calls \textit{ftracodermata}, or teflicose, as we express it. See table of \textit{ftracose and \textit{ftracous} animals. See \textit{Cruftaceous}.

MALACOTTA, in \textit{Geography}, a town of Africa, in the country of Warada; the inhabitants manufacture soap from the oil of ground nuts: 42 miles E. of Satado. N. lat. 12° 30'. W. long. 9° 15'.

MALADUGNO, a town of Naples, in the province of Otranto; 9 miles N.W. of Otranto.

MALAGA, a small, but very ancient city of Spain, in the province of Granada. It was built by the Phcenicians several centuries B.C.: and it was called "Malaca," or "Malaca," on account of the great quantities of salt fish sold here. In process of time, it passed successively under the dominion of the Carthaginians, Romans, Goths, and Moors. Strabo says, that a great quantity of salt was manufactured in its environs, which was disposed of on the opposite coast of Africa. That it was a place of importance under the Romans, we may infer from the wrecks of monuments which have been discovered in its vicinity. Some of these remains, which have been found on the eminences where the light-houfe is placed, and where the castle called by the Moors "Gibert" stands, have been thought to have belonged to a magnificent Pharon, or perhaps to a temple built on this spot by the Romans. It was not till the year 1487, that Ferdinand and Isabella recovered Malaga, after an obstinate reliance, from the dominion of the Moors. Malaga is situated on the coast of the Mediterranean, at the bottom of a deep bay,
on a foil of flate and limetone. To the south it has the sea: to the west it opens into a fertile plain, watered by two rivers; and to the east and north, it is protected by lofty mountains, the tops of which are sometimes covered with snow, and the sides with olive, almond, orange and lemon trees, and vineyard grounds. The town cannot be called handsome, though the houses are high: the streets are narrow, ill paved, and dirty; and it has not one good square. It has, however, a marble fountain, very finely executed, which was a present from the republic of Genoa to Charles 1. The town has three fayoubours. It is the see of a bishop, suffragan to the archbishop of Seville, and the bishopr is worth 150,000 ducats, or 16,439/. 9. 10d. but one-third of this revenue is dispensed of by the king. The whole chapter consists of the bishop, with eight dignitaries, twelve canons, twelve minor canons, and the fame number of prebendaries. The dean receives 600l. a-year; but the other dignitaries only 450l. The town has four parish churches, two chapels of ease, twelve monasteries, ten nunneries, four hosteries, six hospitals, and several chapels and oratories. Of the friars, the Franciscans take the lead, and are held in greatest veneration by the common people; and among these, the Capuchins are the most useful members of society, devoting themselves to the service of the poor. Malaga has a civil and military governor, a king's lieutenant, a major, a minor, and a fixed regiment of infantry of three battalions, bearing its name and attached to the place; an alcaide major for the administration of justice, a municipality composed of a certain number of regidores, a post-captain, a minister and an auditor of the Marine, and a board of public economy. This town has also a college for the instruction of youth, and another college, under the title of St. Elmo, for the instruction of mariners. The population of Malaga under the Moors, was reckoned at 86,000 inhabitants; and in 1747 it was reduced to 32,000; it is now estimated at 50,000, according to the statement of La Bordé; but Mr. Townfend, in his "Travels," mentions the number at 41,593, of whom the greatest proportion consists of females.

Of the buildings, public or private, the only one, particularly worthy of notice, is the cathedral, begun in the year 1528, and, says Mr. Townfend, not yet completed. It is 360 feet by 165, and 135 in height. The choir in this edifice is admirable on account of its carved work, which represents, in very bold relief, the twelve apostles, and the most distinguished saints. The custom-house was erected on a magnificent plan in 1792. The confratule at Malaga have founded a very beneficial establishment, which is a "Mont de pieté," designed for lending money without interest to farmers, in order to prevent their selling their commodities, particularly wines, at a great loss. The funds of this institution arise from vacant benefices.

The port of this town is large and secure: it has water for first-rate ships of the line, and holds 400 merchant men, and 19 men of war. Ships may fall in and out with every wind, and are well sheltered in the harbour, particularly from the N. and E. winds, which are here the most violent. For greater safety two piers have been lately constructed. Malaga has a considerable trade, particularly with England, its imports consist of broad cloths and iron ware, which it takes from the English; of mercury, from Germany, and more especially from Hamburg; and spices, cutlery, tapes, and lace, from Holland. It furnishes those countries, as well as Italy and the northern nations, with wine, fruits, sarsaparilla, and oil. Its exportation of wine alone amounts to about 400,000 quintals yearly, and that of raisins to 250,000 quintals. The amount of the imports is valued at 1,800,000 palisones, or 281,250l. sterling: that of the exports at 3,100,000 palisones, or 515,025l. sterling; so that the balance of trade is in its favour.

The town is a bay on the east coast of the island of Leytia. N. lat. 10° 30'. E. long. 125° 12'.

MALAGAMA, formed of παλαμηδα, I often, a word used by some authors to express a capatalion in general, of whatever nature, or made of whatever ingredients; but some have used it only for eminent captalizations.

MALAGRIDEDA, GABRIEL, in Biography, a native of Milan, and a member of the society of the Jesuits, who was burnt at an "auto da fé," at Lisbon, in the year 1761, as a heretic and false prophet. He had been sent out as missionary to Portugal, where he became exceedingly popular, by his insinuating address, and the fluency of his oratory: he was elevated as a saint, and canonized as an oracle. When the duke d'Avorio was convicted of a conspiracy against the life of the king of Portugal, Malagrida was accused of being an accomplice in the plot: he was pronounced guilty of the charges exhibited against him, but whether with or without justice is a matter of dispute; at any rate, advantage was taken of it to banish all the Jesuits from Portugal, excepting Malagrida and two others, who were referred for punishment. To this probably the confedent of the king could not be obtained, and, therefore, another method was adopted for getting rid of him. He was accused of heresy; in proof of which, two of his treatises were appealed to, viz., one entitled "Tractatus de Vita et Imperio Antichristi;" and the other, written in the Portuguese language, entitled "The Life of St. Anne, composed with the Affiliation of the blessed Virgin Mary and her most holy Son." From these, several extracts were collected that were pronounced extremely heretical; and others were added to prove that he had claim to the power of working miracles; and he also affirmed that God himself had declared him his ambassador, his apostle, and prophet. He was burnt on the 21st of September 1761.

MALAGUETTA, in Geography. See Grain Grass.

MALAHIDE, a town small town of the county of Dublin, in the province of Ireland, 9 miles E. of Schiras.
MAL

Ireland, situates on the Irish sea. There is a well here, dedicated to the Virgin Mary; and also a castle, now the residence of the Talbot family. It is two miles E. from Swords.

MALAI, a town of Arabia; 15 miles S. of Medina.

MALAKERY, a town of Hindostan, in Myfory; 2 miles N.E. of Seringapatam.

MALALAIS, a small island in the sea of Mindoro. N. lat. 11° 18'. E. long. 12° 51'.

MALALEO, a port on the north-west coast of the island of Tappa, in the East Indian sea. N. lat. 0° 6'. E. long. 122° 55'.

MALAMBETO, a town of South America, in the province of Carthage; 40 miles E. of Carthage.

MALAMBO, or BARRANCA DE MALAMBO, a town of South America, in the province of Carthage; 55 miles N.E. of Carthage.

MALAMOCO, an island in the Adriatic, about four miles long and half a mile broad, near the city of Venice; upon which island is a town of the same name, containing about 1100 inhabitants. Besides the cathedral, which is the parochial church, it contains a nunnery, a church, and some neat buildings. This was annually the chief town of the Venetians, the residence of government, and the seat of a bishop. The port of Malamoco is situated at the fairest point of the shore, towards Chioggia, and is defended by two forts, viz. St. Pietro and Della Punta. It is the fairest and most convenient port, and therefore most frequented; but on account of its sand-bars and shallows, ships cannot enter into it without pilots. At this port was constantly garrisoned some thousands of regular troops.

MALANDERS, MALANDIA, a district in hores, so called from the Italian malandarsi, to go ill.

It conflicts in certain ulcerous chaps, or chinks, appearing on the inside of the fore-legs, just against the bending of the knee, which void a red, fliryp, and pungent humour.

This distemper may be cured by washing the parts with a warm lather of soap, or old chamber-ley; and then applying over the cracks a strong mercurial ointment, spread on tow, with which they should be dressed night and morning, till all the scabs fall off; but if this treatment fail, make an ointment of half an ounce of oelthiops mineral, one dram of white vitriol, six ounces of soft green soap; and having clipped off the hair, and cleared away the scabs, anoint often with this, and apply the above unguent over the sores. When they dry up, give a gentle purge or two; or let the nitre balls be taken for two or three weeks. Bartlet.

After washing the parts with soap and water, Mr. Denny advises to rub on a powder, made by mixing together vitriolated zinc and alum, of each pulverized half an ounce twice a day. Mr. White recommends the following ointment, prepared by mixing two ounces of ointment of wax, one ounce of olive oil, oil of turpentine and camphor, of each a dram, and two drams of acetated water of litharge. For the same purpose, Mr. Ryding recommends to mix one ounce of strong quicksilver ointment and ten grains of muriated quicksilver in fine powder.

MALANEA, in Botany, received its name from Aublet, but has been referred by Schreber and Willdenow to another genus CUVINGHAMIA (see that article). Julien and Laimark, however, retain the original name; but we are utterly incompetent to trace its derivation, of which Aublet himself gives no indication.

MALANEE, in Geography, a small island in the Florida stream. N. lat. 24° 56'.

MALANOEO ISLANDS, two small islands in the North Pacific ocean, near the east coast of the island of Luzon. N. lat. 18° 2'. E. long. 122° 28'.

MALANGER, a town of Norway, at the northern extremity of the diocese of Drontheim.

MALANOVA, a town of Ruffia, in the government of Trebolk, on the Iritich; 28 miles N. of Tara.

MALAO, a town on the north-west coast of the island of Mindanao.

MALAPERT, CHARLES, in Biography, a learned Jefuit and excellent mathematician, was born at Mons in the year 1581. He entered into the order in 1600, and was afterwards elected professor of mathematics in Poland; and he next filled the same office in the Jefuits' college at Doway. In 1630 he was appointed, by order of Philip IV, mathematical professor in the new university at Madrid; but he died on his journey to that capital, being in the 50th year of his age. While he was in Poland he published a volume of poems, which have gone through many editions; but his most important works were mathematical. In one, entitled "Oratio de Laudibus Mathematicis," he treats of the phenomena of the newly-discovered Dutch telescope. He published the "Institutions of Practical Arithmetic," and the "Elements of Geometry," "A Paraphrase on the Dialectics of Aristotle," and "Commentaries on the first six Books of Euclid."

MALAR. See MELAR.

MALARIA, or MALARUM OSSA, in Anatomy, a pair of bones belonging to the face, and corresponding in situation to the cheek. See CRANII.

MALARMAT, in Ichthyology, a name given by authors to the fulh called by some lyra altera, and cornita. It is a species of the trigla, and is distinguished by Artedi by the name of the trigla with many cirri, and with an octagonal body. See TRIGLA CATAPHRATA.

MALAKUM OSSA, in Anatomy. See MALARIA.

MALASHLAH, in Geography, a town of Africa, situated on the Atlas, in the southern part of Algiers; 170 miles S. of Algiers.

MALATIA, a town of Asia Turkish, in Aladulia, situated on the west side of the Euphrates; the residence of a Jacobite and Neferian bishop. This town was taken in 1126 by Tunur Bec. The Multifitians redeemed themselves by money, and the Christianes were made slaves; 90 miles W.N.W. of Diarbekir. N. lat. 37° 56'. E. long. 38° 18'.

MALATIVOE, a fortified port of Ceylon, in a romantic and delightful situation, between Trincomalee and Jaffnapatam. Here the Dutch had a small factory, and a house for the commanding officer. It depended upon the garrison of Trincomalee, and was employed chiefly as a port of communication, and to collect provisions for that garrison. For these purposes, and to keep the natives in awe, a few Malay or Sepey soldiers were stationed here; but it never was considered as capable of any defence. Close to the fort is a small village; and a river, which here falls into the sea, forms a harbour sufficient to admit small craft. The principal employment of the inhabitants is fishing; and with this article they supply the fort of Trincomalee. Cattle and poultry are abundant and cheap. Game is plentiful, and the woods abound with wild hogs and deer. Perov's Ceylon.

MALATS, in Chemistry, are salts formed by the union of muriatic acid with alkaline, earthy, or metallic bases. See MALIC Acid.

MALATZKA, in Geography, a town of Hungary; 14 miles N. of Preburg.

MALAVERD, a town of Peria, in the province of Iran; 45 miles N.E. of Isphahan.

Mala-
MALAUCENE, a town of France, in the department of the Vaucluse, and chief place of a canton, in the district of Orange; 14 miles E. of Orange. The place contains 2,556, and the canton 5,458 inhabitants, on a territory of 18,569 kilometres, in 7 communes.

MALAVISTA, a town of the island of Cuba; 36 miles W. of Villa del Principe.

MALAXIS, in Botany, a name applied by Professor Swartz to this new and very distinct genus of the Orchis tribe, established by Dr. Solander and himself. The word, malaxis, expresses rotundity, and seems to allude to the deficiency of habit and structure which marks these plants.—Swartz Act. Holm. ann. 1789. 127. t. 6. f. 2. ann. 1800. 233. t. 3. f. P. Prodr. 119. Orchid. 68. t. 1. f. P. Trad. on Botany, 162. t. 5. Schreb. 603. Wild. Sp. Pl. v. 4. 80. 'Mert. Mill. Dict. v. 3. Sm. Fl. Brit. 940. Michaux Border.-Amer. v. 2. 1. 17. —Chas. and order, Gymnadenia Masconia. N. E. B. Linn. Juff.

Gen. Ch. Cal. Perianth recurved, three-leaved, more or less acute, spreading, permanent, two upper leaves equal; lower salient, in front, deflexed. Car. permanent. Petals two, linear, reflexed, spreading, smaller than the calyx. Nectary an ascending or erect lip, between the two upper calyx-leaves, embracing the organs of fructification with its concave base, its termination obtuse or acute, undivided or slightly lobed. Stem. Anther an hemispherical, deciduous, obliquely terminal lip, of two cells; masses of pollen solitary, fimbriole, oblong or globular, lying on the interior margin of the top of the style. Fil. Germen inferior, either oblong, somewhat cylindrical, or ovoblate, erect, slightly gibbose, excavated in front and at the summit; style erect or ascending, short and thick; stigma on the side towards the lip, beneath the anther, concave. Peric. Capsule oblong or ovate, with three or six ribs, of one cell and three valves, opening by clefs between the ribs. Seeds numerous, minute, each clothed with a chaffy tunic.

Obs. This genus is most allied to Cymbidium (see that article) in character, but differs in its recurved flower, as well as in its peculiar habit, indicated by the small, usually yellow or greenish blossoms, and a general delicacy of structure and texture. In what regards the habit of the flowers, however, independent of their polyn, it must be confessed that Cymbidium corolliflorum approaches Malaxis very nearly, though not at all in habit.

1. M. speciosa. Sw. n. 1. —Leaves two, ovate, shorter than their flowerstalks. Flower-flalk square. racemose. Lip obscurely three-lobed, pointed.—Native of Jamaica. The root is perennial, consisting of an oblong upright caudex, with numerous downy fibres, appearing to grow amongst rotten wood or leaves. Leaves two, radical, spreading, thin, delicate and pale, ovate, rather acute, entire, somewhat wavy, ribbed, smooth, about two inches long, each supported by a membranous, ribbed, tubular, floriferous footstalk, about three inches long. Flower-stalk about a foot high, solitary, radical, quadranqui, smooth, floriferous, at the footstalks at the bottom, and terminating in a coryphose cluster of numerous, small, pale yellowish flowers, each of whose flowerstalks is half an inch, or more, in length, and has at its base a linear, acute, membranous, permanent bract. The lip is acute, with a small lobe at each side near the base, and has a dark central stripe. This seems to be the species which first caused the establishment of the genus; yet it does not well answer to the generic character in Swartz's Prodromus, unless we conceive the central point of the lip to be bent backwards, while the two lateral lobes, projecting forward, have a heart-shaped figure. The specific name is liable to objection, for the flowers are racemose, or corymbose, those of some other species being much more truly spike.

2. M. unbellulata. Sw. n. 2. —Leaves two, ovate, shorter than their flowerstalks. Flower-flalks five-angled. Umbel dense. Lip obscurely three-lobed, pointed.—Native of Jamaica, apparently in similar situations with the foregoing, from which it differs chiefly in being of rather more humble stature, with smaller and greener flowers, growing in a little dense umbel, at the top of the pentagonal stalk.

3. M. latifolia. Leaves several, ovate, longer than their flowerstalks. Spike cylindrical. Bracteas deflexed. Lip three-lobed, the middle lobe largest.—Native of the woods of Upper Nepal; gathered by Dr. P. Buchanan, August 12th, 1803, at Narainhetty, where it is called by the inhabitants Naman. This rose is liable to be confounded with, by many, strong, downy, twisted fibres. Leaves about four, oblong, broad, ribbed, flowerstalks, broad-ovate, pointed, plaited, ribbed and inflated, three or four inches long, being more than twice the length of their stalks. Flower-flalk central, foliary, above a foot high, erect, with several acute angles. Spike terminal, erect, cylindrical, dense, many-flowered, three inches long. Bracteas foliary, deflexed, awl-shaped, concave, membranous, permanent. Flowers sessile, small, yellow. Germin incurved, strongly forced, with crimped angles, its base tapering and elongated. Lower leaf of the calyx linear, reflexed at the sides, ascending at the point; two upper ones shorter, half-ovate and obtuse. Petals linear, widely spreading. Lip short, broad, erect, with three acute lobes, of which the middle is the largest, and entire, the sides one-flamed.

4. M. odorata. Wild. n. 6. (Katsuo-ponnun-marrava; Rheed Hort. Mal. v. 12. 55. t. 28.) —Leaves several, elliptic-lanceolate. Spike cylindrical. Bracteas deflexed. Lip heart-shaped, cloven at the point.—Gathered by Dr. Buchanan on the mafly rocks of Upper Nepal, where it is called Dun Pinula. Rheed says it loves sunny retired places, flowering in January and February, and having a very delightful smell. It has altogether the habit of the ial, but the leaves are narrower, and more elliptical than ovate. The spike is longer, and flowers larger. The lip differs essentially, being of a broad heart-shaped figure, cloven half way down at the upper part, or point, which is obtuse, and embracing the organs of fructification between the bases of its rounded side-lobes. The flowers are altogether of a pale dull yellow, or buff-colour.

5. M. rheedii. Swartz. n. 4. Wild. n. 5. (Epis-enmary refiupinatum; Forsl. Prodr. 61. Balfafa-pouia-marrava; Rheed Hort. Mal. v. 12. 55. t. 27.) —Leaves several, elliptic-lanceolate. Spike cylindrical. Bracteas deflexed. Lip involute heart-shaped, rounded, fringed.—Native of the East Indies and the Society Islands, upon trees or rocks. We know it only by Rheed's and Forster's works. It is nearly allied to the last, and the flowers are said to be delightfully fragrant, but are essentially different from that of M. odorata, not only in being much smaller, and of a vermilion hue, but in the structure of their lip, which is involute heart-shaped, its two rounded lobes being directed upwards; and their edge, moreover, is finely fringed.

MALAXIS.

the lafe.—Gathered by Thunberg, flowering in May and June, near Oaseca and Jedo in Japan, where it is called Gin Ran. It appears to differ from the ball in having the flowers fewer, and much more dilatant, each supported by a broader partial flalk, forming a cluster, not a spike. By Thunberg's long and exact description it is evidently well referred by Swartz to this genus, with which its habit accords. The calyx consists of three equal linear leaves, two of which are lateral, the third lowermost. Petals lateral. Lip uppermost, twice as broad as the petals, obovate or emarginate, forming a fort of gallo. bent backwards in the middle, marked with two callostomes, and a furrow, at the base, without any spur. Style semi-cylindrical, curved upwards towards the lip. Calyx slender, twisted. The flowers are said to be purple, and the minute ovate braitis are of the same colour.

7. M. lanceifolia. Leaves several, ovato-lanceolate, ribbed, acute. Flowers spoke. Bracteas lanceolate, spreading. Lip obovate, abrupt, reflexed, convex.—Found by Dr. Buchanan in the woods at Swembus in Upper Nepal, July 17, 1802. Its affinity to the ball did not escape its learned discoverer, but the present is rather a taller plant, being twelve or eighteen inches high. The leaves are much narrower and longer, about three or four in number, with long sheathing bafes. Stalk angular, bearing a long slender spike of numerous green unspotted flowers, rather smaller than Thunberg delineates those of his Ophrys nervosa. The braitis are lanceolate, and nearly as long as the germs. The lip has no tubercles at its base, but is bent backwards towards the middle, as is M. nervosa.

8. M. ophrygojiliosa. Willd. n. 3. (M. unifolia; Michaux Boreal-Amér. v. 2. 157. Swartz Orchid. 71.)—Leaf solitary, ovate, clasping the stem. Stalk with many angles. Lip cloven at the extremity.—Native of shady woods in North America. Sent from near Lancaster in Pennsylvania by the Rev. Dr. Muhlenberg. A delicate species, with much of the aspect of the two kind, but distinguished from all hitherto discovered by its solitary leaf, which is ovate inclining to heart-shaped, acute, finely ribbed and reticulated, near an inch and a half long, clasping the flalk with its base, and sheathing two inches or more of the lower part with its close, tubular, radical footstalk. The flower-stalk is solitary, rising four or five inches above the leaf, pale, slender, with several unequal angles not exactly five, and terminating in a very delicate corymbose cluster, of numerous small greenish flowers, on capillary flalks, with a small, ovate, acute, membranous bracteal at the base of each flalk. Willdenow observed the lip to be cloven; and its lobes appear to us to be dilant and cucurvate, with a semi-circular fissure between them.

9. M. monophylla. Swartz. n. 5. Willd. n. 4. (Ophrys monophylla; Linn. Sp. Pl. 1342. Fl. Succ. ed. 2. 316. Wolf. in Jacq. Coll. v. 4. 340. t. 13. f. 2. O. monophylla bulbosa; Loepl. Prof. 182. t. 57. O. liliofria Suecia; Linn. Sp. Pl. 1341. n. 7. O. liliofria; Fl. Succ. ed. 2. 316. n. 811, on the authority of Dr. Swartz. Epipactis n. 1933; Hall. Helv. v. 2. 151. t. 56.)—Leaf nearly solitary, elliptic-ovate. Stalk triangular. Lip undivided.—Native of boggy shady alpine places, in Praefia, Sweden, Russia, Carpathia, and, though very rarely, in Switzerland, flowering in the spring. This is closely allied in habit to the ball. Root an aggregate bulb, with numerous fibres, and invested with several ribbed sheaths, altogether more like an Allium, as Wulfen observes, than any of the Orchis tribe. Such, however, is the nature of all the foregoing species, as far as has been ascertained. One elliptical, delicately ribbed, leaf, acute at each extremity, and running down into a long sheathing base, or radical footstalk, embraces the flalk, attended by one or two shorter external sheaths, and often accompanied by a much smaller internal leaf. The flalk is triangular, terminating in a long slender cluster, of very numerous small green flowers, with every character of the genus. Their braitis are like those of the ball, but their lip is undivided, with a taper point. Dr. Swartz assures us the Ophrys laticlavia of Linnæus's Flora Suecica, (erroneously so printed for liliofria,) was no other than a specimen of the species we are describing, in which the second leaf was more remarkable than usual.

10. M. paludosa. Swartz. n. 5. Willd. n. 7. Sm. Fl. Brit. 1942. Engl. Bot. t. 72. (Ophrys paludosa; Linn. Sp. Pl. 1341. Fl. Succ. 316. Rofe Elem. of Bot. append. 455. t. 2. f. 5. Dick. H. Suec. f. 7. 16. Ebr. Phytotop. 16.)—Leaves several, spatulate, rough at the tip. Stalk with five angles. Lip undivided, concave, half the length of the calyx.—Native of turfy bogs in the north of Europe, flowering in July. It is found in Cambridgehire, Bedfordshire, and on Felthorpe bogs a few miles north of Norwich, though now far more rare than formerly, from the general improvement of such grounds by draining. This is perhaps the smallest species of its genus, or even of the whole natural order. The roots consist of little bulbs, connected by a thread-shaped fibre, and exactly accord with those of the foregoing. The leaves are about four, sheathing, an inch long, spatulate, firm and rather fleshy, jagged or rough at the point, slightly glaucous. Flowers in a long dense cluster, of a yellowish-green. Calyx-leaves nearly equal, ovate. Petals rather smaller, reflexed. Lip erect, ovate, concave, undivided, but half the length of the calyx. Germin obvate.

11. M. lilifolia. Swartz. n. 6. Willd. n. 8. (Ophrys lilifolia; Linn. Sp. Pl. 1341. Andr. Repof. t. 65.)—Leaves two, ovate. Stalk triangular. Petals linear-threaded, Lip prominent, obovate, acute. Style deflexed, recurved.—Native of wet places in Pennsylvania. The late Peter Collinson cultivated it about 50 years ago, and plants are from time to time brought to England, though seldom long preserved. This and the two following belong to a tribe which have not so clearly the character of Malaxis as could be wished. The flowers is feldrum truly reversed, though more or less turned, and the lip, of the present species at least, is rather directed forward than upward, while the column, or style, though curved upward, lands opposite, not parallel, to the lip. The whole habit, however, agrees so entirely in every point with Malaxis, and with nothing else, that Dr. Swartz has finally determined to place them here, rather than in the less natural genus of Gymnadenium; especially as the position of their flowers will very often excute, if not justify, the measure. The root of M. lilifolia is an ovate bulb, with a spongy reticulated coat, and many woolly fibres. Leaves two, radical, three or four inches long, equal, opposite, ovate, keeled, ribbed, bluntish, embracing each other at the base, and accompanied by one or two broad, flat, external, sheathing sheaths. Stalk erect, strait, about twice as tall as the leaves, triangular, furrowed, terminating in a loose upright cluster of numerous flowers, as large as those of most of the common orchises, the calyx-leaves are linear, half an inch long, spreading, of a pale yellowish-green. Petals whitish, as long but much narrower, almost capillary, dependent. Lip rather longer than the calyx, olive-green, projecting, somewhat recurved, obovate with a small point, channelled at the base. Style recurved, with a hooked tip to the cover of the anthers. Germin fladder, furrowed, gradually swelling upwards, twitted.

32. M.
MAL

12. M. cordifolia. Leaf nearly solitary, heart-shaped. Stalk furrowed. Petals linear-heart-shaped. Lip prominent, interlockingly heart-shaped, with a small point. Germs usually triangular.—Gathered by Dr. Buchanan, Oct. 2d, 1802, at Narainpetty in Upper Nepal. It grows in watery places, amongst dead leaves, in a micaceous soil. This is closely allied to the last, though abundantly distinct as a species. In size they exactly agree. The roots of the present have a thick, spongy, whitish coat, and very long woolly fibres. There is one principal leaf, which is radical, heart-shaped, pointed, ribbed, nearly three inches long and above two broad, with a shortish sheathing base or footstalk, enveloped in one or two scales. Sometimes, if not always, there occurs, as in M. monophyllus, n. 9, a very small folded ovate leaf, in the bottom of the other. The flower-stalk is twice as tall as the leaf, loosely racemose. Flowers apparently very much like those of M. lilifolia, but the lip is obcordate with a small point, and the genus is very acutely triangular, becoming club-shaped as it advances, straight, not twisted, with three very evident membranous or winged angles. We have only seen one dried specimen.

13. M. Loeieli. Swartz. n. 7. Wild. n. 9. (Ophrys Loelei; Linn. Sp. Pl. 1834. Sm. Fl. Brit. 935. Engl. Bot. t. 47. Dickl. H. Scic. fasc. 9. 11. Ehrh. Herb. 110. O. lilifolia; Hutcl. 380. O. palaudofa; Fl. Dan. t. 877. O. diphyllus bulbifera; Loecl. Prufil. 180. t. 58. O. bifolia bulbifera; Ger. em. 403. Cymbidium Loelei; Swartz Nov. Act. Upsal. v. 6. 76.)—Leaves two, elliptic-lanceolate, stalk triangular. Lips prominent, ovate, channelled, undivided, recurved. Native of marshes on a sandy soil, among rushes, flowering in July, chiefly in the north of Europe. We have it in Cambridgeshire and Norfolk, but it is esteemed a rare plant, and considering its history and affinities, is certainly one of the most interesting in our British Flora. The habit of the roots, with their white spongy covering and woody fibres, exactly accords with the two last described, and indeed with M. paludofa, n. 10. The leaves, however, are much narrower than in lilifolia or cordifolia, and more resemble those of Lily of the Valley. The flowers also are fewer and smaller, more frequently reverted, with broader petals, and a yellow, obviate, slightly wavy, but not divided, lip, opposite to which stand the incurved style. The genus is ovate, with fixed angles. The late Mr. Pitchford, who first met with this species in Norfolk, exchanged his only specimen with Mr. Lightfoot, for above 60 of the rarest British plants.

14. M. euforinia. Leaves several, sword-shaped, equitant, ribbed. Spire very long, dependent. Lip heart-shaped, four-lobed.—This grows parcellarly upon trees at Narainpetty in Upper Nepal, where it was gathered by Dr. Buchanan, November 13, 1802. It is a genuine Malaxis, though different in habit from the usual aspect of the genus. The roots consists of long, long, woolly fibres, with feebly any bulb. Leaves numerous, radical, two-ranked, equitant, spongy, a foot long, sword-shaped, very acute, coriaceous, quite smooth, without ribs, of a fine shining grays-green, separating, by age or drying, at a kind of joint near the base. Flower-stalk solitary, central, radical, roundish, longer than the leaves, terminating in an extremely long, recurved or pendulous, dense, cylindrical spike, of innumerable small flowers, of a dull orange hue. They are truly reverted, the calyx-leaves and petals ovate; the lip erect, longer than the petals; heart-shaped at the base, where it embraces the short erect style; four-lobed in the margin, the two middle lobes rather elongated. Germs short, elliptical, with fix ribs. Such are all the species that we can satisfactorily refer to this genus, not without scruples respecting the 1st, 12th, and 13th. Three others, indicated as doubtful by Swartz, and adopted by Wildenow, we premise, without the least hesitation, to exclude. These are M. cernua. Wild. n. 11. (Bella solda; Rheede Hort. Mal. v. 11. 69. t. 35.)

M. nutans, ib. n. 12. (Limodorum nutans; Roxb. Corom. v. t. 33. t. 40.) M. caudata, ib. n. 13. (Epipedium caudatum; Linn. Sp. Pl. 1749. Helleborine florum folis maculeos et longissimis; Plum. Cat. 9. t. 177.)

Of these the two first, natives of the East Indies, appear to us to have the character of Cymbidium, (fee that article,) and not in any manner to accord with Malaxis. With them certainly agrees in genus the Limodorum recurvature, Roxb. Corom. v. t. 33. t. 39. L. n. 9. Wild. as well as Epipedium terrestre of the Linnaean herbarium, and a non-descript species from Dr. Buchanan.

The last, E. caudatum of Linnaeus, a plant we believe known to Plumen only, does indeed, by his plate, seem to have the reverted flower of a Malaxis; but the habit is so different, and the figure is so incorrectly drawn, the calyx being represented interior with respect to the petals, and the column extremely various and confus'd, that we conceive nothing can safely be deduced from it. We will nevertheless venture to observe, that if this species be referrible, by its essential character, to Malaxis, some new one must be sought to define the genus, in order to exclude a plant so foreign to it, and which evidently belongs either to Cymbidium or Dendrobium. In such cases, however, no prudent botanist will trust to any figure, much less to so inaccurate an one as that before us, but will suspend his judgment till he can examine Nature herself.

MALAZKERD, in Geography, a town of Turkish Armenia, on the Aras; 140 miles N.E. of Diarbekir. N. lat. 38°. E. long. 41° 59'.

MALBARY, a town of Hindoostan, in Vizipour; 6 miles N.E. of Merrith.

MALBAY, a bay of the county of Clare, Ireland, on its west coast, which is deemed unsafe, and not frequented.—Alfo, a river of Canada, which runs into the St. Lawrence, 63 miles below Quebec.

MALBUNGAT, a town of Lower Carinithia; 15 miles S.W. of Villars.

MALCHOW, a town of Mecklenburg; 40 miles S. of Rolfock. N. lat. 53° 50'. E. long. 12° 33'.

MALCOLM, Alexander, in Biography, author of "A Treatise of Music, speculative, practical, and historical," 1714. Edinburgh, 1721. This work, which has considerable merit, is dedicated to the most illustrious directors of the Royal Academy of Music. (See Opera.) We are old enough to remember several of the illustrious personages who were subscribers to this establishment, yet never
never heard of any one of them that was likely to read this book, colonel Blathwaite and general O'Hara excepted: the first a dilettante of eminence; the second possessed of good taste, and, from hearing and comparing great performers and good compositions, an excellent judge of musical talents. The rest were pleased they knew not why, and were drawn into the vortex of fashion by example.

Upon a late perusal of this work, which we had not seen for near half a century, we find in it indisputable proofs of the author's learning, diligence, and knowledge. He has drawn from the purest sources of information concerning ancient music, and does not fear ignorant of the modern. His chapters on composition, however, go but a little way into the mysteries of that art; and indeed given common examples of the three species of movement in melody: oblique, and moto contrario; rising and falling together; one part stationary, and the other moving up or down; and contrary motion. He has also given the treble and base of a few usual cadences, in two parts only. But though his explanations, descriptions, and discussions are numerous, they are rendered fo tedious and full of repetitions and amplifications, that many years fluide, experience, and reading, would be still necessary for a student, after the most careful and attentive perusal of this book, to render him a complete contrapuntist. His instructions are rendered obscure, perhaps, by too great a desire to render them clear; they are involved in too many words. "In vitium duet culpae fuga, fi caret arte." The style is not alluring; it abounds in Scotti idiom, is rough, and often dark and uncouth. The work is too scientific for an elementary tract, and too superficial in the rules for practical harmony. We well remember, at an early stage of fluide, to have taken up this book with a pure and certain hope of finding in it a solution of all our doubts and difficulties; but soon laid it down in despair.

The author seems to have begun at the wrong end of his labour, plunging into theory and speculation before he speaks of practice. The plates at the beginning have a hieroglyphic appearance, and must be totally unintelligible to inexperienced; and the author seems deficient in that agreeable and fascinating manner of writing, in the lively strokes, and variety of occasional instruction, which Bayle allows even to his enemy, Maimbourg. "There are few historians," says he, "even among those who write better, and are more learned and exact, that have the art of engaging the reader's attention so much as he does." Though our author has read and meditated much, yet, by being self-taught, there is an awkwardness of expression in communicating his knowledge to his readers, which wanted practice and good taste to render it clear, useful, and pleafant.

As this work is become somewhat scarce, and was published before the Monthly and Critical Reviews were established, we shall specify some of the principal subjects which the author has treated, and the authorities upon which his text is founded. His doctrine of vibration is taken from Galileo, a Graveland, and Kiel. He mentions Vincenot, Galileo, but not his work learned from Kircher, Dr. Holder, and Dr. Wallis, are cited; the latter on his doubts concerning the vibrations which constitute intervals, from their celerity, as we are unable to count them. He considers ratios and coincidences under the guidance of Merkennis. He does not mention Galileo, in speaking of the doctrine of pendulums; nor does he give any authorities in explaining arithmetical, harmonical, and geometrical proportions. Kepler is quoted, and Des Cartes, on the geometrical part of harmonies by dividing right lines. He denominates the lowest found of a common chord the fundamental, five years before it was used by Rameau as the generator of a chord. Vol. XXII.

The word concinnous, so frequently used by Graffineau, seems adopted from Malcolm. Salmon's Temperament considered; and his proposal for reducing all clavies to one, diversified and approved. Solomonizing according to the hexachords, he severely censures. M. Labord, in his "Études sur la Mal," has given a short article to this work, without saying who or what the author was; but in the index, he calls him "Ecrivain Francois sur la Mufique." None of our biographical dictionaries have honoured him with the least notice; though he certainly ranks high among musical writers in our own language. Walther, however, tells us from Matthewson, that he was "ein gelehrter Schottland/cher edilmann," a learned Scots nobleman. From the materials which he had collected, an ingenious and lively writer might have made a captivating and instructive work. The disciples of Dr. Pupel, the only fludious musicians of that time, condemned him for having disputed the utility of solfemation and the mutations, according to the hexachords. But Chambers, in the first edition of his Cyclopaedia, was indebted to Malcolm for most of his musical articles. And the French seem better acquainted with this book than the English, though we have never seen a translation of it in that language; yet, in Roufeau and others, we perceive a frequent anonymous use of this book. The author has indeed often availed himself of Perrault's philosophy of sound, but not without naming him. He denies music in parts to the ancients, and seems to have been one of the first writers on the subject, who dared to doubt that a music, capable of such miraculous effects as were ascribed to it, should be deficient in that part of modern music which affords us the greatest pleasure.

MALDA, in Geography, a town of Hindoostan, in Mewar; 30 miles S.S.W. of A jealousy.

MALDEE, a town of Peria, in the province of Segeftan, 1311 miles E.N.E. of Malden, or Maldon, an ancient and populous borough and market town in the hundred of Dengey, and county of Effex, England, is situated ten miles distant from Chelsmford, and 37 from London, on the acclivity of an eminence S.W. of the citary of the Blackwater, or river Idumanum. Many of our ancient topographers assign this place as the Canalaodunum of the Romanis; but this subject has been fully investigated in the Beauties of England and Wales, vol. v. under Colchester; which town fee also in this work. The earliest mention of Malden, by historians, refers to the year 913, when Edward the Elder encamped here to impede the progress of the Danes: the entrenchment he formed lies on the W. side of the town, and appears to have been of an oblong form, and to have inclosed about twenty-four acres: three fides of the ramparts may yet be traced; the other is defaced by buildings. Its strength was probably considerable, as in 921 a great army of Danes besieged it without effect. In 953 it was again attacked by the Danish forces commanded by Unlaf. In the Domecral Survey, Malden is figured a lie in two hundred and eleven houses, and a hall held by the burgesses of the king, who had also a house here in his own possession. When Malden was constituted a borough is uncertain; a charter appears to have been granted to the burgesses by Henry II. By another charter from queen Mary in 1555, the borough was incorporated, and its government vested in two bailiffs, six aldermen, and eighteen capital burgesses. Two members are returned to parliament; the right of election is confined to those who obtain their freedom by birth, marriage, or servitude; the number of voters is about 200. The first return was made in the year 1329. The custom of Borough-English, by which the youngest son succeeds to the burgage-
Malden, a town of the county of Middlesex, seven miles E. of Boreckloe.—Alfo, a town of America, in Middlesex county, Massachusets, four miles N. of Bolton, containing 1059 inhabitants.—Alfo, a district or township of Essex county, in Upper Canada, occupying a considerable extent, and situated on the eastern side of Detroit river, about eighteen miles below the town of Detroit. At the lower end of the district there are but few scattered houses; but at the upper end, bordering upon the river, and adjoining to the new British soil that has been established since the evacuation of Detroit, a little town has been laid out, which is rapidly increasing. Either several of the traders have removed, who formerly resided at Detroit. This little town and the new post are denominated "The new British town and post near the island of Bois-Blanc," an island in the river near two miles in length, and half a mile in breadth, that lies opposite to Malden.

Malden Angle, a small island near the coast of Suffolk. N. lat. 40° 12'. E. long. 8° 13'.

Maldive, a cluster of small islands in the East Indian sea, about 270 miles S.W. of cape Comorin, amounting in number, as it is said, to more than 1000, and mostly uninhabited. They form a kind of oblong inclosure, around a clear space of sea, with very shallow water between one another. According to Mr. Dalrymple's chart, they seem to be divided into thirteen groups, nearly equidistant, and each bearing its proper name. The inhabitants of those that are occupied appear to be a mixture of Arabs and Indians of Malabar, from which coast these islands probably were originally colonized. They were discovered in 1508 by the younger Almeida, and conquered by the Portuguese from the Moors, who had usurped the sovereignty from the natives. The Portuguese, however, were soon cut off by the original Maldives. Among the inhabitants, who are governed by a chief called Afil, who is miserably poor, and who are governed in an oppressive manner, there are some Malometans. Their language is the Singalese: their articles of commerce are fairs and cordage, cocoanuts, oil, honey, dry fish, tortoise-shell, and cowries, and these articles are collected in four ports. These islands lie in N. lat. 5° 30' to 5° 4'; and E. long. 72° 30' to 73° 45'.

Maldonado, a town of South America, in the government of Buenos Ayres, on the river Plata; 100 miles W. of Buenos Ayres. S. lat. 34° 50'. W. long. 55° 36'.

Maldonat, John, in Biography, a learned Spanish Jesuit, was born near Lerena, in Estramadura, in the year 1534. He pursued his studies at the university of Salamanca, where he afterwards taught the Greek language and divinity with much success and applause. He allowed the habit of the order when he was at Rome, in the year 1562. In the following year he was appointed professor of philosophy in the college at Paris, which the Jesuits had just founded in that city; after this he commenced a course of divinity in the same seminary which occupied him four years. These lectures were attended by a prodigious concourse of scholars, who would assemble two or three hours before the time in which the lectures began to infuse themselves places. In 1570 he was sent with nine other Jesuits to Poitiers, with the view of forming an establishment of the order in that city, but in this they were unsuccessful. He next re-
turned to Paris, and resumed his lectures with great success, but in the midst of his labours he was interrupted by the exhibition of certain accusations against him, one of which was, that by his influence over the mind of the president St. Andre, he had obtained a fraudulent will, by which his estates were bequeathed to the Jesuits, and the other was an accusation of heresy, for maintaining that the doctrine of the immaculate conception of the Holy Virgin was not a point of faith. After a regular hearing he was acquitted of both these charges, but his mind was unhinged, and he determined to relinquish his lectures, and to retire in a good measure from the world. In his retreat at the college of the Jesuits at Bourges, he employed himself in commentaries on the scriptures, till he was called out of his obscurity by pope Gregory XIII., to superintend the publication of "The Septuagint," at Rome. Here also he finished his Commentaries on the Gospels, which was in 1582; and in the following year he fell sick, and died in the fifty-ninth year of his age. Maldonat was reckoned one of the ablest scholars of the society to which he belonged: he was a capital linguist, an eloquent preacher, and a judicious commentator on the scriptures. He is highly spoken of by Dupin, father Simon, and other learned men. Simon, in reference to his qualities as a commentator and critic, says, "he does not allow one difficulty to pass without examining it to the bottom. When a great number of literal interpretations of the same passage pretend themselves to mutually fixes on the text, without paying too much deference to the ancient expounders, or even to the majority, regarding nothing but Truth alone, strip of all authorities but her own." The principal works of Maldonat are "Commentarii in quatuor Evangelistas," "Commentarii in quatuor Prophetas, Hieremiam, Baruch, Ezekielam, et Danielum;" he was author of many other works, but they were all given to the world after the death of the author; and some pieces have been attributed to his pen, which were not only unworthy of his high reputation, but which have generally been regarded as spurious. Bayle. Moreri, &c.

MALDUAR, in Geography, a small cirearc of Bengal, between Dinapore and Purnahe, about nine miles long, and six broad; which may be considered as part of Rajemul. The chief town is Ranly.

MALE, the chief and most fertile of those islands called the "Maldives;" situated nearly in the centre of the group, about four miles in circumference, and containing a town, in which there inhabits, N. lat. 6° 20'. E. long. 75° 15'; Male, the sex which has the parts of generation without sfide, and which has ordinarily the pre-eminence over the other.

In this sense male islands opposed to female.
For the proportion of males to females, see MARRIAGE.

MALE BALIAN APÉS, in Gardening. See MOSHERDIA.

MALEBYE, I.A., in Geography, a town of Canada, on the river St. Laurence; 70 miles N.E. of Quebec.

MALEA, in Ancient Geography, Cape Malea, a town of Lacoia, situated at the extremity of a chain of mountains, advancing into the sea between the Argolic and Lacoian gulfs.

MALEBRANCHE, NICHOLAS, in Biography, a celebrated philosopher, was born at Paris in the year 1638, and instructed in the Latin and Greek languages by a domastic tutor. He afterwards professed the study of philosophy at the college of de la Marche, and of divinity in the Sorbonne. At the age of 22 years, he determined to embrace a monastic life, and was admitted into the congregation of the Oratory. Weary of the researches of ecclitalical history, to which he first directed his attention, he was advised by father Simon to apply to oriental literature and biblical criticism; but when he had acquired sufficient knowledge of the Hebrew language to read the Old Testament in the original, he deserted from the purport of studies of this kind; and under the influence of a temporary enthusiasm, he seemed inclined to give himself up wholly to devotion, and to wait for divine illumination. But he was routed from this state by the accidental perusal of Des Cartes's treatise "On Man," with the peripatetic reasoning of which he was so much pleased, that he determined to make himself thoroughly acquainted with this author's system of philosophy. With this view, he devoted ten years to profound meditation, and to metaphysical researches, which led him, under the influence of a warm and exuberant imagination, into the very visionary regions of enthusiasm. Conceving the soul of man to be mysteriously united to his body, and apprehending also that a no lefs mysterious union subsisted between the human soul and God, he published, in 1675, the result of his meditations and conclusions, in his famous treatise, entitled "Recherche de la vérité," or "Search after Truth," in three volumes, 12mo. In 1676, he attempted to evince the agreement between true philosophy and religion, in a work, entitled "Christian Conversations, in which the Truth of the Religion and Morality of Jesus Christ is vindicated," 12mo. In 1680, appeared his "A Treatise on Nature and on Grace," 12mo. In 1682, which was the result of a controversy between him and M. Arnauld on the subjéct of grace; and this treatise was succeeded by several controversial tracts, written by both these authors. He published also several other pieces in vindication of his system announced in the "Search after Truth." Our author also published "A Treatise on Physical Premonition," against Bourlier's book, "On the Action of God," and "Reflections on Light and Colors, and on the Generation of Fire," and also other papers, inserted in the "Memoirs of the Academy of Sciences," of which body he was an honorary member in the year 1699. By temperament he maintained a good state of health, notwithstanding the delicacy of his constitution, till near the close of life, which terminated at the age of 77 years, in 1715. His manners in private life were simple, cheerful, and complaisant. He paid little regard to those subjects of studition which employed the thoughts and time of other literary persons; and merely served to make them acquainted with the opinions of different philosophers, without leaving them sufficiently at leisure to think for themselves. For poetry he had no taste; and it is said, indeed, that he never read ten verses without disgust. It was his custom to study with his windows shut, that he might not be disturbed by the light. The speculations of his retirement were the subjects of his conversation, with regard to which he was communicative, and yet modest, and unassuming. His company was much valued and desired; and no foreigner of learning visited Paris without wishing to be introduced to him; and we are informed by one of his biographers, that an English officer, being taken prisoner in the war between the king of France and William III., expressed his satisfaction at being sent to Paris, because he had long wished to see Lewis XIV. and father Malebranche. See the next article.

MALEBRANCHISM, the doctrine or sentiments of father Malebranche (see the last article); which is in a great measure the same with Cartesianism. It must be owned, however, that though F. Malebranche thought the same with Des Cartes, yet he does not so properly seem to have followed him, as to have met with him.
Malebranchism is chiefly contained in the "Recherche de la Verité," of which M. Fontenelle says, "The Inquiry after Truth" is full of God: God is the only agent, and that too in the strictest sense. All power of acting, all actions, belong immediately to him. Second causes are no causes. They are only occasions that determine the actions of God; or occasional causes. This work, which was first published in 1673, passed through several editions; the best of which was that published by himself in 1712, in two volumes 4to, and four volumes 12mo, with considerable variations and enlargements.

F. Malebranche, however, does not here lay down his system entire, with regard to religion, or rather the manner in which he would reconcile religion to his system of philosophy; that he referred for his "Entretiens Christiani," already mentioned, where he proves the existence of a God, the corruption of human nature, by original sin, and the necessity of a Mediator, and of grace.

Dr. Enfield, in his Abridgment of "Brucker's Philosophy," (vol. ii.) has given the following account of the system of Malebranche. "The doctrine of this book," returning to its "Search after Truth," "though in many respects original, is raised upon Cartesian principles, and is, in some particulars, Platonick. The author represents, in strong colours, the causes of error, arising from the disorders of the imagination and passions, the abuse of liberty, and an implicit confidence in the senses. He explains the action of the animal spirits, the nature of memory; the connection of the brain with other parts of the body, and their influence upon the understanding and will. On the subject of intellect, he maintains, that thought alone is essential to mind, and deduces the imperfect state of science from the imperfection of the human understanding, as well as from the inconciency of the will in aspiring after truth. Rejecting the ancient doctrine of practice first from material objects, and denying the power of the mind to produce ideas, he affirms their production immediately to God; and affirms, that the human mind immediately perceives God, and sees all things in him. As he derives the imperfection of the human mind from its dependence upon the body, so he places its perfection in union with God, by means of the knowledge of truth and the love of virtue."

" Singular and paradoxical as the notion of seeing all things in God, and some other dogmas of this writer, must have appeared, the work was written with such elegance and splendour of diction, and its tenets were supported by such ingenious reasonings, that it obtained general applause, and procured the author a very high name among philosophers, and a numerous train of followers. Its popularity might, perhaps, be in part owing to the appeal which the author makes to the authority of St. Augustine, from whom he professed to have borrowed his hypotheses concerning the origin of ideas. The immediate intercourse with this doctrine supposes, between the human and the divine mind, has led some to remark a strong reflex-mixture between the notions of Malebranche, and those of the sect called Quakers."

Dr. Reid (Essay i. p. 163) does not allow, that either Plato or the latter Platonists, or St. Augustine, or the Mysica, thought, that we perceive the objects of sense in the divine ideas. That theory of our perceiving the objects of sense in the ideas of the Deity, he considers as the invention of Father Malebranche himself. Although St. Augustine speaks in a very high strain of God's being the light of our minds, of our being illuminated immediately by the eternal light, and uses other similar expressions; yet he seems to apply those expressions only to our illumination in moral and divine things, and not to the perception of objects by the senses. Mr. Bayle imagines that some traces of this opinion of Malebranche are to be found in Anemillus the Platonist, and even in Democritus; but his authorities seem, as Dr. Reid conceives, to be groundless. Malebranche, with a very penetrating genius, entered into a more minute examination of the powers of the human mind than any one before him; and he availed himself of the previous discoveries made by Descartes, without servile attachment. He lays it down as a principle admitted by all philosophers, and in itself unquestionable, that we do not perceive external objects immediately, but by means of images or ideas of them present to the mind. "The things which the soul perceives," says Malebranche, "are of two kinds. They are either in the soul, or without the soul; those that are in the soul are its own thoughts, that is to say, all its different modifications. The soul has no need of ideas for perceiving these things. But with regard to things without the soul, we cannot perceive them but by means of ideas." He then proceeds to enumerate all the possible ways by which the ideas of sensible objects may be presented to the mind: either, 1st, they come from the bodies, which we perceive; or, 2dly, the soul has the power of producing them in itself; or, 3dly, they are produced by the Deity in our creation, or occasionally as there is use for them; or, 4thly, the soul has in itself virtually and eminently, as the schools speak, all the perfections which it perceives in bodies: or, 5thly, the soul is united with a Being polluted of all perfection, which has in itself the ideas of all created things. The last mode is that which he adopts, and which he endeavours to confirm by various arguments. The Deity, being always present to our minds in a more intimate manner than any other being, may, upon occasion of the impressions made on our bodies, discover to us, as far as he thinks proper, and according to fixed laws, his own ideas of the object; and thus we see all things in God, or in the divine ideas.

However visionary this system may appear on a superficial view, yet when we consider, says Dr. Reid, that he agreed with the whole tribe of philosophers in conceiving ideas to be the immediate objects of perception, and, that he found insuperable difficulties, and even absurdities, in every other hypothesis concerning them, it will not seem so wonderful that a man of very great genius should fall into this; and probably it pleased God to devote a man the more, that it fets in the most striking light our dependence upon God, and his continual presence with us. He distinguished more accurately than any philosopher had done before, the objects which we perceive from the fancies in our own minds, which, by the laws of nature, always accompany the perception of the objects: and in this respect, as well as in many others, he had great merit. For this, as Dr. Reid apprehends, is a key that opens the way to a right understanding, both of our external sense, and of other powers of the mind.

It is obvious, however, that the system of Malebranche leaves no evidence of the existence of a material world, from what we perceive by our senses; for the divine ideas, which are the objects immediately perceived, were the same before the world was created. Malebranche saw and owned this consequence, and therefore he reits the complete evidence which we have of the existence of matter upon the authority of revelation; by which we are assured, that God created the heavens and the earth, and that the word was made flesh. No author, not even bishop Berkeley, hath shown more clearly, that either upon his own system, or upon the common principles of philosophers, with regard to ideas, we have
have no evidence left, either from reason or from our senses, of the existence of a material world. It is no more than justice to Father Malebranche to acknowledge, that bishop Berkeley's arguments are to be found in him in their whole force.

Malebranchism, notwithstanding, appears to many perfect not only illusive and visionary, but even dangerous, and destructive to religion; and it has accordingly been vigorously opposed by many zealous French authors. The first was M. Foucher. After him came M. Arnauld; and in 1715, F. du Tertre, a Jesuit, published an ample confession (as he imagines) of his whole system. It was also charged with atheism by F. Hardouin, in the "Atheists Unmasked!" though his system, formed by a warm and exuberant imagination, tends more to fanaticism and enthusiasm than to atheism. That part which relates to our feeling all things in God, was answered by Mr. Locke, in a small tract printed among his posthumous works.

Those who choose to see this system, attacked on the one hand and defended on the other, with fulness of argument and elegance of expression, and on the part of Arnauld with much wit and humour, may find satisfaction by reading Malebranche's Enquiry after Truth; Arnauld's book of True and False Ideas; Malebranche's Defence; and some arguments of his adversaries. It should be remembered, however, that Malebranche was a Jesuit, and Arnauld a Jansenist; and the antipathy between the Jesuits and Jansenists left Malebranche no room to expect quarter from his learned antagonist. Bayle justly remarks on this controversy, that the arguments of M. Arnauld against the system of Malebranche were often unanswerable, but they were capable of being retorted against his own system; and his ingenious antagonist well knew how to use this defence.

Mr. Norris, an English divine, expounded the system of Malebranche in his "Essay towards the theory of the ideal or intellectual World," published in two volumes 8vo. A.D. 1701.

MALUCH, in Geography, a town of the duchy of Sturia; eight miles N. of Fridam.

MALECOTTA, a town of Hindostan; 42 miles E. of Cochin.

MALEDICTION, Maledictio, in Law, a curse usually annexed to donations of lands, &c. to churches and religious houses; impregnating the most direful punishments on those who should infringe them.

MALEPOETHAS, one of the Solou islands, in the East Indian sea. N. lat. 6° 34'. E. long. 120° 18'.

MALEGHERY, a town of Hindostan, in Mycropoly; 20 miles S. of Ouflour.

MALEK SHAH, in Biography, third sultan of the Seljukian dynasty, and the most powerful prince of his time, born in 1053, was fon, heir, and successor of Alp Arslan. On the death of his father he found himself placed on a throne which had the rule of Asia from the banks of the Oxus to the borders of Syria. The caliph of Bagdad conferred upon him the sacred title of commander of the faithful, which he never before had been conferred upon a subordinate prince. Makk had many enemies to contend with, some of whom were among his nearest relations. In 1075 one of his generals took Damascas, and reduced a great part of Syria. He invaded Egypt the following year, but was compelled to retreat by the inhabitants of Cairo. In 1078 Malek Shah undertook to complete the conquest of Turref, which had been commenced by his father. He reduced many cities to obedience, and extended a nominal sovereignty over the Tartar kingdom of Caffgar. And by allowing his generals to conquer districts for themselves, acknowledging his paramount authority, he stretched his dominion from the Chinece frontier to the mountains of Georgia, the vicinity of Constantinople, the Egyptian border, and the coasts of Arabia. His activity was so great that he is said to have visited all parts of his dominions twelve times during his reign. In these wide and extensive progresseis his favourite amusement was hunting, which he pursued with vast pomp, and sometimes with a train of many thousand horsemen. In 1088 he made a pilgrimage to Mecca, in which he displayed more magnificence than any prince had done before on the same occasion. He abolished the tribute usually paid by pilgrims: he furnished them all with provisions, raised a great number of wells and referraries to be made in the desert, and erected places for rest and refreshment at the different stages, and he took every means to promote the progress of public buildings, by diminishing the taxes, and by attending to the exact and rigid administration of justice. The reformation of the calendar was one of the acts which distinguished his reign; for which purpose he assembled all the astronomers of the East to rectify the errors that had crept into the computations, and they instituted the Jalaleen era, from a name of Jalal, the first word of one of the sultan's titles, which era is reckoned to commence from March 15th, 1079. Much of the splendour and excellence of this reign was attributed to the illustrious vizir Nizam al Moel, who towards the close of it fell into disgrace, though very undeservedly, and who was not only deprived of his employments, but in the 93d year of his age fell by the hand of an assassin. The wound, though fatal, did not prevent him previously to his death, from writing a dignified epistle to his sovereign, asserting his fidelity, and recommending his son to the sultan. Malek, proceeding to Bagdad, with the intention, it is said, of fixing there the seat of his empire, and removing the caliph to some other place, was attacked by a fever, and put an end to his life by an act of suicide, in the 38th year of his age and the 21st of his reign. This prince is highly extolled for his mental and bodily qualities, and for many virtues that adorn a throne. The house of Seljuk attained its highest greatness in his person, from which it declined at his death, or rather at the death of his minister Nizam. Gibbon. Univer. Hist.

MALEI, or MELEI, in Geography, a town of Nigrietia, on a river which runs into the Niger. N. lat. 13° 45'. E. long. 9° 30'.

MALELA, or MALELES, JOHN, in Biography, a monk of Antioch, known chiefly by a chronicle, written in the Greek language, from the creation to the reign of Justinian. It was published from a manuscript in the Bodleian library, by Edward Chilmead, of Oxford. It has been republished as a kind of appendix to the Byzantine historiaries at Venice, in 1733.

MALEMOBO, in Geography, a sea-port of Africa, in the kingdom of Cacongo. It contains about 700 huts or villages, and is surrounded by a wall constructed of rough stones, without mortar. The king has a palace here in which he occasionally resides. The Dutch and Portuguese have warehouses for ivory and raw minerals, which they obtain in exchange for European goods; 15 miles S. W. of Cacongo.

MALERMI, sometimes called MALERBI, NICHOLAS, in Biography, a native of Venice, and by profession a monk, is entitled to a short notice, as having been the author of the first
MAL

A printed version of the scriptures into the Italian language, which was published in two volumes folio, in the year 1471, under the title of "Biblia vulgare Iliorata." It was reprinted in 1475, and again in 1481. He was author also of "The Lives of all the Saints," published at Venice in 1475.

MALESHBERBS, CHRISTIAN-WILLIAM DE LAMOIGNON DE, born at Paris in 1721, was son of the chancellor of France, William de Lamoignon, a defendant of an illustrious family. He received his early education at the Jesuits' college, and afterwands applied himself with ardour to the study of the law, and to other subjects connected with political economy. At the age of twenty-four he was appointed a councillor in the parliament of Paris, and in December 1750 he succeeded his father as president of the "court of aids," an important jurisdiction, the duties of which were to regulate the public taxes. The superintendence of the press had been conferred upon Maleshberbs by his father, at the same time that he received the presidency of the court of aids, and this function, which had usually been exercised to the suppression of all free enquiry, became in his hands the means of promoting it to a degree beyond all former example in that country. It was through his favour that the French Encyclopédie, the works of Rousseau, and the writings of other eminent men, issued from the press, notwithstanding the opposition and anathemas of the hierarchy. In this view of the subject, Maleshberbs, as well as the philosophical party with whom he was associated, may be charged with having been materially instrumental in preparing the way for that revolution which has been the pregnant source of so many calamities. In 1771, when the tyranny of the government had proceeded to the dissolution of the whole legal constitution, and the banishment of parliaments, the court of aids participated in the general destruction, which it provoked by its remonstrances. Maleshberbs was banished to his country-seat by a "lettre de cachet," and the duke de Richelieu, at the head of an armed force, abolished the tribunal. He was disdained by his private virtues, and his time was occupied with his family and his books, and the cultivation of his grounds. His expenditure in public objects was large; he drained marshes, cut canals, constructed roads, built bridges, planted walks, and carried his attention to the comfort of the lower classes so far, as to raise fids on the sides of the river for the shelter of the women at their domestic labours. Thus he fulfilled the part of the beneficent parent of a village, till the accession of Lewis XVI. recalled him to a public station, and in 1774 Maleshberbs received an order to appear at the place where the court of aids had sat, and resume the presidency of the restored tribunal. On this occasion he pronounced a very affecting and patriotic harangue, and afterwards addressed the king in an eloquent speech of thanks. He particularly inveighed against that spirit of delphitom which had abrogated law and justice, and abolished every relic of constitutional liberty. Such sentiments were in perfect union with those of the young and incorrupt king, and they procured for Maleshberbs the appointment of minister of state in June 1777. This elevation was regarded by him only as affording an opportunity of extending his sphere of usefulness. One of his first concerns was to visit the prisons, and restore to liberty the innocent victims of former tyranny, and his services were carried throughout France by persons of all descriptions returning to the bosoms of their families from the gloom of dungeons. He was desirous of abolishing the arbitrary power of issuing letters de cachet, but not being able to effect this great reform, he procured the appointment of a commission composed of upright and enlightened magistrates, to which every application for such letters should be submitted, and whose unanimous decision should be requisite for their validity. Maleshberbs was also a great encourager of commerce and agriculture, in which he had the cordial cooperation of the illustrious Turgot, at that period the comptroller of the revenue. The latter was soon dismissed from his high office by the intrigues of courtiers, and the former, owing to the rejection of some important measures, which his zeal for the public good led him to propone, resigned his post in the month of May 1776. To obtain an accurate view of the manners and policy of other countries and foreign states, he let out on his travels, and visited Switzerland and Holland, and in the course of his journey he noted down every occurrence worthy of observation, and that might, hereafter, possibly be useful to himself, and promote the melioration of his country. On his return, at the end of a few years, he found his native country so much advanced in philosophical principles, that he was encouraged to draw up and present to the king two elaborate memoirs, on the condition of the Protestants, the other on the principles of civil liberty, and toleration in general, replete with the enlarged views of an enlightened statesman, who was at the same time a friend to the interests and happiness of mankind. Difficulties were now accumulating in the management of the government, and the king, in 1786, called Maleshberbs to his councils, but without appointing him to any particular post in the administration. He soon found it impossible to act with the men already preferred of the powers of government, but he was determined, in this critical state of things, to make one effort for opening the monarch's eyes, and drew up two energetic memoirs "On the Calamities of France, and the Means of repairing them;" but such was the avidity which the queen's party had over the mind of the king, that he was prevented from even reading them, nor could he be prevailed upon to grant the writer one private interview; he therefore took his final leave of a court, apparently bent on its own and the nation's ruin. He retreated to his country residence, determined to consult the best means of serving his country by philosophical and agricultural pursuits, and in 1790 published "An Essay on the Means of accelerating the Progress of Rural Economy in France," in which he proposed an establishment to facilitate the national improvement in this important point. He was particularly led to make his proposal at this period, with the hope that the revolutionary changes, though so awful and sanguinary, would finally issue in a free and well balanced constitution. The dreadful scenes which very soon followed in horrible succession extinguished his hopes, and left him to mourn in solitude over the miseries of France. Every energy of his soul was, at length, ruined, by the decree of the national convention for the trial of the deposed and imprisoned king. He now seemed wholly to forget the neglect which had been offered him by the court, at a time when his advice might have effectually forestalled it, and he felt nothing but the desire of serving the king and his family with the utmost extent of his talents. He accordingly wrote to the president of the convention, requesting the liberty of being permitted to act as one of the counsellors of the fallen monarch. Three had already been appointed, but one having, from prudential motives, declined the office, Lewis, who wait at this proof of attachment from his old servant, immediately nominated Maleshberbs in his stead. Their interview was extremely affecting, and Lewis, during the short interval before his death, showed every mark of affection for, and confidence in, his generous advocate. Maleshberbs was the person who announced to him his cruel doom, and was one of the int who took leave of him previously to his execution. After that catastrophe
M A L

catastrophe he again withdrew to his retreat, and with a deeply wounded heart, refused to hear any thing of what was acting among the blood-thirty Frenhans. As he was one morning walking in his garden, he observed four savage
looking wretches directing their courfe to his house, and
hailing home, they found them to be officers from the
revolutionary tribunal come to arrest his daughter and her
husband, who had formerly been president of the parliament
of Paris. The separation of these persons from his family was
depressing to his heart, and it is probable that his own
arrest shortly after was a relief to his feelings. He had long
been esteemed as father of the village in which he lived, and
the rustic inhabitants crowded round to take leave of
their ancient benefactor with tears and benedictions. Four
of the municipality accompanied him to Paris, that he might
not be suffered by soldiers like a criminal. He was shut up
in prison with his unfortunate family: and in a few days the
guillotine separated his fon-in-law Lepelletier from his wife;
and the accumulation of Maleherbes with his daughter and
grand-daughter, "for a conspiracy against the liberties of
the people," was followed, as a matter of course, by a sen-
tence of death. The real crime, as it was basely denomi-
nated, of this excellent man and worthy patriot, and which
the convention never pardoned, was his defence of the king,
an act in which he gloried to the latest hour of his exil-
eement. He probably thought it honour to die by the fame
russian hands that had spilt the blood of his master. The
condemnation of the females almost overcame the manly for-
titude which he displayed in every personal suffering; his
courage, however, returned at the prifon, and they prepared
for the death which was the last and only important event
that they had to encounter. His daughter had exhibited
the noble spirit with which he was inspired, for upon taking
leave of Mademoiselle Sombrueil, who had saved her father's
life on the second of September, he said to her, "You
have had the happiness to preserve your father, I shall
have the consolation of dying with mine." On the fatal
day, Maleherbes left the prifon with a serene countenance,
and happening toumble against a stone, he said with much
pleafantry, "a Roman would have thought this an unlucky
omen, and walked back again." Thus perilled the venera-
able Maleherbes in April 1794, when he had attained to his
seventy-third year. He was unquestionably one of the most
fportled and exemplary characters of his time. The subfe-
cuent government has since made some reparation for the in-
jury; but it is too diftinguishing his bult to be placed amon-
g the great men who have relleived honour upon their

M A L E S H E R B E S, in Geography, a town of France, in the
department of the Loiret, and chief place of a canton, in
the district of Pithiviers; 10 miles N.E. of Pithiviers. The
place contains 945, and the canton 6587 inhabitants, on a
territory of 2423 kilometres, in 22 communes.

MALESTROI, a town of France, in the depart-
ment of Morbihan, and chief place of a canton, in the
district of Ploermel; 7 miles S. of Ploermel. The place con-
tains 1800, and the canton 11,734 inhabitants, on a ter-
itory of 255 kilometres, in 2 communes. N. lat. 47°
40'. W. long. 2° 3'.

nate, where the Dutch have a settlement. N. lat. 8° 55'
E. long. 12° 14'.

MALGARDEN, a town of Weftphalia, in the bisho-
palric of Olmbruck; 3 miles W.S.W. of Vorden.

MALGARO, a town of Italy, in the department of
the Lazio; 10 miles N.E. of Como.

MALHAR, a town of Hindoostan, in Vifapour; 20
miles E. of Poona.

MALHATTY, a town of Bootan; 60 miles N. of
Disangpour.

MALHERBE, Francis de, in Biography, a cele-
brated French poet, was born about the year 1536 at Caen,
in Normandy. His father, who was an inferior law-office,
embraced the Calvinistic doctrines a short time before his
death, which so much displeased the fon, whose governing
maxim on this point was, "That a gentleman's religion
should be that of his prince," that he left his native pro-
vince, and entered into the household of Henry d'Angou-
lee, natural fon of king Henry II., and governor of Pro-
vice. Little is known of the subject of this article, till he
was mentioned by Perron to Henry IV., as one who had
furpassed all other composers of French poetry: two or
three years after this time, i.e. in 1605, Malherbe first
came to court, being then about 50 years of age. The
king received him into his favore, and gave him a liberal
salary. He was chosen, with one other, to make the
morning and evening verses of the monarch. He died at
Paris in 1628. He is represented as of a very unamiable temper; splanetic
and sarcastic, and as having little feeling for the common chapi-
ties of his kindred. He was perpetually engaged in law-
suits, and his bon mots were frequently rude and severe;
to a young lawyer who showed him a poem of his own
composition, he said, "Had the alternative been given you
of being hanged or writing these verses, you might have
been excused producing such a ridiculous piece." Dining
once with the archbishop of Rouen, he fell asleep after
dinner: the prelate waked him to go and hear a sermon he
was to preach: "I can," said Malherbe, "sleep well
enough without that." His ruling passion was that of
guarding the purity of the French language, of which he
exhibited a proof almost in his dying moments, when he
reproved his nurse for using a word that was not of good
authority: and it is farther said, that when his confessor
was describing to him the happiness of a future world in
mean and vulgar terms, he exclaimed, pray say no
more, I despair. With all his de-
fects Malherbe is revered as the father of cultivated French
poetry. His works consist of odes, fantasies, sonnets, ep-
igrams, songs, and other short pieces, some of which are
merely complimentary addressés to the great, and some of
a devotional cast. The best editions of his works are
in 3 vols. 12mo. 1722; and in octavo 1756, edited by St.
Marc. Moreiri.

MALHEUROUX, in Geography, a small island in the
gulf of Mexico, near the coast of West Florida. N. lat.
30° 6'. W. long. 89° 28'.

MALIANA, or MANDIANA, a town of Algiers, much
frequentcd by pilgrims, on account of the tomb of a saint,
called "Sede Youleph," 12 miles S.S.E. of Telfelfad.

MALIC Acid, in Chemistry, is a vegetable compound,
which exists ready formed in many unripe fruits; and con-
tributes, almost exclusively, to give common apples to the
barberry, the plum, and the sloe. It was discovered by Scheele in the year 1785. He has given us the follow-
ing scheme for ex tribunal, in Crel's Chemical Journal
for that date. Saturate the juice of unripe apples with car-
bonat of potash, and to the solution add acriat of lead till a turbi-
a turbidness ceases to be produced. The precipitate, which is a compound of the male acid with oxyd of lead, must be washed in a large quantity of water, and afterwards treated with dilute sulphuric acid; fresh portions being poured on, until the mixture has lost its foundation flavour, and become perfectly clear. The malat of lead, by this treatment, will be decomposed, a sulphat being formed in its place, and the male acid remaining free in the supernatant liquor. To separate them the fluid must be passed through a filter. Vaquerin has since ascertained, that the acid in question may be obtained from the \textit{fumipericium telorrum}, or common house lead, more advantageously even than from the apple. It exists in this vegetable combined with lime; and the mode of operating, which he has recommended, differs but little from the preceding, except in adding acetic of lead to the expressed juice, without the previous intervention of carbonat of potash. Annales de Chimie, t. 34. p. 127.

Besides the above processes for extracting male acid, it may also be formed artificially by the action of nitric acid upon sugar. If equal quantities of nitric acid and sugar be beat together, till the mixture attains a brown colour, two new acids will be found to have been created, having very different properties from the one originally employed. The most abundant of these is the oxalic, or that which gives fourness to the \textit{oxalis acetosella}, or common wood sorrel, whence its name, and which will be more particularly treated of under that article. (See Oxalic acid.) The other is the malic; and the mode of separation employed by Scheele, who was the discoverer of this fact, is as follows: Add lime-water till a precipitate ceases to be produced; and after having filtered the liquor, prefix a farther quantity, sufficient to neutralize the malic acid. Alcohol must next be poured in, which will cause a coagulation to take place. The product is a malat of lime, which, when separated by the filter, and washed with fresh alcohol, must be re-dissolved in water. This, as before, must be decomposed by acetic of lead; and the same means referred to, to collect the free acid.

Male acid, obtained by any of these methods, is a brownish-red liquid of a pungent and very four taste. It is incapable of crystallization, and presents thus a particular distinction from the other vegetable acids. When evaporated, it becomes thick and viscid; and if exposed in thin layers to an atmosphere tolerably free from moisture, it dries, forming a brilliant varnish. By heat it is easily decomposed, becoming first of a deep colour, and exhaling a thick and pungent vapour. The coaly matter which it leaves behind is very light and spungy, familiar to that yielded by mucilage of sugar. The volatile products, when collected in close vessels, are, according to Fourcroy, (System viii. 270.) an acid water, much carbonic acid, and some carburetted hydrogen. The male acid is liable to spontaneous decomposition, when long kept in a fluid state. All the powerful acids act upon it, and change its nature. By the sulphuric it is reduced to coal, and nitric acid changes it into the oxalic; a proof of the latter containing the greatest proportion of oxygen. Male acid unites with different bases, and forms a class of salts denominated malats. These have been but little examined, except by their discoverer Scheele. The malat of potash, soda, and of ammonia are very soluble and deliquescent. The neutral malat of lime exists in the form of irregular crystalls, which are difficult of solution, even at a high temperature. The pungence of a flight excess of acid, however, forms a super-malat, which is very readily dissolved. It is this compound which is contained in the common house leek. Male acid, on being added to barytic water, causes an immediate precipitation; but no such effect occurs with fritton. The latter fact, therefore, we may infer, is considerably more soluble than the former. Of its combination with the other earths, but little more is known than that with magnesia it forms a compound which is deliquescent; while its product with alumina is very difficult of solution. It unites with some metallic oxyds; and precipitates mercury, lead, and silver from the nitrats of those metals. In this latter respect, it exhibits a striking difference from the citric acid, with which it is almost always more or less mixed in vegetables; that substance causing no change in the solutions just mentioned. (See Citric acid.) Male acid dissolves iron and zinc; the former of which yields a brown mixture incapable of crystallization; but the latter melt may be obtained in fine regular crystalls. It decomposes muriat of gold, the oxyd being reduced to the metallic state. This acid is not applied to any useful purpose.

MALICANDURGAM, in Geography, a town of Hindoostan, in Myfor; 19 miles N. of Alumahady. MALICE, in Ethics and Law, is a formed design of doing mischief to another; it differs from hatred. In murder it is maleice makes the crime; and if a man, having a malicious intent to kill another, the execution of his maleice kills a person not intended, the maleice should be confined to his perfon, and he shall be adjudged a murderer. The words ex malitia præsagitata are necessary to an indictment of murder, &c. And this malitia præsagitata, or malice preseoa, may be either express or implied in law. Express malice is, when one with a sedate, deliberate mind, and formed design, kills another; which formed design is evidenced by external circumstances, discovering that intention; as lying in wait, antecedent malignes, former grudges, and concerted schemes to do him some bodily harm. (1 Hal. P. C. 451.) Besides, where no malice is expressed, the law will imply it; as where a man wilfully poisons another; in such a deliberate act the law presumes malice, though no particular enmity can be proved. And if a man kills another suddenly, without any, or without a considerable provocation, the law implies malice; for no person, unless of an abandoned heart, would be guilty of such an act, upon a flight or no apparent cause. See MURDER.

MALICHAN, in Geography, a small island near the coast of China, in Quanzong, 10 miles S.W. of Macao.

MALICHO, a town on the S. coast of the island of Mindanao. N. lat. 7° 48'. E. long. 124° 21'. MALICIOUS MISCHIEF, in Law. See MISCHIEF.

MALICIOUS PROSECUTION. See INJURY.

MALICORNE, in Geography, a town of France, in the department of the Sarthe, and chief place of a canton, in the district of La Flèche; six miles N. of La Flèche. The place contains 1023, and the canton 10,226 inhabitants, on a territory of 225 kilometres, in 11 communes.

MALICOY, a low small island in the Indian ocean, between the Laccadive and Maldives iflands, surrouned with breakers, and dependent on a rajah of the Malabar coast. N. lat. 8° 16' 30". E. long. 75° 9' 30".

MALICURGINAGUR, a town of Hindoostan, in Myfor; 50 miles S. of Seringapatam.

MALIDIA, a town of Africa, on the E. coast of Tunis; 110 miles S.S.E. of Tunis.

MALIGHERY, a town of Hindoostan, in Baramaul; 30 miles S.E. of Dareaipoory.

MALIGNANT, in Medicines, that quality in a difeafe which renders it more than ordinarily dangerous, and difficult of cure.
MALIGNANT

Malignant is generally applied to such fevers as are epidemical or infectious, and are attended with spots and eruptions of various kinds. See Malignant Fever.

MALICHERY, in Geography, a town of Hindustan, in Myalore; 18 miles N. of Seringapatam.

MALIKUL, a lake of Ruffia. N. lat. 48° 20'. E. long. 65° 14'.

MALILLA, a town of Sweden, in the province of Smaland; 45 miles N.N.W. of Calmar.

MALINES, or Mechlin, a city of France, and principal place of a distric, in the department of the Two Nethes; lately the capital of a province of the Netherlands, comprehending a small territory with about nine towns and villages. It was the seat of an archbishop, and contains fix parish churches. The number of inhabitants in the town is estimated at 16,612, and in the two cantons at 246,629, in a territory of 87½ kilometres, in nine communes. The manufactures of the place, which are considerable, are those of bed-quilts, thread, and particularly lace, which is in high estimation all over Europe. In the arsenal is a foundry for cannon, and other instruments of war. The town is distant 12 miles N. from Brussels. N. lat. 51° 1' 50'. E. long. 4° 38' 45'.

MALINHEAD, the most northern cape of Ireland, in the distric of Inishowen and county of Donegal. N. lat. 55° 23'. W. long. 7° 16'.

MALINOV, an island in the mouth of the Volga, at its entrance into the Caspian sea. N. lat. 45° 8'.

MALISTA, one of the small Western islands, near the W. coast of Lewis. N. lat. 58°. W. long. 7° 4'.

MALIT, a town on the N. coast of the island of Timor. S. lat. 8° 24'. E. long. 125° 55'.

MALIVOGONGA, a large river of Ceylon, in the country of Candy, which rives at the foot of Adam's peak, a high mountain S.W. of Candy, and taking a N.E. direction, nearly surrounds the capital, and at length falls into the sea at Trincomalee.

MALIU GO, a town of Naples, in Calabria, 12 miles N.W. of Bifignano.

MALKAR, a town of Hindostan, in the country of Golconda; 54 miles W. of Hyderabad. N. lat. 17° 17'. E. long. 77° 53'.

MALKARABELA, in Zoology, the name of an East Indian species of serpent found in the island of Ceylon. It is remarkably variegated with white and dusky brown, in various figures.

MALKUTITZ, in Geography, a town of Silezia, in the principality of Breslau; nine miles S.W. of Breslau.

MALL, or Mallet, a smaller kind of mace, a weapon used by our ancient English archers for dispatching the enemies whom they had wounded with their arrows.

MALL, or Sea-mall, in Ornithology, the English name of the Larus Canus, which ewe.

MALLA, in Geography, a town of Africa, in the country of Woolly; 15 miles E. of Medina.

MALLABAQUEN, a lake of Chili; 60 miles N.E. of Valdivia.

MALLAMA, a town of South America, in Popayan; 30 miles S.W. of Pallo.

MALLANCY CHOKY, a town of Assam; 50 miles E. of Rangamarty.

MALLAPILLY, a town of Hindustan, in Myalore; 12 miles N. of Venchatighery.

Vol. XXII.

MALLARD, the Anas Bofher, in Ornithology. See Duck.

MALLAWALLE, in Geography, a small island in the East Indian sea, N. of Borneo. N. lat. 7° 2'. E. long. 117° 29'.

MALLEABILITY, in Physics, a property principally confined to some of the metals, by which their form can be changed by the action of the hammer. When the change of figure is effected by rollers, the substance is said to be luminable: when by wire drawing, it is called ductility. The property, however, is the same in all these processes. Some bodies are malleable only at a certain temperature, such as glafs, and some of the metals: others at all temperatures, to a certain degree. This is the case with most of the malleable metals.

Some bodies are not malleable till they have received a certain mechanical treatment. In such cases, it is observed, that when the body is brittle, it is under its crytalline form, or that itate in which its fracture exhibits some regular figures. This is the case with iron and zinc. See Metal and Zinc.

MALLEABLE, something hard and ductile, and that may be beaten, forged, and extended under the hammer, without breaking.

All metals are malleable, not excepting even quicksilver; but gold is so in the greatest degree of all. The chemists have long fought the fixation of mercury, or to render it malleable. See Mercury, and Freezing.

MALLEAM, in Geography, a town of Hindostan, in the Carnatt; 24 miles S.W. of Trichinopoly.

MALLEAMOTH, in Botany, a low tree, or rather shrub, growing in Malabar. Of the roots are made hafts for knives, the leaves serve to drefs the ground, and being fried in oil of palm, furnish a liniment for removing the impetigo, and drying the pufhules of the small-pox. A decoction of the same, in common water, is used as a fomentation to mitigate the pains of the lachrymoids.

The root pulverized with ginger andfaction, and exhibited in an infusion of rice, cures the dropsy by powerfully promoting a discharge of superfluous secretions by the urinary passage. Acula recommends the shrub principally for two effects: first, against fluxes of the belly; for which purpose, however, it is of less efficacy than other medicines; secondly, for curing all kinds of erysipelas, especially such as proceed from mere bile. They macerate the whole root or trunk, bruised in a decoction of rice, and suffer them to remain there for some hours, that the water may contract an aciety; after which they anoint the erysipelas with it, and order the patient to drink a sufficient quantity of the fame twice a-day, the tocmach being first purged. They give the fame water to those who labour under an inflammation of the liver, and the burning heat of a fever; and use it mixed with a small quantity of the juice of the leaves of tamarind, to anoint the lips of the wounds, in order to prevent an inflammation.

MALLEI EXTERNI, in Anatomy, the name given by Albinus and others to a muscle of the malleus, sometimes called laxator tympani. See Ear.

MALLI EXTERNUS, the name under which Winslow and others have described the tenfor tympani muscle. See Ear.

MALLEI SUPERIOR, is the muscle described by Albinus as the laxator tympani, and by some others as the laxator tympani minor. See Ear.

MALLEMANS, Claude, in Biography, descended from a noble family, was born at Beaune, in Burgundy, about
about the year 1646. He came to Paris while he was very young, where he pursued his early studies, and, in 1663, he entered among the prebends of the congregation of the Oratory, and afterwards attached himself to the university of Paris. Here he fulfilled the duties of professor of philosophy for more than thirty years with great reputation, and had the honour of giving instruction in this science to the duchesses of Burgundy. He died in 1723, at the advanced age of seventy-seven, and in circumstances of distress and great poverty. He poissied a very inventive genius, and was a zealous advocate for the philosophy of Des Cartes. He invented a machine for making all sorts of dials, and was author of "A Physical Treatise on the World;" "A New System of the Load-stone;" an attempt to solve "The famous Problem of the Quadrature of the Circle;" he published many papers in the "Journaux des Scavans," between the years 1747 and 1716. Morelli.

MALLE-MUCKE, in Ornithology. See Fulmar and Procera Glacialis.

MALLENOWITZ, in Geography, a town of Moravia, in the circle of Hradisch; 10 miles N.E. of Hradisch.

MALLEOLARIS, in Anatomy, malleolar, an epithet applied to two small branches of the anterior tibial artery, distributed on the ankle joint. They are distinguished as external and internal. (See Artery.) The term is sometimes used in speaking of a process of the tibia, and one of the fibula. See Malleolus.

MALLEOLI, among the Romans, bundles of any combustible matter befiezed with pitch, and used by the Roman soldiers either for giving light in the night-time, or for setting fire to some of the enemies' works.

The malleoli were sometimes fixed to a dart or javelin, that they might be sure to catch firm hold, and communicate the fire wherever they happened to light.

MALLEOLUS, in Anatomy, a technical term equivalent to ankle. It denotes the bony prominences, which protect the joint of the ankle. The inner and smaller of these (malleolus internus) is a process of the tibia; the outer and larger (malleolus externus) is a part of the fibula. See Extremities.

Malleolus, in Ichthyology, a name given by Gara and some others, to the fish called by Arifotle and the other old writers, Phyraena, and by the Italians luzzo marino.

It is a beautiful fish, and seems to belong to the scembri, or mackerel kind. Salvian has figured it under the name of fugis, a name by which it is also called by Varro and some other old authors; but Salvian's figure is very imperfect; he has omitted the back-fin.

Mallealeam, in Geography, a town of Hindooftan, in Myfore; nine miles S. of Sankerdergam.

Mallesundrum, a town of Hindooftan, in My- fore; 10 miles E. of Sankerdergam.

Mallet, David, in Biography, a poet and miscellaneous writer, a native of Scotland, was probably born in Perthshire. The name of his family was Mallow; little is known of him in early life, but in 1720 he was tutor to the children of a Mr. Hope, near Edinburgh, and at the same time attended lectures in the university of that city. He had already distinguished himself by some poetical compositions, particularly by a pastoral, which brought him into notice among the Scottish literati. The treatment which he met with at Mr. Hope's did not accord with his expectations, and in 1723, he gladly accepted the offer of accompanying the two younger sons of the duke of Montrose to Winchell. About this time he printed in the "Plain-Dealer" his admired ballad of "William and Margaret" its success induced him to resume his poetical studies, and in 1728 he published "The Excursoon." About this time he changed his name from Malloch to Mallet, and in 1731 his tragedy of "Eurydice," which had been planned some years before, was brought on the stage, and was favourably received. He had now attained to a sufficient degree of consequence to be admitted to the company of men of rank and literary eminence; among these was Pope, who ridiculed the critics and commentators he echoed, in a poem published in 1733, "On Verbal Criticism." Immediately after this, the prince of Wales appointed him his secretary, with a salary of two hundred pounds a-year. In 1734, he attended the prince of Orange on a visit to Oxford, and presented to him a copy of verses written in the name of the university, on which occasion he was admitted to the degree of M.A. His tragedy of "Muftera" was brought on the stage in the year 1739, and met with some degree of temporary success. The longest poem of this author is entitled "Amynst and Theodora," it is a pathetic tale in blank verse, interspersed with much poetical description, but it is generally deemed tedious. Among the prose pieces of Mallet, the most important was "The Life of Lord Bacon," prefixed to an edition of his works, which appeared in 1740; this, though an elegant and judicious article of biography, is defective in the display of what constitutes the main point of that wonderful man's merit, his character as a luminary of science. After the death of Pope, lord Bolingbroke employed Mallet to blacken his memory, in revenge for clandestinely printing his "Patriot King." In reward for this service, his lordship left him his works, which in 1754 he published in five volumes quarto, but which not only involved him in difficulties, on account of certain sentiments contained in them subversive of the principles of revealed religion, but which did not produce to the editor any profit. After this he was engaged to write the life of the great duke of Marlborough, for which he was liberally paid, with an annual pension, though it is pretty well after-tained that he never made any progress in the business. He was next employed by the ministry to attack admiral Byng, with the view, no doubt, of diverting the public mind from the trial of that unfortunate commander. Byng was executed, and Mallet rewarded with a considerable pension. He died in 1765; is described as a man of agreeable manners and conversation, sufficiently attentive to his own interest, but ready to serve his friends. "Nothing," says his biographer, "elevated or dignified can be discerned in his character or principles. As a poet he may lay claim to elegant diction, splendid imagery, and pathetic sentiment, but he is deficient in energy and judgment." Johnson's Lives of the Poets.

Mallet, Edme, was born at Melun in the year 1713; and in 1751 we find him engaged in serving a cause near his native place, when he came to Paris, and was chosen professor of theology in the college of Navarre. He made himself known by various publications, of which the following were the principal: "Principes pour la Lecture des Poètes;" "Effay pour l'Etude des Belles Lettres;" "Effay pour les Bénéfices Oraîtres;" "Princes pour la Lecture des Orateurs;" "A Translation of Davila's History of the Carnage of War in France." He engaged to furnish the articles of theology, and the belles lettres for the Encyclopédie. His style in all his works is neat, clear, and unaffected. In his several treatises on poetry and polite literature, he limited himself to an accurate exposition of the precepts laid down by the belles lettres, illustrated by select examples. As a man and a friend,
MAL

a friend, he was an object of esteem to all who knew him, on account of his mildness, moderation, and candour.

Mallet, James Andrew, a professor at Geneva, descended from a good family in that city, was born in 1740; he was defined for a military life, but was prevented from pursuing it by an accident in his youth, by which the muscles of his legs became contracted, and he continued lame through the whole of his life. He was educated in the public school of Geneva, and displayed an early attachment to the mathematics. From Geneva he went to Bafil, and studied with great success under the celebrated David Bernouilli. In 1764 he obtained a prize from the academy of Lyons for the best answer to a mathematical prize question, and in the following year he made a tour to France and England, in the course of which he formed an acquaintance with Lalande at Paris, and the late Dr. Mallet, at London, and the tale which M. Mallet acquired for astrology, was no doubt a consequence of his intimacy with these eminent men. In this science he was greatly assisted by his profound knowledge of the mathematics, in which he was continually exercising his genius and talents. He wrote two papers on the calculation of chances, which were inferred in the "Acta Helvetica;" and at the request of Lalande, he calculated a table of the aberration and nutation of the stars of the first and second magnitude, which was published in the "Connoissance des Temps," and afterwards in Lalande's great work on astronomy. On his return, he lived some time in the bosom of his family, till he was appointed by the academy of Peterburgh, by the recommendation of Lalande and Bernouilli, to observe the transit of Venus in 1769, at one of the northern stations made choice of for that purpose. He was accompanied by M. J. L. Pièret, but the object of their mission was in a great measure lost by the unfavourableness of the weather. On his return, he formed an intimate acquaintance with J. A. Pièret of Geneva, who assisted him in his astronomical observations, with instruments which Mallet had procured at his own expense from England. In 1777 he was elected a member of the commision appointed to draw up a plan for settling the disputes by which the harmony of the little republic had for fifteen years been disturbed, and which were at length silenced for some time, by the intervention of foreign powers. Though Mallet was not at all ambitious of literary fame, he was honoured with unfrequented marks of distinction by several foreign societies. He was one of the members of the Academy of Sciences at Paris, and some of his best astronomical observations may be found in the memoirs of that learned society. He maintained an epitaphial correspondence with the most learned astronomers in Europe; and at his country house, where he spent the greater part of his time, he employed himself in making astronomical observations, and in conversing with the neighbouring farmers on subjects of rural economy. While at Geneva, he led a retired life, but had a weekly meeting of literary friends at his house, and attended the meetings of the Society for the Encouragement of Arts. He was visited by many foreigners of distinction, and was universally esteemed for his talents, integrity, and benevolence. He died in the year 1790, of an apoplectic fit. Gen. Biog.

Mallet, a large kind of hammer, made of wood; much used by artisans who work with a chisel, as sculptors, masons, and stone-cutters, whose mallet is ordinarily round; and by carpenters, joiners, &c. who use it square. See Hammer.

There are several sorts of mallets used for different purposes on ship-board. The caulking-mallet is chiefly employed to drive the oakum into the seams of a ship, where the edges of the planks are joined to each other in the sides, deck, or bottom. The head of this mallet is long and cylindrical, being hooped with iron to prevent it from splitting in the exercise of caulking. There is also the forging-mallet, used in forging the rigging, by binding the spun-yarn more firmly about it than it possibly could be done by hand; which is performed in the following manner; the spun-yarn being previously rolled up in a large ball, or clump, two or three turns of it are paffed about the rope, and about the body of the mallet, which, for this purpose, is furnished with a round channel in its surface, that conforms to the convexity of the rope intended to be served. The turns of the spun-yarn being Strained round the mallet, fo as to confine it firmly to the rope, which is extended above the deck, one man paffes the ball continually about the rope, whilst the other, at the same time, winds on the spun-yarn by means of the mallet, whose handle, acting as a lever, strains every turn about the rope as firm as possible. Falconer.

Mallet, Maul, or Mall, in Military Language, a weapon formerly used both by the English and Scots. In the memorable combat fought in Bretagne, in the year 1315, between thirty champions on the part of the English, and the like number on that of the French, one of the English champions, named Billesford, was armed with a leaden mallet weighing twenty-five pounds. We learn also from father Daniel, that the English archers still used mallets in the time of Louis XII., who began his reign in 1515, and died in 1554; in the ancient poem of the battle of Flodden, the mention of leaden mallets often occurs; and from the following description there given of it, it seems as if the head of the mall was entirely of lead, hooped round at the ends with iron:

"Some made a mall of mally lead, Which iron all about did bind."

Ralph Smith equips an archer with a malle of lead, five feet long, and a pike with the same, hanging by a girdle with a hook; meaning, probably, by this description, that the handle of the mall should be of this length, the end armed with a pike or spike; and this implement, we may imagine, was worn at the back, hung by a hook fixed in the centre of its handle, with a loop, or some other contrivance, to keep it nearly perpendicular. Father Daniel has engraved one of these mallets, which, in form, exactly resembles the present wooden instrument of that name, except that its handle is somewhat longer. This weapon seems to have been of French extraction; for we find, that in the reign of Charles VI., on occasion of a riot, the populace forced open the arsenal, and armed themselves chiefly with mallets, whence they were called "Maillotins." Mallets were tremendous weapons in the hands of strong active men, such as are described to have wielded them in the following verses:

"Two Scotch earls of an ancient race, One Crawford called, the other Montrose, Who led twelve thousand Scotchmen strong, Who manfully met with their foes With leaden mals and lances long."

"Then on the English part with speed The bills rested forth, and bows went back; The Moorish pikes and mallets send Did deal there many a dreadful thwack." Grose's Mil. Ant. vol. i.

Malletar, in Geography, a town of Hindooftan; 60 miles E.S.E. of Cochin.
MALLUS, in *Anatomy*, one of the small bones contained in the cavity of the tympanum. See EAR.

MALLI, in *Ancient Geography*, the inhabitants of the country now called Moulton, which lies. Their capital was situated not far from the river Ravee (anciently Hydraotes), somewhat below the present town of Towamba, which is a famous port on the Ravee, between Lחרore and Moulton.

MALICOLLO, or MANICOLA, in Geography, one of the New Hebrides, which, to the S.E., extends N.W. and S.E., and in that direction is eighteen leagues long. Its greatest breadth, which is at the S.E. end, is eight leagues, the remaining two-thirds nearer the middle one-third; a contradiction which is occasioned by a wide and pretty deep bay on the S.W. side. Captain Cook represents it as fertile and well inhabited: the land on the sea-coast is rather low, and lies with a gentle slope from the hills which are in the middle of the island. The inhabitants, forming what Cook denominates an ape-like nation, are deformed as the most ugly ill-proportioned people he ever saw, and different from any met with in this sea. They are a very dark-coloured and diminutive race; with long heads, flat faces, and monkey countenances. Their hair, mostly black or brown, is short and curly; but not quite so soft and woolly as that of a negro. Their beards are very strong, crisp, and bushy, and generally black and short. But what most adds to their deformity is a belt, or cord, which they wear around their waist, and tie so tight over the belly, that the shape of their bodies is not unlike that of an overgrown pimiento. The men go quite naked, except a piece of cloth, or leaf, used as a wrapper. Few women were seen, but they were not less ugly than the men; their heads are two-thirds this breadth, red; they wear a kind of petticoat; and some of them had something over their shoulders like a bag, in which they carry their children. Their ornaments are ear-rings made of tortoise-shell, and bracelets, wrought with thread or cord, and studded with shells, worn just above the elbow. Round the right wrist they wear hogs' tufles, bent circular, and rings made of shells, and round their left a round piece of wood, designed probably to ward off the bow-darting. The bridge of the nose is pierced, in which they wear a piece of white stone, about 1 1/2 inch long, and of a curved form. As signs of friendship, they present a green branch, and sprinkler water with the hand over the head. Their weapons are clubs and spears made of hard and iron-wood, and bows and arrows. The bows are four feet long, made of a stick split down the middle, and partly circular; the arrows are a fort of reeds, sometimes armed with a long sharp point of bone, and the points were covered with a substance found to be poison. Their arrows they carefully preserve in a quiver; and some of them are armed with two or three points, each with small prickers on the edges, to prevent the arrow from being drawn out of the wound. Their language is different from that of any other nation; the letter R often occurs in their words; and they express their admiration by hiking like a goose. Their houses are like those of the other isles, low, and covered with palm thatch. Their fruits, such as the bread-fruit, plamains, and cocoa-nut trees, are not so good as those of the Society or Friendly isles; but their yams appeared to be very good. Their animals are pigs and fowl; they have not so much as a name for a dog, and consequently they have none. Pieces of cloth, and marbled paper, were articles which they most esteemed; but edge tools, nifs, and beads, they seemed to disfavour.

The harbour, visited by captain Cook, is situated on the N.E. side of Malicollo, not far from the S.E., and in S. lat. 16 25' 20". E. long. 167 52' 23", and was called by him Port Sandwich. It lies in S.W. by S. about one league, and is one-third of a league broad. A reef of rocks extends out a little way from each point; but the channel is of a good breadth, and has in it from forty to twenty-four fathoms of water. In the port the depth of water is from twenty to four fathoms; and it is so sheltered, that no winds can disturb a ship at anchor there. Another great advantage is, that you can lie near the shore, as to cover your people, who may be at work upon it. Two reddish fish, resembling a large herring, and of the same size, were caught in the harbour, which appeared, by their effects on the hole where they take them, to be poisonous. This fort of fish is mentioned by Quiros under the name of abebus. Cook's Second Voyage, vol. ii. See New Hebrides.

MALLING, W. or Town Malling, a market-town and parish in the hundred of Larkfield, lathe of Aylesford, and county of Kent, England, is situated six miles distant from Maidstone, and thirty from London. The manor was given, says Lambard, "to Barbecue, bishop of Rochester, by king Edmund, the brother of Athelstane, under the name of Three Plough-lands in Mealinges." After a temporary alienation, it was restored to the bishops of this see, previously to the Domeday Survey, at which time "here was a church and a mill." In the year 1190, bishop Gundolph founded a Benedictine nunnery here, and endowed it with the manor, church, and other cites: he governed it in person during his life, but directed that in future it should be under the jurisdiction of an abbess, subordinate to the bishops of Rochester. In 1190, the abbey, as it was then called, and the village, suffered by fire, but were soon repaired: in the time of king John, the abbots had a grant of free-warren for all her demesne; and Henry III. added the privilege of a weekly market, and three annual fairs. After the dissolution, the manor and abbey-buildings were exchanged with archbishop Cranmer, and have since passed through various families to the Honeywoods. The late Filmer Honeywood, esq. pulled down the abbey-house, and with the materials erected the present manor, preferring, as much as possible, the ancient style and form. It is now the residence of George Talbot Hatley Foote, esq. Many parts of the conventual pile are, however, yet standing, being used as offices, together with a portion of the west end of the abbey-church, which is an interesting remain of Norman architecture, and is ornamented with sculptures of heads, animals, and interlacing arches. The abbey grounds are watered by a clear stream, which flows from Nether-Well, in the hamlet of St. Leonard's; where is yet standing the ruined tower of St. Leonard's chapel, a very strong remain, much resembling the keep of a Norman castle: its present height is seventy-one feet; the walls are seven feet in thickness.

The town of Weft Malling consists principally of one spacious, well built, and about half a mile in length, together with several detached manors belonging to respectable families. The parish church is a large fabric, consisting of a nave and chancel, with a Norman tower: the nave has been mellowly rebuilt since the year 1778, when the whole roof fell in, through the decay of the main columns. Here are some ancient and curious brasses. A small free-school was built in 1632, by a bequest of Mr. Francis Treffe. The population return in the year 1801, stated the inhabitants of Weft Malling to be 1693, occupying 192 houses.

In East Malling, a village about a mile distant, is Bradbourne, the seat of sir John Papillon Twyfden, bart., which, though not particularly extensive, forms one of the most delightful residences in Kent. Some good portraits of the learned

MALLOCCOCA, in Botany, so called by Forster and in the Upala Transactions, is a species of Grewia. See that article.

MALLOTUS, according to Loureiro, was so named from μαλλοτος, hairy, the capsule of this plant being profusely and remarkably beset with hairs. Loureiro. Cochinch. v. 2. 635. — Chaf and order. Diosia Polyandria. Nat. Ord. Trinocera, Linn. Euphorbii, Jaff.

Gen. Ch. Male, Cal. Perianth inferior, of three roundish, concave, woolly leaves. Cor. none. Stam. Filaments numerous, short, inserted into the receptacle; anthers two-lobed, roundish. — Female, Cal. Perianth of three triangular, equalateral, hairy, expanded leaves. Cor. none. Pfl. German superior, roundish, three-lobed; style none; stigmas three, oblong, hairy, coloured, reflexed. Peric. Capsule roundish, of three lobes, six valves, and three cells, single-seeded, covered with a multiplicity of long and soft hairs. Seeds roundish on one side, angular on the other, remaining on their proper stalks upon the receptacle, after the capsule has fallen away.

Obf. Loureiro remarks, that this genus is nearly related to Clifortia, but that it differs in having the capsule superior and three-celled, as well as in having three felisfle figmas.

1. M. Cochinchinensis. Cây. Bét. of the natives. Loureiro. — Found about hedges and neglected gardens, in Cochinchina and China. — The only species known. — This tree is of middling height. with spreading branches. Leaves alternate, roundish, generally three-lobed, a few however are undivided, ovate, pointed. all of them站立 on footstalks, are toothed and downy. Flowers reflexed, in loose clusters, ending in a spike.

Loureiro found the Male Flowers of Mallotus occasionally to vary, in having their calyx-leaves lanceolate, hairy, and spreading. Filaments upwards of forty, shorter than the calyx; anthers ovate, erect. — He met with this variety growing near Canton, but could find no female flowers in that neighbourhood.

MALOW, in Botany, &c. See MALVA.

MALLOW, Buffard. See MALOPE.

MALLOW, Jesus. See COCHCHORUS.

MALLOW, Indian, See URENA.

MALLOW, Indian, or Yellow. See SIDA.

MALLOW, Red. See ALCEA.

MALLOW, Sea, MALVA marina, in Natural History, a name not very judiciously given by some writers to a species of submarine substance, supposed in some degree to resemble the leaves of the common mallow. It is very common in the places where they fish for coral, and grows to the rocks without any regular root; it is found at different depths, but most usually far from the surface, and its height is usually about two inches; it is of a dusky greenish colour, with an admixture of faint yellow; it is composed of several leaves about half an inch broad, and a little more than that in length: each of these is falked to a pedicle of about an inch and a half long; the leaves are of a fine thin membranaceous substance, but their stalks or pedicles are thick and rough like horn. When examined by the microscope, many glandules discover themselves upon the surfaces of the leaves, but the flalks or pedicles are entirely covered with glandules in form of small prismatic bodies, which make it as rough in those parts as the common thistle. The flalks when cut transversely shew an infinite number of pipes or vessels running up to every part of the leaves. Count Marfigli has given an elegant figure of this, both as it appears to the naked eye, and by the microscope.

MALLOV, Syrian, in Botany. See Hibiscus.

MALLOV, Tree, varied-leaved, or Venetian. See LAVATERA.

MALLOV, Vervain. A species of the malva, or common mallow. Some have called the alcea by this name.

MALLOV, Yellow. See SIDA.

MALLOV, in Geography, a poft-town of the county of Cork, Ireland, situated on the river Blackwater, over which it has a stone bridge. It is much frequented on account of a soft and tepid spring (discovered in 1724), of the fame nature and efficacy as the Hot-wells of Bristol. Mallow was incorperated in 1688, and is governed by a provost and burgesses; and it lends a member to parliament. It is 117 miles S. W. from Dublin, and 15 N. by W. from Cork. A tract of country on each side of the river constitutes the liberties of Mallow, and is inhabited by several respectable families.

MALM, in Agriculture, a term sometimes applied to a fort of white marley clay. It is a substance that has been found beneficial on soils of the stiff clayey kind when laid on in pretty large proportions, as about sixty tons per acre. In one instance of this kind of soil, mentioned in the fourth volume of Communications to the Board of Agriculture, when applied in this proportion on a very large scale, the produce was full three times as great per acre, as in the original state. It is affected that the quality of this substance may be best proved by common vinegar; in which case a portion should be dried, and put into a wine glafs full of vinegar; when, if it inflantly begins to effervece and attract the acid, it may be depended on to be highly useful as a manure. It may be useful in other cafes also with great benefit.

MALMEDY, in Geography, a town of France, and principal place of a district, in the department of the Ourte; 23 miles E.S.E. of Liege. The place contains 4344, and the canton 12,067 inhabitants, on a territory of 2322 square miles, in fixed communes. This town has some mineral springs, which are reckoned equal, if not superior, to those of Spa. Its principal manufacturers are employed in making cloth and dressing of cotton. The town was taken by the French in October, 1794. N. lat. 51° 24'. E. long. 6° 7'.

MALMESBURY, a borough, market-town, and parish in the northern part of Wiltsshire, England, is a place of note in the monastic annals of the country, and still retains some interesting remains of its ancient splendour. Its early history is involved in doubt, and is so blended with the romances of monachism and superstition, that it is difficult to separate the facts from the fables of old chronicles. Legend states that a castle was built here four or five centuries before the Christian era. Other writers say that Dunwallo-Maltmattius, king of the Britons, gave it the appellation of Cær Bladon, and that it was afterwards successively denominated Ingleburne, Maidulfburgh, Aldelmibirg, and Meildum.

The history of this town is intimately connected with the history of its religious establishments. A convent of Brittany nuns, under the direction of Dunoth, is said to have been settled here towards the close of the sixth century, but its inhabitants being accused of living in a state of incontinency with
with the soldiers in the castle, it was suppressed by Augustin, the first archbishop of Canterbury. About this time Medolph, a Scot, remarkable for his piety and strict holiness of life, who had left his own country on account of persecution, fixed his residence here, and established a school for his support. Having collected a number of persons disposed to embrace a monastic life, he built a small monastery, which was shortly afterwards received under episcopal jurisdiction.

The town, at this period, seems to have been a place of considerable importance, but no records in its secular history are extant prior to the year 878, when it appears to have been attacked and burned by the Danes. It afterwards suffered again by fire in the reign of Edward the Elder, who constituted it a borough by charter, so that it is amongst the most ancient corporations in the kingdom. In the time of his successor Athelstan, two battles appear to have been fought in this neighbourhood, with the piratical invaders, already mentioned, in which the men of Malmesbury displayed great valour, and in consequence received a confirmation of their charter, with additional privileges. The place was subsequently the theatre of the contest, which king Stephen had to maintain against his turbulent barons, as well as against his competitor Henry of Anjou. The latter prince having laid siege to, and took it in a very short time, together with the castle, except one tower, which finding too strong to be taken by assault, he blocked it up with the view of reducing it by famine, and notwithstanding the vigorous attempts of Stephen to produce its relief, ultimately effectcd his object.

After this period nothing worthy of notice occurs in the history of Malmesbury, till the era of the civil wars in the reign of Charles I., when it was several times besieged and taken both by the republicans and royalists.

This town is built on a commanding eminence, peninsulated by two streams which unite to form the lower Avon. According to the parliamentary returns of 1801, it then contained 207 houses, and 1027 inhabitants, of whom 87 were returned as employed in different branches of trade, but this must be erroneous. In former times it was much more extensive than at present, many of the streets described in old records being totally demolished. The principal manufacture carried on here is that of woollen cloth, for which it was famous at an early period, but a number of hands are employed in the leather trade, and in the manufacture of gloves, parchments, glue, &c. There is a weekly market on Saturdays, and one also on the last Tuesday of each month, called the great market. Besides the churches belonging to the establishment, there are four places of public worship appropriated to the meetings of dissenters. The only charitable institutions are two alms-houses, and two free schools.

It has been already mentioned that the original charter to this town was granted by Edward the Elder, and confirmed by his successor Athelstan. Charters of confirmation, with additional privileges, were likewise bestowed by several succeeding monarchs. The present one is dated in the reign of William III. and by virtue of it the government is vested in an alderman, a high steward, twelve capital burgesses, and twenty-four assistants. The alderman and high steward, or their deputies, are Justices of the peace.

The other persons connected with the borough are styled landholders and commoners. In the latter charters the commoners are denominated free-burgesses, and constitute the lower members of the corporation. The landholders occupy a situation between them and the almighty burgesses, and are entitled by their office to the possession of an acre of land for life. Two members have been sent by this borough to parliament, from the third year of the reign of Edward I. During the last century it was celebrated for its electioneering contests, the higher branches of the corporation claiming the exclusive privilege of voting at elections, while the lower members maintained their title to participate in the nomination of their representatives. The point, howevcr, was finally decided by a committee of the house of commons in the year 1795, in favour of the alderman and twelve capital burgesses, who will, therefore, probably enjoy their privileges henceforth without opposition.

Malmesbury abounds with remains of antiquity, which sufficiently declare its former greatness. The most extensive and important of these is the abbey. By the donations and grants, both of princes and private individuals, this institution soon rose into great celebrity. The church was built in the form of an cross, and the whole buildings are said to have covered no less than forty-five acres of ground, including the garden and offices belonging to the monks. The church was a noble structure of great extent, and surmounted by two magnificent towers, one of which stood in the middle of the transept, and the other at the west end. This, as well as every other portion of the monastery, was built at different times, at least enduring such alterations and repairs as, no doubt, changed materially the original edifice. The western front is faced by Brown Willis to have been an uncommonly fine piece of architecture, and richly adorned with sculpture. Over the entrance, on this side, was a very magnificent window filled with painted glass. About a fourth of the building only now remains. Both the towers are long ago levelled with the ground, that at the west end having been battered down during the civil wars, when, it is probable, the cloisters also were demolished, as no trace of them can be discovered above ground. Part of a mosaic pavement, however, was found a few years ago, in a garden to the north-west of the church which is supposed to have formed the floor of that portion of the monastery. The southern porch of this church is a truly curious and interesting specimen of ancient architecture. It consists of two distinct divisions; an exterior arch, or coved recess, with a series of archivolt mouldings, charged with a great variety of sculptured figures in basso-relievo; within this is a square apartment, or vestibule, on each side of which are large statues in basso-relievo, and over the door is another compartment, said to be meant to represent the Deity on a throne, supported by angels, and jut within it is a head, supposed to represent our Saviour crowned with thorns. In the interior, the nave is divided from the side aisles by round columns, with plain capitals, above which are three rows of arches. The roofs in the vaulting are adorned with foliage and heads. On this altar-piece are carved griffins, dragons, and other grotesque figures. At the north-east of the church stands a building, denominated the abbot's house, the lower part of which is a remnant of that edifice.

A particular history and description of the abbey church, with several plates, illustrative of its architecture, have been published in the first volume of Britton's "Architectural Antiquities of Great Britain."

The remains of the old parish church of St. Paul stand on the southern side of the cemetery, and opposite, on the same side, is the old vicarage house. The building called Chapel-house, on the western side of the town, is supposed to have conformed the church of the ancient nunnery already mentioned. The White-hon inn, and the alms-house, together with the workhouse, and some other buildings, present remnants of more ancient structure, in general dedicated to religious purposes, or connected with monastic establishments,
As to the castle, erected by Roger, bishop of Sarum, as some suppose on the site of an older one, no traces of it can now be discovered with any certainty; but there is a well, still called the Castle-well, which probably belonged to it. In the market place stands a very beautiful market cross of stone, of an octagonal shape, and much enriched with a variety of sculpture. About a mile south from the town lies a field, called "Cam's Hills," in which are two enclosures, one of them perfectly square, and the other of an oblong shape, both of which are usually esteemed velligies of a Roman encampment.

Malmebury no less claims the attention of the biographer than of the antiquary, some of the greatest luminaries of remote and modern times having been born here. Among the more ancient worthies may be reckoned Myrdalpuf, Aldhelm, Johannes Scotus, and Roger le Poer, all of them men distinguished for their piety and learning. William of Malmebury is one of the most celebrated historians this country can boast of; and Thomas Hobbs, whatever prejudice may reply to the affersion, was undoubtedly a philosopher of great acuteness. He it was who laid the foundation of that moral and metaphysical system, the illustration and development of which have bestowed immortality on the names of Hartley, Hume, and Priestley. Moffatt's History, &c. of Malmebury, 8vo. 1805.

MALMIGNATTO, in Natural History, a name given by the inhabitants of the island of Corfica to a species of animal, or large insect, called by some tarantula, and igno- rantly supposing to be the same with the tarantula of Apulia. (See Tarantula.) This island produces neither wolves, serpents, nor many of the mischievous and detractive animals which infest the neighbouring countries; but it produces two species of this venomous insect, called the mal- mignatto; the one of these has a round body, and the other an oblong one, resembling that of our large kind of ant; it has also fix legs, not eight, and never makes any web: from all which it appears not to be a spider, but truly of the ant kind, though a monstrous sized one, and very venomous. The round-bodied kind, by its bite, occasions violent pains, a febulation of coldness and cramps all over the body; and the long-bodied one is yet more venomous. Its sting occasions an immediate lividness of the flesh, with intolerable cramps and convulsions over the whole body; sometimes the natural evacuations by stool and urine are also wholly stopped by it. The cure, in both cases, is to be attempted by cutting and cauterizing the wound, and dressing it with Venice treacle, as also by giving the same in large doses diffused in wine.

MALMISCH, in Geography, a town of Russia, in the government of Vitiatka, on Vitiatka; 100 miles S. of Viatka. N. lat. 56°44'. E. long. 50°14'.

MALMO, a small island on the W. side of the gulf of Bothnia. N. lat. 63°15'. E. long. 18°46'.

Malmö, a sea-port town of Sweden, reckoned by some writers the capital of Scania or Schonen, situated on the Sound. This town is surrounded with walls, moats, and bastions, and is defended by several fortifications and a castle towards the sea. Here are two burgo-masters, a good school, one Swedish and one German church, an orphan-house, a large market-place, fine regular streets, and several woolen manufactories; nine miles S.W. of Lund. N. lat. 55°36'57". E. long. 13°11'44".

MALMSEÅ, a town of Sweden, in Sudermanland; 23 miles W.N.W. of Nykoping.

MALSBEY, or MALVAY, a rich luxurious kind of wine brought from Greece or Candia; so called from Mal-vaia, a city in Peloponnesus, the ancient Epidaurus, whence this celebrated liquor was first brought.

That brought from Candia is now esteemed the best.

MALNEY, or Malvays, is also the name of a kind of mul- cade wine brought from Provence.

MALNAIR, in Geography, a town of Hindoostan, in the province of Sirhind; 40 miles S.W. of Sirhind. N. lat. 30°26'. E. long. 75°25'.

MALNOS, a town of Hindoostan, in the circuit of Sirhind; 20 miles W.S.W. of Sirhind.

MALO, a town of Italy, in the Vincentin; 11 miles W. of Vicenza.—Allo, a town of Africa, in the kingdom of Fonia.

MALO, or Malos, St. a sea-port town of France, and principal place of a district, in the department of the Ille et Vilaine, situated on a small island joined to the continent by a mole, at the head of which is a strong fort. Before the revolution, it was the fee of a bishop suffragan of Tours, who was lord of the town. The harbour is large, and much frequented, though difficult of access on account of the rocks which surround it. It is strong by its situation on a peninsula, connected with the land by a narrow mole about six or seven hundred yards in length, and by the defence of 250 pieces of cannon mounted on its ramparts. But as it has no outworks, its fortifications could not long resist a regular siege. Its strength both by nature and art lies towards the sea. Several attempts have been made against it, at different times, but without success. It has always been a port for privateers, and on this account has been injurious to the trade of England. N. lat. 48°39'3". W. long. 2°11'26'.

MALO-de-la-Lande, St., a town of France, in the department of the Channel, and chief place of a canton, in the district of Coutances. The place contains 449, and the canton 10,532 inhabitants, on a territory of 400 kilometres, in 13 communes.

MALOBATHRUM, among the Romans, a precious kind of ointment, brought from the Indies through Syria to Rome.

MALOGOCCZ, in Geography, a town of Austrian Poland, in the palatinate of Sandomirz; 60 miles W. of Sandomirz. N. lat. 50°4'. E. long. 20°18'.

MALOGRANATUM. See Pomegranate.

MALOJAROSLAVETZ, in Geography, a town of Russia, in the government of Kaluga; 32 miles N. of Kaluga. N. lat. 55°. E. long. 36°14'.

MALOKETSKOI, a town of Russia, in the government of Tobolsk; 30 miles S.W. of Kamtski.

MALONG, a town of Hindoostan, in the Carnatic; 18 miles S. of Madura.

MALOOD, a town of Hindoostan, in the circuit of Cica- cade; 16 miles N.E. of Gunjam.

of the lilamen; figmas many, simple, brille-shaped. _Pet-
cric. Capsules roundish, of many cells, equal in number to
the figmas, forming a little head. Seeds solitary, kidney-
shaped.

Eff. Ch. Calyx double, the outer one of three leaves.
Capsules irregularly heaped together, single-seeded.
dows in Tuscan and Algiers.—_Root annual._ Stem erect,
hairy, rough. Leaves somewhat heart-shaped; the lower
ones obtuse; the upper generally three-lobed. Flowers
rarely-coloured; the petals wedge-shaped, truncated. Fruit
collected into a head, like the blackberry.—The whole plant
has greatly the appearance of a mallow, especially in the
shape and colour of its flowers. Desfontaines notices a var-
yety of this, whose leaves and corolla are twice the usual
size.
heart-shaped, even. Peduncles scarcely longer than the pe-
tiole. A native of Peru, where it was discovered by Domb-
by. — _Root annual._ Stem about a foot high, much branched,
red, villose. Leaves alternate, on footstalks, nerved, bright
green. Flowers axillary, on stalks, solitary, occasionally
two together, purple.—Professor Martyn observes that
"there are other Peruvian species with a simple calyx, which
might therefore constitute a distinct genus."
Leaves roundish, undivided, notched, villose. Stalks three
or four together, axillary. —A native of Spain.—Cavanilles
describes it thus. "Stem about six inches high, not much
branched. Flowers small and white. Fruit proportionally
larger than in the other species."
—Leaves oblong, three-lobed, pointed, toothed, smooth.
Stalks solitary, axillary. —Found in meadows both in Spain
and Barbary.—Wildenow says it differs from the last in
having its leaves three-lobed, more acute, and thicker.
MALOPES, in Gardening, contains a plant of the herba-
ceous kind, of which the species cultivated is, the betony-
leaved malope (M. malacoides.)
Method of Culture.—This plant may be increased by fow-
ing the seeds, in the places where the plants are designed to
remain, as it does not bear transplanting well; when they
are found upon a warm border in August, the plants also
frequently fland through the winter, and flour early the
following spring, so as to produce good seeds; but when
found in the spring, this is rarely the case.
It is moitily necessary that the plants found in the spring in
pots should be protected in winter under a frame. They
f seldom continue longer than two or three years at most, as
good plants.
All of them afford variety among other plants in the bor-
ers, clumps, &c, of ornamented grounds.
MALOPINGOVSKOI, in Geography, a town of Ru-
ffia, in the province of Ulbing; 108 miles N. of Ulbing.
MALORN, a small island in the N. part of the gulf of
Finland. N. lat. 66° 32'. E. long. 23° 27'.
MALO-ROUSANS, the denomination of those people
who inhabit the country between the Dnieper and the Don-
etsk, called in the maps Little Russia. They are described
by Dr. Clarke (Travels in Russia) as a race much superior
to the Russians; being not only of a better aspect, but more
industrious, more courageous, more cleanly, and more polite.
With regard to their cleanliness, a traveller might fancy him-
self transported from Russia to Holland. In their features,
the Malo-Russians resemble the Cossacks; and the similitu-
date which both bear to the Poles, seems to imply a descent
from a common origin. In one point, however, viz. the
love of liquor, the Malo-Russians are unfortunately as gross
delinquents as their neighbours to the eastward.
MALORY, a town of Hindoostan, in Myfor; 13 miles N.E. of Oudnore.
MALOSCHANY, a town of Russia, in the govern-
ment of Pikov; 24 miles N.E. of Pikov.
MALOUCA, a town of Syria, which has two churches;
20 miles N.N.E. of Damafk.
MALOUR, a town of Hindoostan, in Baramul; 13 miles N. of Namucul.
MALOWITZ, a town of Bohemia, in the circle of Ko-
gnignitz; seven miles E. of Gitchin.
MALOWPUR, a town of Hindoostan, in Oude; 48
miles W. of Lucknow.
MAL-PADDY, a town of Hindoostan, in Myfor; 11
miles W. of Tripatore.
MALPARTIDA, a small town of Spain, in the pro-
vince of Estramadura, containing a population of about
1300 inhabitants. It is tolerably well built; and has a
handsome parish church, built with granite, supplied from
an adjacent quarry; about three miles from Placentia.
MALPAS, a mountain of France, through which the
Languedoc canal passes.
MALPFAS, a market town and parish in the hundred of
Broxton, and county palatine of Chelver, England. It is
situated on a lofty eminence at a short distance from the
river Dee. The name of this place is supposed to have been
derived from the term Malo plana, illustrative of the steep,
narrow, and intricate road by which it was anciently ap-
proached. The manor was one of the baronies granted, at
the time of the conquest, to Hugh Lupus, earl of Chelver,
from whom the present noble family of Cholmondeley is
descended. The magnificent castle by which it was adorned
for several centuries, is now to entirely demolished; that
fearfully a vellige of it can be discovered. Three streets,
tolerably well built and paved, form the chief part of the
town, which, according to the parliamentary returns of
1801, contained 191 houses, and 966 inhabitants. In the
church is a vault, appropriated as the burying place of the
casts of Cholmondeley, who derive their title of viscount
from this town. The living is a rectory, and being very
valuable, is divided into two portions, supporting two rectors,
and the like number of curates. Malpas has a free-grammar-
school and alms-house, both of which were founded by sir
Randle Breerton. Adjoining the town is Cholmondeley
Hall, the magnificent mansion of earl Cholmondeley, a mo-
dern building, seated on a pleasant, and somewhat elevated
site. The ancient structure, though venerable in appear-
ance, and moated round, was a very disagreeable residence,
from being placed in a low and marshy situation. Lyfons's
MALPICA, a town of Portugal, in the province of
Beira; 16 miles S.S.E. of Castel Branco.
MALPICO, a town of Spain, in Galicia, on the sea-
coast; 20 miles W. of Coruna.
MALPIEVS, a town of Spain, in New Castile; 25 miles
W. of Toledo.
MALPIGHI, Marcello, in Biography, a celebrated
Italian naturalist, was born at Crevalcore, near Bologna, in
1628. Having devoted himself to the study of medicine,
which he selected for his profession by the advice of Natalis,
his tutor in philosophy, he began to apply himself to ana-
atomy
tomy with great zeal under Maffani, who had a school for dissection in his own house. He soon became distinguished by the philosophical spirit of observation with which he pursued his enquiries, and his ardent zeal for natural knowledge was accompanied with a singular modesty. His merit procured him, in 1653, the degree of doctor in medicine, and the appointment of professor of physic, in the university of Bologna, in 1656; soon after which he was invited to Pisa by the grand duke of Tuscany, Ferdinand II. This prince, partly from his own hereditary taste, and partly at the invitation of his accomplished brother, the cardinal Leopold de Medici, was very desirous of encouraging the arts and sciences in his dominions. He here formed a friendship with the celebrated Borelli, to whose communications he acknowledged himself indebted for the discovery of the utility of the philosophy of the schools, and of the necessity of experiment as the sole foundation of a true philosophy. The air of Pisa, however, did not agree with Malpighi, whose health was always delicate, and he was obliged to return to Bologna in 1659, where he was immediately re-appointed to the professorship of medicine. Here he resumed his inquiries with great diligence, and was the first who employed the microscope in examining the circulation of the blood. In 1662, on the death of Cattelli at Mefiina, Malpighi was invited by the magistracy to succeed him as professor of medicine in that school, with a large salary. He occupied this post almost four years with considerable reputation; but as he paid little respect to the doctrines of the Galenists and Arabians, and excited much jealousy in his colleagues, he became involved in controversies, which rendered his life very uneasy. He therefore resolved to return to Bologna in 1665, and accepted the offers of his countrymen to continue among them, notwithstanding the pressing invitations which he received to return to the chair of the body of his alma mater. His anatomical pursuits now occupied a great portion of his time, at a villa, in the vicinity of Bologna; and his reputation extended throughout Europe, as a philosophical inquirer; so that, in 1669, he was elected a member of the Royal Society of London; which body afterwards testified their regard for him by printing his works at its own expense. At Bologna, he continued to teach others, and to instruct himself, with great reputation, till the year 1691. Cardinal Pignatelli, who had known him, during his own residence as legate at Bologna, being that year raised to the papacy, by the name of Innocent XII., chose Malpighi for his chief physician and chamberlain. The latter of course gave up his academical appointments, and removed to Rome, where, having previously suffered from gout and nephritic complaints, he died of an apoplexy at the palace of Monte Cavallo, November 29th, 1694, in the 67th year of his age. His remains were embalmed, and conveyed to Bologna, where they were interred with great funeral honours in the church of St. Gregory, and a statue was erected to his memory. He was married to the fider of his preceptor Maffari; but left no issue. Malpighi is described as a man of a serious and melancholy temperament, which is confirmed by his portrait in the meeting-room of the Royal Society at Somerset House. He was indefatigable in the pursuit of knowledge, on the pure ground of experience and observation, ever candid in his acknowledgments to those who had given him any information, and devoid of all ostentation or pretension on the score of his own merits. He ranks very high among the philosophers of the physiological age in which he lived, the age of Harvey, of Rea, of Rudbeck, and of Bartholin, when nature began to be studied instead of books, and the dreams of the schools gave place to practical enquiries and observations. Hence arose the discoveries of the circulation of the blood, the appetent system of the animal body, and the true theory of generation. To such improvements the investigations of Malpighi, relative to the anatomy and transformation of insects, particularly the silk-worm, and the development of the chick in the egg, lent no small aid. From these enquiries he was led to the anatomy and physiology of plants, in which he is altogether an original, as well as a very profound observer. His line of study was the fame as that of Grew, but these philosophers laboured independent of each other, and their frequent coincidence evinces the accuracy of both. See Grew.

The first work which he published in 1661, and which was afterwards frequently reprinted, comprised his microscopical observations relative to the intimate structure of the lungs, and was entitled "Observationes Anatomicae de Pulmonibus," &c. He published separate tracts concerning the brain, the tongue, the external organ of touch, the omentum, throat, and the niginate ducts, between the years 1661 and 1665; and subsequently, other tracts respecting the structure of the viscera, the kidneys, spleen, liver, membranes of the brain, &c.

Malpighi became a fellow of our Royal Society, as we have already mentioned, in 1669, in which year his essay "de formatione pulni in ovu" was frist printed, at London, in quarto, as well as his remarks on the "Bombus" or silk-worm, and "De Glansulis conchabatis," forming his three "Differtationes Epistolicae." His "Anatome Plantarum," addrested to the Royal Society, accompanied by observations on the incubation of the egg, was published by that learned body in folio, with many plates, in 1675 and 1679. His works were republished at London in 1686, making two folio volumes; and more correctly at Amsterdam, in 1687, 4to, and a polliumous volume appeared here, accompanied with an anecdote of his life, in 1687, of which a re-impression was given at Venice, and another at Leyden, the ensuing year. Some other dissertations are to be found in the "Bibliothea Anatomica," published by Le Clerc and Marget at Geneva in 1683; especially "De Cornuvm Vegetatione," "De Utero et Viviparorum Avis," and "Epitome quedam circa illam de ovo differtationem." His only medical work, "Consullatunm Medicinalem Centuria prima," was edited by Galperi, in 1713, 4to. Patau. He is not, indeed, distiguished as a practioner, but he deserves praise for pointing out the mischiefs of blood-letting, in the malignant epidemics prevalent in Italy in his time. An edition of the whole of his works was printed at Venice, in 1753, in folio, by Gavinelii.

The merits of Malpighi as a vegetable anatomist are of the highest and most original kind. The structure and component parts of plants had been little attended to before he entered upon his enquiries. His illustrations of their anatomy, as well as of their external configuration, even of such of their differences as arise from the attacks of insects, whence the various kinds of galls are formed, (see Galls,) are all no less faithful than original. As a vegetable physiologist, too, he doubtles advanced very far; and that subject being for entirely new when he and Grew entered upon it, nothing could be more unjust than to complain of the errors into which they have fallen. The principal of these, however, requires to be mentioned. They both conceived the woody fibres of plants to transmit the sap, though no perforation could be discovered in them. If this hypothesis now excite our wonder, we must recollect that no less a philosopher than Du Hamel adopted, and laboured with all his might to support, the fame opinion. Grew went a step nearer the truth than Malpighi, when he observed what they both took for trachea, or air-vessels, to be sometimes filled with sap; but
he did not hence correct his original idea, of those spiral-coated vessels being the lungs of plants, nor were they, till very lately, known to be the real sap-vessels, or arteries of the vegetable frame. (See Circulation of Sap. Drew, and Du Hamel.) Malpigha Opera. Hall. Bibl. Bot. Dryandr. Bibl. Banks. Dict. Elyo Dict. Hist. del la Méd.

Gen. Ch. Cal. Perianth inferior, of one leaf, deeply five-cleft, erect, very small, permanent, converging; with two honey-bearing, oval, gibbous glands, adhering to three, four, or to all the segments, on the outside at the bottom. Cor. Petals five, orbicular, large, plaited, fringed, spreading, convolute; with long, linear claws. Stam. Filaments ten,awl-shaped, short, erect, forming a cylinder, combined at the base; anthers ovate, or rather heart-shaped Pyl. German superior, ovate; styles three, two, or only one, short, zigzag globoso. Peric. Drupa globoso, turuloso, large, one-celled. Seeds three or two, bony, oblong, obtuse, angular, single-celled; occasionally solitary, globoso, and three-celled. Keratn oblong, obtuse.

Eff. Ch. Calyx of one leaf, very deeply five-cleft, with two honey-bearing pores at the base of the segments externally. Petals five, roundish, with claws. Filaments adhering at the base. Drupa of one cell, with three seeds.

Obf. Most authors have described the calyx of Malpighia as composed of five leaves, but it is rather to be considered as of one leaf only, very deeply cloven.—We find nine species in Linnaeus, thirteen in the new edition of Hortus Kewensis, and twenty in Willdenow, from which we select the following as sufficiently illustrative of the genus. Many of them are beautifully figured in Jacquin’s works.

M. globosa. Smooth-leaved Barbadoes Cherry. Linn. Sp. Pl. 669. Att. Hort. Kew. ed. 2. v. 3. 105. Sims in Curt. Mag. t. 819. - Leaves ovate, entire, smooth. Peduncles umbellicated. - A native of the West India islands, where it is cultivated for the sake of its acid pulpy fruit, in flower and shape somewhat resembling our cherries. Jacquin says that the fruit is usually made into a preserve with sugar, but that he has eaten it in a crude state without suffering any inconvenience. This tree flowers in the winter and spring, and grows to the height of sixteen or eighteen feet, seldom however exceeding ten feet in this country. Trunk erect, delicately branched. Leaves opposite, nearly sessile. Flowers in terminal, axillary clusters, of a beautiful pink colour, and five-lobed, somewhat like a jasmine.

M. pyriformia. Many-seeded Barbadoes Cherry. Att. Hort. Kew. ed. 2. v. 3. 103. Andr. Repoll. t. 563. - Leaves entire, oblong, smooth, shining, with two glands at the base underneath. Clusters axillary. Flower-flakes with one gland. - A native of Trinidad, and one of those splendid plants of which lord Seaforth when he was governor of Barbadoes. It flowered in the flow of A. B. Linnamert, et al., at Boyton, in Wiltshire, in the month of April, whence Andrews’s figure was taken.—A floribunda of fine growth. Branches twiggy, covered with a brownish bark. Leaves opposite, large and handsome, on silky bristly stalks. Flowers in a spikelike cluster, yellow, appearing in November, but not expanding till the spring.

M. glandulifera. Quadrangular Malpighia. Att. Hort. Kew. ed. 2. v. 3. 103. Jacq. and Rar. v. 3. t. 1469. - Leaves elliptic-ovate, acute, undulated, downy, with four glands at the base underneath. Clusters axillary on uniglandular stalks. A native of woods in the Caracaces, flowering in June and July, but never bearing fruit.—This floribunda is about twelve feet high, branched. Leaves opposite, on short footstalks, from three to five inches long. Clusters axillary, solitary. Petals yellow, crisped at their edges, with furrowed claws and roundish borders.

M. volubilis. Twining Barbadoes Cherry. Att. Hort. Kew. ed. 2. v. 3. 105. Sims in Curt. Mag. t. 809. - Branches twining. Leaves oval, acute, shining. Clusters corybiform, terminal. - A native of the West Indies, flowering in our climates during the Autumn. - Stem shrubby, Bark befit with warty excrements, of an extremely small size. Leaves opposite, drooping, on weak, flattish footstalks. Flowers chiefly terminal, yellow, of very short duration.—This shrub (says Dr. Sims) is known in our nurseries by the name of Hiring excellens, but does not at all correspond with the character of that plant in Jacquin’s Historia Sismiana Americanorum.

M. coccigera. Linn. Sp. Pl. 611. Jacq. Rar. v. 3. t. 470. - Leaves subovate, toothed, or spinous. - Found also in the West Indies. - Stem two or three feet high, branched. Leaves lucid, cut off apparently at the ends, thorny. Flowers lateral, on single-flowered stalks, pale bluish-coloured.

Professor Martyn has added five species from Jacquin, which are unnoticed by other authors, though perhaps comprehended by them. These are named macrincenfis, diphyllas, adorata, grandifolia, and altafiri. Jacquin says also that the fruits of several species of Malpighia are gathered profusely and eaten in the West Indies. They have a pleasant acid flavour, which is always grateful to the inhabitants of hot climates. M. glabra however is most esteemed on this account. - This genus is well deserving of attention from cultivators potted of flowers or hot-houses, because many of its species retain their leaves all the year, and continue flowering from December to March, when there is the greatest scarcity of other flowers.

MALPIGIAH, in Gardening, comprehends plants of the exotic, evergreen, shrubby kind for the flower, of which the species cultivated are, the smooth-leaved Barbadoes cherry (M. glabra); the pomegranate-leaved Barbadoes cherry (M. puniceofolila); the flowering Barbadoes cherry (M. urceolata); the narrow-leaved Barbadoes cherry (M. angustifolia); the shining-leaved Barbadoes cherry (M. nitida);
The gently growth has been noticed as if possibly the fruit, which fe. She and her lord are very popular deities in the country of the Mahattas, where, at the elegant temple of Jejury, they are propitiated by numerous pilgrims. (See Jejury.) It does not, however, appear that the tales related of this avatar are extensively known, or that they are to be found in any very ancient books.

**MAL SCH**, in Geography, a town of the duchy of Baden; ten miles E. of Spire.

**MALS ENA**, a town of Italy, in the Veronese; 18 miles N.N.W. of Verona.

**MALKAR**, two small islands in the gulf of Bothnia. N. lat. 61° 55'. E. long. 21° 7'.—Alfo, a small island on the E. side of the gulf of Bothnia. N. lat. 61° 55'. E. long. 21° 7'.

**MALT**, in Agriculture, a name applied to barley, after it has undergone the process of malting; as by this means it becomes fit for making ale, beer, or other similar liquors.

Malpighia is the general name of a genus of plants, belonging to the family of the Malvaceae, which are more or less extensively cultivated in hot-houses. They are all ornamental, and many of them are of great size; some even attaining the height of a house, and being afterwards placed in a dry stove, and kept in a moderate warmth, water being occasionally given in small quantities at a time.

They all afford ornament among collections of plants of similar kinds in hot-houses.

**Malpighiæ**, in Botany, so called from the principal genus among them, a natural order of plants, the 67th in Jullien's system, or seventh of his thirteenth class. For the characters of this class, see Gerania and Guttiferae. The Malpighiæ are thus defined.

*Calyx in five deep divisions, permanent. Petals five, alternate with the calyx, furnished with claws and inserted into a glabrous disk placed under the germin. Stamens ten, inserted into the same disk, five of them opposite to the petals, the five alternate ones opposite to the segments of the calyx; the filaments are sometimes united at their base, another roundish. German either simple or three-lobed; styles three; stigmas three or five. Fruit either consisting of three capsules, or of three cells, the capsules or cells single-seeded. Corolla dilute of albumen, with a straight radicle, the lobes reflexed at their base. The plants are either small trees or shrubs. Leaves opposite, simple, with more or less appearance of stipules. Flower-flanks sometimes terminal, more frequently axillary, either single-flowered and several together, or solitary and many-flowered, the flowers either somewhat umbellate, or spikèd, or panicled, their partial flanks being, for the most part, jointed in the middle, and furnished there with a pair of small scales.*

The first section, with a three-lobed germin, and a fruit of three capsules, contains Boñifera and Tripotes.

The second section, with a simple germin and fruit, consists of Malpighia alone; see the preceding article.

A third section, of genera allied to the above, comprises: Tri- gonia of Aublet, and Erythronium of Browne and Linnaeus.

Cavanilles refers the genera of this order to the class Mal- adelpìa of Linnaeus, on account of a flatus, and by no means universal, combination of the bases of their filaments; or rather perhaps from the infection of those parts into one common annular disk or receptacle. This appears to us to be not only forcing nature, but to lead to much inconvenience in practice. It is the error of those who, undertaking the study or explanation of any particular tribe, or family, of natural productions, are ever devious of augmenting it by all possible means, and perhaps, with prejudiced eyes, see almost every thing as appartaining to their favourite subject.

**Malpláquert**, in Geography, a village of Hainaut, famous for a battle fought there Sept. 11, 1709, between the allies under the command of the duke of Marlborough and Prince Eugene, and the French under marshals Villiers and Bouillé. Victory was valiantly and obstinately contested; till at length the field of battle was abandoned to the confederates, who lost on this occasion 20,000 of their best troops, whereas the vanquished enemy did not lose half the number; 8 miles S. E. of Mons.

**Malpolon**, in Zoology, the name of a species of serpent found in the island of Ceylon, and beautifully va- negrated with red marks in the form of flars.

**Malsara**, in Hindu Mythology, a manifestation of the goddess Parvati to accompany her lord Siva, in his avatar, or incarnation, under the name and form of Kandela Rna, which he. She and her lord are very popular deities in the country of the Mahattas, where, at the elegant temple of Jejury, they are propitiated by numerous pilgrims. (See Jejury.) It does not, however, appear that the tales related of this avatar are extensively known, or that they are to be found in any very ancient books.

**Malseeena**, a town of Italy, in the Veronese; 18 miles N.N.W. of Verona.

**Maliskar**, two small islands in the gulf of Bothnia. N. lat. 61° 55'. E. long. 21° 7'.—Alfo, a small island on the E. side of the gulf of Bothnia. N. lat. 61° 55'. E. long. 21° 7'.

**Malt**, in Agriculture, a name applied to barley, after it has undergone the process of malting; as by this means it becomes fit for making ale, beer, or other similar liquors.

It is said, that the soil on which barley grows makes a considerable difference in the grain, and that the barley fittest for malt is that which grows on a rich, light, or gravelly soil, and which has been raised from seed brought from a farm of a different soil and situation. The fullest and largest grained parts of such crops should be chosen for making malt. It should be heavy, and perfectly sound, and such as has not suffered any accident in the field. Its being a very little heated in the mow is by some considered rather an advantage, as the grain will be more equally dried, and will consequently the more equally imbibe water; but when it has been so much hurt in the mow as to look blackish when broken at the thick end, it is unfit to make good malt. It is also found by experience, that barley taken immediately from the field does not malt so kindly as that which has been some time in the house or mow. And particular care should be taken that it is free from the seeds of weeds; for these in the malting are apt to give the grain a bad taste, which cannot afterwards be got rid of.

It is noticed that in the processes of germination, all the principles of the grain are put in action. The heat which it undergoes separates and divides its parts; and the viceract which it before possessed, is removed or converted into a sweet principle, or sugar.

But in order to its being malted, the barley is put into a cistern lined with lead or stone, and covered with water about five inches deep above the barley, to give room for its swelling. All the good grains sink in the water, but after flaring it, the imperfect or damped ones rise to the surface. These should be skimmed off, and given to poultry or hogs, for they will never make good malt. By the water's gaining admittance into the barley, a great quantity of the air is expelled, as appears from the number of bubbles which rise on the surface.

It is usual for the barley to be left in the water two or three days, more or less, in proportion to the heat of the weather and the dryness of the grain. A judgment is formed that grain is fully saturated with water, from its appearing turgid, and easily giving way to an iron rod, dropped perpendicularly into it. Or, by taking a corn from the middle of the cistern, and holding it steadily, by the two ends, between the fore-finger and thumb; profiling it gently, and if it continues firm when so profiled, and the skin does not break, it must soak longer; but if it bruises together and feels mellow, and the skin cracks, it is watered enough. Niceties in this is a material point, and can be learnt only by experience. If the grain should be suffered to remain too long
M A L T.

long in the water, it would begin to lose part of its sweetness. When it has been steeped sufficiently, the water is drawn off.

And the water used for this purpose should be that of a clear running stream, or rain-water; or if such cannot be had, pond-water, provided it be sweet and clean, will do very well; or pump-water, which should be rendered soft, if it be naturally hard. If the water made use of is in any way tainted, it communicates to the malt a taint which it never loses.

When taken from the cistern, the barley is laid in a regular heap, where it must remain thirty hours, or till it contracts a heat. It must then be worked in one or more heaps, and turned every four, six, or eight hours, according to the temperature of the air; and as it comes, as its spire is commonly termed, the heap must be spread thinner to cool it, lest it be heated too much, and the germination be carried on too fast. The turning of it must be continued in proportion as it is more or less flow in growth, so that it may be brought tolerably dry to the skin. When the spire begins to dry, the couch must be thickened again, and often turned, that the growth of the sprout may not revive. At this time the spire should be near piercing through the outer skin of the barley; as if it grows quite out, the strength of the malt will be too much consumed. After the malt is made thus far, the common practice is to lay it at once on the kiln; but the best way is to gather it all up in one heap, to let it lie in that flat for twelve hours, and then to turn it every fourth hour during the space of twenty-four hours. No part should be suffered to tread on the malt with their shoes while it is on the floor, because many grains are inevitably bruised thereby, and, vegetating no longer, afford the roots of the other grains a fermentation into which they extend their fibres, and are by that means entangled in bunches; and besides this, the bruised corn acquires a degree of putrefaction which taints the liquor made from the malt. Equal care should also be taken, that the grain be not bruised by any other means.

According to some, the time most proper for malting is, when the temperature of the air is such, that the grain naturally begins to germinate. How far the limits may be extended, experience alone can determine. The warmer the weather is, the greater must be the disadvantage under which the malter labours; because the motion of the fluids is then so strong, that the proofs go on too quick, and the finer parts are apt to fly off, the confinence of which is, that instead of a sweet, the malt inclines to a bitter taste. This is so universally experienced, that brewers carefully avoid purchasing what is termed latter made malt.

The grain thus prepared for drying is spread on the kiln, where, meeting with a heat greater than is suited to vegetation, its further growth is stopped. It is spread on the kiln three or four inches thick, and turned every three or four hours. The laying off it thicker is attended with inconveniences, among which is particularly its being unequally dried; and therefore that should be avoided. The strength and duration of the fire are different, according as the malt is intended to be dried pale, amber, or brown. The pale malt requires more leisure, and less fire, than the amber or brown. Pale and amber malt are dried with coke or culm, which not omitting any finale, gives it a brighter colour; and does not communicate that bad flavour which it has when dried with wood, straw, &c. Coke is best, as it affords a fluid and constant heat, whereby the malt is dried more uniformly. Where wood, or any vegetable fuel is used, it should be extremely well dried, in order that, being as free as possible from moisture, it may yield less finale.

An ingenious and attentive malter found the degree of heat in the malt whilst on the floor to be, during the first ten days, between fifty and sixty degrees. During the next three or four days, from sixty to sixty-five, and seventy-seven degrees; and during the last days of its being there eighty, eighty-four, and eighty-seven; which last was the degree of heat when the malt was put on the kiln. There cannot be any absolute rule as to the difference of heat during the different times in the process of malting, because it must be suited to the heat of the air; at least we have not yet sufficient data whereon to found such a calculation. The heat of the malt on the kiln, when fit for pale malt, was 120 degrees, and when it was fit for brown malt, 147.

The observation, that malt is fit for what is called pale, when its heat is 120 degrees, suggests a caution which should be carefully attended to, namely, that whatever colour it be intended to give the malt, the heat at first should be the same; thus, for example, malt which is dried to the degree of high brown, should first be rendered pale malt, then amber, and so on progressively; not by a sudden increase of the fire, but by a longer continuance of it. In this manner the whole body of the grain is equally and gradually dried; whereas a strong and quicker fire would parch, or as it were, finge the outside, while the internal parts remained moist; and as that moisture is afterwards evaporated, it must crack the surrounding hardened crust, and damage the grain in another respect.

As soon as the malt is dry, it must be removed from the kiln, and spread thin, that it may cool to the temperature of the air. It cannot be supposed that any of its parts are capable of retaining the heat in such a manner as not to suffer it to escape, through force have conceived that to be the case. In proportion as malts are dried, their particles are more or less separated, and coming in contact with water, they strongly attract from it particles which fill up their interstices. In malting, this action between the malt and the water generates a small degree of heat, but not durable; though from hence arose the opinion, that brown malt is full of fire or heat.

It should be stated that the size of the malt-kilns should be proportioned to the quantity of malt for which it is intended. Some build their kilns square, and others make them round; but this last is undoubtedly the best form, as the heat of the fire is more equally diffused therein, and the grains is of course more equally dried. Various substances have been made use of for covering the kiln, such as tiles, plates of tin, and wire: of these the wire is to be preferred, because it does not contract so great a degree of heat as to parch the grain in contact with it; but for this very reason, hair-cloth is probably preferable to any other covering; as when any part of the malt is in immediate contact with a substance much more solid than itself, and therefore capable of receiving a proportionally greater degree of heat, the malt in contact with that heated body is parched or burnt, by the heat which is not equally diffused through the whole mass; which malts cannot, therefore, be all equally heated. The hair-cloth is spread upon small wooden rafters, and these are supported by bars of iron laid across the kiln. See Kiln.

There can be little doubt that the grain may, at a medium, be laid to lie by malting one-fourth of its weight, including what is separated from it by the spires and censers; but this proportion varies according as it is more or less dried. The condition of the barley, as to its greenness or ripeness, at the time of its being gathered in, is clearly discernible when it is malted. If it was gathered green, it rather loses than gains in quantity; the malt becomes
MALT.

Malt which has not had a sufficient time to florish, so that its plume, or aerojäre, as the adepts in making call it, may have reached the inward skin of the barley, remains charged with too large a quantity of its unattenuated matter. All those parts which have not been put in motion, by the act of germination being, when laid on the kiln to dry, so hardened as not to be readily soluble in water, and consequently will be lost to the strength of the liquor. When it is suffered to grow too much, or until the spire has shot through the skin of the barley; though all that is left of malt, yet, as too large a portion of its essential part will have been expended in vegetation, the malt must be greatly diminished in proportion to what it ought to have been, and what remains cannot be so fit for brewing drink for long keeping. And such as has been duly worked on the floor will, if it has not been sufficiently dried on the kiln, be apt to germinate or sprout after, perhaps take on a very great heat; and should it continue long with a moderate degree of heat, the least evil that can be expected is, that it will grow mouldy and have an ill flavour. When it has been well worked, but over dried, it will be so hardened, that it will not imbibe from the air that moisture which is necessary to mellow it, and render it fit for brewing; for when it has been previously softened by the moisture of the air, it mixes more easily and more intimately with the water, and by that means yields a more copious extract than it would otherwise do. Such malt as has jult, or but lately been taken from the kiln, remains warm a considerable time. Until it becomes as cool as the surrounding air, it does not mellow by the addition of a due quantity of moisture from the air, and the work made of such malt requires a much longer boiling before it breaks, than that which is made of malt some months old.

The practice of sprinkling water upon malt newly taken from the kiln, to give it the appearance of having been made a proper time, or to plump it, is highly prejudicial, as tending not only to defraud, as less grain fills the bubble, but if not used speedily, heats,soon grows mouldy, and sufferers great damage.

It is obvious, that malt dried on a kiln not sufficiently heated must require a proportionally longer time for it to receive the due effect of the fire; for want of which it will be in the same flatte as that not thoroughly dried. Or if the fire be too quick, or too fierce, instead of gently evaporating the water from the corn, it forcers the outward skin, and separates it from the body of the grain. The malt to which this happens is called brown malt, and is very bulky; and if such a fire be continued, it changes some parts of the grain into a brittle sublunance, that the malt is said to be glaify. The particles which are thus hardened will not dissolve, or but in small proportion; so that they frequently occasion an almost total want of extract, which, in the phrase of the art, is termed the setting the grist.

It is suggested that the goodness of malt may be known by the following marks: when a grain of it is broken, and it takes mellow and sweet, breaks soft, and is full of flour from one end to the other, it is good. If it has a round full body, and upon putting some grains into water, they swim on the surface, it is good. Barley sinks in water, and malt that is not well made will do the fame; but it is to be observed that this is not an invariable proof, because, if the malt be broken, or in the least cracked, it will take in water, and sink. Malt that is rightly made will not be hard, but of so mellow a nature, that if drawn over an oak board across the grain, it will leave a white line upon the board, like a mark of chalk. Its smell also may be con- fused; for malt, though otherwise good, may have contracted an ill scent from the fuel, or from the water used in the steeping.

In respect to the changing the water in steeping, some maltsters think it no wise necessary; others, on the contrary, approve of it, but do it indiscriminately in the same proportion during the whole season. They are probably in both respects wrong; for the times when the water requires to be changed oftener, are the beginning and latter end of the season, in autumn and spring, when the weather is warm; for in the middle of the winter the weather is too cold to admit of the water being as all changed to any advantage. Suppose the barley to be left in steep forty-eight hours in the spring; if the weather is inclined to be warm, the water may in that space of time be changed three times; in other cases twice may be enough; but the belt rule is, as it is well known, that in the autumn and spring, if barley is left too long on the steep in the same water, the water will grow slimy, and sometimes four: the maltster should watch the changes of the water, and when he finds that it is smooth and oily to the touch, and that it is inclinable either to smell or taste four, let him by all means have it instantly changed; but he must observe, if he regards his interell, a particular method even in doing this. The usual way of changing the water is, first to draw off that in which the barley was steeping, and afterwards, by pails full, or by pumping, fill the cistern again. But it is advised, as a better method, to have some water in readiness to pour on immediately after the first is withdrawn, as by that means the danger of heating is prevented. Much mischief often arises from the not changing the water at these feasons.

In converting this sublunance to the purpose of brewing, it should be freed from the tails and dust before it is ground, which would otherwise heighten the colour of the wort, render the liquor muddy, and give it a bad taste, which cannot afterwards be got rid of. A cylindrical sieve will be useful for this purpose.

In grinding, when too small, its flour will mix too freely with the water, and cause the wort to run thick. Many are of opinion that the belt way is only to crack it, so that none of the grains may come out whole; for the intent is, that the water should draw out an extract, but not be mixed with the mealy part, in the manner of a pale or gruel. Some think that malt is better ground by a stone-mill than by a fliee one, because the former bruises it, and the latter only cuts the grains.

After it is ground it should lie some time to mellow in a cool room, where no sun comes. The time for this is different, according to its kind. Brown malt may be ground as from three to four or five days before it is used, in order that the corn, which is rendered uncommonly hard by the degree of drying, may be gradually softened by the moisture of the air; by which means it will become the more soluble in water. The pale malts require only one or two days. After lying thus in the air, left mellowing suffices; the strength of the malt is more perfectly extracted, and the beer will be considerably stronger than it would be with the same quantity of malt taken directly from the kiln; but care must be taken that it get no damage.
M A L T.

of malt in all its branches is a very critical business; as it is then particularly necessary that the beds, or couches, should be frequently turned, or the malt will not come kindly; as the first root will be apt to shoot forth vigorously, thrashing the other roots, and preventing them from accompanying it in its growth; this must be checked, and the remedy is, to turn the couch often, spread it thin, and give it sufficient quantity of air, at the same time keeping it cool and temperate. This will stop the progress of the first root, give the others time to sprout, and the barley will then malt kindly and more regularly.

A thin-flinned fine-coated barley is said to be best for making malt, and it is not worse for not being very full-bodied; but a lean, half-flinned, unripe grain should not by any means be recommended. And such as has grown on lands highly manured is not so good for making malt as that which has been produced on land of a moderate richness without it. In fact, a luxuriant soil, whether naturally so or enriched by art, is not, in general, best for yielding barley for the maltster's use. Some prefer, for malting, a grain which is the product of a soil that is rather poor than rich, rather light than strong, and more inclined to a gravel than a clay; as this grain is clean-coated, taper, and elegant in its form, is full of flour, molily transparent when watered, and will be sufficiently wetted in forty-eight hours. It also increases in the malting, fills the buihel well, and makes a fine, sweet, wholesome, clean, full-bodied malt, from which the beer may be brewed, either brown or pale, according as the malt has been dried higher or lower.

Mixed grain, or such as is grown on various soils, and in different situations, should never be purchased when it can be avoided, as it will be apt to disappoint the buyer, from the kernels spiring at different times, and some of them not at all; so that after the couch is dried, some part of it will only be half malted, and a great deal not malted at all.

The following method is recommended to discover malt that has been made of mixed, or in part unripe barley. Take a bowl of water, throw into it a couple of handfuls of the malt, giving it a gentle stirring, and the barley which has not been malted will sink to the bottom; the half-malted grains will have one end sunk, being in a vertical position; and the true good malt swim. It is, however, remarked, that the same barley, though very good, will not malt alike well at all times: for instance, take it as soon as it is houled, it comes well, but while it is in its sweat, by no means so; yet after it has done sweating, it comes well again, and bar ey which has been got in early in a very dry season, makes but indifferent malt; while the same barley, if it is left abroad till rain falls on it to loosen the husk from the kernel, malts very well, and yields a large increase. Also old barley, mixed with that of the last harvest, does not malt well, as it does not all spire or put forth its beard, at the same time. These niceties, though little attended to, are of importance in the making of good malt in all cases.

Several regulations relating to the manufacture and sale of malt are enacted by various and successive acts of the British legislature: of which the principal are as follow.

By 12 Ann. 1st. cap. 2, continued yearly, and by 33 Geo. II. cap. 7, there shall be paid by the maker for all malt made in England, except it be made for exportation only (12 Geo. c. 4. a duty of nine-pence a buihel: and by 10 Geo. III. c. 25, an additional duty of 15l. per cent. which duty is under the management of the Commissioners and officers of excise. (See Tax, Malt.) By 43 Geo. I. 1st. c. 69.
MALT.

C. 59, additional duties are likewise imposed. The last annual malt act is the 50 Geo. III. c. 1. Every maltster shall take out a licence from the office of excise annually, paying for the same 5s., if the quantity of malt made by him shall not exceed within the year, ending the 33d of June in each year previous to his taking out such licence, the quantity of 50 quarters.

and a farthing.

And every person who shall first become a maltster, for every such licence 5s. and within 10 days after the 33d of July next after taking out such licence, such further additional sum as with the said 5s. shall amount to the duty hereinafore charged, according to the quantity of malt made by him within the preceding year. (33 Geo. III. c. 69.) If he shall neglect to take out such licence and renew the same annually, 10 days at least before the end of the year, he shall forfeit 10l. (34 Geo. III. c. 41.) No malt shall be imported, on pain of forfeiting the same and its value. (12 Ann. Iat. 1. c. 2.) By the same act places for making malt are to be entered, on pain of 50l.

The maltster is required to give 24 hours notice within a city or market town, and elsewhere 48 hours' notice in writing to the officer, of the time of the day when he intends to wet the corn to be made into malt; and he shall not begin but between eight in the morning and two in the afternoon; nor empty any grain out of the cylinder, &c. for wetting or steeping, except between seven in the morning and four in the afternoon; the omission of such notice, &c. incurs a forfeiture of 100l. by 3 Geo. III. c. 13. 42 Geo. III. c. 58. 48 Geo. III. c. 74.

Out of every 20 bushels of malt, gauged and charged upon the floor, after the same shall have been taken out of the cylinder or other utensil, by the space of 26 hours or more, and before it shall be dried upon the kiln, shall be allowed 10 bushels, and so in proportion for any greater or lesser quantity. But if corn be continued under water for 40 hours, before the water be taken from it, the maltster shall not be entitled to the said allowance. (42 Geo. III. c. 38. 43 Geo. II. c. 7.) Every round bushel, with a plain bottom, 18¾ inches wide throughout, and eight inches deep, shall be deemed a legal Winchester bushel. (12 Ann. Iat. 1. c. 2.) No maltster shall wet, sprinkle, &c. any corn or grain in the process of being made into malt, after the flame has been cut off from the flameless vessel, until the expiration of 12 days, or 208 hours, on pain of 200l. (48 Geo. III. c. 74.) And if malt be wetted after it hath been taken from the kiln, and before it be delivered to the brewer who may have agreed for the same, except in the ordinary process of brewing beer from such malt; every such offence shall incur a forfeiture of 100l. (42 Geo. III. c. 38.) And by 48 Geo. III. c. 74, the penalty incurred by every workman, who shall wet corn contrary to the provisions above-mentioned, is 50s., and in default of payment, commitment to the house of correction for a term, not exceeding 12 months. But

a maltster may drain water from grain whilst steeping before the expiration of 48 hours after being first wetted; provided that no such water shall be drained unless the maltster shall have given notice of the same and the precise time between eight in the morning and four in the afternoon; nor shall the water be drained more than once during the said space of 40 hours, and such corn or grain shall be again completely covered with water within one hour from the beginning to so drain. (42 Geo. III. c. 38.) Servants of maltsters beginning to wet or remove any corn or grain, in a manner contrary to this act, may be fined 50l. by any justice, who may commit him for non-payment. (48 Geo. III. c. 74.) By 42 Geo. III. c. 38, excise officers may at all times enter every malt-house or place used for the making of malt, and the penalties of obstruction is 200l. (See 43 Geo. III. c. 34.) And if the officer shall refuse or neglect (after demand in writing, 12 Geo. II. c. 28.) to leave a copy of the gauge for the maker at the time of taking it, he shall forfeit 40s. The officer shall measure corn making into malt by the gauge only, and not by the bushel. (12 Ann. II. 1. c. 2.) By 2 & 3 Edw. VI. c. 10, no person shall make any barley malt, except in June, July, and August, when flour shall not be thinned before or corn in malt in these months, under 17 days, (unless it be for his own house,) on pain of forfeiting for every quarter 2s.; and filling of malt, which has not been well drestled, so that there may not be fanned out of one quarter half a peck of flour or more, incurs a forfeiture of 20d. for every quarter; and mixing bad malt with good for sale is liable to a forfeiture of 2d. for every quarter. In the procees of maltings, prelling of malt in the cilinor to prevent its swelling, mixing corn of one wetting with corn of a former wetting, and mixing malt with unmalted corn, incur each of them a penalty of 52. a bushel. (1 Geo. III. c. 3. 2 Geo. II. c. 1. 1 Geo. I. c. 2. 48 Geo. III. c. 74.) Again, mixing of malt that has been gauge with the ungauge, subjects to a forfeiture of 200l. (1 Geo. III. c. 3.) By 48 Geo. III. c. 74, if any maltster shall tread, ram, or otherwise force together in the cylinder, &c. any grain steeping or steeped in order to its being made into malt, he shall forfeit 100l. instead of the sum of 52. for every bushel of corn or grain steeping or steeped, that shall be so trodden, &c. mentioned in 48 Geo. III. c. 2; and every esche of making malt, be found hard and compact, as to manifest its having been forced together for preventing its rising and swelling, the maltster, &c. in such case shall forfeit 100l.

If any maltster, &c. shall fraudulently conceal any grain making into malt from the view of the gauger, or officer appointed to take an account of the same, he shall forfeit 200l. (48 Geo. III. c. 74.) And any maltster fraudulently conveying away from the cylinder, &c. any steeping or part of any steeping of corn making into malt, so that no gauge can be taken in the back by the officer, shall forfeit 100l. (1 Geo. III. c. 3. 48 Geo. III. c. 74.) By the latter act, the penalty for erecting or extending cylinders, &c. for the manufacture of malt, without previous notice, is 200l. The maltster is required to make monthly entry at the office of excise of all the malt made by him in such month (for sale or not for sale), on pain of 100l. (12 Ann. Iat. 1. c. 2. 44 Geo. III. c. 54.) By 48 Geo. III. c. 74, every maltster shall within the space of 14 days, next after the time of entry (as before) clear away all the duties, unless security shall have been given, to the satisfaction of the commissioner of excise, by bond in double the value of such duties as are likely to become due within any five months, for the due payment.
payment at the end of every four months at the day of entry, and if such.fertility be not given, and any maltster, &c. neglect to clear off at the end of 14 days such fums as shall have become due, he shall for the fuch offence forfeit double the duties.

A drawback of the duty is allowed for malt damaged in exportation, and also for malt destroyed by fire or water. (12 Ann. tit. c. 2.) By the 12 Geo. c. 4, and 3 Geo. II. c. 7, no malt entered and made for exportation shall be liable to the duties, and no drawback shall be allowed for any malt exported. By 1 Geo. III. c. 5, and 4 Geo. III. c. 19, there shall be allowed for every 20 quarters of grain made into malt for exportation 30 quarters of malt and no more, on exportation; and notice shall be given of keeping and the quantity, on pain of 50l. and this shall be kept separate from that designed for home consumption, on pain of 5l. a bushel. (12 Geo. c. 4.) And the corn of one keeping shall be kept separate from any other, until it hath been measured, on pain of 50l. (3 Geo. II. c. 7.) Persons opposing officers shall forfeit 50l. (12 Geo. c. 4.) Notice of measuring shall be given; and the malt carried on ship-board, or kept separate and locked up, on pain of 50l. (12 Geo. c. 4. 3 Geo. II. c. 7. 50 Geo. III. c. 1.) Opening such locks, and carrying away the malt, without the consent of the officer, or notice given to him, incurs a forfeiture of 500l. (3 Geo. II. c. 7. 50 Geo. III. c. 1.) The officer having received 40 hours notice shall attend, keep an account of the malt delivered out, and of the person to whom it belongs, and give a certificate to the officer of the division to which it is to be removed, who shall file the name and make entry thereof: and if the proprietor neglect to deliver such certificate, he shall forfeit 50l. (12 Geo. c. 4.) Those intending to ship malt for exportation shall give 24 hours notice to the officer of the port in writing, with the name of the ship, on pain of 5l. a bushel. (6 Geo. c. 21.) If ground malt shall be exported, it shall be computed at so many bushels as it contained before it was ground. (12 Ann. ft. c. 3.) The penalties relating to this article (unless otherwise directed) shall be fixed for, levied and mitigated as by the laws of excise, or in the courts at Westminster; half to the use of the king, and half to him that shall file. (6 Geo. c. 21. 24 Geo. II. c. 49. 44 Geo. III. c. 58.) Perons aggrieved may appeal to the next quarter sessions, giving six days notice in writing. (12 Ann. ft. c. 2. 1 Geo. II. ft. 2. c. 16.) The act 48 Geo. III. c. 74. has made several alterations of the penalties and regulations pertaining to the making of malt, and enacted several provisions by which maltsters and makers of malt are to ascertain, and make entry of the quantity of barley in their poñeflion, and also other provisions for rendering appeals more certain; for which we refer to the act itself. (See Barley and Corn.)

The infufion of malt has been much recommended as an antifcorbutic. See Scurvy and Wurr.

Good malt may be made of the grain of the maize or Indian corn, but then a particular method must be taken for the doing it. Our barley malt makers have tried all their skill to make good malt of it in the ordinary way, but to no purpose; that is, the whole grain will not be this way malted or rendered tender and floury, as in other malts: for it is found, by experience, that this corn, before it is fully malted, much sprouts out both ways, that is, both root and blade, to a considerable length, that of a finger at least and if more the better. For this purpose it must be laid in a heap a convenient time; and in this process, if it be of a sufficient thickness for coming, it will quickly heat and grow mouldy, and the tender sprouts will be too entangled, that the leaf moving of the heap will break them off; and the further maturation of the grain into malt will be hindered by this means; and on the other hand, if it be laid thin, and often stirred and opened to prevent too much heating, those sprouts which have begun to form ease growing, and consequently the corn again ceases to be promoted to the mellowness of malt. Phil. Trans. N 142.

To avoid all these difficulties, the following method is to be used: take away the top of the earth in a garden or field, two or three inches, throwing it up half one way, and half the other; then lay the corn for malt all over the ground so as to cover it; the earth that was pared off is now to be laid on again, and nothing more is to be done till the field is all over covered with the green shoots of the plant. The earth is then to be taken off, and the roots of the grain will be found so entangled together, that they will come up in large cakes or parcels; it must be gently washed in order to take off all the dirt, and then dried on a kiln, or on a clean floor exposed to the fun. Every grain of the maize will be thus tranformed into good malt, and the beer brewed with it will be very pleasant and very wholesome, and of an agreeable brown colour, but very clear.

It may be worth trying whether the same process is not with due care applicable to the making of turnips, potatoes, carrots, parsnips, and the like. It might possibly be of service also to attempt this left laborious way of making malt of barley and other small grains: the disadvantages would be the not so easily separating the dirt from the grain as in the larger kind; and as barley requires the root oly, not the ear, to shoot in order to the making of malt, it would be some difficultly to know the exact time of taking it up; but with all these disadvantages the method is worth a trial.

Malt-Dust, in Agriculture, the dust or subflance that separates from the malt in the act of drying, or during its preparation. It is sometimes called malt combes, and has been found useful as a manure, in lessening the effusion of fliff heavy soils. But it may probably be made use of to the greatest advantage, as a top dressing when fowen over crops in the early spring season. The following experiments are recorded, with respect to the diluted point of its being more adapted to barley than wheat crops. It has often been allerted, by some, that malt-dust is much better suited as a manure to barley than wheat; as from the latter lying a whole year in the ground, and the malt-dust being sown with it, the virtues of the manure are exhausted long before the summer, when the corn principally wants nourishment; being too early advanced in it growth, and rendered winter-proof by it; while others, contradicting this assertion, lay it is well for wheat, making it appear, that it often causes very good crops of corn, particularly after a hard winter. In order to make some experiments to ascertain this matter, a field of ten acres was fixed upon, which had borne a good crop of orfe-beans; after which it was sown with turnips which, being fed off, it was summer-fallowed, being intended for wheat. The soil was a stiffish lean, in good heart, and tolerably clean. It was divided by
by deep furrows into ten equal parts, each containing one acre, and numbered 1, 2, 3, 4, 5, 6, 7, 8, 9, and 10. The whole field during the course of the following had four ploughings given it, which reduced it to a fine tilth or mould. As wheat-feed time came, No. 1 was sown broadcast, with three bushels of wheat, and ploughed in, laying on no manure whatever. No. 2 was sown with the same quantity of wheat, after which ten quarters, or eighty bushels, of malt-duft were strewn over it, and that and the seed ploughed in together. No. 3 was also sown with wheat in the same manner, except that the strewn on the malt-duft was deferred till the latter end of January. No. 4 had a dressing of dung in the ordinary way, and was sown with three bushels of wheat like the other parts. No. 5 was dressed by heap-folding, and was also in like manner sown with wheat. No. 6 was sown with wheat in the same quantity; and in February, after sowing, received a half dressing of very rotten dung which had been several times turned and mixed. No. 7, after receiving a ploughing in the spring, was sown with ten pecks of barley, which was harrowed in, and no manure at all applied. No. 8 was sown with barley, as above, but had ten quarters of malt-duft laid on it. No. 9 had in the winter a good dressing of dung, and was sown in the spring with the same quantity of barley. No. 10 was sown with barley, like No. 8, only it had five instead of ten quarters of malt-duft laid on it.

It is observed, that all the pieces of wheat were sown the first week in October, and all the barley the second week in March. In January, on examining the wheat, it was found that the acre marked No. 2 looked moist and floury; though there was in appearance but little difference between that and No. 4. The Nos. 1, 3, and 6, neither of them looked so vigorous as those already noticed; and No. 5 seemed rather thin on the land; but the wheat-plants were in good condition and healthy. And on another examination in May, of the wheat-crops, it was found that No. 1 was tolerably clean and promised well; and No. 2 gave hopes of a large crop, and was surprizingly clear of weeds. No. 3 was greatly improved since the laying-on of the dressing of malt-duft. No. 4 looked very vigorous and strong, but was very foult, having several sorts of weeds not to be met with in other parts of the land. No. 5 was thin of plants, and they did not branch much; however, they still seemed healthy and strong. No. 6 was like No. 5, greatly improved; but it was foul, and what appeared strange, had many weeds of a nature quite different from those with which No. 4 was infested, though the dung laid on both these parts was taken from the same heap.

And at this time, on looking at the pieces sown with barley, No. 7 was found promising and clean. No. 8 was forwarder, and afforded the prospect of a large crop. No. 9 was forward and fine, but foul with weeds. No. 10 bore much the same appearance as No. 1, and promised well.

At harvest, No. 3 of the wheat was first fit to reap, after which succeeded No. 4; and the rest were ready nearly at the same time.

Of the barley, Nos. 8 and 10 were first ready to mow. It is almost unnecessary to observe, that those crops which were cleared of weeds were the soonest fit for carrying. These crops were all laid separately, as well as all separately threshed, and dressed as early as possible in the winter.

The produce of the several crops, on being distinctly noted, were the following:

Vol. XXII.
a better manure than dung; but the difficulty is, whether it is most profitable to lay it on when the wheat is sown, or by way of top-dressing in January or February. The above experiments seem to shew, that the best time to dress heavy land with it, is in January or the following month. It is also stated, that nothing surpasses this manure when laid on cold grassy grounds, to the amount of about eight quarters or sixty bushels an acre. Its effects in this way are said to be very great.

In an experiment of Mr. Bedford's, in which a piece of land was manured with this substance at the rate of four quarters to the acre, and sown with barley and clover, the barley was very luxuriant, producing nearly seven quarters per acre, and the clover extremely fine ; from which it is concluded, that it is a valuable fort of manure, being cheaper than rape-durd or any other sort of top-dressing, as it only costs about twelve shillings the acre.

About Dunstable this fort of manure costs one shilling a bushel, is sown by hand at the rate of from twenty to thirty-two bushels the acre over the barley land, and harrowed-in with the feed. It is seldom used to wheat in that district, but would probably answer well to it as a top-dressing, in the proportion of about thirty bushels to the acre, sown over the crops in March.

The black malt-durt, or that which falls through the kiln, is preferable to the white, from the seeds of weeds being destroyed by the heat in drying.

Malt, for the manner of preparing liquors of, see Brewing.

Malt Liquors have different names as well as different virtues, properties, and uses, both from the different manners of preparing the malt, whence they are distinguished into pale and brown; and from the different manners of preparing or brewing the liquors themselves, whence they are divided into beer and ale, strong and small, new and old.

Malt drinks are either pale or brown, as the malt is more or less dried on the kiln; that which is the flenderest dried, tinging the liquor least in brewing, and therefore being called pale; whereas that higher dried, and as it were roasted, makes it of a higher color. A mixture of both these makes an amber colour; whence several of these liquors take their name.

Now, it is certain, the pale malt has most of the natural grain in it, and is therefore the most nourishing; but for the same reason, it requires a stronger constitution to digest it. Those who drink much of it, are usually fat and sickly in their bloomer, but are often cut off by sudden fevers; or, if they avoid this, they fall early into a debilitated old age.

The brown malt makes a drink much less vifcid, and lighter to pass the several strainers of the body; but, if very strong, it may lead on to the same inconveniences with the pale; though a single debauch wears off much more easily in the brown.

Dr. Quincy observes, that the best pale malt liquors are those brewed with hard waters, as those of springs and wells, because the mineral particles, with which these waters are impregnated, help to prevent the coagulation of those drawn from the grain, and enable them to pass the proper secreteions the better; as the vifcid particles of the grain do likewise defend thefe from doing the mischief they might otherwise occasion. But softer waters seem better suited to draw out the substances of high-dried malts, which retain many fiery particles in their contexture, and are therefore best left in a smooth vehicle.

For the differences in the preparation of malt liquors, they chiefly consist in the use of hops, as in beer; or in the more sparing use of them, as in ale.

The difference made by hops is best discovered from the nature and quality of the hops themselves: these are known to be a subtile grateful bitter: in their composition, therefore, with this liquor, they add somewhat of an alkaline nature, i.e. particles that are subtile, active, and rigid. By which means, the vifcid parts of the malt are more divided and fubtilized; and are, therefore, not only rendered more easy of digestion and secretion in the body, but also, while in the liquor, they prevent it from running into such coagulations as would make it vifcid, vapid, and sour.

For want of this, in unhopped drinks, that clammy sweetness, which they retain after working, soon turns them acid, and unfit for use; which happens sooner or later, in proportion to the strength they receive from the malt, and the commination they have undergone from fermentation.

It is a common opinion, that ale is more diuretic than beer, that is, liquor left more watered than with that with a greater quantity of hops in it: which may hold in some consti- tutions, because ale being more smooth, softening, and relaxing, where urine is to be promoted by enlarging the passage, as in thin, dry constitutions, this is the most likely to effect it. But where the promoting of urine is to be done by attenuating and breaking the juice, and rendering them more fluid, it is certainly best answered by those drinks which are well hopped.

As to the dispute, whether or no hops tend to breed the stone, it is too long to enter upon here. Quincy is of opinion, there is but little reason for the affirmative side of the question; and, in general, makes no scruple to fear that, for one constitution damaged by beer, there are numbers spoiled by ale. This malt manfully foolds the glands, fluffs the vellus with flume and vifcidity, makes the body unwieldy and corpulent, and paves the way for cachexies, jaundice, asthmas, and at last incurable dropsies. The urinary passages, also, which it is supposed to clear, will, in time, be filled by it with slough, and matter of as ill consequence as gravel.

The different strengths of malt liquors also make their effects different. The stronger they are, the more vifcid parts they carry into the blood; and though the spirituous parts make thefe imperceptible at first; yet when those are evaporated, which will be in a few hours, the other will be sensibly felt by pain in the head, nauseates at the stomach, and alteration of the conformation of the liquor.

This, those are the most sensible of, who have experienced the extremes of drinking these liquors and wines; for a draught of wine they find much sooner worn off, and they are much more lively and brisk afterwards, than after intermittently using malt liquors, whose vifcid remains will be long before they be shaken off.

Malt liquors, therefore, are, in general, the more wholesome for being small, i.e. of such a strength as is liable to carry a small degree of warmth into the stomach, but not so great as to prevent their being proper diluters of the necessary food. Indeed, in robust people, or those who labour hard, the vifcidities of the drink may be broken down into a convenient nourishment; but in persons of another habit and way of living, they serve rather to promote obstructions and ill humours.

The age of malt liquors is the last thing by which they are rendered more or less wholesome. Age seems to do nearly the same thing as hops; for those liquors which are longed kept are certainly less vifcid; age breaking the vi-
MALT

This is an extensive article of trade, and by which very large fortunes are made. The art is to convert fermented malt liquors into a clear inflammable spirit, which may be either fold for use in the common flat of a proof strength, that is, the same strength with French brandy; or is rectified into that purer spirit usually sold under the name of spirit of wine; or made into compound cordial waters, by being distilled again from herbs and other ingredients. See Brewing, Spirits, and Wash.

The due preparation of the subject confits in its being justly malted and well ground. When the grain is not sufficiently malted it is apt to prove hard, so that the water can have but very little power to dissolve its substance; and if it be much malted, a part of the fermentable matter is lost in that operation. The harder and more flinty the malt is, the finer it ought to be ground; and in all cases, when intended for distillation, it is advisable to reduce it to a kind of finer or coarser meal. When the malt is thus ground, it is found, by experience, that great part of the time, trouble, and expense of the breathing is saved by it, and yet as large a quantity of spirits will be produced; for thus the whole substance of the malt may remain mixed among the tincture and be fermented and distilled among it. This is a particular matter very well deserves the attention of the malt distiller, as the trade is at present carried on; for the dispatch of the business, and the quantity of spirit procured, are more attended to than the purity or perfection of it.

The secret of this matter depends upon the thoroughly mixing, or briskly agitating and throwing the meal about, first in cold, and then in hot water; and repeating this agitation after the fermentation is over, when the thick turbid wash being immediately committed to the still, already hot and dewy working, there is no danger of burning, unles by accident, even without the farther trouble of stirring, which in this case is found needless, though the quantity be very large, provided that requisite care and cleanliness be used; and thus the bung of brewing and fermenting may very commodiously be performed together, and reduced to one single operation. Whatever water is made choice of, it must stand in a hot flat upon the prepared malt, especially if a clear tincture be desired, but a known and very considerable inconvenience attends its being applied too hot, or too near to a flat of boiling, or even folding with regard to the hand. To save time in this case, and to prevent the malt running into lumps and clods, the belt way is to put a certain measured quantity of cold water to the malt first; the malt is then to be stirred very well with this, so as to form a sort of thin uniform palate or pudding; after which the remaining quantity of water required may be added in a state of boiling, without the least danger of making what, in the distillers language, is called a pudding.

In this manner the due and necessary degree of heat in the water, for the extracting all the virtues of the malt, may be hit upon very expeditiously, and with a great deal of exactness, as the heat of boiling water is a fixed standard which may be let down to any degree by a proportionate mixture of cold water, due allowances being made for the season of the year, and for the temperature of the air.

This little obvious improvement, added to the method just above hinted for the reducing brewing and fermentation to one operation, will render it practicable to very considerable advantage, and the spirit improved in quality as well as quantity.

A much more profitable method than that usually practiced for the fermenting malt for distillation, in order to get its spirit, is the following: Take ten pounds of malt reduced to a fine meal, and three pounds of common wheat-meal: add to these two gallons of cold water, and stir them well together, then add five gallons of water boiling hot, and stir all together again. Let the whole stand two hours, and then stir it again, and when grown cold, add to it two ounces of solid yeast, and let it be left covered in a warm place, to ferment.

This is the Dutch method of preparing what they call the wath for malt spirit, whereby they save much trouble, and procure a large quantity of spirit; thus commodiously reducing the two businesses of brewing and fermenting to one single operation. In England the method is to draw and make for spirit as they ordinarily do for beer, only instead of boiling the wort, they pump it into large coolers, and afterwards run it into their fermenting backs, to be there fermented with yeast. Thus they bellow twice as much labour as necessary, and lose a large quantity of their spirit by leaving the gros bottoms out of the still for fear of burning.

All simple spirits may be considered in their different rates of low wines, proof spirit, and alcohol, the intermediate degrees of strength being of less general use; and are to be judged of only according as they approach to, or recede from, these. Low wines, at a medium, contain a sixth part of pure inflammable spirit, five times as much water as spirit necessarily arising in the operation with a boiling heat. Proof goods contain about one-half of the same totally inflammable spirit; and alcohol entirely consists of it. See Spirits.

Malt low wines, prepared in the common way, are exceedingly nauseous; they have, however, a natural vinoity, or pungent agreeable acridity, which would render the spirit agreeable to the palate, were it not for the large quantity of the gros oil of the malt that abounds in it. When this oil is detained in some measure from mixing itself among the low wines, by the stretching a coarse flannel over the neck of the still, or at the orifice of the worm, the spirit becomes much purer in all respects; it is less fullsome to the taste, les offensive to the smell, and less milky to the eye. (Shaw's Essay on Distillery.) When these low wines, in the rectification into proof spirits, are distilled gently, they leave a considerable quantity of this gross fetid oil behind them in the still along with the phlegm; but if the fire be made fierce, this oil is again raised and brought over with the spirit; and being now broken somewhat more fine, it impregnates it in a more nauseous manner than at first. This is the common fault both of the malt distiller and
of the rectifier; the latter, instead of separating the spirit from this nothy oil, which is the principal intent of his process, attends only to the leaving the phlegm in such quantity behind, that the spirit may be of the due strength as proof or marketable goods, and brings over the oil in a worse state than before. To this inattention to the proper business of the process, it is owing that the spirit, after several rectifications, as they are miscalled, is often found more flinking than when delivered out of the hands of the malt distiller. All this may be prevented by the taking more time in the subsequent distillations, and keeping the fire low and regular, the sudden fliring of the fire, and the hasty way of throwing on the fresh fuel, being the general occasions of throwing up the oil by spirits, where the fire in general, during the process, has not been so large as to do that mischief.

The use of a balsam Marire, instead of the common oil, would effectually prevent all this mischief, and give a purer spirit in one rectification, than can otherwise be procured in ten, or indeed according to the common methods at all.

Malt low wine, when brought to the standard, or proof spirit, loses its milky colour, and is perfectly clear and bright, no more oil being contained in it than is perfectly dissolved by the alcohol, and rendered miscible with that proportion of phlegm, which is about one-half the liquor; its taste also is cleaner though not more pleasant; there being left of the thick oil to hang on the tongue in its own form, which is not the case in the low wines, where the oil, being undissolved, adheres to the mouth in its own form, and does not pass lightly over it.

When proof spirit of malt is distilled over again, in order to be rectified into alcohol, or, as we usually call it, spirits of wine, if the fire be raised at the time when the farts begin to come off, a very considerable quantity of oil will be raised by it, and will run in the visible form of oil from the nose of the worm. This is not peculiar to malt spirit, but the French brandy flows the same phenomenon, and that in so great a degree, that half an ounce of this oil may be obtained from a single piece of brandy.

Malt spirit, more than any other kind, requires to be brought into the form of alcohol, before it can be used internally, especially as it is now commonly made up in the proof state, with as much of this nauseous and viscid oil as will give it a good crown of bubbles. For this reason it ought to be reduced to an alcohol, or totally inflammable spirit, before it is admitted into any of the medicinal compositions. If it be used without this previous caution, the odious taste of the malt oil will be distinguished among all the other flavours of the ingredients.

Malt spirit, when it has once been reduced to the true form of an alcohol, is afterwards more fit for all the curious internal uses than even French brandy, it being after this purification a more uniform, hungry, tarekef and impregnable spirit, than any other spirits which we enfeem so much finer.

A pure spirit being thus procured, should be kept carefully in vessels of glass or stone, well stoppered to prevent the evaporation of any of its volatile part. If preferred in claret, it is apt to impregnate itself very strongly with the wood. The quantity of pure alcohol obtainable from a certain quantity of malt, differs according to the goodness of the subject, the manner of the operation, the season of the year, and the skillfulness of the workman; according to which variations, a quarter of malt will afford from eight or nine, to thirteen or fourteen gallons of alcohol. This should encourage the malt distiller to be careful and diligent in his business, as to very large a part of his profit depends wholly on the well conducting his proceedings.

After every operation in this business, there remains a quantity of farts, which in their own coarse state ought never to be admitted into the true spirit; these are to be faved together, and large quantities of them at once wrought into alcohol. It is easy to reduce these to such a state, that they will serve for lamp spirits. Their disagreeable flavour being corrected by the adding of aromatics during the distillations, the reducing them to a perfect and pure alcohol is practicable, but not without such difficulties, as render it scarcely worth the trader’s while. One way of doing it is by distilling them from water into water, and that with a very slow fire. By this means a pure alcohol may be made out of the fouleat farts.

The malt distiller always gives his spirit a single rectification per fe, in order to purify it a little, and make it up proof; but in this state it is not reckoned fit for internal uses, but serves to be diluted into geneva and other ordinary compounds for strong waters for the vulgar.

The Dutch, who carry on a great trade with malt spirit, never give it any farther rectification than this, and it is on this account that the malt spirit of England is in general so much more in esteem. The Dutch method is only to dilute the wath into low wines, and to add pure proof spirit; they then directly make it into geneva, or else send it as it is to Germany, Guinea, and the East Indies, for the Dutch have little notion of our rectification. Their spirit is by this means rendered very foul and coarse, and is rendered yet more nauseous by the immediate use they make of rye meal. Malt spirit, in its unrectified state, is usually found to have the common bubble proof, as the malt distiller knows that it will not be marketable without it.

The whole matter requisite to this is, that it have a considerable portion of the gross oil of the malt well broke and mixed along with it; this gives the rectifier a great deal of trouble if he will have the spirit fine; but in the general run of the businesse, the rectifier does not take out this oil, but breaks it finer, and mixes it fatter in by alkaline salts, and disguises its taste by the addition of certain flavouring ingredients. The spirit loses in these processes the invisibility it had when it came out of the hands of the malt distiller, and is, in all respects, worse, except in the disguise of a mixed flavour. Shaw’s Essay on Distillery.

The alkaline salts used by the rectifier, destroying the natural invisibility of the spirit, it is necessary to add an extraneous acid in order to give it a new one. The acid they generally use is the spiritus nitri dulcis; and the common way of using it is the mixing it to the taste with the rectified spirit: this gives our malt spirit, when well rectified, a flavour somewhat like that of French brandy; but this soon flies off; and the better method is to add a proper quantity of Glaser’s strong spirit of nitre to the spirit in the still. The liquor in this case comes over impregnated with it, and the acid being more intimately mixed, the flavour is retained. See Spiritus nitri dulcis.

MALTA, in Geography, anciently Cypria and Melita, from which latter the Saracens have formed Malta, an island in the Mediterranean, about fifty miles from the coast of Sicily, twenty miles long, and twelve miles in its greatest breadth, and about sixty miles in circumference. It consists of an immense white soft rock of fine-flone, covered with a thin stratum of earth, most of which has been brought from Sicily, seldom more than a foot above the surface of the rock; and this earth is removed once in ten years,
years, in order to clear the rock of a thick crft which forms, and prevents the moisiture from sufficiently penetrating. It was anciently reckoned a part of Africa, but now belongs to Europe. The soil, watered by the night-dew and well cultivated, produces cumin-feed, anise-feed, cotton, excel- lent fruits, such as melons, oranges, lemons, and particularly figs, vegetables, and pastures; but it yields neither grain nor wine sufficient for its inhabitants, who are eli- minated at about 63 or 64,000, including those in the neighbouring islands. It furnishes plenty of excellent and finely-flavoured honey, sea-felt, considerable fisheries, and a profitable coral-fishery. The island is divided into small enclosures of free-fonic, is well planted, and contains sev- eral towns and villages; the principal of the former are La Valetta, Citta Vittorioa, Senglea, Barmola, Citta Nuovo Cottonera, and Malta. The coast is for the most part secured by shelves and perpendicular rocks, without one port or safe road for ships; but on the east and west shores there are several commodious harbours. The two most considerable are those on the S. E. side, one called Marsa Murzet, and the other Marsa, which signifies port, and is the largest of the two. They are divided by an ob- long peninsula, on which is built a strong fort or castle, called St. Elmo, which defends the entrance into both. Within that of Murzet lies a small island, near which the ships suspected of infection are obliged to perform quar- rantine. Those places which are accessible are defended by fortifications of great strength, so that it would be very difficult to reduce it by force. Mortars, the mouths of some of which are fix feet wide, are cut out of the rocks near the different creeks, where a debarkation might be attempted. Considerable quantities of sea-shells and fish-bones petrified are found all over the island, even in parts most elevated and remote from the sea.

During summer Reaumur’s thermometer is generally below 25°, and seldom above 28°, or from about 68° to 9° of Fah- renheit. In the winter it is seldom lower than 8° below zero of Reaumur’s, or 14° of Fahrenheit. The alternate changes from heat to cold are often very sudden. Cold is occasioned by the north and north-west winds; and a south wind brings heat. His wind, prevailing over the greater part of Africa, is dangerous, but is of no long duration, and frequently succeeded by a calm, during which the heat is suffocating. Whilft the frecoco continues, iced beverages are copiously used; and, therefore, snow is considered at Malta as one of the necessaries of life. It is brought from Sicily, and administered to the sick; and whenever there is a scarcity, all that remains in the ice-house in entirely re- served for the use of the hospitals. Cold bathing is also successfully used as a preventative against the ill effects of the frecoco.

This island has often changed its masters. Its original inhabitants were the Phcenicians, who were expelled by the Phcenians, and these again by the Greeks. It next became subject to the Carthaginians, and they were succeeded by the Romans, who established in it a prefect, as he is called in the Acts of the Apostles, ch. xxviii. 7, and this pre- fect was dependent on the praxor of Sicily. Upon the de- cline of the Roman empire, it fell under the dominion of the Goths and afterwards of the Saracens. Roger, the Norman, earl of Sicily, took possession of it about the year 1190; and from that time it continued under the dominion of the kings of Sicily, till it fell under that of Charles V., by his conquest of Naples and Sicily, who gave it in 1525, by a grant which was ratified by the pope in 1530, to the knights of Rhodes, afterwards of Malta. (See the next article.) Charles V. was induced to make this grant by

an ambition of becoming the reforer and second foundcr of an order, which for many ages had been devoted to the defence of Chrarians, and also by the hope of thus pro- tecting the sites of Sicily and Sardinia, the kingdom of Naples, and the coasts of Italy from the incursions of the infidels; filipulating with the knights that they should main- tain a perpetual war against the Turks and Corfairs. These knights, after their establishment in Malta, fortified the island. Solymans, incensed by observing that his ships were constantly exposed to the attacks of enemies, which he had, in his own imagination, destroyed when he drove them from Rhodes, determined, in 1565, to make an at- tempt against Malta. For this purpose he sent 30,000 men against the town of Malta, which was defended by 700 knights and 8000 soldiers, under the command of the grand master John de Valette, at the age of seventy-one years. When some of his friends saw that their brave commander was wounded, they intreated him to retire; but he replied, “At seventy-one, can I finish my life more gloriously than by dying with my brethren?” After having maintained a siege of four months, they were relieved by a force of 6000 men, sent from Sicily to their succour, and the Turks were compelled to raise the siege.

Hence this town obtained the name of “Citta Vittorioa,” which it retains to this day: La Valetta was built by La Valette, and called after his name. One of his suc- cezors made a magnificent aqueduct in 1616, to bring wa- ter to this new city; and others constructed various works of importance to the safety of the place. When the town was finifhed, the convent and habitation of the knights were removed hither. That the work might not be inter- rupted, when money failed, they paid in copper, which was afterwards called in at its full value. The inscription on it was, “Non est fed fides,” not money but loan. In pro- ceds of time this island maintained itself against the whole Ottoman power; but the order was never rich enough to attempt foreign conquests, nor to equip numerous fleets. They were, however, as liberal as they were brave in afhil- lating their neighbours, and also in defending themselves against the Turks and the Corfairs of Algiers and Tripoli. In the year 1724, a truce was concluded with the Turks for twenty-one years, subject to renewal if both parties should think proper. While it continued, the Maltese were to enjoy in the states of the grand seignior the fame privileges as the French. They also fluctuated for the exchange and random of slaves. The sultan agreed not to give any affil- iance to the states of Barbary; and the treaty was to be void when any of the Chrarian princes were at war with the Porte. In 1798 the island surrendered to the French, and the knights were dispersed; and in September 1800, it was taken by the British, who retained the possession of it. The principal disadvantages, says Barrow (Travels in Southern Africa, vol. ii.), that would refult to England by leaving Malta in the possession of the French, appear to be, in the first place, the power it would give them of excluding our ships from that port, undoubtedly the belt in the Mediterranean, and of increasing their forces here to the complete destruction of our Mediterranean trade; and, secondly, the means it affords of facilitating their views upon Egypt, by enabling them to throw into that country a force sufficient to renew their project upon India. See the next article.

Before the knights took possession of that island, it was so barren and uninviting, that when Charles V. offered it to them, they sent commissaries to examine, and after their report, they could hardly be induced to accept the grant. But by subsequent exercices of skill and industry, they have
effected a surprising alteration, not only in its means of defence, but in its internal cultivation. The capital of the island is "La Valetta," or Citta Nuova, which is situated on the cliff east, and was founded, as we have already observed, in 1566, on an elevated peninsula, having on its extremity the castle of St. Elmo. This town contains the palace of the grand master, the arsenal, the infirmary, the church of the prior of St. John, and hotels for the knights of different languages. On either side of the peninsula is a good harbour. "Citta Vittorio" is a fortified town on a narrow point of land that projects into the Marza, or great harbour, opposite to Valetta, and is defended by the strong castle of St. Angelo, standing on a high rock, and communicating with the town by a bridge. In this town was the palace of the inquisition, an arsenal, and a lodging of slaves; the Greeks have also a church here. "Senglea," or the isle of St. Michael, is a confiderable town on a peninsula, separated from Citta Vittorio by the canal Porto della Galere, and joined to the harbour by the canal Porto della Renna. But we must not confound this Malta with old Malta, called "Citta Vecchia." Malta, or Medina, the capital, was a confiderable town previous to the arrival of the knights of Rhodes; it is now a small fortified place and bishop's see, containing a cathedral and several religious houses, on an eminence near the centre of the island. In its vicinity are extensive catacombs, which form a labyrinth. "Burmola" is a little town of 700 houses behind Senglea. "Citta Nuovo Cottonera" is a regularly fortified town, including the old fort of St. Margherita. The five towns above enumerated, may be considered as portions of one large city, separated from each other by hedges, and containing 20,000 inhabitants. The houses are built of stone, flat-roofed, and covered with thatcher. The harbours are capable of receiving whole fleets; and, as the situation is naturally strong, no art is wanting to render the fortifications impregnable.

"Forte di S. Thomas" stands on a point of land projecting into the sea, about two miles S.E. of the capital. "Malta," "Forte Rossu" stands on a peninsula opposite to the island of Comino.

The climate of Malta is not infallible; the excessive heat being mitigated by the wetterly and north-wetterly winds. Although there are no rivers in the island, there are interperfed some excellent springs of fresh water; but where these fail, the people are forced to dig wells in the rock. Their towns are commonly fupplied by rain-water, which they preserve in cisterns. Fuel is very scarce, as there is little wood upon the island; so that the common people are under a neccessity of using dried cow-dung or wild thistles to dress their meat, heat their ovens, and warm their apartments in cold weather. Although pasture is scarce, they breed here a great number of sheep and goats, whose fheu is exquisite, as they chiefly feed on aromatic plants that grow on the rocks. Here are hogs in abundance, and good apples, pears, and some fhorps that are fed with barley and chestnuts. The poultry are large; those of the wild kind, particularly partridges, come from other countries in large flights, especially in the months of March and October.

The Maltese resemble the inhabitants of Barbary; and their language is nearly the same, being the old Punic or Arabic, which is very differently spoken in different places. But in the city of Valetta and among persons of rank the language most in use is the Italian. The natives are industrious, active, economical, and brave; they are mercenary, passionate, jealous, superstitious, and vindictive. Their dress in general consists of a cotton shirt, a vell, a cloak, with a girdle round the waist. They also wear trousiers, and a coat of shoes called "korch," which is merely a leathern sole, with fringes to fasten it round the leg. Their cap is white or coloured. They are remarkably temperate; a clove of garlic, or an onion, anchovies dipped in oil, and salted fish, being their usual diet. On great festivities they eat pork.

Their principal trade is in cotton; of which a great quantity is annually exported. The imports are corn, cloth, wood, oil, wine, brandy, &c. As they are seldom without cruisers at sea, their captures of the Turkish and Barbary corsairs constitute the principal branches of their commerce; for they are thus able to furnish Sicily and other parts of the Levant, with spices, sugar, and other commodities, in return for which they bring back grain, pulse, flesh, both fresh and salted, wood, oil, salt, and other necessaries. But the chief profit of their goes to the order, the native inhabitants having no other share than by the exchange they make of them with the produce of their own lands and industry. The forces of the island, exclusive of the knights and those who belong to the order, consist of those who are able to bear arms, and who are in general robust and well disciplined. They are obliged, at the firing of the signal cannon three times, to appear under their proper standards, in all their martial accoutrements. Under the discipline of the Maltese knights, they are become expert in the use of fire-arms. They are also reckoned good horsemen. Every knight that has four feudi per day is obliged to maintain a horse for his own use and at his own charge. The number of galleys which the order furnishes is greater or less, according to the exigence of the occasion. These galleys are strongly built, well manned and commanded; having usually each 100 warriors and 25 knights on board; and that, which is called the "Capitanis," and carries the standard of the order, has most commonly 30 knights. Besides these, they have a number of galleons, and other inferior vessels, the crews of which consist chiefly of slaves, of whom they have seldom less than two or three thousand. All along the coast the island is well garrisoned and fortified; and on the left appearance of danger, beacons are set on fire on the high grounds, and these signals are answered by the firing of the city guns; so that the alarm is soon spread through the whole island. The grand master has the whole revenue of Malta, as well as that of Gozo, over which he is invested with the sovereign power during his life. His revenues arise from a certain tax upon the island, and include the duties on salt goods imported and exported, and such like imports. These, with some additional perquisites, formerly amounted, cumnibus annis, to about 60,000 crowns. Buigelin's Ancient and Modern Malta, &c. 3 vols. 4to.

Malta keeps accounts in feudi of 12 tari, each tari being subdivided into two carlini, 20 grani, or 120 picchioli. These money of account are valued both in silver money and copper money; meaning by copper money (not metal), but the current value of the coins of the island, and by silver money their value in foreign exchange. Silver money is to copper money as three to two. The gold coins are double, single, and half Louis-d'ors, coined by the grand master Rihan, at 20, 10, and 5 feudi, copper or current money. The silver coins are ounces and half ounces, coined by the fame grand master, at 35 and 15 tari; feudi and halves, at 12 and 6 tari; pieces of one, two, and four tari, all in current money. The real copper coins are tari, and pieces of 10, 5, 21, and 1 grani. Spanish quadruples pafs for 345 feudi; Venetian equins for 6 feudi; Dutch ducats for 538 feudi; Sicilian ounces for 64 feudi; &c.
dollars for 30½ tari; current or copper money. The finest both of gold and silver is expelled in carats; but the gold is divided into 24 carats, and the silver into 12. Gold and silver are weighed by the pound of 12 ounces; the ounce is divided into 16 parts, or 32raphe; and the raphe into 18 grani. This pound weighs 4.888 English grains; so that 720 lb. or oz. of Malta is = 611 lb. or oz. troy. According to the rate of coinage, the double Louis-d’or is to weigh 3½ of an oz. of Malta, or 267 English grains; and the gold is to be 20½ carats fine. The ounce or piece of 30 tari is to weigh 1 oz. of Malta, or 458½ English grains, and the silver is to be 10 carats (or 3½ths) fine. The feuud and inferior silver coins are almost 9 carats, fine. The angle Louis-d’or is worth 19½. 8d.Sterling; the piece of 30, tari, or 2½ feuud, is worth 53½d. Thus the feudo current money is worth 21½d. Sterling.

The commercial weights are the heavy and the light cantaro; the former consisting of 111 heavy rotoli, each of 2½ lb.; the latter of 100 light rotoli, each of 2½ lb. The heavy cantaro is = 23½ lb. avoirdupois, and the heavy rotolo = 30½ oz. do. The light cantaro = 175 lb. avoirdupois; and the light rotolo = 28 oz. do.; 10 lb. of Malta = 7½ lb. avoirdupois.

The measures are a faina of corn, nearly equal to an English quarter, or 64 famina = 63 English quarters: the cassbho, a measure for oil, contains 5½ English gallons. The canna, a long measure, is divided into 8 palms, and is 922½ French lines, or 81½ English inches; hence 40 canna = 91 English yards. The foot of Malta is 11½ English inches, and 72 feet of Malta = 67 English feet. The Sicilian weights and measures are likewise used here, for which see Sicily.

In 1808 the Sicilian dollar of 2½ feudi or 30 tari was exchanged for 5½ pencé sterling, in government bills in England at 30 days sight. Kelly’s Universal Cambist, vol. i. N. lat. 55 47’. E. long. 14 10’.

MALTA, a town of America, in Saratoga county, New York, taken from the western part of Stillwater; four miles E. of Balltown spring. MALTA, Knights of, an order of military religious, who have borne various other names; as Hospitale of St. John of Jerusalem, knights of St. John, knights of Rhodes, order of Malta, religion of Malta, &c.

About the year 1548, some Neapolitan merchants founded a church after the Latin rite at Jerusalem, giving it the name of Santa Maria della Latina, or St. Mary of the Latins. They also founded a monastery of religious after the order of St. Benedict, for the reception of pilgrims; and afterwards an hospital near the monastery, to take care of the diseased, under the direction of a master or rector, to be nominated by the abbot of Santa Maria della Latina. Besides which, they also built a chapel in honour of St. John Baptized.

In 1599, Godfrey of Balicign, having taken Jerusalem, endowed this hospital with some demesnes, which he had in France; and others imitating his liberality, the revenues of the hospital became considerably augmented. Upon this, Gerhard de Didier, a native of Provence, their rector, in company with some of the leading nobility of France, exhorted the abbot and religious of Santa Maria, and to form a distinct congregation, under the name and protection of St. John Baptized: and hence it was that they had the name of “Hospitale, or Brothers of St. John of Jerusalem.” Their habit was black; and they wore on their breasts a white cross of eight points, in token of the eight beatitudes.

Pope Pascual II, by a bull in the year 1113, confirmed the donations made to this hospital, which he entitled under the protection of the holy see; ordering, that the rectors, after Gerhard’s death, should be chosen by the Hospitale. Raymond du Puy, Gerhard’s successor, took the title of “maister,” and he gave a rule to the Hospitale, which was approved by pope Calixtus II, in 1120. Such was the first rule of the order of Malta.

Their first grand-master, finding the revenues of the hospital vastly to exceed what was necessary for the entertainment of poor pilgrims, and dined in professors, resolved to employ the surplus against the infidels: and with this view he offered himself to the king of Jerusalem.

He divided his Hospitale into three classes; the first consisting of nobles, whom he defined to the preef of arms, for the defence of the faith, and the protection of pilgrims; the second consisting of prelates or chaplains, who were to lay-maps; and the third of servitors, who were not noble, but were also appointed for the war. He also regulated the manner of admitting knights brothers; and had the whole confirmed in 1179 by pope Inocent II, who commanded that the standard of the knights should be “gules, a full crof argent.”

After the loss of Jerusalem, they retired first to Margath, then to Acre, which they defended very vigorously in 1290. After the entire loss of the Holy Land they withdrew to Cyprus, where king Henry of Luxembourg, whom they had followed thither, gave them the city of Liminon. Here they continued eighteen years, when, taking the island of Rhodes from the Saracens in 1308, they settled there. And now it was that they first took the name of “knights,” and soon after “knights of Rhodes.”

Andronicus, emperor of Conflantinople, granted to their grand master, Fulik de Villaret, the invetilat of this order, and the donation was confirmed by pope Clement. The year following, with the assistence of Amadeus IV. duke of Savoy, they defended themselves, and their island against an army of Saracens. In 1480, their grand master d’Aubuflon made a vigorous defence against Mahomet II., and preferred the island in faire of a formidable army, which believed it for the space of three months. But in 1523, it was attacked by Solyman II. with an army of 350,000 men, and taken by him, after having been in the possession of the knights 213 years.

After this loss, the grand master and knights retired first into the isle of Candia. Some time after pope Clement VII. gave them Viterbo. Lailly, Charles V. in 1525, gave them the island of Malta, which grant was confirmed by the pope in 1530: and hence they obtained the appellation of “knights of Malta;” though their proper name is that of “knights of the order of St. John of Jerusalem;” and their grand master among his other titles, still retains that of “master of the hospital of St. John,” and “guardian of the poor of our Saviour Jesu Chrift.” The badge of the order is a “gold cross of eight points enamelled white, and worn by all the knights at their breast, pendant to a black ribbon.” The knights of this order, whether novices or professed, when they go to war with the Turks, wear over their coats “a red jacket or tabard, charged both before and behind with a great full white cross, without points.” See the preceding article.

The order of Malta have no other dominions besides their island, and some other little places in the neighbourhood, the chief whereof are Gozo and Comino.

The government is both monarchical and arilocratical, the grand master being the sovreign, and the chapter the senate. It is monarchical with regard to the inhabitants of Malta, and the titles adjacent, and even with regard to the knights in every thing relating to the statutes and rules of
their order; and it is arithmetical with regard to the decision of any important affairs, which are not to be dispatched but by the grand master and the chapter. There are two councils; the one ordinary, composed of the grand master, as chief, and the grand cross; the other complete, consisting of the grand master, the grand cross, and the two senior knights of each language.

By the languages of Malta are meant the several nations of which the order is composed. Of these, authors have reckoned eight, viz. Provence, Auvergne, France, Italy, Aragon, Germany, Caffile, and England.

The pillar (as he has been called) of the language of Provence is the grand commander of the order; he of Auvergne the grand marshal; he of France the grand hospitaller; he of Italy the grand admiral; he of Aragon grand confervator, or draper, as he was anciently called; the pillar of the language of Germany is grand bailiff; and he of Caffile grand chancellor; the language of England, which has been extinct since the time of the Reformation under king Richard; VIII. has since been annexed to the language of France. The whole army of the order is composed of Coris, or the grand turcopier, or colonel of the cavalry. The language of Provence is the first, on account of Gerhard, a native of Provence, or of Raimond du Puy, their first grand master, who was a Provençal.

In each language there are several grand priories, and capital bailiages. To each language belongs a hall, where the knights eat, and hold their ordinary assemblies. Each grand prior has a number of commanderies.

The commanderies are either magisterial, or else by right, or, finally, by favour. The magisterial are those annexed to the grand master'ship, of which there is one in each grand priory: commanderies by right are those which come by right of seniority; their seniority is computed from the time of their admission; but they must first have lived five years at Malta, and have made four caravans, or cruising voyages, on the Turks and Coris: commanderies by favour are those which the grand master, or the grand prior, have a right to conferring; one of these they confer every five years on whom they please. The noble knights are called major knights, which can be or chieftains, or grand priors, or grand masters.

Knights by favour are those who, not being noble of themselves, are raised on account of some great exploit, or some notable service, into the rank of nobles.

The fervitors, or serving-brothers, are of two kinds: 1. The fervitors of war, whose functions are the same with those of the knights. 2. The fervitors of religion, whose whole busines is to sing the praises of God in the conventual church, and to officiate each in his turn as chaplain on board the vessels and galleys of the order.

The brothers of obedience are priests, who, without being obliged to go to Malta, take the habit of the order, make the vows, and attach themselves to the service of some of the churches of the order, under the command of a grand prior, or commander, to whom they pay obedience.

The knights of majority are those who, according to the statutes, are admitted at sixteen years of age. The knights of minority are those who are admitted from the time of their birth; which, however, cannot be done, without a dispensation from the pope.

The chaplains can only be admitted regularly from ten to fifteen years of age; after fifteen they must have a brief from the pope; till fifteen, the grand master's letter is sufficient. These are called diaconos, and must give proof of their being born of creditable families.

For the proofs of nobility to be made before the admission of knights, in the language of Germany, they go back fix generations; in the rest, it is sufficient to go back to the great grandfather on the father's or mother's side.

There are also female hospitalers of the order of St. John of Jerusalem, sometimes also called chevaliersesses, or the knights, whose busines is to take care of the women-pilgrims, in an hospital apart from that of the men. This order was instituted in the year 1107, by Agnes, abbess of the hospital of St. Mary Magdalene, who, with her companions, made profession of the same rule, took the same habit, and bound themselves to observe the same vows, as Gerhard de Didier had done in the year 1699. The badge of this order was the cross with that of the knights of Malta.

Since treaties of alliance between Christiian and Infidel powers are now as common as between Christiian powers alone; and since the Barbaryle Corsairs are less formidable and injurious to commerce than they were formerly, the order of Malta, notwithstanding its claim to the gratitude of European powers for a long, long series of pious services, seems to have declined in importance and estimation.

The order, however, has the privilege of the grand priors and the sovereigns being added to those of Malta; several commanderies, situated in Poland, were restored; and a new language was infallibly, the Anglo-Bavarian; to which was afterwards united the grand priory of Russia, created by the emperor Paul, who, enamoured of chivalrous exploits, and well aware of the commercial and political advantages which Russia would derive from the poffeision of Malta, assumed the title of protector of the order, and was invested, together with the whole imperial family, with the grand crofs of Malta.

Nevertheless, the European powers were very indifferent as to the independence of the order.

That the legislative assembly of France should pass a decree, annulling the order of Malta, was not matter of surprise: it was the natural consequence of a previous law, that every Frenchman, who was a member of any order of knighthood which required proofs of nobility, should no longer be regarded as a French citizen. Nor can it be matter of surprise that, by the same decree (Sept. 19, 1792), all its property should be annexed to the dominions of France.

The original hospitalers, and the first knights were Frenchmen; out of the eight languages France had three, besides commanderies situated in Alarce, Rouffillon, and French Navarre, which were all dependencies of the two languages of Germany and Aragon. The confiscation of all this property was quite consonant with the prevailing atrocious fyllem of revolutionary policy and morals. The enormous deficit which this plunder occasioned, ought to have excited the compination, if it had not called forth the generosity of other states; instead of which we find the order afflicted to support the coalition against France. Thus, between two armies, the knights of Malta bear the blows of both! The Spanish and Portuguese commanderies, which had never before paid any taxes to their respective governments, were now called upon for a tenth of their revenue; those in the kingdom of Naples and in Sicily were subjected to heavier ones; and the order was treated with all the generosity and care which part of the property of the knights of Malta was ordered to be sold.

The revenue of the order in the year 1788 amounted to 5,156,719 French livres, and the expenditure to 2,967,503, leaving a surplus of 189,116. To the confiscation of its property in France, yielding an annuual revenue of 1,392,974 livres, and its taxation by different sovereigns in support of the war against France, must be added the enormous losses which the treasury sustained by the depreciation of paper money, when it became necessary to realize the revenues duc
due from Spain and part of Italy. The left bank of the Rhône being ceded to the French by the treaty of Campo Formio, the order was deprived of all its property in these new departments; and the different new republics, formed on every side, succesively robbed it of what it possessed in Helveria, and the Ligurian and Cisalpine republics. Malta, by these accumulated losses, was deprived of two-thirds of its revenue. It was compelled to borrow to the amount of six millions of livres; and at last its credit was fallen so low, that no one could be found to advance more. In the year 1796, the plate belonging to the men of war and to the gallies was melted down, and coined into money, as was also part of the grand master’s, together with some of that employed for the use of the sick in the hospital. It was very evident, therefore, that this noble order, which for seven hundred years had been the terror of infidels and the bulwark of Christendom, was no longer held in that estimation and respect by the European potentates, which the remembrance of its valuable achievements might have been expected to inspire. Rufina, under Paul I., certainly manifested a desire to afford Malta relief; the order also expected the payment of about a hundred thousand crowns from Spain, which most unfortunately did not arrive till a few days after the French had landed in the island, and which, of course, became a prey to them.

Notwithstanding the low state of the finances, Malta, at the time the French fleet made its appearance, was perfectly able to have made a formidable resistance against any attempt at landing; and if a landing had been effected, a still more powerful defence of the city Valetta. “Never to reckon the number of the enemy” made a part of the oath of every knight, on his admission into the order; and “to die at his post was a first principle of honour.” The bulwarks of the island were master-pieces of fortification, and if the knights and the Maltese had been as faithful to themselves and to each other as at the siege by Solyman, Bonaparte would have retired from this rock of resistance abashed, confounded, and defeated. The treacherous surrender of the island gives an ample verification to the statement of the Maltese deputies: “The defection,” say they, “and treason of which the order was guilty, will form an epoch in the annals of the world as striking as that by which we are again thrown under its despotic dominion, after it had abandoned us to an army unfaithful to all its promises and engagements.”—No one is ignorant that the plan of the invasion of Malta was projected in Paris, and confided to the principal knights of the order, resident at Malta. Letters in cyphers were incessantly passing and re-passing, without, however, alarming the suspicions of the deccded grand master de Rohan, or of the grand-master Hompech. On the evening of the 6th of June, 1798, the French landed their troops at Magdalen creek, and on their approach “one single cannon shot” was fired from fort St. George. At day-break their Sally-ports were seen advancing towards seven different points, Gozo, Cumino, La Mèlche, Salmon, St. George, St. Julian, and La Trombrella, none of which made any resistance, except Goza, which was attacked by general Regnier, and defended by the commander de Megrini. A dreadful scene of slaughter ensued: the Maltese people fought with a two-edged sword; they attacked the invaders with valour, and flew, without discrimination, the knights of the order, by whose treachery they had been sufFered to effect a landing. That some among the Maltese were deluded by the promises universally lavished by the French, of liberty, equality, &c. cannot be doubted; but by their subsequent conduct it is fully proved, that the bulk of the people were most determinedly hostile to the admifion of the French, and that their defection of the order was inexpressibly incrased by a detection of its treachery on this occasion. When Bonaparte fell, some of the knights actually unfiiff under his banners!

It is unnecessary to give an account of the conduct of the French on their possession of Malta; everything in the public buildings, “which bore the flame of nobility, or recalled to mind the celebrated exploits performed by illustrious chiefs, was broken and destroyed.” The arms of the order, together with those of the principal chiefs, were effaced not only in the principal insis, but in the palace of the grand master, himself being present on the occasion! The knights who were not in the French interest, were ordered to quit the island in three days, and a disgraceful salary was voted to Hompech, as an equivalent for the property annexed to the grand master’ship. The knights who were attached to the French interest had but little reason to applaud the wifdom of their political speculations: exiled to the rage of the Maltese, and unprotected by their new friends, they were shut up in different fortresses, some fled, some absolutely perished from want, and all were despifed and hated.

The few who remained faithful to their duty were scattered in different places. Hompech retired to Tripoli, separated himself from the companions of his flight, and resigned the office of grand master, which he had to ingloriously filled. Many retired to the dominions of the emperor of Rufina, who took upon himself the title of grand master, and created a new Rufian priory for the benefit of the nobles in his dominions, who followed the rites of the Greek church. Notwithstanding the flight of Hompech, and the knights who accompanied him, and notwithstanding the treachery of those apolite members of the order who remained behind, attached to the provisional government established in the island by the French, the brave inhabitants rofe in arms against their invaders, who were shut up within the gates of Valetta, without daring to issue forth and face the terrible vengeance of the people. The blockade of Malta by the English lasted two years; namely, from September 2, 1799, to September 4, 1800, when the city surrendered. The situation of the city was so deplorable from the alarming mortality among the troops and inhabitants, arising doubts from the fear of provisions, that a surrender appeared absolutely certain. In September, 1799, a bower, which before the blockade, used to sell for 6d. fold for from 2l. 3s. to 2l. 10s. English; a pigeon was worth a farthing; a rat from 1s. to 1s. 6d.; fresh pork fold for 7s. a pound, and cheese for the same. The flesh of mules and mares was in such request, that the people complained bitterly whenever they were deprived of it. The French, however, raised vegetables, bred poultry, rabbits, &c.; and, under the vigilance and unceasing encouragament of their general Vaubois, contrived, as much as possible, to relieve their wants and support their spirits. The garifon was put upon half-pay in the month of August; in the following December it was entirely dropped, as was their allowance of wine and brandy. To the honour of the French troops, for it is impossible to contemplate such conduct without admiration, not a murmur was heard, and during a whole twelve-month there were scarcely twenty defectors, and the great of the these were either volunteers or failures! The situation of the inhabitants now became every day more and more difaificious; and such were the effects of poverty, dilfance, and frequent emigration, that of 40,000 souls in September 1798, there only remained 13,000 in 1799: these were reduced to 10,000 in the following October, and to 7,500 in March 1800.
period of the blockade provisions rofe to an incredible price: a bottle of oil fold for 24S: a pound of coffee for 2f. Ss. and a pound of sugar for a few shillings less; aleis, mules, horfes, dogs, and cats, were almost all consumed; and general Vauhoun was at laft compelled, by famine, to propofe terms of capitulation. He received from the English fuch as were due to fo perfevering and courageous a refiftance, and fuch at the fame time as proved that Britons pay just homage to the bravery of an enemy. The native Maltese were the only party who had reafon to complain of the capitulation, and still greater the treaty of Amiens, which again configned them to the order which had given fuch irrefragable proofs of cowardice and treachery.

By the treaty of peace between Great Britain and the French republic, concluded at Amiens 27th March 1802, it was stipulated, that the iflands of Malta, Gozo, and Cuminho, fhould be referved to the order of St. John of Jerusalem, to be held on the fame conditions on which it profiffed them before the war, and under the following stipulations.

1. The knights of the order, whole languages fhall continue to fubfift after the exchange of the ratification of the prefent treaty, are invited to return to Malta as soon as the exchange fhall have taken place. They will then form a general chapter, and proceed to the election of a grand master, chosen from among the natives of the nation which prefer their language, i.e. a right of election, as belonging to a particular Catholic nation, unless that election has been already made since the exchange of the preliminaries. It is underftood that an election made fubfquent to that epoch, fhall alone be confidered valid, to the exclusion of any other that may have taken place at any period prior to that epoch.

2. The governments of the French republic, and of Great Britain, defirous to place the ifland and order of Malta in a state of entire independence with refpect to them, agree that there fhall not in future be either a French or English language, and that no individual belonging to either the one or the other of these powers fhall be admitted into the order.

3. There fhall be eftablifhed a Maltefe language which fhall be supported by the territorial revenues and commercial duties of the ifland. This language fhall have its peculiar diftinction, and an ifland grand master fhall not be necessary for the admission of knights of this language; and they fhall be moreover admissible into all offices, and fhall enjoy all privileges, in the fame manner as the knights of other languages. At leaft half of the municipal administration, civil, judicial, and other employments depending on the government, fhall be filled by inhabitants of the iflands of Malta, Gozo, and Cuminho.

4. The forces of his Britannic majesty fhall evacuate the ifland and its dependencies, within three months from the exchange of the ratifications, or sooner if poifible. At that epoch it fhall be given up to the order in its prefent flate, provided the grand master or confirnaries, fully authorized according to the ratutates of the order, fhall be in the ifland to take poifession; and that the force which is to be provided by his Sicilian majesty, as is hereafter stipulated, fhall have arrived there.

5. One-half of the garrison at leaft fhall be always composed of native Maltefe; for the remainder the order may levy recruits in those countries only which continue to profiff the languages. The Maltefe troops fhall have Maltefe officers. The command in chief of the garrison, as well as the nomination of the officers, fhall pertain to the grand master; and this right he cannot reign, even temporarily, except in favour of a knight, and in concurrence with the advice of the council of the order.

6. The independence of the ifles of Malta, Gozo, and Cuminho, as well as the prefent arrangement, fhall be placed under the protection and guarantee of France,
of luxury, cared for and revered as so many sovereigns; if in this condition the French could command them to quit their terrestrial paradise, to wander in the wide world, and could induce them to become partisans of their cause, what must not the power of the same French over them be, dependent, degraded, dishonoured, reduced to beggary, in whom is extinct every spark of honour, and who have been guilty of the blackest, the most horrible infidelity, apostasy towards their God, and violation of the sacramental ordinances?"—"With respect to the guarantee of this or that power, but too well is our island acquainted with the French and the order, not to be convinced of the fallibility of such a proposition. The first war, whether of length or short duration, puts an end to it entirely. If ever a third power were to occupy some parts of the fortresses, the troops would be corrupted by French money and French principles; and immense are the sums that would be expended for that purpose. The military polls are dependent one upon the other. We are able to point out," say the representatives, "the utter impossibility of occupying a part, without the whole. We can clearly demonstrate how they can, and will obtain their several ends. We can make it evident, that there is no security for the inhabitants, unless British troops are placed in possession of all the fortresses, and unless the administration of justice is placed in the hands of a British civil government."—Bolleglin's Anc. and Mod. Malta.

MALTA, or Medina. See CIVITA FRIEBIA, and MALTA, jago, or isola.

MALTA Earth, in the Materia Medica. See MELTENUS TERRA.

MALTEPEC, in Geography, a town of Mexico, in the province of Mechoaxcan; 60 miles E.S.E. of Mechoaxcan.

MALTISE, in Biography. The proper name, the birthplace, and the education of the ingenious painter who bears this appellation, are alike unknown; but his works, which consist chiefly of objects in still life, are valued for their exhibition of freedom, boldness, and truth. They are generally composed of fruit, carpets, jewellery, shells, tapestries, &c. to which, by a judicious management in their composition, a brilliant colour, and a ready and powerful touch, he produced a strong and brilliant relief; and often a most enchanting effect of chiaro-oscuro.

MALTA, Meskis, in Antiquity, denotes any cement, or glutinous body, which has the faculty of binding things together. See CALESTANT CEMENT.

Ancient writers make mention of divers sorts of maltha, native and fictitious; one of the latter which was in use was composed of pitch, wax, platter, and grease.

Another kind, with which the Romans plated and whitened the insides of their aqueducts, was made of lime flaked in wine, incorporated with melted pitch, and fresh figs.

Natural maltha is a kind of bitumen, called "mineral pitch," with which the Alhafis plate their walls. When this is once set on fire, water will not quench it; but serves rather to make it burn more fiercely. See BITUMEN.

MALTHA, in Ichthyology, the name of a voracious fish of the shark kind, called the fartand, and the lamia, by some authors, a diminutive of lamia, signifying a small shark. Its teeth are broad and pointed, like those of the shark; the fish has also many rows of thorns; the nose is short, and its flesh lax and soft. See SQUALUS.

MALTODODE, a term by which the Greek writers express the emollient topical remedies prepared with oil. Hippocrates expressly forbids the use of thence in old ulcers.

MALT, or New Malt, in Geography, a borough and market-town in the wapentake of Ryedale, North Riding of the county of York, England, is situated 18 miles distant from York, and 217 from London, on an eminence overlooking the river Derwent, which runs through a beautiful valley on the south-east side of the town. Malton was of some note in the Saxon times. Immediately before the Norman conquest, it was poisselled by a nobleman named Colebrand, from whom it was taken by the Conqueror, who gave it to Gilbert Tyton, one of his followers. In the reign of Henry I., Entace St. John poisselled this lordship by inheritance from his mother, who was grand-daughter and heiress of Gilbert Tyton. In the contest between the empress Maud and King Stephen, the town was reduced to ashes. It was rebuilt by Entace, and then acquired the name of New Malton. In the reign of James I., Ralph, lord Eure, who was then in possession of the manor, built a magnificent house here; but leaving no issue, his estates came to his uncle William, lord Eure, who left two daughters, co-heiresses. These disagreeing about this noble manse, it was, after a tedious and expensive litigation, determined that it should be pulled down, and its materials divided: and so ferupulously was the division made, that the "tomes were even shared one by one." But it seems that some person or another took place before the dilapidation was completed, as the lodge in the front, with three arched passages, are yet standing. The manor was afterwards conveyed to Sir Thomas Wentworth, and from him descended to Thomas, marquess of Romneyan, who was succeeded in titles and estates by his son Charles, the late marquess; after whose death, the estates devolved on his nephew, earl Verzwil.

Malton is about half a mile in length from east to west. The entrance at the east end is by a spacious stone-bridge over the Derwent, whence the principal street rises with a continued, but gentle ascent through the town. The houses are mostly built of stone; and in the year 1801 were in number, according to the population survey, 604, and were occupied by 3027 persons. The town comprises two parishes, St. Michael's and St. Leonard's; each having its respective church: the spire of the latter has a singular appearance. Malton is a borough by prescription, and has lent two members to parliament ever since the 23rd year of Edward I.; the right of election being vested in the holders of about 100 burgage tenures. The town is governed by a bailiff. Markets are held on Tuesdays and Saturdays; and a brisk trade is carried on in corn, of which a great quantity is sent into the western parts of Yorkshire, and to several other places. The Derwent is navigable to Malton, where the quantity of corn shipped in the year 1796 amounted to 36,265 quarters. Here are three annual fairs, which exhibit a great show of horses and cattle, and are much frequented by farmers, graziers, and horse-dealers. Hindersnott's History of Scarborough. Beauties of England and Wales, vol. xvi. by John Bigland.

MALT, a town of Sweden, in Angermanland; 42 miles N.W. of Herno.

MALVA, in Botany, is thought by Ambrosius to have obtained its name from modified, alluding to the soothing or emollient qualities with which it is endowed. The ancients reckoned it an excellent stomacie, frequently mixing it with Lactea in their phials. Its Greek name μαλβία is of similar origin, being derived from μαλλίς, to smell. Horace, as every body knows, speaks of "levis malvae," apparently meaning light of digestion; and Martial says, "Utere lacteae, et mollibus uteris malvae." Linn. Gen. 554. Schreb. 466. Willl. Sp. Pl. v. 5: 574. Mari. E. 2: 78: 58. Nill.
MAL

Gen. Ch. Cal. Perianth double, inferior; the outer generally narrower, of three ovate or heart-shaped, acute, persistent leaves; the inner of one leaf, leaf-like half way down, larger, broader, permanent. Cor. Petals five, obcordate, abrupt, flat, fixed by their base to the tube of the flammes. Stam. Filaments numerous, united below into a tube, separate and loose at the top, and along the surface; anthers kidney-shaped. Pist. German superior, orbiculate, deprested; style cylindrical, short; stigmas many, bristly, as long as the style. Peric. Capsule roundish, composed of the same number of two-valved cells as there are stigmas, placed in a whorl about a columnar receptacle; finally deciduous. Seeds solitary, occasionally two or three, kidney-shaped.

Obs. Schreber remarks that some species have only two leaves to the outer calyx, and that in M. caroliniana each capsule is divided into two cells by a transverse membrane. This extensive genus furnishes many ornamental plants, though chiefly of exotic growth. We select the following species to illustrate its history. Linnaeus has defined only twenty-six in the 14th edition of his Systema Vegetabilium. Professor Martyn however has thirty-four, and Willdenow describes fifty-five. They are arranged under two fections, namely, such as have undivided leaves, and such as have angular leaves, all our three native Mallows belonging to the latter section.

Sec. 1. Leaves undivided.

Sec. 2. Leaves angular.

M. sfylleflris. Common Mallow. Linn. Sp. Pl. 969. Engl. Bot. t. 671. Curt. Lond. f. 2. t. 51. Woody. Med. Bot. t. 54.—Stem upright, herbaceous. Leaves with seven sharpish lobes. Leaf-stalks and flower-stalks hairy.—By hedges and paths both in cultivated and waste ground all over England, flowering from May to September. Root perennial, spindle-shaped, branched, whitish. Stem generally erect, branched, round, hairy, many-flowered. Leaves alternate, on footstalks, heart-shaped, folded, seven-lobed, roughish, notched; the upper ones nearly palmate. Stalks crowded together, hairy, single-flowered. Flowers reddish-purple or lilac-coloured, veined with a deeper tinge; petals obcordate, thrice as long as the calyx, which is hispid. "The whole herb," says Dr. Smith, "especially the root, abounds with a pure mucilage, and possefles the emollient qualities of the Marsh Mallow, Alsab, though perhaps in an inferior degree. It has, however, the advantage of being much more common, and within every body's reach."

M. rotundifolia. Dwarf Mallow. Linn. Sp. Pl. 969. Engl. Bot. t. 1692. Curt. Lond. f. 3. t. 43.—Stems prostrate. Leaves roundish heart-shaped, five-lobed. Fruit-stalks bent downwards.—Common in waste ground, flowering copiously from June to September. Root annual, branched, whitish, mucilaginous. Stems numerous, prostrate, almost simple. Leaves smaller than in sfyllefris, five or seven-lobed. Flowers flesh-coloured. A variety of this is sometimes found with smaller petals, indeed not longer than the calyx. This was considered as a distinct species by Mr. Hudson, who called it parviflora, and Dr. Smith figured it in Engl. Bot. t. 241, under the name of psilica, but he afterwards was satisfied of its being a mere variety of M. rotundifolia.

M. mochbata. Musk Mallow. Linn. Sp. Pl. 971. Engl. Bot. t. 754. Curt. Lond. f. 4. t. 56.—Radical leaves kidney-shaped, cut; those on the stem in five deep pinnatifid and finely divided segments. Calyx hairy.—Not uncommon by the sides of fields and roads in a gravelly soil, flowering in July and August. Root perennial, somewhat woody, tenacious. Stems erect, rather branched. Lower leaves heart or kidney-shaped, lobed; upper divided to the base into five segments, which are deeply pinnatifid, cut and channelled. Flowers large, handsome, rose-coloured. The whole herb gives out a strong, musky odour, which is scarcely perceptible, however, in cold or damp weather.

M. Alca, was once reckoned a British species, and Willdenow still mentions it as such, but without reason. Some variety of mochbata, with broader leaves than usual, is supposed to have been taken for it.

MALVA, in Gardening, comprehends plants of the herba-
ceous, annual, biennial, perennial, and shrubby kinds, of which the species cultivated are, the spiked mallow (M. spicata); the American mallow (M. americana); the Peruvian mallow (M. peruviana); the creeping mallow (M. caroliniana); the oriental mallow (M. orientalis); the white-flowered mallow (M. verticillata); the curled mallow (M. crifpa); the palmed mallow (M. egypca); the vernain mallow (M. alca); the musk mallow (M. mochbata); and the gooseberry-leaved or cape mallow (M. capenis).

In the laaor Cape species, there are varieties in which the stems are thicker and higher, of a brownish-red colour; the leaves hirsute, broader, with wider segments, less deeply cut, but with the teethlets sharper and serrate; the whorls of fruit a little larger, and not mucilaginous, in which the hairs of the leaves and stem are simple, not compound; the flowers almost upright, not drooping or bending downward.

Method of Culture.—It may be observed that the ten first sorts are all capable of being raised from seeds, which, in the hardy kinds, should be sown in the situations where the plants are to grow, in patches of four or five each, in the spring or beginning of autumn, covering them to the depth of half an inch. They may likewise be sown upon a bed of fine earth, and be afterwards removed to the places where they are to flower. Those which are natives of hot climates should be sown in pots, and plunged in a hot-bed.

In the two latter modes, when the plants have attained some growth, they should be removed into their proper situations, or into other pots, to be afterwards managed according to the difference of the kinds.
And the last fort and varieties may be raised also by feed, which should be fown upon a hot-bed, or in pots, and plunged in it. When the plants have attained some growth, they should be removed into separate pots, replunging them in the hot-bed till nearly rooted, when they should be gradually inured to the full air, managing them afterwards in the same manner as other exotics of the greenhouse kind. The hardy sorts afford a pleasing variety in the shrubbery and other parts, while those of the more tender and shrubby kind produce a good effect in the green-house, and among potted gathered in other places.

MALVA Arborea, in Botany. See Hibiscus and Lavatera.

MALVA Rosae. See Alcea and Hibiscus.

MALVA Syriaca. Common Mallow, in the Materia Medica, has a strong affinity to the althea and Epidauros both in a botanical and in a medicinal respect; but the roots of the malva are nufes, while those of althea are of greater efficacy than any other part of the plant. Accordingly we find, that only the leaves and the flowers of the former are directed by the college for pharmaceutical purposes. Formerly the malva was admitted among the more common articles of diet. To this purpose it is referred to by Horace, l. i. od. 31.

—— Me pascunt olivae
Me circiora levesque malva.

The Chinese are said to eat the leaves of mallow, either raw as fallad, or boiled as spinach. As to the medicinal qualities of this plant, we shall refer to the article Althea; observing, that the leaves afford a similar glutinous juice, which is fitted to answer the same purposes as those of marshmallow, and are therefore principally used in fomentations, cataplasm, and emollient eczemas; but the internal use of these leaves seems to be wholly superfluous by the radix altheae. Cicero (Epist. lib. vii. ep. 26) mentions the laxative quality of this plant. Wood, Med. Bot.

MALVA, in Ancient Geography, a large and deep river of Africa, in Mauritania Caelestinia, which runs into the Mediterranean.

MALVACEÆ, in Botany, a natural order of plants, the 7th in Jussieu’s fifth, or the 14th of his 13th class, equivalent to the Columbine of Linnaeus, which article the reader will find in its proper place.

MALVANA, in Geography, a town of the island of Ceylon; 12 miles E. of Cumbuco.

MALVASIA, a town of European Turkey, situated on a promontory, almost surrounded by the sea, on the eastern coast of the Morea: its harbour is good, but not large. It is the see of a Greek archbishop, and one of the strongest towns in the Morea: the territory belonging to it is about three miles in circuit; and furnishes, in part, those celebrated vines, from which was obtained the wine, formerly much valued, under the name of Malmsey. This was formerly a place of great resort for the worship of Eucalipus, which was brought hither by the inhabitants of Epidauros (which see). This place is called by the Turks “Mernosche,” and it is distant about a league from the ruins of Epidaurus Limera (which see), and 40 miles E.S.E. of Miftra. N. lat. 36° 43′. E. long. 23° 4′.

MALVAVISCUS, in Botany, so called by Dillenius in his Hortus Elthamensis, t. 2. 210. t. 170. f. 208. Linnaeus however considered it as a species of Hibiscus, and gave it the name of H. Malvaviscus, Linn. Sp. pl. 978. It is now the Acanthus of Banks and Solander, and is characterized by a convoluted corolla, ten stigmas, and a pulpy fruit; (see Hibiscus and Acanthus.) Malwaeus of Garrett, t. 135, is Hibiscus populneus of Linnaeus, certainly a distinct genus from Hibiscus, but the name is untenable.

MALUCO, in Geography, a town of Peru, in the diocese of Truxillo, on the coast; 45 miles N. of Payta. S. lat. 4° 35′.

MALVENTRA, a small island near the west coast of Sardinia.

MALVERN, Great, a village and parish in the lower division of the hundred of Perleshore, and county of Worcestershire, England, is situated on the eastern declivity of the Malvern hills, at the distance of eight miles from Worcester, 24 from Cheltenham, and 120 from London. A hermitage, or religious society for seclusas, was founded here in the time of Edward the Confessor, and obtained some endowment from that monarch. About the year 1083, Aldewine, the chief of this place, was permitted by St. Wulfstan, bishop of Worcester, to become a Benedictine monk; upon which he immediately set about procuring benefactions for building and maintaining a priory of that order. Gilberet, then abbot of Welfminder, alligned several manors and estates to its support, whereby, with the munificence of devotees, the monastery was raised to great wealth and consequence. Few velliges now remain, except the church, which, at the dissolution, was purchased by the inhabitants, and rendered parochial. This is still a magnificent structure, being 171 feet in length, and 63 in breadth, with an embattled and pinnacled tower, rising from the centre to the height of 124 feet. The painted glafs in the windows, representing many scenes from Scripture history, was once the object of universal admiration; but, through time and neglect, is now in a mutilated state, though enough is left to afford an idea of its former beauty. Several parts of the choir are ornamented with telflicated pavement, exhibiting the arms of many ancient and noble families. The tombs and monumental inscriptions are very numerous, and some of them of remote antiquity; the remains of Walcher, the second prior of Malvern, which was discovered in 1735. Among the tombs is one of a Saxon knight, with his battle axe and other accoutrements, supposed to be the only one of this kind in England. Malvern has long been noted for two medicinal springs; that called St. Anne’s well, about a quarter of a mile from the church, is bituminous, and effemed very fulatory; the other is chalybeate, but is in a great measure neglected. Great Malvern, according to the population return in the year 1815, contained 1891 inhabitants.

About three miles distant is the hamlet of Little Malvern, which was once a confiderable village, but now contains only six houses, inhabited by 32 persons. A Benedictine priory was founded here, in the year 1171, by two brothers, Joceline and Edred, who were successively priors. The church was rebuilt in 1482 by John Alcock, bishop of Worcester, but is now in a ruinous state.

MALVERN HILLS, are situated in the counties of Worcestershire, Gloucestershire, and Herefordshire, but principally on the south-west part of the former, making a distinct boundary to the rich vale of the Severn, lying to the sail, and standing as a frontier between Worcestershire and Herefordshire. This lofty range of hills occupies a space about nine miles in length from north to south, and from one to three miles in breadth. The highest parts are those called the Herefordshire and Worcestershire Beacons, about four miles distant from each other; the former rising to the height of 1280 feet, and the latter to 1313 feet above the surface of the Severn. On the Herefordshire Beacon are the remains of an ancient encampment, containing of a double entrenchment; the outermost about half a mile in circumference. The
The avenues and paijes are sill to be seen, and the greater part is in fine preservation. The velleiges of another entrenchment, consisting only of a single ditch, appear about a mile and half further to the south; and on the declivity of the Beacon is a cave cut in the rock, about ten feet long, six broad, and even high, of rude workmanship and unknown origin.

From the Malvern hills issue various springs, of different qualities, according to the sublacies they are impregnated with; but that which has for several ages been reputed of peculiar medicinal efficacy, and has obtained the name of the Holy-well, rises about half-way up the eilt side of a hill, nearly mid-way between Great and Little Malvern. The source of the spring is secured by a convenient erection, containing a bath and other accommodations. The district called Malvern-Chafe contains about 8000 acres, chiefly in Worcestershire; only about 700 being in the two adjoining counties. Ruff's History of Cheltenham, 8vo. 1803.

Shaw's Tour into the Weft of England, 8vo.

Malvern Waters. See Malvern Waters.

MALVINDA, in Botany. Indian Mallow, a name of Dillenius for some species of the Sida of Linnaeus. It is sill more exceptional than Malvaviscus.

MALVISANO, in Geography, a town of Italy, in the Brefian; 13 miles S. S.E. of Brescia.

MALUNG, a town of Sweden, in Dalecarlia; 55 miles W. of Fahlun.

MALA, in Botany. The Sanskrit name of the Crcataua marmelos of Linnaeus. (See CATEVA.) It is also called bilwa or bilva by the Hindoos, who reckoned it a sacred shrub and fruit especially dedicated to Siva, probably because the latter is of a conical form, cones being typical of Siva, as the personification of fire. Many superstitious practices, and apparently idle tales, are connected with this fruit, in the mythological usages and legends of the East Indians. Chaplets of bilwa flowers decorate the statues of Siva, but of no other deity, nor are they offered in sacrifices to any other. A pious Hindoo feeding any of these flowers fallen on the ground, would, it is said, reverently remove them to a temple of Siva. The Hindoo poets call it Sripal, the flower of Sri, or Lakshmi, the goddess of abundance; who is fabled to have bestowed it on mankind, at the request of Isvara, or Siva. (See LAKMMI.)

The fruit is warm, cathartic, of delicious taste, and exquisite fragrance, and of valuable aperient and digestive qualities. The mucus of its seed is used as a cement. See Asiatic Researches, vol. ii.

MALUS, the ancient Latin name of an apple-tree, derived from the Greek μαύλος, is retained generically by Jussieu, Gen. 334, after Tournoufert, t. 406, to distinguish the apple from the pear, merely because the fruit of the former is umbilicated at its base, and the fleshes united at their lower part. The latter character is the most material, and appears to be founded in truth; but surely these plants form one natural genus. See Pyrus.

MALUS A PHYLLA. One of the many names given by the ancients to the citron; they also call it malus Medica, and by several other names, as these were expressive of the country whence they had the fruit. See Citrus and Citrea Malasie.

MALUS AMERICAN. See CaCTUS, Crateva, and Hip-POMANE.

MALUS ARMENIAC. See Prunus.

MALUS AVULSIS. See Citrus.

MALUS INDICA. See Rhamnus Jujuba.

MALUS LINNEAAAA. See Citrus.

MALUS Persica. See ACHIRAS, AMYGDALUS, and MAM.

MALUS PUNICA. See PUNICA Granatum.

MALUTAYA, in Geography, a small island in the sea of Mandora. N. lat. 11° 12'. E. long. 120° 52'.

MALWA, a province or soubah of Hindooft, one of the most extensive, the most elevated, and highly diversified in Hindooft; and belonging to the extensive empire of the Mahrafas. It is bounded on the N. by Agimere and Agra, on the E. by Allahabad, on the S. by Candeif, and on the W. by Guzerat. Ougcin is the capital of one Mahf rac prince, and Indore of another. It is now ruled in sovereignty by Dowlut Rao, nephew and successor of the late Madaji Sirdar. The noble river Narmada, or Nerbudah, washes it on the south, dividing it from the province of Candeif. The Chumbal on the N.W. divides it from Ajmec and Guzerat. On the S.E. it joins the dominions of the raja of Berar, and on the N.E. the British territories under the government of Bengal. Malwa may be roundly estimated at about 350 miles in length, and nearly as much in breadth. This lohabh is very temperate in respect of climate, its capital city, Ougcin, nearly centrally situated, being just within the northern tropic. (See Ougcin.) It is well watered, having, besides numberless lakes and smaller streams, the rivers Sipera, Kalihind, Neem, and Narmada flowing through it. It is an elevated region; and is very productive in grain and fruit, including wheat and grapes. Here are several noble cities and flourishing towns, of which Ougcin, Guurrah Mandla, Chandery, Bepal, Manduah, Dhar, and Naderbor, may be reckoned the chief. In the Ayen Akbery, Ougcin is stationed, on the personal knowledge of the author of that work, to have contained, when he visited it in 1596, 360 Hindoo temples. Chandery is described as having 14,000 stone houses, 384 markets, 360 caravanerais, and 12,000 moufiques. Its military strength is also very highly raised. We take this occasion to correct the typographical error in the article INDIRA, whence reference is made to this. About the middle of the second column of that article is a flop and break at the word Malwa, and a new article commenced with INDIRA Malwa. These two words are to be struck out, and the lines will then run thus— "particularly Upajin, or Oujcin, the capital of Malwa; the hereditary possession of the family of Sindu." For further particulars, see MAHALLATAS.

MALWALLY, an island in the East Indian seas, about 15 miles in circumference, containing two good harbours. N. lat. 7° 0'. E. long. 115° 20'.

MALZIEU, a town of France, in the department of the Lozere, and chief place of a canton, in the district of Maryjols; five miles N.N.E. of St. Chely. The place contains 1050, and the canton 57,412 inhabitants, on a territory of 160 kilometres, in 10 communes.

MAMADEBAD, or MAM-ABAD, a town of Hindooft, inhabited by Banians, who carry on a considerable traffic in thread and cotton.

MAMADISCH, a town of Russia, in the government of Kazan, on the Viafta; 16 miles N.E. of Kazan. N. lat. 56° 26'. E. long. 50° 35'.

MAMAK, a sea-port town of Abacina, on the Black sea; 110 miles W. of Isgaur. N. lat. 43° 26'. E. long. 38° 23'.

MAMA-KATING, a township of America, in Ulster county, New York, on Delaware river; containing 1631 inhabitants.

MAMAKATUN, a town of Turkish Armenia, on the Euphrates; 12 miles N. of Arzingeran.
MAMALEGERY, a town of Hindooftan, on the confines of Dindigul; 60 miles E. of Cochin.

MAMALAKÉ, one of the Calaur islands. S. lat. 6° 40'. E. long. 123° 33'. Also, a cluster of small islands extending about 60 miles in length from N.W. to S.E. and 30 in breadth, in S. lat. 6° 50'. E. long. 121°.

MAMALUKES, MAMELUKES, Mamelouks, or Mamoulks, the name of a dynasty, which reigned a considerable time in Egypt.

The name 7 reges, imperatores, the Arabic participle of which is 7 reges, Mambe, which signifies sufficiens, or one under the dominion of another. Scaliger holds, that the word is Arabic, and that it properly signifies something bought with money; but others will have it signify anything acquired or poiffed either as prize or purchase; and this gives the sense of faire.

The Mamelouks, or Mamouls, were originally Turkish and Circassian slaves, who were introduced into Egypt, in consequence of an expedition which took place in the year 1227. The Moguls, sword in hand, pillaging, burning, and murdering, without distinction either of age or sex, reduced the whole country of Shoum, quite to the Tigris, to a heap of ashes; and passing to the north of the Cafopian sea, extended their ravages even into Ruffia and the Cuban.

The Tartars, weary of maffacring, bad brought back with them a prodigious number of young slaves of both sexes, filling with them their camps and the markets of Afia. The successors of Salah-ed-din, or Saladin, son of Alâb, who usurped the title of sultan of Egypt in 1174, and who died in 1193, perceived that, having an opportunity, as Turkmans, of corresponding with the coasts of the Cafopian sea, they might form, at a cheap rate, a body of soldiers of tried courage and remarkable beauty. Accordingly one of them, viz. Malek Salah, about the year 1230, purchased to the number, as Velney says, of 12,000 of these young men, who were Pherkerkises (Circassians), Minorchians, and Abazans.

These he designed to be his guard and marine; and by training them up to military exerçices, he soon obtained a body of the handiwork and belt soldiers in Asia, though at the same time, as experience soon taught him, the most mutinous. This soldiery, like the Pratorian hands of Rome, ere long gave laws to their master. Malek Salah died in 1140, and was succeeded by his son Tûran Shah, who in the following year captured St. Louis, and his army of 20,000 men. On the 1st of May 1250, the Mamoulks depofed and massacred Tûran Shah, and alligned the feepre to his step-mother, and afterwards to a Bey of the Alîbite race; and this event closed the dynasty of the Alîbites in Egypt.

At this period commenced the dynasty of the Mamoulks. The first sovereign of this denomination were the "Baharite Mamoulks," who were fo called, from having been originally employed as "mariners" on board the ships of the sultan of Egypt. These were Turks or Tartars from Kiprak. The first sovereign of this dynasty was Ezz-ed-din Manz iragh, who began his reign A. D. 1254; and terminated in the same year by affaffination. Most of his succifors efeled their lives in the fame manner. The laft of the Baharite Mamoulks was Sheiben Ajezer, who was the first sultan who ordered thefe, or defendants of the prophet, to wear a green turban. The next race of Mamoulks was denominated "Borgite Mamoulks:" it was of Circassian estraçt, and continued to rule Egypt till the French invasion. This dynasty commenced in 1352: but under succeeding sultans of this dynasty the Mamoulk aristocracy became gradually more and more precarious. From their first eftablishment, the eftects corresponded with the means. Without any other bond of union than the interrell of the moment, or any public right to authority, but that of conquest, thes Mamoulks, or military slaves, had no other rule of conduct and government than the violence of a licentious and infoleent foldiery. The first leader whom they elected, having found employment for their turbulent spirit in the conquest of Syria, reigned 17 years; but the government of his succifors was of shorter duration. The fword, the bow-fling, or poifon, public murder, or private affaffination, have been the fate of a feries of tyrants, 47 of whom are enumerated in the pace of 257 years. At length, in 1517, Selim, sultan of the Ottomans, having taken and hanged Tomán Bey, their laft chief, put an end to that dynasty. Selim was contented with abolifhing the "monarchy" of the Mamoulks, but suffered their "arifocracy" to retain its former power, on certain conditions; the chief of which were, an annual tribute, obedience in matters of faith to the mufti of Conflantinople, and the infention of the name of the Ottoman emperors in the prayer, and on the coin. At the fame time he projected fuch a form of government that the power, being distributed among the different members of the large, fhoald preferve fuch an equilibrium as should keep them all dependent on himself. See Bey.

The Mamoulks, on obtaining the government of Egypt, adopted meafures which feem to fecure to them the poffeflion of the country. The most efficacious is the precaution they have taken to degrade the military corps of the Arabs and Janizaries. Thfe, and the other Turkifh troops, are only a rabble of artizans and vagabonds, who guard the gates of thofe who pay them, and tremble in the presence of the Mamoulks, as much as the population of Cairo. In reality, the whole military force of Egypt con- fifts in the Mamoulks.

Some hundreds of thfe are dispersed throughout the country, and in the villages, to maintain the authority of their corps, collect the tributes, and improve every opportunity of extortion; but the main body continually remains at Cairo. From the computation of well-informed perfons, it appears, their number cannot exceed 8,000 men, reckon- ing Beys and Cachefs, common freed-men, and Mamoulks who are still slaves. In this number there is a multitude of youth under 20 and 22 years of age.

The moft powerful houfe is that of Ibrahim Bey, who has about 600 Mamoulks. Next to him is Mourad, who has not above 400, but who, by his audacity and prodigality, forms a confuipofite to the infatiable avarice of his rial: the ref of the Beys, to the number of 18 or 20, have each of them from 50 to 200. Besides thfe, there is a great number of Mamoulks who may be called indivifual, who, being fprung from houfe which are ex- tinct, attach themselves elernetimes to one, and sometimes to another, as they find it their interest, and are always ready to enter into the service of the belt bidder. The Mamoulks, therefore, permit the inhabitants of Egypt to be carried only by mules or aifes, referring to themselves the exelusive privilege of riding on horfeback; and of this they make fufficient ufe; for whether they are in town or the country, or if they only make a visit to the next door, they are never seen but on horfeback. Their efus, as well as the support of their dignity, obliges them to this.

Their efsus confifis in a wide shirt of thin cotton, of a yellowish colour, over which they wear a fort of gown of Indian linen, or the light fluffs of Damascus and Aleppo. This robe, called antari, descends from the neck to the ankles, and folds over the fore-part of the body, towards the hip, where it is fattened by two flings. Over this shirt covering is a second, of the fame form and width, the ample folds of which defend likewife to the lower
MAMALUKES.

ends. This is called a cosfian, and is usually made of silk fluff, richer than the former. Both these are fastened at the waist by a long belt, which divides the whole dress into two bundles. Above them is a third, which is called ajouda, which is of cloth without lining, and is made nearly in the same manner, only the sleeves are cut at the elbow. In winter, they are garnished with fur, and is converted into a pelisse. Lastly, over these three wrappers, they put on an outer garment, called the beneficje. This is the cloak or robe of ceremony, and completely covers the whole body, even the ends of the fingers, which it would be deemed highly indecent to suffer to appear before the great. The whole habit, when the beneficje is on, has the appearance of a long fack, from out of which is thrust a bare neck, and a bald head, covered with a turban. The turban of the Mamlouks, called a laouk, is of a cylindrical shape, yellow, and turned up on the outside with a roll of muslin artificially folded. On their feet, they wear a stock of yellow leather, which reaches up to the heels, and flippers without quarters, always liable to be left on the road. But the most singular part of this dress is a sort of pantaloons or trousers, so long as to reach up to the chin, and so wide that each of the legs is large enough to contain the whole body, and made of that kind of Venetian cloth which the French call faîlole, which, although as pliant as the d'Etoffe cloth, is thicker than the burro of Rouen; and that they may walk more at their ease, they fall, with a running fast, all the loose parts of the dress we have been describing.

As to their horse accoutrements, they are far from having adopted any modern improvements. Continually the flaves of custom, the horses faddle among them is a clumsy frame, loaded with wood, leather, and iron, on which a truellequin rides behind, eight inches in height above the hips of the horfeman. A pummel before projects four or five inches, so as to endanger his breast, should he fall. Under the faddle, instead of a tuffed frame, they spread thick woolen coverings, and the whole is fastened by a furengile, which, instead of a buckle, is tied with leather thongs, in very complicated knots, and liable to flip. They use no crupper, but have a large maringale, which throws them on the horse's hinder part. Each flrippur is a plate of copper longer and wider than the foot, of the form of a circumscribed ellipse, three inches high in the middle and gradually declining toward each end; the edges are sharp, and are used instead of spurs, to make long wounds in the horse's sides. The common weight of a pair of these flrippurs is between nine and ten pounds, and frequently exceeds twelve or thirteen. The faddle and faddle clothes do not weigh less than five-and-twenty; thus the horse's furniture weighs above six-and-thirty pounds, which is so much the more ridiculous, as the Egyptian horses are very small.

The bridle is equally ill contrived; it is a kind of halter, but without a joint, and with a curb, which, being only an iron ring, binds the jaw so as to lacerate the skin, so that the bars are injured, and the horse absolutely has no mouth. This neceressarily results from the practice of the Mamlouks, who, instead of managing the mouth, like us, destroy it by violent and sudden checks, which they employ particularly in a manœuvre peculiar to them. This consists in putting the horse on a full gallop, and suddenly plunging him, when at his highest speed. Cleverly thus by the bit, the horse bends in his hind legs, flattens the fore, and slides along like a horse of wood. How much this manoeuvre must injure the legs and mouth may easily be conceived; but the Mamlouks think it graceful, and it is adapted to their mode of fighting. Notwithstanding how ever their short flrippurs, and the perpetual motion of their bodies, it cannot be denied that they are firm and vigorous accoutrements, and that they have a warlike appearance, which pleases the eye even of a stranger; it must also be allowed, they have shown more judgment in the choice of their arms.

The principal weapon, among the Mamlouks, is an English carbine, about thirty inches long, and of so large a bore as to discharge ten or twelve balls at a time, which, even without skill, cannot fail of great execution. They besides carry at their belt two large pistols, which are fastened to some part of their garments by a silk ferring. At the bow of the faddle sometimes hangs a heavy mace, to knock down their enemy, and on the left thigh is suffed, by a shoulder-belt, a crooked fable, of a kind little known in Europe; the length of the blade, in a right line, from the hilt to the point, is not more than twenty-four inches, but measured in the curve is at half thirty. This form, which appears whimsical to us, has not been adopted without motives; experience teaches us, that the effect of a straight blade is limited to the place and moment of its fall, as it acts merely from preasure; a crooked blade, on the contrary, presents its edge in retort, slides by the effort of the arm, and continues its action longer. The Barbarians, who generally apply themselves most to the destructive arts, have not suffered this observation to escape them; and hence the use of cymemors, so general and so ancient in the Eastern world. The Mamlouks commonly procure theirs from Constantinople, and from Europe; but the Beys rival each other in Persian blades, and in fabres of the ancient steel of Damascus, for which they frequently pay as high as forty or fifty pounds sterling. The qualities they esteem in them are lightness, the equality and ring of the temper, the waving of the iron, and, above all, the keenness of the edge, which it must be allowed is exquifite; but these blades have the defect of being as brittle as gyps.

The art of using the arms above described, constitutes the education of the Mamlouks, and the whole occupation of their lives. Every day, early in the morning, the greater part of them resort to a plain, without Cairo, and there, riding full speed, exercise themselves in drawing out their accoutrements from the branches, discharging it with good aim, and then throwing it under their thigh, to seize a pitoil, which they fire and throw over their shoul der; immediately firing a second, and throwing it in the same manner, trusting to the firing by which they are fastened, without losing time to return them to their place. The Beys who are present encourage them; and whoever breaks the earthen vessel which serves by way of butt, receives great commendations and money, as a recom pense. They pradicate also the management of the fabre, and especially the coup de revers which cuts upwards, and is the most difficult to parry. Their blades are so keen, and they handle them so well, that many of them can cut a claw of wet cotton, like a piece of butter. They likewise shoot with bows and arrows, though they no longer use them in battle. But their favourite exercise is throwing the djrid: this word, which properly means a reed, is generally used to signify any fluff thrown by the hand after the manner of the Roman pilum. Instead of fluff, the Mamlouks make use of branches of the palm tree, fresh stripped. These branches, which have the form of the stalk of an artichoke, are four feet long, and weigh five or six pounds. Armed with these, the cavaliers enter the lists, and riding full speed, throw them at each other from a considerable distance. The assailant, as soon
as he has thrown, turns his horse, and his antagonist pursues, and throws his in his turn. The horses, accustomed to this exercise, fecond their masters so well, that they seem to share in the pleasure. But this pleasure is attended with danger; for some can dart this weapon with so much force, as frequently to wound, and sometimes mortally.

As to military skill the Mamlouks know nothing of our military arts; they have neither uniforms, nor order, nor discipline, nor even subordination. Their troops are a mob, their march a riot, their battles duels, and their war a scene of robbery and plunder, which ordinarily begins even in the very city of Cairo; and, at the moment when there is the least reason to expect it. A cabal gathers together, the Beys mount on horseback, the alarm spreads, and their adversaries appear: they charge each other in the street, fabre in hand: a few marthers decide the quarrel, and the weakest or most timid is exiled. The people are mere cyphers in these affairs. Of what importance is it to them that their tyrants cut each other's throats? But it must not be imagined that they stand by indifferent spectators, that would be too dangerous in the midst of bullets and feyemsters; every one makes his escape from the scene of action till tranquility is restored. Sometimes the populace pillage the houses of the exiled, which the conquerors never attempt to defend.

In the field, they advance towards their enemies, mutual defiance pans, the attack begins, and every one chooses his man: they fire, if they can, and presently fall on with the fabre: it is then the manageablewensof the horse and dexterity of the cavalier are displayed. If the former falls, the destruction of the latter is inevitable: In defeats the valets, who are always present, remount their masters; and if there are no witnesses near, frequently knock them on the head to get the sequins they happen to have about them. The battle is often decided by the death of two or three of the combatants.

The interested and inconstant character of this militia is a necessary consequence of its origin and constitution. The young peasant, fold in Mingrelia or Georgia, no sooner arrives in Egypt, than his ideas undergo a total alteration. A new and extraordinary scene opens before him, where every thing conduces to awaken his audacity and ambition; though now a slave, he seems destined to become a master, and already assumes the spirit of his future condition. He calculates how far he is necessary to his patron, and obliges him to purchase his services and his seal; thence he mean- fers his fabrics, and the fabric he receives, or that which he expects; and as in such fables money is the only motive, the chief attention of the master is to satisfy the avidity of his servants, in order to secure their attachment. Hence, that prodigality of the Beys, so ruinous to Egypt, which they pillage; that want of subordination in the Mamlouks, so fatal to the chiefs whom they deftall, and those intrigues, which never cease to agitate the whole nation. No sooner is a slave enfranchised than he aspire to the principal employments; and, who is to oppose his pretensions? In those who command, he discovers no superiority of talents which can impress him with respect; in them he only sees followers like himself, arrived at power by the deceit of fate; and if he please fate to favour him, he will attain it also, nor will he be less able in the art of governing, which consists only in taking money, and giving blows with the fabre.

From this sytem also, has arisen an unbridled luxury, which, indulging the gratification of every imaginary want, has opened an unlimited field to the rapacity of the great. This luxury is so excessive, that there is not a Mamlouk whom maintenance costs less than 2500 livres (or 104l.) annually, and many of them cost double that sum. At every return of the Ramadan, they must have a new suit, French and Venetian cloths, and Damascus and India stuffs. They must often likewise be provided with new horses and harness. They must have pistols and fabrics from Damascus, gilt stirrups, and saddles bridled with silver. The chiefs, to distinguish them from the vulgar, must have trinkets, precious stones, Araban horses of two or three hundred pounds value, shaws of Cashmir worth from five- and-twenty to fifty pounds each, and a variety of pelisses, the cheapest of which costs above twenty pounds. The women have rejected the ancient custom of wearing sequins on the head and breast, as not sufficiently splendid and costly, and in their head have substituted diamonds, emeralds, rubies, and the finest pearls; and to their fondness for shaws and furs, have added a passion for Lyons stuffs and laces. When such luxuries are become the necessaries of those whose authority is without control, and who neither respect the rights of property, nor the life of their inferiors, it is easy to conceive what must be the condition of their subjects who are obliged to furnish them with whatever their caprice may require.

As to the manners of the Mamlouks, though born for the most part in the rites of the Greek church, and circumcised in the moment they are bought, they are considered by the Turks themselves as renegades, void of faith and of religion. Strangers to each other, they are not bound by those natural ties which unite the rest of mankind. Without parents, without children, the past has done nothing for them, and they do nothing for the future. Ignorant and superstitious from education, they become ferocious from the murders they commit, perfidious from frequent cabals, seditions from tumults, and base, deceitful, and corrupted by every species of debauchery. They are, above all, addicted to that abominable wickedness which was at all times the vice of the Greeks and of the Tartars, and is the first lesson they receive from their masters. It is difficult to account for this tafle, when we consider that they all have women, unless we suppose they seek in one sex, that poignancy of refuflal which they do not permit the other. It is however very certain, that there is not a single Mamlouk but is polluted by this depravity; and the contagion has spread among the inhabitants of Cairo, and even the Christians of Syria who reside in that city.
Indian fea; 50 miles N.E. of Borneo. N. lat. 6° 26'. E. long. 118 45'.

MAMBLEY, a town of Hindooistan, in Myforce; 23 miles E.S.E. of Chenna Bahaburun.

MAMBURAO, a town on the W. coast of the island of Mindoro. N. lat. 13° 12'. E. long. 120 45'.

MAMDEBAO, a town of Hindooistan, in Oude; 12 miles S.W. of Ooruckabad.

MAMELLIS, a small island on the N. side of lake Superior. N. lat. 48° 26'. W. long. 88° 41'.

MAMENSA, a town of Hindooistan, in the circuit of Guntoor; 10 miles N.W. of Innacaunda.

MAMERS, a town of France, and principal place of a district, in the department of the Sarthe; 23 miles N.N.E. of Le Mans. The place contains 15,913 inhabitants, on a territory of 2134 1/2 square miles, in 22 communes.

MAMERTINI, in Ancient Geography, a people of Italy, in Campania; they puffed over into Sicily, and established themselves at Messina, where they became so powerful, that they were masters of the place.

MAMERTIUM, a town of Italy, in Brutun, near the source of the Metaurus, and the Brutin forest. The name was formed of Mamers, which was the appellative of the god Mars, in the language of the country. It is probable, that the followers of whom Polybius speaks, who made themselves masters of Messina, and who were denominated Mamer-tini, derived their name from this town.

MAMERVAN, a town of Persia Armenia; 45 miles S.S.W. of Karab.

MAMHOFKA, a town of Poland, in the palatinate of Bancha; 36 miles S.E. of Bancha.

MAMIRA, in the Materia Medica of the Arabians, a root frequently mentioned by Avicenna, Serapion, and other of the Arabian writers. It is feen mentioned as a poisonous drug, and is so described, that it seems to be the same with one species of the durungeni, or dorianicum of the same authors, and the common dorianicum of the shops, distinguished from the antithora, or other sort of durungeni, by the yellowness of the inside of the root. Avicenna says that it is hard and woody, and formed of knots or joints. This is the very description the same author gives of the durungeni of the first or poisonous kind. - Paulus Agineta says its root is composed of several joints afo; and Alphagus calls it a node or jointed root. Some have supposed that the root of the same plant in which we call bisoncel- dine, but this has no title to be placed among the plants suspected as poisonous, nor any other place to be given at as the manira, but only because its root confit of many tubercles. Many things beside have been conjectured to be the manira of the Greeks and Arabians, but the dorianicum seems to be the plant. See DORICUM.

MAMISTA, in Geography, a town of Asia, in Cilicia, which was taken by the emperor Phocas, and probably was the name with "Mamistra," often mentioned by William of Tyre. See MOSSUSTIA.

MAMM, in Anatomy. See BREAST.

MAMMA, Cancer of. See CANCER and SCHIRZ.

MAMMA, Removal of. The operation of amputating a diseased breast is described in the article EXPIATION.

MAMMALIA, in Natural History, the first class of animals in the Linnean system, divided into seven orders, viz. primates, bruts, fore, glives, pecora, bullae, and etc.

The characters of this class, according to the description of Linnaeus, are as follows: the heart has two auricles and two ventricles; the blood is warm and red; the lungs require regularly, alternate; the jaws are horizontally incept on each other, and covered with lips, within which the teeth are, for the most part, included; they procreate by an inconstant penis; and are viviparous and lactiferous: their organs of sense are the tongue, nostrils, eyes, ears, and cutaneous papilla; they are covered with hair, which is thin on the animals of the warmer regions, and very scanty on aquatic animals: their motive organs are four legs and feet; except those which are entirely confined to the water, whose hinder legs are wanting: most have tails.

MAMMALIA, Anatomy of. has had much attention bestowed upon it, under the supposition of its being immediately applicable to the explanation of the functions of the human body. Particular parts of the subject have been successfully prosecuted with this view, both on the continent and in this country; but it is only lately that the anatomical history of the class has been formed into a system, chiefly by the labours of Cuvier and his assistants, who have not only filled up many details that were required, but have added many interesting facts of several quadrupeds, hitherto but little known.

Naturalists have almost universally included human beings in the class of mammalia, in consequence of their poising the peculiar characters which distinguish this class from those of other animals. In this dictionary, however, the arrangement of animals for the purpose of describing their anatomy has been made under a combination of the mental endowments, and the moral and moral properties of man, which we conceive entitle him to a distinct rank in the scale of living beings; but if it were otherwise, it became necessary, according to the plan of this dictionary, to separate man from mammalia, in order that human and comparative anatomy might be treated as distinct subjects.

Organs concerned in the Exercise of the vital Functions.

The Mouth and its contained Parts, or the Organs of Mastication.—The aperture and internal cavity of the mouth have a different form in mammalia from that in the human subject, with the exception of those species of monkey which approach mankind in general conformation. The mouth of mammalia, in general, is capable of being opened widely, in consequence of the division of the lips being extended on each side backwards. This structure is most remarkable in the mastic of prey, and least so in the gnawing quadrupeds. The aperture of the mouth is peculiarly small in the ant-eaters and other insectivorous quadrupeds.

The cavity of the mouth, except in some of the monkey tribe, is considerably longer from before backwards, than in the transverse direction. This is particularly the case in the ruminant and gnawing quadrupeds, and is a shape of the mouth peculiarly well adapted for the minute division of the aliment, as they are more completely subjected to the action of the grinding teeth, and to the motions of the tongue, and the muscular parietes of the mouth.

The figure and magnitude of the cavity of the mouth depend upon the form and mechanism of the two jaws, but especially the lower one, which we shall describe when treating of the organs of motion. The membrane which lines the mouth of mammalia is commonly more largely supplied with mucous glands than it is in the human subject; it is also more plainly covered by cuticle. Many of the graminivorous quadrupeds have a very thick cuticle spread over the inside of the mouth. Several quadrupeds, and especially those which ruminate, have the roof and sides of the mouth covered with flat and pointed processes; these are mostly directed backwards, from which it would seem, that they are designed to facilitate
tate the passage of the food through the mouth. When these processes form soft pointed projections, somewhat like fringe on the inside of the lips, they may constitute a surface for receiving the impression of Rapid bodies.

There are three sorts of teeth found in mammals. The first are employed in the simple division, and the grinding or chewing of the food: the second can only be used for seizing and detaining the prey until it is swallowed; and teeth of the third kind are intended for weapons or instruments of defence.

The first description of teeth admits of being divided into three sorts: first, the incisive or cutting teeth; secondly, the canine or lacerating; and thirdly, the molar or grinding teeth. We shall first describe the form and composition of the teeth, and afterwards speak of their mode of growth.

The incisive teeth are always situated, as a matter of necessity, in the front of the mouth. They are commonly supposed to be formed of two substances: the proper offensory part which constitutes the base of teeth in general, and the enamel. In some quadrupeds, however, we have found the third substance that enters into the composition of teeth, or the annula petrofa, upon the fangs and fides of the incisors of some quadrupeds. The front teeth appear to be originally covered with annulla petrofa in the bove; certainly some of this substance remains in the cavity of the cutting edge, and upon the fides and fangs of the incisors of the bove during life.

The figure of the incisor teeth is more or less that of a wedge. In the monkey tribe, they almost resemble those of the human subject, having rather thin and flat bodies, full-faced upon round flanks. In the llama, the lower incisors have a triangular position; they lie down before. In the flying lemur (galopilobus) the front teeth are divided for some way from the edge into narrow procies, which stand parallel to each other, like the teeth of a comb. Some cats likewise have them denticulated upon the edge. Several carnivorous quadrupeds have the incisors terminating in one or more points.

The saligade mammalia are distinguished by the peculiar structure of their incisive teeth. There are usually two of them in each jaw, placed in the centre of the front of the mouth. They have more commonly a thin sharp edge. In some species of the rat kind and the squirrels, the inferior incisors are pointed and compressed upon the fides. The enamel is not uniform with respect to the teeth, but is deposited only upon the anterior surface; the confluence of which is, that as the substance wears faster than the enamel, the latter always presents a sharp edge. The enamel is sometimes triturated traversefully, or is longitudinally grooved, as in the bove. There are several incisor teeth in the upper jaw of the kangaroo, but only two in the lower jaw: these are directed so much forwards, that they would seem to have but little concern in the division of the food. All the front teeth of the kangaroo are the harder, and more of coëlic texture, that it is splintered porcelain, or a semi-vitrified substance. No animals employ their incisor teeth so constantly or with so much effect as the saligade quadrupeds. Every person is well acquainted with the destructive powers of the rat kind. The bove is able to gnaw trees across. It is upon the mode of using the front teeth that Cuvier has established his order in mammalia of Rodentia, which includes the same animals that we have denominated saligade, from their keaping manner of propagation. The incisive teeth of the rodentia are continually wearing away at the end, more especially those in the lower jaw; and to make up for the waste, they polish a long root, which contains a large vascular pulp that is always adding new officious matter to the tooth. In the bove, and many of the rat genus, the length of the roots of the gnawing teeth is very remarkable. They extend backwards as far as the coronoïd process of the lower jaw, and are contained in a canal which runs beneath the molar teeth in the substance of the maxillary bone. In the upper jaw this canal does not pass farther back than above the first molar tooth. In order to procure the continual wear and growth of the front teeth in the gnawing quadrupeds, it is only necessary to take one of this tribe that makes much use of its incisors, and detain it for some time upon soft food, when it will be found that the lower teeth will grow so long as to turn up and penetrate the fikc.

Among the large quadrupeds with several hods, or the pachydermata of Cuvier, there is consideruble variety in the incisive teeth. They are wanting in the elephant and in the afican rhinoceros. The Atlantic rhinoceros lies in the upper jaw two large wedge-shaped teeth and two small lateral ones, which are called pyriform, and in the lower jaw there are two large cylindrical teeth, and two very small conic teeth between.

Cuvier remarks that, generally, the many-hoofed quadrupeds lose the whole or part of their incisors at a certain period of life, without their being replaced by others.

The hippo want incisors in the upper jaw.

The incisive teeth of the bove have a depression of slight cavity in their cutting surface. The enamel is continued into this cavity, and we have likewise discovered that the crista petrofa passes into it, and gives a covering to the enamel, notwithstanding which the front teeth of the bove gradually wear down until their cavities are obliterated. The degree of waste which the incisors experience serves to determine the age of horfes. The incisors of the bove, marmot, fquirrel, &c. are of a brown colour on their anterior surface. This would seem to be a film of the enamel, and not an incrustation, such as takes place upon the teeth of several of the eumen-footed quadrupeds. The latter are a dark coloured earthly substance, which receives a polisli and a green metallic appearance upon the surface. This imbrication has always appeared to us to be of the nature of the bezoxar stones, found in the alimentary canal of the same quadrupeds.

All the front teeth of the bove are conical and sharpen-pointed, and are therefore more calculated for holding the animal's prey than dividing it.

The debe (tribecus rufus) has two little truncated teeth, similar to molares, in the intermaxillary bone between the tufks, but no front teeth in the lower jaw.

The canine or lacerating teeth in the orang-outang, and some other monkeys, have the same form of the incisors, in which circumstances these animals resemble the human subject. In most of the monkey kind, however, the teeth in the corners of the front of the mouth possess their proper characters, being pointed, conic, and fo long as to pass each other in a greater or less degree when the jaws are shut. In some baboons the canine teeth are remarkably long.

The lemur has them hooked and compressed upon the fides. They are long and conic in the levi. The flying lemur (galeopilobus) has them short, broad, and notched like a faw.

In some of the plantigrade mammalia, as the hedge-hogs and ferrets, they do not rise much above the neighbouring teeth, and are bicuspids.

Blumenbach describes small canine teeth in the boar genus, which are situated immediately behind the principal canini.

Blumenbach describes small canine teeth in the boar genus, which are situated immediately behind the principal canini. He noticed this remarkable structure to exist in the brown bear of the Alps, the black bear, the polar bear, and in the P1 2 Wapiti.
Mammalia.

Skeleton of one whose country is unknown, preserved in the National Museum at Paris.

It is in the digitigrade quadrupeds that the form of the canine teeth is most perfect: in these they always are long, pointed, sharp, curved backwards, and generally those of one jaw pass the corresponding ones of the other jaw considerably, when the mouth is closed. The molars of this species are set at the edges, post-cuts, and bodgers.

Naturalists have considered the tusks of the multungulate, and of the moles, dugong, and narwhal as canine teeth, which from their situation they are entitled to be considered, but as they can only be employed as weapons, we shall refer their description to a subsequent part of this article.

The canine teeth exist only amongst such of the eleven-footed quadrupeds as want the true horns. In the flag, camel, dromedary, and lama, they do not grow to any length, and appear to be in a great measure useless to these animals. The same structure obtains in the horse. The tusks, as they are popularly called, in this animal are short, and soon become blunt. They are peculiar to the male, who it is said in a wild state employs them as weapons, but this does not seem to be practicable.

The interior composition of the canine teeth agrees with that of the incisors. They are made in all the carnivorous quadrupeds of the common substance of the teeth, and covered with enamel; but we have discovered crusta petrofa upon the tusks of the horse, and we conceive it probable that it exists upon the canin of the other graminivorous beings.

The grinding or molar teeth are always situated in the back part of the mouth, in order to gain the advantage of the lateral motion of the jaws, the supply of saliva, and the assistance of the tongue and cheeks in moving the food while it is undergoing trituraction.

The figure and composition of the molars vary according to the nature of the food, and the habits of the animal to which they belong.

In the genus Simia the grinding teeth are very similar to those of the human subject: in some species of monkey, however, the last molar is larger than the rest, and furnished with a fifth tubercle; others have the last molar the smallest.

In the genus Lemur the molars begin to be pointed.

In the truly carnivorous quadrupeds they are (with the exception of the molar posterior teeth) thin or conical, and end in either one or more sharp points. They are so placed in the two jaws likewise, that they are not exactly opposed to each other when the jaws are brought together, but pass each other in a degree, so as to divide rather than bruise and comminute the food.

The cat genus has only one molar tooth with a flat crown and blunt processes, which is situated in the upper jaw, and does not correspond with any teeth of the inferior jaw. It is often lost without any inconvenience.

The swine and martins have a single tuberculated molar tooth at the back of both jaws. Those of the upper jaw are broad.

The hyena has one large molar, with blunt tubercles on each side the upper jaw, and a corresponding one with a pointed process in the lower jaw.

In the genus Canis there are two tuberculated molars on each side, above and below.

In the other digitigrade quadrupeds there is some little variety in the number and shape of the posterior tuberculated molars, which scarcely deserves notice.

In all these animals the molar teeth have the same composition as the canine and incisors, i.e., the form of the tooth depends upon the common osseous substance, which is covered on that part seen above the gums by enamel. The molars of the carnivorous quadrupeds, from the manner in which they are used, do not wear.

The small plantigrade, such as the hedgehog, the mole, and the ferrets, and amongst the pedimana, the opusmum tribe and the peramites, resemble each other with respect to the sharp tubercles upon several of their molar teeth. Cuvier has observed, that this form of the posterior molars belongs to the insectivorous quadrupeds, and that another general character of these animals is to have their superior teeth broader transversely than those below.

Amongst the foligrade quadrupeds those that live upon a mixed food, as the marmots and the rat genus, have the molar teeth with tubercles, covered with enamel which does not wear. The other animals of this order have the crowns of the molars flat upon the top. The osseous substance of the teeth is not clothed but intermixed with layers of enamel, which produce a flat or grooved appearance on the surface as it wears. Some of the foligrada have their molars entirely composed of transverse and vertical layers; others have the enamel only forming upon the crown some angles, circles, or other figures, without dividing the teeth into separate parts.

The cow has in the upper jaw the first molar composed of one plate, the second of two, the third of three, the fourth of four, and the fifth of six. In the lower jaw each of the three first is made of two laminae, and the last of eleven laminae. Many of these laminae, especially anteriorly, are bifurcated. The grinding surface of these teeth is quite plain, and ascends obliquely from within outwards.

The guinea-fowl the molars are composed of each of two bifurcated laminae. The molars of the hare and rabbit are likewise made of two laminae, but they are not bifurcated. The phalangeous has molars resembling those of the cow.

In the beaver there is to each molar an angle returning to the external side from below, and to the internal from above, and three others more deep on the opposite side. When the teeth are worn by use, the last form only elongated and transverse ellipses upon the crown.

The jerboa of the Cape has but one angle returning to the internal side below, to the external above.

The molars in the kangaroo are furnished with tubercles, and those situated posteriorly have their tubercles united by transverse eminences.

The molar teeth of the dormouse have their crowns flat upon the grinding surface, which is regularly flattened or grooved. The teeth appear, however, to receive only a superficial covering of fine pearl-coloured enamel.

In the field the molars are, like all the other teeth, conical. The posterior ones, however, present some points. They cannot be used in any other manner than as incisive or lacerating teeth.

The maz and dugong have the molars cylindrical in their shape, and with a flat grinding surface. The latter animal has them also grooved upon the side.

The lama has two rectilinear transverse eminences, except on the last molar teeth, which has three. They are notched before they are worn.

The teeth of the otter, as before observed, are not calculated to perform any of the masticating processes; they can only be used to seize and detain the prey of these animals.

The most perfect examples of the true grinding teeth are found amongst the large herbivorous quadrupeds, particularly the multungulae. The teeth, necessarily, are continually wearing in those quadrupeds that are furnished, exclusively, upon vegetable matters. They are, therefore, most commonly
commonly found to be intermixed with the enamel, and to be either covered externally or filled up with the crufa petrofa.

If a section be made of the grinding tooth of the *sloep*, the appearance of two crescents will be seen with an oblong dark-coloured hole in the centre. The crescents are formed by the defending projections of enamel, covered on the inside by a layer of the crufa petrofa.

In the *cows*, and in the "cloven-footed" beasts generally, the enamel and crufa petrofa are deposited in the interior of the teeth, so as to produce upon the grinding surface, or on a transverse section, the appearance of crescents, leaving a space in the centre, which is usually full of the masticated food of the animal. Mr. Home has furnished us with observations which shew that the enamel is deposited in the cavities of the grinding teeth of graminivorous quadrupeds, supplants the place of crufa petrofa, and contributes to form the masticating surface. We have never observed it to be so hard as to answer this purpose, and the cavity which contains it is always, we believe, covered by a layer of the crufa petrofa.

In the graminivorous quadrupeds there is generally (and perhaps always, though not observed) more or less of the crufa petrofa deposited around the bodies of the molars as well as in the interior. When the teeth are a very little worn, the prominent parts appear uncovered, and the enamel, and the crufa seems only to have filled up the inequalities upon the surface. In the *sloep* there is no crufa apparent upon the outside of the tooth after it has been used; but it is not improbable, from analogy of structure, that when the grinders of the *sloep* first come out of the gums, that they have a thin covering of crufa petrofa.

The grinding surface of the molars of the *bore* presents an undulating or zig-zag line, formed by the obsoletance of the tooth and enamel encompassed in the crufa petrofa. The holes in the *bore*’s teeth are much smaller than those of ruminating quadrupeds. Mr. Home has furnished us with observations which shew that the original enamel of the molars of the *bore* became effused in the cavity of the teeth occupied by the processes of the capsule which secreted the crufa petrofa.

In the *rhinoceros* and *daman* (*byraxis*), the inferior molars are formed of two crescents placed in a row, and a little obliquely. The tooth farthest back in the mouth has three crescents, the anterior molar only one. The molars of the upper jaw are square, have a prominent line parallel to the external sides, and two others which pass transversely and a little obliquely. The second of these transversely lines in the *rhinoceros* sends forwards a large hooked process. In the *daman* they have each a small one. The posterior molar of the upper jaw has somewhat of a triangular shape. The anterior tooth has but one transverse line.

In the *hippopotamus*, the molars in the middle part of both jaws have two pairs of cones, let, as it were, back to back. There are two grooves on the opposite sides to those that are applied to each other; each cone, when worn down, presents on the top the figure of a trefoil. Both Dr. Blake and Mr. Home represent that the crufa petrofa does not enter into the composition of the teeth in the *hippopotamus* and the *rhinoceros*. It has, however, been fincerely discovered, by Mr. Macartney, upon the whole of the external surface of the grinding teeth of the *hippopotamus*. It is a thin layer, which is seen worn away from the prominent parts, thus exposing the enamel, and occasioning the mottling respecting its exfoliation. It is highly probable that a similar layer of the crufa petrofa is spread over the molars of the *rhinoceros* when they are first formed.

The molars of the *elephant* are the plainest examples of the construction of graminivorous teeth. In the Afantic species, each grinder consists of a number of thin processes of the obsoletance of the substance, covered with enamel, united and enclosed by a mass of the crufa petrofa. These processes or plates are situated transversely with respect to the tooth; and when a vertical section is made of the latter, they have exactly the form of the teeth of a comb, imbedded in a third substance, which is the crufa petrofa. The grinding surface, after it has been used, presents a number of transverse narrow rough ridges, which are continuous at the edges of the tooth, so as to exhibit the appearance that would arise from the two sides of an oval being compressed together. They correspond to the obsoletes that are covered with the enamel. The interspaces between them are filled up with the crufa petrofa, which wears softer than either of the other two substances composing the teeth.

In the *African elephant* the processes of the obsoletance and the enamel are diffused in the crufa petrofa in such a manner, as to give the appearance of rough lines or ridges which form lozenges upon the grinding surface that touch each other in the middle of the tooth.

In the *sus ethiopicus* the molars are formed of several cylindrical processes of obsoletaneous substance and enamel consolidated together by the crufa petrofa: their grinding surface exhibits oval or angular figures in rows of three each.

The *mammoth*, or the animal whose fossil remains have been found on the banks of the Ohio, has long been known to possess molar teeth that have the same structure as those of carnivorous animals, notwithstanding that in the general its skeleton resembles the elephant's so much, that most people now believe it to have been the elephant of the American continent. The teeth of this animal are very large; the crown is entirely covered with a thick coat of enamel, and there is no crufa petrofa intermixed with it. The grinding surface is not flat, nor worn down, but presents two rows of short cones. The only appearance there is of friction prefers itself upon the sides of these cones, or pyramidal eminences, and seems to be occasioned by the teeth of the two jaws fitting into each other, notwithstanding the molar teeth of the *mammoth* appear to be so well adapted for masticating animal food. If we may judge from the skeleton exhibited in this country, it is utterly impossible the *mammoth* could have been a beast of prey. It must have been disqualified from hunting by the structure of its limbs, the form of the head and neck, and the unwieldy figure of its whole body. It has been conjectured by some, and not improbably, that the *mammoth* subsisted upon the fith of the large rivers, on the banks of which its bones have been occasionally found.

The *duck-billed animal* of New Holland (*ornithorynchus paradoxicus*) has parts in the back of its mouth which correspond to the molars of other mammalia, but which have a different composition. They are not bone, but a horny substance: they are oblong, flat, and are merely fixed in the gums. There is one on each side in both jaws. Mr. Home has described, how these two horny processes in this animal on the back of the tongue, which he supposes to be designed to prevent the food being swallowed before it is sufficiently masticated.

The molar teeth of the *Cape ant-eater* (*Dryopotes Geoffri*.) are extremely singular. They have the form of two cylinders joined to each other in the sides. They are entirely composed of a great number of minute, flat, and parallel tubes. If a transverse section be made of these teeth, it presents exactly the same appearance that is seen on cutting across a ratah, or other monocotyledon; that is, a number of very small pores. This tubular structure pervades the whole tooth, except at the grinding surface, which is solid.
Mammalia.

Cuvier flates, that there is no large cavity in the teeth of the Ornithorhynchus.

The Ornithorhynchus hypsirhoe has six transverse rows of pointed processles at the back of the palate, and about twenty similar ones on the base of the tongue; these have all a horny structure as the teeth of the O. paradoxus.

The grampus (Delphinus ora) has been reported to have teeth in the palate. Cuvier supposes they may be horny processes, similar to those of the O. hypsirhoe above-mentioned. But we have lately detected this species of Delphinus, and have found that nothing of the kind existed in the animal.

The organization and mode of growth of teeth, in general, have been much illustrated by observing their formation in the larger quadrupeds. The vascular tender substance which secretes the rudiment or nucleus of the tooth, and on which the tooth continues to grow, is popularly called the nerve in the human teeth, from the superposition of its being a prolongation of the dental branches of the maxillary nerves. In large teeth the pulp is easily seen to be formed of a peculiar fpongy substance, which in the young animal is nearly as soft as jelly; its blood-vessels are extremely numerous and minute; its nerves are probably the same, for there is no large branch of the dental nerve contained in the pulp. The structure of the pulp of the teeth seems to resemble in a great degree that of the pulps of feathers and hairs, and of other excrementitious productions. See the articles Feathers, Hairs, Horns, &c.

In those animals which have the enamel passing down into the substance of the teeth, there are several processles of the pulp which produce a corresponding number of hollow shells or moulds, which have been called denticles in speaking of the compound teeth of quadrupeds.

The osseous part of the teeth is more compact and hard, particularly in the molars of the large herbivorous quadrupeds, than it is in the teeth of the human subject. There is also a sensible difference between the composition of the external and internal parts of the osseous moulds of the teeth in quadrupeds. The first deposits of the pulp are very hard, it seems longitudinally of a yellow-greenish hue, and semi-transparent, like topaz. The parts deposited by the pulp afterwards are more opaque, of the common colour of bone, and showing but little appearance of lamine. They approach very nearly in structure the fangs, which are laid for, mostly resemble common bone. The gradual variation in the hardness of the osseous part of the teeth may be discerned, though less plainly, in the human subject. The flecked appearance above-mentioned, shows evidently that the osseous moulds of the teeth are secreted by the pulp in layers. The growth of this part of the tooth by layers has been likewise proved by Mr. Hunter's experiment of feeding a young pig with madder, when the teeth were forming. The osseous layers that were deposited during the use of the madder, were flained of the pink colour which this dye-fluff produces with phosphat of lime, and the portions of the tooth formed either before or after the madder had been employed, retained their natural colour. Cuvier describes the formation of the osseous moulds of the teeth as being effected by fucceibive layers, as in the shells of the bivalve mollusca, which fact, he says, he had an opportunity of observing very satisfactorily in the gums of the teeth in the young elephant.

In carnivorous quadrupeds, as in man, the roots or fangs of the teeth are formed about the time that the crowns make their way through the gums, but in those graminivorous quadrupeds whose teeth are subjected to much wear, the roots are added some time after the eruption of the teeth from the gums, by which means their proper length is preserved a longer time for mastication.

The structure of the enamel is very plainly seen in the teeth of the large quadrupeds. The eccentric arrangement of its fibres is particularly striking, when a section is made of any of the large grinding teeth, in which the enamel passes beyond the surface. The fibre are in these infiuences intermixed at their extremities with the cutaneous fibers, and produce an appearance not unlike the bars of a feather. Cuvier, in speaking of the enamel, compares it in the tooth of the young elephant to the fibres of aesthles, or to the pile of velvet. He observes, also, that these fibres are not always rectilinear, more frequently describing curves, of which the convexity is turned towards the crown of the tooth. The same arrangement of the fibres of the enamel, he says, exists in the ruminant quadrupeds. It has, however, escaped our attention.

It is well known that the enamel is a production of the capsules of the teeth, but it seems yet undecided whether he be a secrection immediately performed by the capsule, or a crystallization of the fluid contained in it. Mr. Home adopts the latter opinion, and supposes that the fluid in the capsules of the teeth is similar to fynovia, which yields, upon chemical examination, a certain portion of phosphat of lime.

It appears to us that the quantity of earthly matter found in fynovia, supposing it to be the same in the fluid of the capsules of the teeth, is quite insufficient to account for the production of the enamel. There are only 21 parts of residue out of 970 parts of fynovia, and but a small part of this residue is found to be phosphat of lime; besides, it should be observed, that the fibrous arrangement of the enamel is unlike what would probably be produced by a process of crystallization; the distribution of the enamel as to quantity also would be different from what it is upon the surface of the tooth: thus in some teeth there is little or no enamel upon the posterior surface, in the incisors of the gnawing quadrupeds and the tusks of the hippopotamus.

Writers have disagreed with respect to the chemical composition of the enamel. Some have denied that it contains any animal matter; most, however, allow, that it possesses a very little, upon which, most probably, its fibrous structure depends. Morrichini, a chemist at Rome, found fihoric acid in the enamel of the fofill teeth of the elephant, and afterwards in fels quantity in the enamel of the human tooth, the different proportions he ascribed to the fofill teeth containing fels animal matter. His experiments upon the human teeth go to shew that the enamel consists of 93 parts of animal substance, 22 parts of fluid and phosphat of lime, with some magnesia, alumine, and carbonic acid. Mr. Hatchett and Mr. Brade both failed to detect any fritel of lime in the enamel of teeth.

In the compound teeth of the graminivorous quadrupeds, where the enamel is extended from the surface between the denticles, there are corresponding processles of the capsule which pass from the side of the gans. These have, in our opinion, been very improperly called ligaments by Mr. Home. They neither resemble ligaments in their functions or structure; they are much more like the pulps.

The third substance entering into the composition of the teeth is peculiar to certain mammiferous animals, and is not found in the human subject: the history of it, therefore, is only to be obtained from the late writers upon the subject. It was first called crufa petrofa by Mr. Blake, a very appropriate name, as it appears like a ftony or inorganic incrustation on the other substances of the teeth. Mr. Home, from considering that it more nearly approaches the nature of common bone than the other parts of the teeth, has termed...
MAMMALIA.

termed it the effused or bony portion. The French writers have called it the cement; on account of its consolidating into one the different denticuli of the grinding teeth in gram-
nimal quadrupeds.

This fixture has a pale yellow colour, is uniform in its texture, exhibiting neither fibres nor layers; it is more solid, dense, and heavy, but less hard, friable, or elastic, than the other parts of the tooth; it resembles more the calcious or the effused matter, poured out in consequence of inflammation, than any other fixture in the animal body. It always is found deposited in the interstices or depressions of the tooth, and it is only after these are filled, that it appears to give a covering to the more prominent parts. The superficials of the crista petrosa is never regular or smooth, until it is worn by mastication; and on many parts of the teeth, particularly about the roots, it presents the appearance of concealed drops of a matter which had been in a fused state. In the early, however, it contains a multitude of regularly arranged pores.

Tenon supposes that the crista petrosa is produced by the ossification of the membrane which had enveloped the teeth. Mr. Blake ascribes its formation to the surface of the membrane opposite to that which secretes the enamel. Cuvier, however, gives a more rational account of the matter: he says, that the internal membrane of the capsule, after it has deposited the enamel, undergoes a change of structure, becoming thick, spongy, opaque, and more vascular, in order to furnish the crista petrosa; that this is shed, as it were, in drops, which form irregularly upon the surfaces of the teeth. When the internal membrane of the capsule is prolonged into processes that pass into the interstices of the compound teeth of the large quadrupeds, they become changed in like manner, after depositing the enamel in these situations, and then secrete the crista, which serves to unite the denticuli into one tooth. This circumstance he had an advantageous opportunity of observing, during the development of the teeth in the elephant.

The crista petrosa wears faster than either the effused mould or enamel of the teeth, and thence its use in the herbivorous animals; the two first always presenting upon the grinding surface of the teeth certain eminences, which vary in their figure in different species, as already described, and which operate in the division of the food in the same manner as the irregular eminences on millstones.

The succession of the teeth is regulated in mammalia in general as in the human subject. The front teeth are replaced by larger ones, at an early age; and after these and the grinders all come forth, they remain during the life of the animal. In those quadrupeds which employ their teeth in a way that subjects them to much wear, particular provisions become necessary. We have already mentioned, that the growing teeth of the phylake mammalia continue to grow in the same proportion as they wear; and the consumption of the grinding teeth, in some of the large herbivorous quadrupeds, is supplied by a succession not only of fresh teeth, but by the manner in which these come forth from the jaw.

The elephant affords the most striking example of this mode of succession. Although this animal has the rudiments of several teeth formed in its jaws, we never find more than two on each side of both jaws at once, i.e. eight grinders in the whole; often there is only one apparent in each side of both jaws. The molars of the elephant, as before observed, are compound, or consilt of several laminae or denticuli, united together by crista petrosa. The first, or milk grinder, as it is called, pushes through the gum eight or ten days after birth, and is not completely exposed until the third month; it consists of four laminae or denticuli. The second grinders, which consist each of eight or nine denticuli, are uncovered in two years. In proportion as the new teeth appear, the preceding ones gradually wear down, and finally have their fangs, and the sockets which contain them, removed by absorption. The whole of a tooth is never seen in the mouth at any one time; indeed it does not exist; for the posterior portion of the tooth is not completely formed, and does not penetrate the gum, until the anterior portion is entirely worn down. Thus a grinder, comprising of twelve or fourteen denticuli, will have the anterior part worn, and even absorbed, a few denticuli of the middle partially worn and in use, and the posterior denticuli imbedded in the jaw, and their fangs in a state of growth, all at the same moment. This mode of growth and presentation of the teeth in the elephant is admirably calculated for maintaining the grinding surface.

In proportion to the elephant's age, the new grinders are formed, larger and of a greater number of denticuli, by which they remain longer in use. Thus the third set have each twelve or thirteen denticuli. They begin to appear when the second set have been all exposed, and displace these at six years of the animal's age. The fourth set of grinders are made of fifteen denticuli, and present the different parts of their grinding surface from the sixth to the ninth year of age. From the fourth set to the eighth the number of denticuli varies from fifteen to twenty-three, which is the greatest number that has yet been discovered in the grinding teeth of the elephant. The periods at which the last sets of teeth penetrate the gums have not been clearly ascertained; but it is supposed by Mr. Corse, who has paid much attention to this subject, that each set requires one year longer for its development than the set preceding it.

Mr. Home has discovered that the teeth of the Jat sphin-
picus, which are composed of several denticuli, have a mode of succession similar to what has been described in the elephant. He concludes from hence, that this animal has greater longevity than the others of the same genus.

Something of the same kind exists in the wild boar, and in the animal incognito, according to Mr. Home's observations.

The periods at which the molares of the horse come forth, and are shed, have been lately ascertained by Mr. Tenon; by which it appears that the anterior molares are shed, and the posterior are late in appearing; that last molar cuts the gum only at the fifth or sixth year. The milk grinders of the horse are oblong at first from before backwards; but, by the pressure of those behind, become square; the teeth which replace them are also square.

The mode of succession is nearly the same in the teeth of the ruminating quadrupeds.

It is only upon animals which live in a domestic state, that accurate observations can be made with respect to the succession of the teeth. This partly accounts for the very few number of facts known upon the subject. Blake states, that the grinders of the beaver present themselves in a manner somewhat similar to what has been described in the elephant.

The second kind of teeth, or those for seizing and de-
taining the prey of the animal, are found in the cetaceous tribe of mammalia.

In the genus delphinus, the teeth are numerous in both jaws. They are nearly conical in their form; those of the porpoise, however, have the bodies of the teeth flattened, and the roots cylindrical. In the grampus, the natural shape is very much altered by wearing. In this genus, the teeth are lodged in regular bony alveoli; and we have ascertained that a fur-
Mammalia.

A succession is kept up, by new teeth forming in the bottom of the sockets, which push out the old ones as they are worn down.

The teeth of the genus delphinus are composed of two substances: the usual opaque part, which constitutes the mould or basis of all teeth; and a cortical substance of an intercalated texture between enamel and crulfa petrofa. In the porpoise this external part is hard and polished, and does not readily wear; but in the grampus we have found it to be feebly, if at all, different from the common crulfa petrofa, and to wear like it softer than the opaque substance of the teeth. In fact, there is a gradation to be observed in the cortical part of the teeth of different animals, from the pure crystalline enamel to the opaque and comparatively soft incrustation found in the true graminivorous teeth. This variation might be expected, when we consider that both these substances are secretions of the internal membrane of the capsule of the teeth.

In the sphenaceti whale (plasyor), the teeth are situated in the lower jaw, and received into corresponding sockets of the upper jaw. They are conical, according to Hunter, at both extremities, and are not placed in alveoli, but grow in the gums. In a specimen we possess, the root of the tooth is nearly as large as any other part; the crown is worn into the shape of a compressed pyramid, and the cortical part resembles almost exactly crulfa petrofa in its texture, and not enamel: it is extended entirely over the root of the tooth.

Hunter states that the small bottle-nose whale has a number of conical teeth in both jaws, viz. forty-fix in the upper jaw, and fifty in the lower. He supposed that the teeth of the whale tribe were renewed by the jaws growing forwards, and being abscorbed at the symphysis, while new teeth made their appearance in the posterior part of the jaws.

The narwhal (monodon) has only the two remarkable tusks, which we shall speak of under the head of the weapons of mammalia.

The hippodon, formerly placed in the genus delphinus, but lately separated by Lacèpede, is said to have teeth in the palate, similar to those of the ornithorhynchos, and also in the jaws.

But the most singular apparatus for retaining the prey in the mouth is the sublal bone of the true whales. This substance resembles, in its organization and mode of growth, hair, horn, &c. (see those words in this dictionary.) The whale-bone is situated only in the palate and upper jaw: it forms a great number of lambs, even so many, according to Hunter, as 300 on each side of the mouth. These are of various sizes and lengths. Towards the interior of the mouth they are very short, about fix inches; and become gradually wider and longer, as they approach the posterior and outer part of the palate and jaws: the most external lamina in the large sublal bone whale are flated by Hunter as measuring 12 or 15 feet long, and 15 inches broad. According to Cuvier, they measure 10 feet long. All the plates are placed transversely, with respect to the line of the body, and growing downwards, their unequal lengths give the palate and upper jaw the figure of a vault, or the interior of the roof of a house.

The plates of sublal bone are always found to terminate in a number of long fibres or hairs. This has hitherto been considered the effect of a mechanical division of the end of the plate from the sublal bone, but these fibres are, at least when fully formed, round and smooth, and of a thickness in some degree proportioned to the size of the lamina to which they belong, which makes it probable that the interior part of the plates confuits of round fibres agglutinated into one

mafs, somewhat in the manner of the horn of the rhinoceros. The superficies of the plates of whale-bone is smooth, and appears to have a lamellated form.

The lamina of whale-bone are hollow at their root, and are penetrated for some way by pulps, in the same manner as hairs. The interior parts of the whale-bone are secreted by the pulps, and the external layer by the same vascular substance extended upon the jaws. This likewise secretes a whitish horny substance, which surrounds and fills the interspaces of the basis of the plates.

Both the plates and the intermediate substance are worn by use, and renewed by a continual growth. The external part of the plates very soon, (or rather, we believe, immediately upon their protrusion) breaks off in scales, and exposes the fibrous or hairy appearance at the extremity of the plates. As the hair grows, more of the external part of the plate gives way, so that the end of the plate that is turned towards the mouth always terminates in loose fibres.

The white intermediate substance, when it grows as high as the edge of the skin of the jaw, becomes soft, and decays away like old cuticle.

The third description of teeth, or those exclusively intended for tusks, usually occupy the situation of the canine or lacerating teeth. They are peculiar to some of the large quadrupeds with several horns, or the muntungula, to two of the genus trichius, and to the narwhal. Naturalists have often described the form of these defenses, that it is unnecessary to repeat the account of it here.

The interior substance of the tusks has been distinguished by the name of ivory: its composition is somewhat different from the bony part of teeth in general. In the elephant the ivory is less hard than in other animals; it likewise becomes founser yellow on exposure to the air: it is marked by many curved lines, which run from the centre to the circumference of the tusk. The cortical part in the elephant is smooth and harder than the rest of the tusk. Cuvier believes it possesses a thin layer of enamel; but in our opinion, the superficies of the tusk is crulfa petrofa.

In the hippopotamus the substance of the tusks is hard, and regularly lacerated. There is a moderately thick layer of fine crystalline enamel on the fore part of the tusks.

The ivory in the tusks of the sus ethiopica, Cuvier states to be nearly similar to the preceding. In the common boar there are no flaire to be observed, but sometimes layers of a brown substance.

The mafly tusks of the mops are very dense in their structure, and want the lacerated appearance. The middle part of the tusk is formed of little round grains, not arranged in any order, but like the bone called pudding-stone. The ivory of the dugong has a uniform composition.

The singular teeth, or horns, as they are sometimes called, of the narwhal, have appeared to us to consist of an offiacous substance throughout, which is similar to the crulfa petrofa of the teeth in quadrupeds. The superficies is polished, as it would seem, by friction. The spirally grooved appearance of these teeth it is very difficult to explain, either with respect to its production or its use.

All the tusks of mammalia appear to continue to grow during the animal's life. The cavity in the root remains of a considerable size, and is always filled by a vascular pulp. The protruded growth of this sort of teeth has produced some effects that have been made use of as arguments for the existence of vaclularity and organic actions in the earthly superficies of the teeth. Thus, several instances have been discovered of balls, spear-heads, &c. being lodged in the tusks of elephas, and being surrounded by officious matter, evidently deposited in consequence of inflammation. In all
the caries of this kind which have come under our observation, the offensive deposit appeared to have been made from the interior of the tooth, and no doubt was the confluence of an injury to the pulp; indeed we cannot conceive that it could possibly be effected in any other manner. To supose that the offensive substance of teeth is capable of being inflamed by a mechanical injury, is absolutely inconsistent with the very purposes for which teeth are designed, not to say that it is contrary to some particular facts and experiments. Teeth actually exhibit no morbid actions, either in consequence of injury, constitutional diseases of the bones, or the gradual decline of the vital powers. They wear, like any inorganic substance, by friction, and what is called their caries is a change in the interior arrangement of their particles, commencing on the surface, and proceeding in a manner perfectly similar to the decay of artificial teeth, when placed under similar circumstances. The pain of tooth-ache depends upon an affection of the pulp, a part extremely susceptible of disease, either in consequence of external influence, or of constitutional derangement. The irregular and exuberant deposits of offensive matter are made by the same parts which produce the natural tooth. Thus, the internal membrane of the oyster, when wounded, is excited to a more copious and irregular secretion, and those excrescences called pearls are formed. For a more detailed discussion of the question of the valance of the teeth, we shall refer the reader to the article Teeth Plate I. of the Anatomy of Mammalia, is explanatory of the structure and growth of the teeth. Fig. 1. shews a grinder of the sheep; a is the crown of the tooth polished, in order to expose more distinctly the creafcentic form of the enamel which penetrates the body of the grinder, and the dark coloured cavity left in the centre. Fig. 2. exhibits the grinding surface of the molar tooth of the horse, polished: a indicates the zig-zag line, formed by the enamel in the interior of the tooth; b is the cruenta petrofa; c, the hole. Fig. 3. shews the grinding surface of the molar teeth of the African elephant, in a certain degree worn down; a, a, a, point out the toozege figures of the denticuli, the fides of which are clothed with enamel; b b b refer to the cruenta petrofa, a cement which is interposed amongst these denticuli. Fig. 4. is the molar tooth of the cape ant-eater (orycteropus) divided longitudinally, and worn upon the crown; a, the lateral view of the tubular structure of the tooth; b, the appearance of pores upon the end of the tooth. Figs. 5 and 6 represent the horny shells, which exit in place of offensive teeth in the ornithorhynchus paradoxus. Fig. 5. shews the external surface, and Fig. 6. the surface by which the tooth is connected with the gums. Fig. 7. is the capsule of a grinding tooth in the calf, laid open on one side; a, a, the parietes of the capsule; b, b, the procuces of the pulp, seen passing upwards, the shell of the tooth having been removed; c, c, the procuces from the capsule which secrete the enamel and cruenta petrofa, passing downwards. Fig. 8. exhibits the lower jaw of the rat, divided in a vertical direction, in order to bring into view the course and manner of growth of the gnawing tooth; a is the jaw-bone; b, the gnawing tooth, also divided, to expose the cavity into which the pulp passes, and remains always of a considerable size, for the purpose of affording a continual supply of offensive matter. The root of this tooth is seen to be lodged in a canal, extending below the molares to the back of the jaw. Fig. 9. is a large grinder of the Asiatie elephant divided vertically; a a a indicate the offensive part of some of the denticuli; b b b the enamel with which they are covered; c c the cruenta petrofa, filling the intercalaries between the denticuli; d points to the fore-part of the tooth, which is worn down; e, the fangs of the anterior denticuli, nearly absorbed; f, f, the middle and back parts of the crown of the tooth, with the cruenta petrofa entirely enveloping the ends of the denticuli; g, the fangs of the posterior denticuli, not fully formed, that portion of the teeth not yet having been brought into use. Fig. 10. exhibits a lateral view of one of the plates of whale-bone in the Balena rorqualis: a is the part of the plate which projects beyond the gum; b, the portion sunk in the gum; c, the white substance that surrounds the whale-bone and forms a projecting head, and also passes between the plates to produce their internal lamelle; d is the part analogous to the gum; e, a fleshy substance, covering the jaw-bone, on which the inner lamelle of the plate are formed; f, the fibres in which the lamelle terminate.

The tongue of mammalia, as far as it is concerned in the acts of mastication and deglutition, does not differ materially from the same organ in the human subject, except in the ant-eaters and the cetacea. The former have the tongue very long, projectile, and furnished with some singular muscles for its protrusion and retraction: the latter have the tongue short, flat, and very limited in its motions even in the mouth, in which circumstance the cetacea resemble fishes, as might be expected from their having similar modes of feeding.

Cuvier has thus described the mechanism of the tongue in the porcupine anti-eater (echidna). The organ in this animal becomes suddenly slender and elongated, the place where it arises from the palate, and appears to be composed afterwards of two very small and long muscular cones, lying in contact with each other; their point is that of the tongue itself. Each of these cones consists of two muscles; the one external, composed of a great number of little distinct fasciculi, which encompass in so many circles or rings the internal musculc.

The internal longitudinal muscle is composed of distinct fasciculi rolled spirally upon themselves. The most superficial of these fasciculi terminate at the first rings of the muscular annulus. Those deeper stated end upon the next rings, and so on with respect to the other fasciculi, until they are all expended. The most internal finish at the tip of the tongue. The annular muscles serve to protrude the tongue by diminishing its thickness; the longitudinal muscles withdraw it into the mouth, and are likewise capable of turning it in every direction.

In the echidna, the genio-glosso muscles form the greatest part of the base of the tongue, but do not enter into the composition of the elongated part, that proceeds from the palate. There is a kind of mylo-glossus which has the same attachments as the mylo-hyoides. There is no flylo-glossus in the echidna.

The common anti-eaters have a tongue constructed nearly like the preceding animal. There are a longitudinal and annular muscle, which constitute, as in the echidna, the elongated part of the tongue. The longitudinal muscles arise from the eniform cartilage of the ronxum, which is broad and flat, to give them attachment. They pass on the inner side of the ronxum, through the breast, and upon the sides of the larynx and os hyoidei, to reach the back of the tongue. They are enclosed in this piafage by a tendinous sheath, furnished by the genio-glosso. Blumenbach found, in the two-toed anti-eater, the tongue $\frac{3}{2}$ inches long, and not larger than a crow's quill at the root. It was cylindrical, and faintly..
marked with a groove along the superior surface. He states that the usual muscles of the tongue, particularly the genio-
glossus, were very strong.

According to Cuvier in the dolphin (delphinus delphis), the genio-
glossus muscles arise from the superior and anterior edge of the stylo-
oid bone. The kyoglossus comes from the middle of the convexity of the body of the os hyoideus. There is but one mylo-
glossus, the fibres of which proceed obliquely backward and inward, from the anterior circumference of the lower jaw toward the tongue.

There is a curious tendinous fasciculus under the tongue of the dog, which is popularly known by the name of the worm. It lies in a kind of membranous sheath, and has no connection, like other tendons, to any muscle.

Culver's thought it useful to the dog in the peculiar method of taking liquids by lapping, and Blumenbach is inclined to agree with him in this opinion, from finding the same sort of tendon under the tongue of an offspur he had observed to drink, by lapping as dogs do.

A very dangerous notion has been entertained since the days of Pumy, that removing the worm from the tongue of a dog will prevent the animal from swallowing. A proof of this delusion which is probably as ill founded, is that dogs which have been wormed, if they should be affected with hydrophobia, will not shew any disposition to bite. The curiosity which has always prevailed respecting the mode of preventing and of curing this disease, has been attended with the most mischievous effects in superfecting the only rational means of security.

The tongue, as an instrument of mastication, is very actively employed. Its muscles give it the power of moving in every possible direction, and therefore of conveying the food from any one part of the mouth to another; it places the unbroken aliment between the grinding teeth; retains there until they are sufficiently divided; and then carries them into the pharynx to be swallowed. The performance of these actions requires a nice feeling in the tongue, which is known to polecats in an eminent degree. Besides being an organ of taste, the tongue has a more discriminating touch than any other part of the body, and hence it is employed by jewelers and other artists in ascertaining properties that would escape the examination of the other sense.

The taste upon the surface of the tongue in many quadrupeds are calculated to improve the palatable powers of this member in a great degree. In the cat genus there are horny processes, which are fo harp and strong, that they will tear off the skin locking it. Many of the herbivorous quadrupeds, like the horse, have the tongue armed with process's, which are favorable in tearing up their food. The corporal process on the back of the tongue of the omnivorous hyaenæ should perhaps be cliéd with the papillets of that organ, instead of being placed among the teeth.

Fig. 11. Plate 1. of the Anatomy of Mammalia, represents the general muscles of the tongue in the cebda: a is the mylo-
hyoideus muscle; b is its anterior portion; c a part of the genio-
hyoideus; d the g. mylo-glossus, with its additional portion, e, are turned, are; f is the inferior layer of the mylo-
glossus, separated from the palatine membrane, by which the superior layer of this muscle is seen at g: h b b indicate the freno-glossus, terminating in minute filaments in the muscle and jaws; h i f are the angular muscle partially exposed, and at one place cut and turned back to expulse the freno-glossus falling through it: z is the membrane covering the tongue.

The salivary glands are the same in number, with a very few exceptions, in mammalia as in the human subject. The buccaeals and labiales, however, are often hardly perceptible. The structure of the salivary glands is essentially the same in all cases; we have only to point out some varieties in the relative size of the glands, to notice those instances where one or all of them may be absent, and to describe some auxiliary glands which exist in a few species.

The salivary system is most striking in the carnivorous quadrupeds, than in those that confine vegetable food. The porcials are diminished in particular, being generally as small as the sub-maxillary glands, and sometimes even smaller; as may be observed in the bat, the dog, and the American or oil (delphine virginiana). The texture of the salivary glands also is firmer, and their colour more red in the carnivorous than other quadrupeds.

The sublingual glands are not found in the cat, and in the dog they are but the prolongation of the sub-maxillary.

The molar glands, which are so small and obscure in man, are often very plain, and indeed considerable in quadrupeds. In the cat they form a close oval mals. In the dog they make an uninterrupted series, extended opposite the inferior molar teeth. In this animal there is a salivary gland, also situated in the zygomatic fossa; it is half the size of the sub-
maxillary gland; it ascends as far as under the globe of the eye; its duct, which is very large, sprints behind the tympanum, and opens into the mouth, at the extremity of the alveolar border of the inferior maxillary bone.

The submaxillary mammals have the salivary glands larger than the carnivorous or digeridous, but, like them, the glands which pour their fluid into the front of the mouth exceed the parotids in size.

The tardigrades mammals have the parotids smaller than the sub-maxillary glands.

There are greater varieties to be observed in the salivary system of the edentata than in that of any other tribe of mammals.

In the two-toed ant-eater, the sub-maxillary glands are of great size, they form a compound mals, which covers the fore-part of the neck, and the top of the breast. They are filled between the mane, opposite the sternum, and extend forwards as far as the larynx. They then proceed upon the sides of the neck, and, extending round the ears furnish a narrow process, which pales forwards between the maffeter and mylo-hyoidens muscles. Although this gland seems to be only one mals, it appeared to Cuvier, from whom this narration is borrowed, to have two principal excretory ducts, which indenticate themselves along the edge of the mylo-
hyoidens, and accompanying this muscle on each side as far as behind the arch of the chin, where they open into the mouth. Cuvier, however, speaks doubtingly of this description, as the subject from which it was taken had not been well preserved.

The molar glands in the same animal are united into one long mals, covered by the buccinator muscle.

The sublingual are formed of glandular grains disposed in a series under the membrane of the mouth, the length of the genio-glossus muscles.

The parotids appear to be replaced by the superior part of the glandular mals already described as the sub-maxillary glands.

Another salivary gland, which from its situation in some quadrupeds might be called the zygomatic, or temporal, also exists of a large size in the two-toed ant-eater. It is continuous inferiorly to the upper edge of the maffeter muscle; posteriorly and above, it corresponds to the temporal mucle, and it embraces anteriorly the globe of the eye. The sub-

![Image](https://via.placeholder.com/150)
flance of this gland is more compact than that of the parotid: its duct opens behind the superior maxillary bone.

There is, l tally, a gland in the ant-eater, the use of which is probably to furnish a musus to the tongue, that is necessary for detaining the infects on which these quadrupeds subsist.

This gland is of an oval flattened figure, and defends before the tendon of the mactrfler, behind the angle of the lips, and then along the border of the lower lip, as far as the middle of it. The excretory duct of this gland opens externally in a groove at the commissure of the lips. When the gland is prehended, there issues from this orifice a white, thick adhesive matter, which, no doubt, is defined for the use already mentioned.

In the porcupine ant-eater, (echidna,) the sub-maxillary glands are extremely large. They extend far backwards. The lobes of which they are formed are very distinct, and the small excretory ducts of the glands are seen to terminate by plain orifices in a principal duct, the diameter of which is very considerable. The chief duct proceeds in the direction of the axis of the gland, upon the muscles which go to the tongue, and penetrates the membrane of the mouth very near the fmmphysis of the jaw.

There are also in the echidna two sublingual glands, of an oval form, smaller than the sub-maxillary, and with more compact lobes. They are situated behind the membrane of the mouth, on each side of the base of the tongue, and pour out their secretion through a number of small foramina at that place.

In the multungulata the salivary sytem is extensive. The pig has two sublingual glands. The first is very narrow and long, composed of little lobes of a pale red color, and accompanies the duct of the sub-maxillary gland from the angle of the jaw as far as the second sublingual gland, and opens by one small orifice. The other sublingual gland is placed anterior to this; it is square, flat, and composed of lobes of a larger size, and a redder colour, than those of the first sublingual gland. It has eight or ten excretory ducts, which permeate the membrane of the mouth in a row.

The molar glands of the pig are two long masses, which are of a reddish colour, and consist of large lobules, like the second sublingual of this animal.

In the bisulca, or eleven-footed quadrupeds, the salivary glands are of a great size, particularly those which are situated posteriorly with respect to the mouth.

In the ox and sheep there is a cluster of glands in the zygomatic fossa, which extends as high as the globe of the eye, and descends below the zygoma, under the mactrfler. Its excretory ducts open behind the laft molar tooth.

The zygomatic glands in the horse are the continuation of the molar, which ascend behind the upper jaw near the adductors of the eye. The parotids in the horse are very large, passing upwards behind the external ear, and downwards as far as the angle of the jaw.

In all these animals that inhabit the water, the salivary glands are either very small, or absent altogether. In the common seal, the parotids, the sublingual, and the zygomatic glands are wanting. There are two sub-maxillary, the one is larger than the other, and they have a common excretory duct, which opens as usual under the frenum of the tongue.

In the cetacea there is no vestige of salivary glands.

From the preceding description it will be seen the relative and absolute size of the salivary glands depend upon the use that is made of the teeth. When a species of food is taken that requires much mastication, the glands that pour their saliva into the sides of the mouth are particularly large.

When the food is of a kind that needs but little division, the salivary glands are smaller, especially those which furnish their fluid to the grinding teeth. In the whale tribe, which do not masticate at all, the salivary sytem is unnecessary, and accordingly does not exist. The great size of the salivary glands of the invertebræ quadrupeds would seem to be an exception to general rules, but it is to be remarked that in these animals the salivary glands immediately subervent to mastication are wanting. The great bulk of the others may, therefore, be necessary for entangling and detaining the ants upon the tongue, and facilitating their passage into the oesophagus.

No accurate or comparative examination has yet been made of the chemical properties of the saliva of quadrupeds, but the structure of the glands being similar, it is probable that the fluid they secrete does not differ materially from the saliva of the human subject.

In some mammalia, there are dilatations of the internal membrane and integuments of the mouth, in which the food is deposited for a time previous to its being swallowed, and in which it is softened by maceration in the saliva. These cavities have received the names of cheek pouches, and jaw sacs.

A great number of species of monkey possess these cheek pouches. They are not large, and the openings into the mouth are nearly as wide as the faces themselves. Being situated opposite to the inferior molar teeth, they are well supplied with saliva from the parotids. When they are empty, the face of the monkey looks thin and fumken.

The macerating pouches connected with the mouth are much larger in the hamster (mus criocetus), and several other species of mus allied to the hamster. The most remarkable pouches, however, are found in the Canada rat, (mus burcarius,) a species described by doctor Shaw in the 5th vol. of the Linnean Transactions. He has distinguished it by a specific name expressive of its enormous pouches. In the figure he has given of it, the pouches are seen to hang down like two oval bags from the jaws, each of them equalling the size of the whole head.

Where the macerating pouches are large, they are said to be used for carrying the animal's food to their habitations, in which they deposit a winter store.

Pouches which appear strictly for macerating, have been described by Mr. Home in the ornithorhynchos pavulunx. In Plate II. of the Anatomy of Mammalia, fig. 1, represents a front view of the head and shoulders of the mus burcarius, with its enormous pouches distended. The appearance of blood-vesicles ramifying upon them is to be seen.

The pharynx of mammalia resembles in most particulars that of the human subjeqt. Cuvier mentions some slight alterations in the direction and actions of the phyllo-pharyngeus muscle. He states that in the mouse this muscle seems to be the continuation of the phyllo-majloideus, and in the elephant it is united to the phyllo-hyoideus as far as the top of the pharynx.

In addition to the usual muscles of the pharynx, many quadrupeds, particularly the elephant, bear, &c. have been observed to have the proper muscles of the tube of the cophagus continued upon the bag of the pharynx. These layers Cuvier calls the pharyngeus proprius.

It is somewhat singular that the weasel is a part peculiar to man and the monkey.

The pharynx of the whale tribe is formed into two pouches, by means of the curious larynx of those animals, which is elevated so high as to be inserted into the aperture, corresponding in some degree to the posterior nares. The structure of these parts will be better understood after the description of the larynx in the whale.
Mammalia.

Oesophagus.—This tube in most mammals has the muscular coat formed of two layers, the fibres of which have a spiral direction; the external layer takes one course, the internal an opposite one; so that they always decussate each other. Some anatomists have supposed that these spiral muscles were peculiar to the oesophagus of ruminant quadrupeds, although they were figured in the dog above a century ago by Blainius. They have likewise been found by Cuvier in several quadrupeds, and by us in others, from which it would seem to be a tolerably general structure in mammals. The muscular coat has been found to consist of dense fibres of the human subject in the kangaroo, in which animal it is also thicker than the muscular tunic of the rest of the alimentary canal.

The cuticular membrane is very plain in many quadrupeds, especially those that have the oesophagus partially lined with cuticle. There is a very strong white cuticle in the oesophagus of the okapi tribe.

The internal membrane of the oesophagus exhibits longitudinal folds in many quadrupeds. Cuvier has remarked, besides these, some transverse folds about the middle of the oesophagus in several carnivorous mammals, as the tiger, lion, lynx, and the Virginian opossum, in all of which these folds are very striking, forming a species of valves. They exist likewise, but in a slighter degree, in the civet, and in the cougar (felis concolor).

These valves, or transverse folds, are placed close to each other. They do not include the whole of the circumference of the oesophagus; but there are usually two or three which unite at an acute angle, in order to complete the circle.

The oesophagus of quadrupeds, in conveying subtlances into the stomach in a direction contrary to the gravity of the viscera, is clear in its functions in all animals. Its actions are always peristaltic, like those of the intestines. The successive contraction and dilatation of the different parts of the canal are obviously seen when a horse, or other long-necked quadruped, is drinking; the water does not pass in a stream along the gullet, but in the form of globes, the muscular fibres contracting behind them, as they pass forwards. The oesophagus is, therefore, always in a comparatively collapsed state, except at the very parts of the canal which contain the portions of food or drink.

The termination of the oesophagus is open and direct in the carnivorous quadrupeds, but in many of the herbivorous, particularly those with complicated stomachs, it is constricted, or enters obliquely. The oesophageal orifice of the stomach in the horse is diminished by a projection of the tunics, which has somewhat the appearance, and, as it is supposed, the effect of a valve. This structure is commonly believed to render the horse incapable of vomiting. We are, however, well informed that horses have been known to vomit when very active medicines have been employed. We believe, also, that it is equally difficult to excite vomiting in the ruminant animals, although they have the power of spontaneously bringing back the contents of the stomach into the mouth at all times. We must, therefore, seek for some other explanation for the inclination to vomit in these animals, than the mode in which the oesophagus terminates in the stomach. Shall we attribute it to the parts of the stomach adjoining the oesophagus being less susceptible of irritation, from being covered with cuticle? or is it that the medicines that have an emetic effect upon the human subject have a different operation upon them? It is a fact well known, that medicines have different, or even opposite effects upon different animals. The stomach of the dog is provoked to vomit by eating grafts.

A peculiar glandular and moveable bag has been described behind the palate in the camel, which is supposed to carry water for moistening their faces. Cuvier states it to exist only in the dromedary, in which it is thrust forth on the neck in the rutting season.

Stomach.—The history of this organ in mammals forms one of the most interesting branches of comparative anatomy. The varieties in its form and structure, suited to the various kinds of food used by these classes of animals, are highly instructive, and have been particularly investigated as being applicable to the explanation of the functions of the stomach in mammals.

The most simple form of the stomach belongs to those mammals which subsist upon flesh. In many of the beasts of prey the stomach is nothing more than a slight dilatation of the alimentary canal. The cardiac or oesophageal end is larger than the pyloric, but there is no cul-de-sac, or dilated part placed out of the course of the subtlances through the viscus in which they can be detained. The belf examples of the carnivorous stomach are found in the pole cat, and moff of the genus mustela, the dogs, hyena, badger, some of the genus felis, &c. In all these cases the smaller curvature, as it is called, is slightly hollowed, the dilatation being entirely in the great or lower curvature, and chiefly, as before observed, at the left or cardiac end. In the felis the stomach has great resemblance to that above described; the oesophageus forms even less of an angle with the stomach, but enters it at the end of the left extremity. The lesser curvature is not concaive, but nearly presents a straight line, and there is near the pylorus a degree of circular contraction.

The enlargement of the great end of the stomach, and the inflection of the oesophageus somewhat nearer to the middle of the stomach, is the form which is more or less required in that of the horse. This is calculated to receive a larger quantity of food, and to retard in some degree its progress through the viscus; we accordingly meet with it in those animals that live upon a mixed food, or upon vegetable matters, either prepared by cooking, or some other means, to render them more digestible. This form of stomach exists in the human subject, in most of the night mammalia, and of the bats, in some of the pangolins, and many of the felis species.

The intestines of the stomach more than any other of the monkey genus. Several of the other species differ in the degree of cul-de-sac produced at the great end, by the dilatation of the oesophageal orifice, and some other in the alimentary cirumstances which are pointed out in Cuvier's Anatomie comparée, tom. iii.

In the galapheus the pyloric half of the stomach is prolonged somewhat in the form of an infeline.

In the brown bear the portions on each side of the entrance of the oesophagus are directed towards the diaphragm. In the barb-saw, also, the pyloric and cardiac ends of the stomach are a little towards the diaphragm.

In the brown cat the stomach resembles in figure a pear, the pyloric end corresponding to the flanks, and the oesophageus being inserted into the side of the fruit.

The Parilian academicians described the stomach of the lion as being in the same direction as the oesophagus, until the pylorus, when it turns upwards, or forms the small curvature, in the same manner as frequently is seen in the stomach of fishes. The academicians also found some dilated parts or pouches in the lion's stomach, but these differed in form and situation in different individuals. In the figure given by Cuvier of the lion's stomach, it has the same direction, but wants the dilated parts observed by the academicians. The preparations we have seen of the stomach of the lion resemble those of the common cat, in which
Mammalia.

which the cavity is larger than in the perfect carnivorous stomach.

The figure of the stomach is singular in the garden squirrel of Pennant (myoxus niella). It is that of a globe, at the top of which both the oesophageal and pyloric orifices are situated close to each other. The tubes of the oesophagus and intestine are both small compared with the size of the stomach.

The form of the stomach is also globular in the cape ant-eater (oryctorhopus), but the part which leads to the intestine is a process from the right of the upper part of the globular face: this prolongation has a very strong muscular coat.

In the echidna the stomach is large and has thin coats; the figure is oval; the cardiac and pyloric orifices are nearly at the two ends of the ellipse: there is a flight oval enlargement at the origin of the intestine. The stomach is glandular near the pylorus, and the muscles are distinct at the same place. The internal membrane is thrown into some fine rugae at the cardia, and forms larger and more numerous folds near the pylorus, which make a kind of radiated fringe. The pyloric orifice is not diminished by a circular fold, but the parietes of the stomach, which are thicker than those of the duodenum, form a projection into the latter.

The most extraordinary form found amongst the single stomachs of mammals belongs to the ornithorhynchus paradoxus. It resembles a wine bottle, flat at the bottom, nearly straight on the sides, and tapering at the top. The oesophagus corresponds to the neck of the bottle. The duodenum arises from the part similar to the top of the body of the bottle, and soon becomes about half as wide as the stomach, which is extremely small in proportion to the rest of the alimentary canal, and to the size of the animal.

The rhinoceros has an unusual form of single stomach. The cardiac portion is distinguished from the pyloric by a permanent contraction of the stomach. The former is an elongated oval. The oesophagus enters at nearly midway between the great end and the contracted part. The pyloric portion has a globular figure. The intestine arises out of the centre of it, and in a direction towards the great or left end of the stomach. The rhinoceros affords a real instance of a division of two portions of the stomach, without any process of the internal membrane forming a line of separation.

Mr. Home has fancied that a division of the stomach into two cavities exists in all single stomachs during life, by means of a permanent contraction of the muscular fibres of the middle of the stomach.

The effect of such an hour-glass contraction of the stomach would necessarily be to detain the food in the great end, either as a temporary or a preparatory reservoir, neither of which are required from the nature and preparation of the food of those animals which possess a simple stomach. Mr. Home's hypothesis tends to reduce the complicated and single stomachs to one kind, or class, and to break down all the distinctions established by nature, to correspond with the different kinds of food, and the various modes of its preparation.

It has frequently occurred to many experimental physiologists, and to ourselves, to see the figure of the stomach in the living body, but a regular and constant division into two portions by means of the muscular coat has not been remarked. We have observed different parts of the stomach in a contracted state: the muscles near the pyloric act most strongly, as might be expected, in order to propel the alimentary matters into the intestine, and the great end of the stomach is in general found most distended, as being the part in which the food first arrives, and consequently, is in some degree accumulated.

In many of the simple stomachs, the great end, or cardiac portion, is distinguished from the pyloric by having a thinner muscular coat; this difference of structure is usually accompanied by a larger capacity of that part. In some of these cases, likewise, the cuticle of the oesophagus is continued over the cardiac portion of the stomach. These facts prove the gradual approaches that are made in the structure of the stomach from a simple digestive organ, to the additional functions of a preparatory reservoir. The division of the stomach into two cavities, by means of structure and the prolongation of the great end into a more perfect cul-de-sac, are particularly well seen in a general of the rat genus, and some other species of salpingoid mammals.

In some of the last mentioned tribe, the stomach is even more decidedly divided into two cavities than in the species to which we have alluded.

The kangaroo (macrurus), has the stomach formed of two cavities, the fides of which are conjoined, and communicate together by an orifice, apparently about the width of the duodenum, in the same animal. The oesophagus belongs to the left cavity, but enters at the junction of the two. The cardiac cavity or portion first extends outwards, and then turns up at the part corresponding to the great end of the stomach. The pyloric half is of a more irregular shape, and has thicker coats than the full. When distended, it has, in a degree, a facciuined appearance from some dilated parts of its parietes. The communication between the two sides of the stomach is guarded by a fold, which is fringed upon the edge.

In the water rat the stomach is converted into two cavities, by means of a contraction situated a little to the right of the cardiac orifice, which is nearly about the middle of the stomach. The left or cardiac cavity is almost transparent from the thinness of its coats, shewing the division of the stomach to be designed to produce the effect of a reservoir.

The short-tailed rat of Pennant (mus arvalis) has the stomach divided in the same manner as the water rat.

The lemming, or Lapland marmot of Pennant, and the mus lagurus of Pallus, have also two cavities: they are separated in the latter animal by a very thick fold, that projects internally, and is fringed upon the edge.

The stomach of the mole rat of the Cape (mus cepifer), is curved upon itself, and the oesophagus opens near to the pylorus; it is also divided into two cavities by a semi-lunar fold, which is furnished posteriorly by the internal coat.

In the mole rat (mus zibethicus), there is a contraction of the middle of the stomach, by which two cavities are formed.

The mus typhlus, and mus abnormus, have the stomach divided into three pouches. In the former there are two reflections of the internal membrane, which proceed from each fold of the cardia. The one on the right is carried on throughout the whole circumference of the stomach. It has a dentrulated edge, and there is a round gland in the most projecting part of its large curvature.

The stomach has a very singular conformation in the kangaroo. It is greatly elongated, and doubled twice upon itself. It resembles very much the great intestine of the lope, not only in figure and great extent, for it nearly fills up the abdomen, but in being divided into a great number of sacculi by means of longitudinal muscular bands, such as exist upon the fides of the colon. The oeso-
gus enters the stomach at about $\frac{2}{3}$ of its length from the end of the cul-de-sac. The cardiac end furnishes two processes; the external one has thick and glandular coats, while the other is smooth, whitish, and irregularly corrugated, like the rent of the internal surface in the cardiac portion of the stomach. This appearance of the internal membrane is preferred around the cardia, and in a part of the right portion where there are two long triangular bands.

In the remainder of this portion, the inner surface is more grey, mucous, semi-transparent, uniform, and without rugae. There are two appendices which arise beyond the middle of the pyloric portion, and are curved backwards, like two short caeca. The mucular coat forms a projection around the pylorus, by which it is much contracted, and the internal surface presents an annular burst at the same place, which consists of follicular glands. The mucular coat of the stomach in the *kingaroo* has transverse fibres going from the one longitudinal band to the other on the right portion, but on the left part of the organ there are only the longitudinal mufes to be seen.

The stomach of the *kingaroo* rat is divided into two portions, not only by its figure, but a difference of structure. The oesophagus opens at the place where the cardiac and pyloric cavities join, and there is a projecting fold which is continued from the oesophagus into the pyloric cavity, the design of which is evidently to conduct the food, under certain conditions, more immediately into the fundus cavity. The whole stomach possesses longitudinal bands, which produce contractions in its parietes, but this structure is particularly striking in the cardiac half, which is thrown into numerous deep facs or pouches. The internal membrane of the left portion forms strong longitudinal rugae on the posterior half of this cavity, and flight folds passing between some many-slied areas on the ret of the cardiac, and the beginning of the pyloric division of the stomach. The remainder of the latter is smooth, and without rugae internally. There is a narrow gland, which extends the length of the first division of the stomach, and discharges its fluid through numerous small orifices upon the internal membrane.

In the *daman* (kyrax), the stomach has two cavities. The first is nearly globular, and receives the oesophagus in its right side: the second is pyriform, and has the pylorus at the top, where there is a strong marked annular contraction. The part by which the two cavities are conjoined is very small.

The *porcupine* has the stomach consisting of three globular pouches. One corresponds to the cardiac portion; another to the pyloric; and the third, a smaller pouch than either, is placed between the two first, just at the termination of the oesophagus. Internally there is a fold which proceeds from the right of the cardia, and separates the left pouch from the two others. There is at the pylorus, on the side of the little pouch, a semi-lunar burr, composed of glands. The intine and oesophagus are seen to arise close to each other, so that the whole figure gives the idea of a heart with the large veiles. The internal membrane is uniform throughout.

In the *vampire bat*, the oesophagus, before it enters the stomach, is dilated into a large oval sac, which communicates very freely with the cavity of the latter, and may therefore perhaps be considered as belonging to it. The stomach is long, resembling, in some degree, the colon of an animal. The left end is turned upwards, and at the extremity is curved backwards. Mr. Home describes this portion of the stomach as being divided into two dilatations, with a neck between them, the one having a rugous, and the other a smooth surface. The distance from the oesophageal orifice to the pyloric is more than two-thirds of the whole length of the stomach: it first proceeds to the right side, and then turns back upon itself; the reflected part is puckered, or thrown into facettis. The pylorus has a valve, which, when closed, will not permit air to pass through it.

The *folded bat* has also the dilatation at the termination of the oesophagus; but all the other species of *vespertilio* appear to have a simple globular stomach.

We shall now proceed to the description of some stomachs which are more complicated in their forms than any hitherto mentioned.

In the *Pecari*, or *Mexican hog*, there are two remarkable processes from the cardiac portion of the stomach, which are turned downwards, and appear to render the cavity of three parts. There are several contractions dividing the pyloric portion of the stomach from the other. The cardiac portion is by much the larger. Daubenton has represented the stomach as being divided into a greater number of pouches or processes than are described by Cuvier or Home.

In the *buccalpumus* the cardiac portion contains three pouches, two of which only appear on the outside: the stomach then becomes long and cylindrical, like an intestine, and terminates in a narrow appendix, which opens into the duodenum. There are many transverse folds or valves in the first part of the cylindrical portion. The internal membrane is hard and granular in this part, from the hul valve, and in the two larger pouches: beyond the valves it is smooth and folded; there are no folds in the appendix, but the mucular coat of it is very thick, particularly around the pylorus.

The stomach is extremely complicated in the *tardigrade* quadrupeds, and approaches, in a considerable degree, the conformation of this organ in those that chew the cud. In the *two-tailed flat* bushy, it appears, when viewed externally, to consist of two cavities. The left is very large in proportion to the oesophagus and the intestines; is nearly figure in its figure, and exhibits, at least upon the anterior part, three elevations, or dilated parts. When the stomach is laid open, these are found to correspond to three cavities, or apartments, which are separated from each other, internally, by projections of the coats. The left, or cardiac division, of the organ in these animals should, therefore, be properly considered as three cavities. The pyloric, or right division of the stomach, is formed like an intestine, or rather, from its dilatation towards the middle, it resembles the simple carnivorous stomach in its figure. It is much smaller than the left portion, under which it is curved in the direction from right to left. The first half of it has very thin coats. The remainder has them thicker, particularly about the pylorus, the orifice of which is much contracted. These two parts of the right division of the stomach are flated to be separated by a semblar fold. The first of these seems to be again divided by a little fold, finely denticulated upon the edge. The internal coat is different in the two portions. The first portion terminates in a little cul-de-sac, which is seen anteriorly upon the right side of the first, or cardiac division of the stomach, between two others. These little appendices appear to be glandular.

The inner coat is smooth in both the cardiac and pyloric divisions of the stomach of the *two-tailed flat*: it appears even to be tendinous in the two first cavities, or pouches, of the cardiac division.

In the *three-toed flat*, the appendix of the second stomach...
MAMMALIA.

is much longer than in the preceding species, and is divided into three apartments by two longitudinal septa.

In both these species, the \textit{cæophagus}, on entering the cardiac division of the \textit{stomach}, becomes connected with a canal, which arises, by a circuitous course, in the pyloric, or right division, into which it opens by a contracted orifice. The existence of such a communication as this would lead us to expect, that the \textit{flanks} had the power of \textit{ruminating} but Cuvier states, that he found both divisions of their \textit{stomachs} equally filled with some ligneous substances, reduced to a fort of mould, or earth. We shall refer the reader for a more particular account of the \textit{stomachs} of the \textit{tardigrade} mammals to Cuvier's Anatomie comparée, tom. iii. Daubenton Histoirre Naturelle, tom. xiii. and Wiedemann's Archives, vol. i.

We have next to describe the \textit{stomachs} of the \textit{ruminating} quadrupeds. There are some differences to be observed between the ruminants with horns, and those without. We shall first give an account of the \textit{stomachs} of the horned ruminants, and as the most familiar example, take for this purpose the \textit{ox}.

In this tribe of animals there are four \textit{stomachs}, which fill up a great part of the abdominal cavity. The first \textit{stomach} is called the \textit{paunch}, (\textit{rumen, pedala, magnus venter, &c.}) It occupies the left side of the belly, and is larger in the adult than the three other \textit{stomachs} taken together. It has an irregular globular figure. When laid open, it is found to be, in a certain degree, divided into three cavities, by means of two ridges, or projections of its coats, which crofs it obliquely. The upper hollow contains the mouth of the second \textit{stomach}, which is so large, that the two first \textit{stomachs} should, perhaps, be considered as parts of the same cavity. The reflections of the coats, which form the ridges above mentioned, contain, besides the muscular coat, some tendons. The edges of the ridges are, therefore, thick and rounded. All the muscles of the \textit{paunch} are particularly firm in their texture. The internal membrane is of a brown colour, and covered with strong papillose in most places. The edges of the ridges are smooth. There is a thick cuticle lining the \textit{paunch}, which may be detached by maceration, when it is seen to have given a covering to each of the papilloses. The contents of the \textit{paunch} are the vegetable matters imperfectly malticated, and unmixed with any of the animal juices, or even the drink. It is in this \textit{stomach}, therefore, that fermentation of green food is liable to occur. Many of the horned cattle have their body greatly distended by the extraction of air during this process in the \textit{paunch}.

The only remedy is to plunge a knife into the left loin of the beast, when the \textit{paunch} will be penetrated, and an immense quantity of air will rush out. This expedient, although apparently so desperate, we believe, is never followed by any but consequent. It is generally in the first \textit{stomach}, rarely in the second, that the concretions of hair, or of vegetable fibres, or calcareous substances, are found. The \textit{hair-balls}, occasionally met with in the \textit{paunch} of the cow, are licked off from the body. They are curiously interwoven, and sometimes are covered with an earthy matter, which receives a fine polish. The balls found in the \textit{stomach} of the \textit{chamois} are composed chiefly of the fibres of the \textit{abysa musum}, and are covered with a fine black incrustation. The \textit{bezoar stones} are earthy concretions, formed in a similar manner. See \textit{Bezoar}, in this Dictionary.

The second \textit{stomach} of the \textit{ox}, which is called the \textit{honey-comb bag}, the \textit{bonnet}, and king's-bowel, (\textit{rectum, mollus, &c.}) might be considered, if it were not for its internal structure, as a globular appendage of the \textit{paunch}; it is placed upon the right side of the former, with which it communicates very freely, as before-mentioned. The internal surface is elevated into thin folds, which unite to each other, so as to produce many-plied meshes, or superficial cells. The sides of the \textit{folds} are grooved, and their edges dentilicated. The area of the \textit{cells} is papillated as the \textit{paunch}, but with finer eminences. The second \textit{stomach} is lined by a continuation of the cuticle which covers the first. The muscular coat is generally thicker and fatter in the second than in the first \textit{stomach}.

The \textit{cæophagus} opens at the junction of the first and second \textit{stomachs}, so as to be capable of communicating freely with the cavity of both, but the operations of swallowing and regurgitation are materially influenced by the actions of a mucular groove, or channel, which is continuous with the tube of the \textit{cæophagus}, and ultimately leads into the third \textit{stomach}. This groove is formed by two mucular columns, which proceed from the fibres of the \textit{cæophageal orifice}. The right band, or column, extends the length of the superior surface of the \textit{honey-comb stomach}. The left runs within the edge of the opening from the first into the second \textit{stomach}, and is prolonged upon the left surface of the latter. Each of these columns pales round the orifice leading from the second into the third \textit{stomach}, decussating upon the inside of it. The internal membrane, where it covers these mucular columns, is thick and regularly pleated transversely. The membrane, on the contrary, is very thin between the columns, and forms, in the concave part of the groove, some longitudinal folds. There also is in this situation a layer of muscular fibres, which pass behind the groove, and connect one border of it with the other. This channel is the chief characteristic of the \textit{ruminating} \textit{stomachs}. When a portion of food is to be re-conveyed to the mouth, it is received into the groove, which, by the contraction of its mucules, approximates the two borders, and forms a perfect tube, and thus transmits the morful into the \textit{cæophagus}.

Again, when \textit{ruminating} is finished, and the morful swallowed, the groove forms a tube, and conveys it into the third \textit{stomach} directly. When the food and water are first received into the \textit{stomach}, the \textit{fides} of the \textit{groove} are necessarily open, but it is probable, at the same time, that the orifice of the third \textit{stomach} is closed. The different actions of the \textit{groove} are evidently subjected to the will of the animal, which is extremely curious, as it cannot be accounted for by any peculiarity in the anatomy of the part. The same \textit{fibres} of nerves and vessels belong to the \textit{groove} as to the \textit{stomach} of other quadrupeds.

Mr. Home says, that the food contained in the \textit{paunch} is always dry, and that the water the animal drinks palates into the second \textit{stomach}, without mixing with the food in the first. The office of the \textit{honey-comb bag}, therefore, seems to be in a principal and convenient manner the liquid and dry admixtures. In this point of view, the first \textit{stomach} is the receptacle of the most; the second, of the drink, which will appear still more probable, after we have described the \textit{ruminating apparatus} of the camel, &c.

The third \textit{stomach} has received the names of \textit{many places}, (\textit{cæophagus, mollus, &c.}) This cavity in the \textit{ox} is larger than the \textit{honey-comb bag}, and resembles in figure a hedge-bog rolled up, and thence one of its appellations. Its connection with the second \textit{stomach} is very contracted. The cavity is filled with thin folds, or reflections of its coats, which arise from the smaller curvature, and have few edges at the large curvature corresponding to the back of the hedge-bog. These folds, or lepae, are of unequal dimensions. According to Mr. Home's observations there are twenty-four lepae, seven inches broad; about twenty-three that are four inches broad; and about forty-eight of one inch.
inch and a quarter in breadth. These are arranged in the following order. A broad one, with one of the narrowed next it; then a narrow one, with one of the narrowed next it, then a broad one; and so on. Whatever paffes into the cavity of the third flomach must fall between these fepta, and describes three-fourths of a circle, before it can arrive at the orifice of the fourth flomach, which is so near the other, that the direct line between them does not exceed three inches. The many ples are covered with cuticule as well as the first and second flomachs: they are covered also with little granular papillae. The many ples form a projecting valve at the orifice of the fourth flomach, at which place the cuticule terminates.

The food that is found in the third, or plicated flomach, is distributed amongst the different fepta in a compressed form. It has the confidence of thick pafle, and a peculiar unpleafant fhmell.

The fourth flomach is called the red bag, (abomasum, fa-
lifeus, ventriculus internaflus, &c.) It has an elongated pyri-
form shape, somewhat like the simple digifive flomach of mammalia. According to Mr. Home, it measures in the ox about two feet nine inches in length; its internal mem-
brane has eighteen longitudinal ples (nine on each fide), beginning at its orifice, and extending about twenty-two inches in the cavity. They are four inches broad, and in-
creef very much the internal surface. Beyond these, the inner coat forms fome perpendicular, or zig-zag rages. The cavity is a little enlarged near the pylorus, where there is a glandular body, which blocks up the pylorus when the parts are in a contracted ftate.

The flomachs of the other ruminants with horns differ very little from those of the ox. In the deer, the paunch has three projections, fern externally, which correpong to as many dilatations of its cavity. In the deer, fleep, and antelope, the papille, and other eminences of the inner coat of each of the flomachs, are less eminent than they are in the ox.

The flomachs of the camel, although agreeing in many refpefts with those above defcribed, differ in some points materially. The beft description of these flomachs has been given by Mr. Home, from which we fhall chiefly borrow the prcdfent one.

The paunch of the camel is divided into two compartment, on its posterior fide, by a prominent ridge, or column, composed of mufcule, which paffes down from the right fide of the orifice of the afophagus. This column forms one fide of the groove that proceeds from the cardia to the orifice of the f formulate, and it is continued beyond that to the lower part of the paunch. Beneath the orifice of the second flomach the column fends off, at right angles, from its left fide, eight ilrong mufcular bands, which afterwards form curved lines, till they are inenfibly loft in the coats of the flomach. These are at equal distances from each other, and being interfefted, in a regular way, by tranverse muscular fepta, form the muscular pareties of a number of large cells, situated on the left fide of the back of the paunch. There is a series of twenty-one fmaller cells of the fame kind, which extend towards the right fide of the paunch. They commence on the right of the chief mufcular column, but have no connection with it. On the left fide of the termination of the afophagus, a broad mufcular band has its origin from the coats of the ifh flomach, and paffes down in the form of a fold parallel to the great ridge already defcribed, and with it forms the groove as far as the entrance of the second flomach. After entering this cavity, it takes a new direftion, paffing along the upper edge of it, and terminates within the orifice of the third flomach.

The orifice of the second flomach is at right angles with the fide of the paunch: it is nearly closed when the mufcular band, which paffes through it, is not in action. It is a pendulous bag, in which there are twelve rows of cells, formed by as many ilrong mufcular bands, paffing in a tranferve direftion, and interfefted by weaker mufcular bands, fo as to form the orifices of the cells. Above these cells, and between them and the mufcle which paffes along the upper part of the flomach, is a smooth surface extending from the orifice of this flomach to the termination in the third.

The second flomach of the camel neither receives the solid food in the firft infufance, as in the ox, nor does it after-
wards pafs into its cavity or cellular structure. The food goes firft into the general cavity of the fift flomach, and that portion of it which lies in the recels immediately below the entrance of the afophagus, under which the cells are affuated, is kept moif, and is readily returned into the censms along the gene; but when the recels, by the action of the ilrong mufcle, which surrounds this part of the flomach, fo that the cellular portion of the firft flomach in the camel performs the fame office as the fegood in the ruminants with horns. While the camel is drinking, the action of the mufcular band opens the orifice of the second flomach, at the fame time that it directs the water into it; and when the cells of that cavity are full, the rret runs off into the cellular structure of the fift flomach immediately below, and afterwards into the general cavity. It would appear that camels, when accustomed to go journeys in which they are kept for an unusual number of days without water, acquire the power of dilating the cells, so as to make them contain a more than ordinary quantity as a supply for their journey; at least fuch is the account given by thofe who have been in Egypt.

When the cud has been chewed, it has to pafs along the upper part of the fegood flomach before it can reach the third. How this is effected, without its falling into the cellular portion, could not from any infpecfion of dried fpe-
"The third flomach of the camel is very small, and quite unlike that of the ox. It is nearly spherical; four inches in diameter; is not lined with cuticule; nor has it any fepta pofiting into it. It has a honey-comb appearance upon its internal surface, but this is fo light as to require a fchew infpecfion to perceive it. This flomach affwrs the pur-
"The fourth flomach of the camel has, for a great part of its length, the appearance of an intinefse; it then contracts partially, and the lower portion has a near refeemblance in its shape to the human flomach.

The whole length is four feet four inches: when laid open, the
the internal membrane of the upper portion is seen to be
thrown into longitudinal narrow folds, which are continued
for about three feet of its length: these terminate in a
welted appearance: the rugae are large, as in the ox, but not
so prominent, nor so serpentine in their course; and for the
latt nine inches the membrane has a villous appearance, as in
the human stomach. Close to the pylorus there is a gland-
ular projection of the coats. Immediately succeeding the
pylorus, there is a very considerable globular dilatation,
appearing like a fifth cavity of the stomach. The duode-
num arises abruptly from one side of it.

The description given of the stomach of the dromedary
by the Parisian defsectors, is so very brief and imperfect,
that scarcely any knowledge can be obtained from it. They
describe the four stomachs as succeeding each other in nearly
the same line. The third as being very long, and the
second as containing about 20 cells for holding water.

Cuvier has given a very excellent description of the rumi-
ning stomachs of the lama, as he found them in an
individual that had been born dead. The age is very neces-
sary to bear in mind, as the fize and even internal structure of
the different cavities of the ruminating organs are much
influenced by it. Thus, before the calf or lamb begins to
feed upon grain, ruminating cannot be performed; the milt
passes immediately into the digestive stomach, the groove
always forming itself into a tube during the act of deglutit-
ion; the paunch is small, and the fourth stomach large in
relation to what it afterwards becomes, and the cells and
other eminences of the two first stomachs are comparatively
light.

In the young lama dissected by Cuvier, the paunch had an
irregular globular figure, being elevated upon some parts,
which corresponded with pouches or dilatations interiorly. It
was larger than all the other three stomachs together; two
of the pouches contained square water-cells, similar to tho-
se of the camel; one pouch had six rows of cells, each con-
taining about 12, which could be discovered externally, by
some swellings of the coats. The other pouch had only
five similar cells. Between this pouch and the cardia, there
was a third dilatation, which was the smallest of all, and
exhibited some folds upon its inner surface, but no cells.
The remainder of the inner coat of the paunch had some
irregular folds, which, however, generally lay in the direc-
tion from before backwards.

The second stomach, placed anteriorly, and on the right of
the paunch, was an oval bag, divided transversely by eight
principal rows of cells, which were divided into smaller
cells, and each of these terminated in a gutter grooved in a
transverse direction, which was prolonged and lost in the
paunch.

The channel leading from the oesophagus to the third
stomach, was distinguished by a large fold, such as exits in
the camel.

The third stomach was elongated and cylindrical; its in-
ternal surface exhibited some longitudinal folds, united to
each other by transverse ones. These disappear towards
the end.

The fourth stomach was not separated by any contraction.
It was wider and shorter than the third, and turned back-
wards upon it. Its inner surface appeared villous, and pre-
fected on the posterior part some convolutions and irregular
folds near the pylorus. A rounded glandular body pro-
jected into the cavity at the orifice of the pylorus, which it
completely closed as a valve. Immediately beyond the
pylorus the canal was dilated into a round fac, as in the
camel.

From the preceding descriptions of the stomachs of the
camel and lama, it will be seen that the chief dilatations in
the ruminants without horns, are the second stomach being
exclusively designed for a reservoir of water; the third
being a sort of affilient digestive one: and from Cuvier's
description of the lama, we may suppose the paunch of that
animal is nearly as large before, as after ruminating com-
mences. These animals have long been known to carry a
quantity of water in their stomach, which was only mixed
with the food as occasion might require. This water is
retained in the cells already described, by means of the mus-
cular fibres surrounding their orifices, contrasting so as to
close the cells. The camel, it is said, will not drink every
day, but when it does, it takes in between seven and eight
gallons of water. All that found in the cells of the second
stomach is perfectly pure and limpid, and hence it is, that
the animal is sometimes killed when travelling in the desert,
for the sake of the water in its paunch.

The stomachs of the southern lamae, and of the cetacea,
are as complicated as those of the ruminant animals, al-
though they do not perform the same office.

In the southern lamae (tricheus australis), there are pro-
perly two stomachs with appendages from them. The first
pouch is large in its figure, but longer in the transverse direc-
tion than any other. It receives the oesophagus into the
middle of its anterior part. The internal membrane of this
stomach is villous, and it has its cavity divided into two at
the anterior part, by a fold which is on the right of the
cardia. There is a little procefs or appendix from the side
of the first stomach, the orifice leading into which is so
small, that no food can pass into it. This procefs discharges
a liquor into the stomach, and should therefore be considered
as a gland. The second stomach is smaller than the first,
and of a long shape; it gives origin at its commencement
to two little procefses; the one superior, the other inferior.
The internal membrane is villous, and slightly corrugated
transversely.

Anatomists are not agreed as to the number of stomachs
in cetacea. Cuvier and Blumenbach reckon four. Hunter,
on the contrary, described five in the porpoife, grampus, dol-
phin, and piked whale, and seven in the bottle-nosed whale.
This difference arises from the manner in which the parts are
considered, and not upon any errors of observation; perhaps
it would be still more proper to view the two first cavities as
the first and second stomachs, and the subsequeat ones as
belonging to the intestina channel.

The first cavity in the porpoife is a large oval bag, into
the top of which the oesophagus opens. It is lined with a
thick cuticle. The other opening of this bag is near the
oesophageal orifice, or, as one might state it, in the shoulder
of the bag, the oesophagus constituting the neck. It seems
not improbable, from the vicinity of these two apertures,
that food may, under some circumstances, pass from the oeso-
phagus directly into the second stomach. The communica-
tion of the first and second stomachs is extended into a short
channel, into which the cuticle of the first pouches and abruptly
terminates. This channel is corrugated in the longitudinal
direction.

The second stomach in the porpoife is considerably less
than the first, and situated on the right side of it. It is like-
wise an oval cavity, but dilated or rounded at the ends.
It is divided upon the anterior part by a deep contraction,
which leaves on the right the appearance of a distinct
cavity. This portion is that which some anatomists have

considered

Vol. XXII.
MAMMALIA.

considered as the third stomach. The internal surface is in both these cavities smooth and spongy, without cuticle, and forms rugga, which crosses each other at right angles.

The opening into the fourth cavity, or stomach, as it has been considered, is at the right side of the bottom of the cavity just described, and is marked by a decided annular contraction, similar to a pylorus. The fourth cavity also resembles exactly an intestine. It makes three serpentine turns, and terminates in the lower side of an oval face, of an inconceivable size, which is the fourth stomach of some authors, or the fifth of others. The coats of this cavity are thin, smooth internally, and tinged with bile, as it is into it, that the biliary and pancreatic ducts open, which is a strong reason, in addition to the form of these parts, for considering all, except the two first stomachs, as belonging to the intestine. At the place where the contraction and projection of the coats forwards form the second stomach into two cavities in the grampus, we have found two glandular masses. They are like roundish cakes in the coats; the one measures about seven inches and a half in diameter, the other about four inches. There are some ragged irregular depressions upon the inner surface, corresponding to the glands, which appear to be the outlines of mucous follicles upon a very large scale. The glandular cakes, therefore, probably take the place of the pyloric glands in other animals.

The projections of the inner coat in the stomachs of the carnivora, are much more remarkable than in the porcine or grampus; the rugae are very eminent, and in some there is a strong reticulation on the inner membrane that projects into folds, which are indented into each other.

In describing the stomachs of some mammals, we have mentioned the existence of cuticle and glands, when these happened to have occurred along with other peculiarities. These points of structure are, however, so remarkable in other instances, that they deserve a distinct consideration.

The cuticle of the stomach is extended for some way into the stomachs of several of the fahigrae animals, generally covering a layer more than the great end, and terminating by a prominent deteculated edge, as instances of which we may mention some of the rat kind. There is some cuticle also in the stomach of the kouprea, the common hog, and the cassowary. The curricular covering of the great end exists in all the fahigrae, whose stomachs are otherwise very simple in form and structure. It is obvious, that the portion of the cavity which is covered by cuticle, is incapable of performing any other function than that of a reservoir.

The glands that we have had occasion to notice in the preceding account of the digestive organs, were generally situated at the pylorus, and were not very remarkable as to size; but some mammals have a glandular apparatus at the cardiac orifice of the stomach, which is very curious.

In the beaver there is a large oval mass of glands on the right side of the oesophageal orifice of the stomach. It consists internally of a number of cells, decreasing in size, and unlined with each other from the surface next the inside of the stomach. It pours out its liquor into the stomach through a number of irregularly-shaped holes. Mr. Home reckons fifty of these holes, which he states to be arranged upon three ridges, on the surface of the gland next the interior of the stomach; nine on each side of a middle ridge, and seven on each of the lateral ridges.

The glandular structure of the beaver's stomach has been long known, and was considered the only instance of the kind; but a similar apparatus was discovered several years ago in the stomach of the common dormouse by Mr. Macartney. The oesophagus, just before its entrance into the stomach, makes a serpentine turn, and at that place becomes greatly enlarged, and surrounded by a cellular glandular structure. The cells produce on the superficies of the gland a number of slight elevations, which give it the appearance of a mulberry. The entire size of the gland is, however, about that of a pea. The oesophagus, before it enters the gland, would scarcely receive a pin; and after the dilatation in the gland, it again contracts in a degree, where it opens into the stomach. The openings of the gland into the oesophagus are much fewer and larger in proportion that they are in the beaver, so that nearly the whole of the cellular structure can be seen by looking at the interior surface, if the part be diffused or spread out. This gland approaches more nearly to the bulbous glandular lotus of birds, than any similar structure does in the chafis mammals. In Mr. Home's account of this gland, he appears to claim the discovery of the internal structure, although preparations and drawings of both the external and internal appearances were annually shown by Mr. Macartney in his lectures, for seven years before Mr. Home wrote upon the subject.

In the erombat, there is a glandular mass that occupies a great part of the small curvature of the stomach, which almost exactly resembles the glands in the beaver. There are many irregularly-shaped openings on the inner surface, within which are smaller openings or cells. A very fine plate of this structure has been published by Mr. Home in the Phil. Trans. for 1808.

A perfectly similar apparatus was found by Cuvier in the posterior part of the stomach of the pangolin (manis penta-
dactyla). The stomach of this animal is also remarkable on account of the great thicknese of the coats towards the pylorus, which appears to operate in the same manner as the gizzards of birds, for the pangolin swallows small stones and gravel.

The ornithorhynchus hystric is likewise reported to take food into its stomach. These extraneous substancess, in both cafes, are, no doubt, digested to triturrate the food, and supply the want of teeth in these animals.

Cuvier describes in the northern lanamin (trichos boro-
dactylus) a glandular mass on the oval gland, as large as the human head. It is placed near the cardia, and appears to project exactly the same structure with those above-mentioned. The fluid secreted is a whitish colour. Cuvier supposes, and with every appearance of probability, that the small appendix of the first stomach in the southern lanamin corresponds to this gland. The appendix is evidently designed for secreting a fluid, and not retaining the food: from the alliance between the two animals, therefore, it can scarcely be doubted, that the appendix and gland perform similar offices.

The use of the cardiac glands is commonly supposed to be for furnishing an extraordinary quantity of the gastric fluid, and Mr. Home endeavours to prove that similar glands, upon a smaller scale, exist in all stomachs. There are, however, some reasons for questioning this opinion. The structure of these cardiac glands, and of their small glandular pores that are generally found in the stomachs of mammals, more nearly resembles that of mucous follicles than any other secretory apparatus. The fluid furnished by the glands of the stomach is in every respect similar to the mucus of the intestines. The situation of the cardiac glands, also, is not the most favourable for the application of a digestive fluid, it being immediately adjoining that portion of the stomach which receives the food in the first influence, and in which it is deposited for some time, as a reservoir in certain species. The cardiac glands might be supposed, perhaps with greater propriety,
propriety, to be designed for the secretion of a fluid capable of macerating and preparing the food for digestion, instead of a really loint or affumulating liquor.

Plate II., III., and IV. of the Anatomy of Mammalia, are intended to exhibit the structure of the stomach Fig. 2. Plate II. represents the stomach of the ferret, as a part of the form of this organ in the carnivorous mammalia. Fig. 1. of the same plate, is the stomach of the garden-pigeon (Columba livia): a is the cæophagus; b, the interline, arising close to it; c, the globular stomach. Fig. 4. exhibits the stomach of the oriental peacock (Pavo cristatus), which is selected on account of the singularity of its form: a, the cæophagus; b, the interline; c, the bottle-shaped stomach; d, the biliary duct. Fig. 5. represents the double stomach of the buffalo: a, the cæophagus; b, the cardiac half or portion of the stomach, much turned up at the left end; c, the pyloric half of the stomach, exhibiting three dilated parts; d, the duodenum. Fig. 6. shews the stomach of the great kangaroo: a indicates the cæophagus; b, the cardiac portion of the stomach, at the left extremity of which are seen two procefs, e and d. At the doubling of the pyloric portion e, are also seen two procefs like eca, which are pointed out by the letters f and g. The pylorus is shewn by the letter h. Fig. 7. represents the shape of the digestive organ in the young bat: a is the cæophagus; b, the dilated part, by which that tube communicates with the stomatch: c, the cardiac end of the stomach; d, d, the two convolutions of the pyloric portion of the stomach; e, the duodenum. Fig. 8. exhibits the external form of the stomach in the tawny-old: a is the cæophagus; b, b, b, indicate the elevations upon the surface of the cardiac or first division of the stomatch, which are produced by the three cavities into which it is separated internally: c, the pyloric portion of the stomach. Fig. 1. Plate III. of the Anatomy of Mammalia, represents a view of the first stomach or paunch of the camel, laid open on the anterior part to expose its internal structure and communication with the second stomach: a is the cæophagus; b, b, the longitudinal ridge, dividing the cavity into two compartments; c, c, the muscles which pafs to the third stomach; d, the opening into the second stomach; e, e, the muscular cells on the right side of the cavity; f, f, the larger cells on the left side, the water of which serves to moisten the food lying over them, and to make it of a fit consistence to be regurgitated into the mouth, along the canal formed by the intestinal ridge, and the muscle going to the third stomach, a broad muscular band forming the cellular structure into two parts. Fig. 2. of the same plate, exhibits a posterior view of the four stomaches of the camel, in which the first is unopen'd, but the succeeding three are cut open, and preferred in three relative situations to the first stomatch: a is the cæophagus; b, b, point out the posterior surfaces of the first stomarch in a dilated state; c shews the communication between the first and second stomaches; d, d, the muscle running along its upper part to terminate in the orifice of the third stomarch. This muscle, when it acts with its greatest force, brings forward the orifice of the third stomarch nearly close to that of the second, and by so doing, thrusts up the rows of cells in the lower part of the cavity, so that no part of the solid food can pass into them; e, e, the rows of cells which form a reteroir for the water; f, the opening leading into the third stomarch; g, the cavity of that stomarch; h, the orifice of the fourth stomarch; i, i, the longitudinal plices of the fourth stomarch; k, k, the rugous structure at the lower part of the same cavity; l, l, the glandular tube, applicable to the orifice of the pylorus; m, m, the pylorus; n, the dilatation or membraneous cavity between the pylorus and duodenum; o, the duodenum.

Fig. 3. Plate III. of the Anatomy of Mammalia, is designed to shew the directions of the muscular fibres, which run upon the orifces and fides of the cells in the first and second stomaches of the camel. The celles of the left fide of the first stomarch are employed as examples, on account of their being the largest, and their muscules the most diffus, but the same structure exists in the cells of the second stomarch also: a a, the longitudinal ridge, to shew its muscular structure, and the mode in which the fibres go off, to furnish the orifces of the cells; b b b b point out the courfe of the fibres going from cell to cell to clofe their orifces; c, c, the muscular fibres, by means of which the cells throw out their contents. In Plate IV. of the Anatomy of Mammalia, fig. 1. is a view of the internal surface of the stomarch in the rat: a is the portion of the stomarch over which the cuticle of the cæophagus is continued. This cuticular coat terminates in an eminent pucked border; b, the pyloric portion of the stomach. This figure is of the natural size. Fig. 2. of the same plate, exhibits the external appearance of the stomach of the dormouse of the natural size, keen posteriorly: a, the cæophagus; b, the gland, seen full, on account of the curvature which the cæophagus makes before it enters the stomarch. Fig. 3. is a view of the cellular structure of the gland, which is exposed by cutting through the second division of the stomarch as the stomarch is left with the gland. Fig. 4. shews the stomarch of the armadil, less than the natural size, and inverted, to expose the internal appearance and foramina of the cardiac gland. The inner surface of the stomarch displays some reticulated lines at the great end, from which longitudinal lines are extended towards the pyloric portion of the stomarch: a, the cæophagus, covered with cuticle; b, the gland. Fig. 5. of the same plate, shews the stomarch of the porpoife, of course much less than natural: a is the cæophagus; b, the first stomarch or reteroir of the food; c is the second stomarch; d is a portion of it, distinguished on this side by a fuffure, which forms have consifdered as separating it into a third stomarch; e is the interlineal-rounded stomarch, which we are disposed to admit as the beginning of the duodenum; f is the laft stomarch, or, as we fuppofe, the dilated part of the duodenum for receiving the pancreatic and biliary fluids; g is the interial canal.

Inteflines.—It may be flated as a general observation, from which there are scarcely any exceptions, that the capacity of the alimentary canal is in proportion to the difficulty of affimulating the kind of food used by the animal. It is, for example, all in those animals that live upon raw fibrous, or woody vegetables; less in those that confume succulent or cooked vegetables; lefs still in those that eat animal food occasionally; and lefs of all in those that subsist exclusively upon flesh, fowl, and eggs.

It should, however, be remembered, that the length of the intestinal canal by no means determines the extent of the digestive apparatus. The length should always be calculated in reference to the width in general of the intestines: the dilatation of particular parts, and the extension of their internal surfaces by folds or valves. The complication of the stomarch, and the perfection of the organs of mufication, should also be considered as influencing any conclusion to be drawn from the length of the intitial canal.

In the truly carnivorous mammalia, the whole tract of the intestines usually exceeds the length of the body, only in the ratio of three, four, or five to one. In the great bat (vivipara vivipara), the intestines are but twice the length of the animal. The proportion of the alimentary tract to the length of the intitial, in this species of bat, is not or twenty-eight. In the lynx, the intitial canal is eight times longer than the body, but then the proportion of the cir-
Mammalia.

eumference to the length of the small intestine, is as one to one hundred and ten; that of the caecum as four to nine; and that of the colon and rectum, taken together, as one to

In the human subject, the length of the intestines is six or seven times that of the body.

In the monkey tribe, this proportion varies from five to eight.

In the lemurs, with the exception of the loris, the intestines vary from four to six times the length of the body. The lemurs, it should be observed, have a larger cæcum than the monkey kind. The loris have still shorter intestines in proportion to their body; but the latter is very long.

Amongst the carnivorous mammals, the vamafyre both has the intestines about seven lengths of its body. It has a complicated stomach and no cæcum.

In the greatest number of the planigrade quadrupeds, the intestines have a considerable length. This is counteracted by the smallness of the canal, and the want of a cæcum. The fœcuses have the intestines short, and in other respects like the carnivorous digitigrade mammals.

In the herbivorous planigrade, the length of the alimentary canal is considerable, besides the addition of the cæcum, but in the rat genus, which live on a mixed food, the length of the intestines does not exceed that of the monkeys.

The intestines are short in the edentata, and very much so in the tardi-grade, which seems hard to explain, as they want the cæcum, and live, neverthelesse, upon vegetable matters. Cuvier supposes that the gallbladder may be particularly alive in the tardi-grade animals.

The echidnas have the intestines seven times its own length. In the armadillos they are only five lengths of the body.

In the elephants, the intestinal canal is only seven times as long as the body, but it is very wide. In the hippopotamus it is nine times as long as the body. In the daman it is about the same.

The ruminating quadrupeds have the longest intestinal canal of all. In the ram it is twenty-seven lengths of the body.

The folivora have the intestines about eight to ten times as long as the body, but the want of extent is amply made up by the prodigious volume of the cæcum and colon.

The fœcuses, although supported by animal food, has the intestinal canal eighteen times as long as its body, the diameter, however, is small, and its stomach is very simple, and its teeth incapable of minutely dividing its food.

The southern lumantin (triclesus australis) has the intestines only about five lengths of its body, although it lives upon vegetables; but it has a complicated stomach furnished with a large gland.

The cetacea have a long alimentary canal, but it is very narrow, and wants the caecum. In the grampus we found the large blood-vealls, as the vena cava and portae, and the aorta, to be nearly the same width of the intestines.

It is curious to observe the occasional difference between the length of the intestines in the wild and tame species of the same genus. Thus, in the wild boar, the body bears the proportion to the intestines of 1 to 9; in the hog, of 1 to 13.5; in the wild cat, it is as 1 to 3; and in the domestic cat, as 1 to 5. This proportion is different in the wild and tame rabbit; the former has it as 1 to 11.4, the latter as 1 to 9.3.

Cuvier has given a very full table of the proportionate lengths of the different parts of the alimentary canal, and also of their circumference, in the third volume of the "Anatomic comparée," to which we shall refer the reader.

The length of the whole intestinal canal, in relation to that of the animal, is greater in mammalia than in the other classes of animals. This unquestionably becomes necessary from the food undergoing a more tedious process of assimilation, but it likewise depends, in a degree, on the more elongated form of the body. This observation particularly applies to fishes, in whom the tail becomes incorporated with the general figure of the animal. To calculate the relation of the intestinal canal to the body, the capacity of the one, in all directions, should be compared with the entire bulk of the other. The length and the width also of the great intestines are greater in proportion to the small intestines of mammalia than in any other class. It is in these animals that the terms of great and small intestines are only indeed appropriate.

The great and small intestines are nearly of the same length in the planigrade quadrupeds; sometimes the former are even longer: for instance, in the paca, the length of the small intestines is to that of the great, as 1 to 1.3, and in the water-rat, as 1 to 1.2. In the bampier and field-rat, it is, however, in the proportion of 2 to 1, and in the Norway rat and common mouse the small intestines are four times the length of the great.

In the bovid quadrupeds there is not a great difference between the length of the two divisions of the intestine in general. What there is, however, is in favour of the small intestines, but it should be recollected that the great intestines are commonly the broadest in the different quadrupeds.

In the omnivorous quadrupeds, the small intestines exceed the great in length somewhat more, although the great are not so much dilated as in the large herbivorous species.

But it is in the carnivorous tribes that the small intestines are very materially longer than the great. Thus, in the lion and jaguar, they bear the proportion of 6 to 1; in the dog and wolf, 5 to 1; in the hyena, 6.2 to 1, &c. In some monkeys, and in the human subject, they are also about 5 to 1, but this is in a degree counteracted by the width of the great intestines.

We shall now proceed to the description of the forms and structure of the intestines in mammalia, which will be necessary to treat a little in detail.

The intestinal canal of the monkey kind approaches in general structure that of the human subject. In the orang-outang, there are both a cæcum and an appendix vermiformis, as in man; but in the other species of monkey the latter is wanting. The cæcum of the orang-outang, according to the representation given of it in Tyron's Anatomy of the Figyn, does not project much out of the line of the intestines; but in the other species of simia, the cæcum forms more of a cul-de-sac than in man, except the gibbon or long-armed ape. The Parian dissectionDavis1 describes the cæcum of the cafipous, or the subgenus callitrix, as being two inches and a half long and one inch wide at the origin, after which it becomes smaller, and ends in a pointed manner. They likewise describe some valves on the inside of the colon of the cafipous, similar to those found in the colon of the gibbon.

The lemurs have the cæcum more elongated than the monkeys. In the lemur macaco, the colon is much wider in the beginning than the small intestines, but afterwards becomes rather lefs. The cæcum is wider than the latter at its origin, but becomes gradually smaller at the end. It is a considerable length, and forms many spiral convolutions, and has a good deal the appearance of a coiled worm. In the tardigrade and slender lemurs, the parities of the intestinal canal are thin, and dilated at intervals into flues; the cæcum is long and but little dilated. The lemurs of Tallas has the great and small intestines about an equal width.
width, except the cæcum, which is long and prodigiously dilated.

In the galagothcebus, the first portion of the colon and the cæcum have three longitudinal bands, which throw them into numerous and regular faces. This faccated part of the gut is very wide compared with the rest. The small intes-tine opens into it at a right angle, about half way between the extremity of the cæcum and the termination of the dilated and faccated part of the colon, which is continuous with the cæcum.

The bats have the great and small intes-tines nearly of the same width, and the internal coat has no transverse folds or valvular conviventes. It has merely villi on the surface, which decline as usual in the great intes-tines. They have no cæcum, but sometimes a flight projection at the origin of the colon. The vampire bat has the first part of the canal wider than the rest, and with very thin coats. It is more contracted and has thicker coats in the rectum, in which there are also some longitudinal folds internally.

The carnivorous placental quadrupeds, except the ichneumons, have the intes-tinal canal nearly of the same width throughout. In general the coats of the rectum are thicker than in the other parts, and there are some longitudinal folds in it. There is no cæcum, but at the part corresponding to it there is a row of mucous glands upon one side of the intes-tine. The internal coat of the canal is more or less villous in the different genera. In the mole, for instance, the villi are short; in the hedge hog they are long in the small intes-tines. The ichneumons have a small proceeds at the origin of the colon, which Cuvier terms a cæcum, but which ought rather, perhaps, to be called an appendix vermiformis. In the figure he has given of this part in the Egyptian ichneumon, it appears a good deal less than the small intes-tine, which is itself not half the diameter of the colon. Hedwig describes the intes-tines of the bear as having long and handfome villi.

Amongst the digitigrade carnivorous quadrupeds, the genus myfsets is distinguished by the want of a cæcum. The otter has a flight dilation at the place where the cæcum might be. The inner membrane is finely villous in the small intes-tines. The folds increase towards the part of the canal corresponding to the great intes-tine, and are again to be found near the anus. The row of intes-tines, which is usually observed to cover a considerable extent of the side of the canal at the origin of the colon, is very striking in this genus.

The other digitigrade carnivorae have always more or less of cul-de-fac at the origin of the colon. Their great intes-tines are however short, and without any faces or dilatations by which the progres of the food is retarded through them. There are, likewise, no valvular conviventes in the small intes-tines, but the inner coat has fine villi. The genus viverra has a short flender cæcum, similar to that of the ichneumon. The small intes-tine has an oblique or a valvular opening, and the inner coat exhibits at that place some marked longitudinal folds.

In the genus felis, the small intes-tines have a much less diameter than the others. The villi are very evident, in some species particularly. In the lion the villi are long and floating. The cæcum in this genus is short, and terminates in an obtuse cone, of which the coats are thick, and contain many mucous glands. There are some longitudinal rugae towards the end of the colon, and in the rectum.

In the dog kind, the villi of the small intes-tines are long. The cæcum forms some curves, which adhere to each other, and to the side of the small intes-tine, by means of the cellular substance, which renders the passage of any substances through it more difficult. There are some longitudinal folds in the great intes-tines, as in the cats. The whole canal is nearly of the same width.

The coats of the intes-tinal canal are thin in the hyena. Their diameter continues to increase from the pylorus to the cæcum. The latter is long and narrow, and has a rounded termination.

In the pedinonous or marsupial animals, there is some variety in the intes-tinal canal. The Virginian opossum has the small intes-tine a third less than the great; they have fine villi internally: there are no rugae or valvulae. The cæcum is not long, and appears to be a proloc gation of the colon. In the marmoset or marine opossum, the small and great intes-tines are about the same diameter; they have some contractions. In the capyrolla, or Mexican opossum, the duodenum is wider than the rest of the small intes-tines. The cæcum is long, straight, and twisted in a spiral manner. The colon is larger at the origin than elsewhere. The brown phalanger (dendrophis orientalis) has the small intes-tines one-third less in diameter than the great. The cæcum is very long, wide, and formed into numerous faccules along the sides, and terminates in a small canal, which Cuvier considers a species of appendix vermiformis.

In the kangaroo rat, the coats of the intes-tines are thin. The small guts have the internal membrane without villi; but it is thrown into very fine folds, which form zig-zags transversely: the cæcum is short, wide, and round. The colon is very large at its origin.

In the large kangaroo the intes-tinal canal differs very much from that of the preceding species. The diameters of the small intes-tines diminish gradually from the duodenum to the ileum. Their inner surface is without rugae, but is villous. The cæcum is capacious, very long, and is facculated by two longitudinal bands, which also extend for some way upon the colon, producing the same effect upon it. The great intes-tine afterwards becomes narrow. The facculated portion of the colon has irregular folds internally, and there are some flight longitudinal rugae in the remainder of the great gut. The intes-tines of the kangaroo referably those of the feligrade quadrupeds, in which tribe we have placed it in other classification.

In the phaloloum, or marsupial rat of New Holland, which also should be clasfied with the feligrade quadrupeds, the whole tract of the intes-tines, even the cæcum, is nearly of the same width. The cæcum is short, round, and smooth; there is an appendix vermiformis which goes off at the angle formed by the small intes-tine with the cæcum. It has a small orifice guarded by a valve. The phaloloum and the porcupine are the only vititates in mammalia which have both a cæcum and a vermiform appendix: in this circumstance they resemble the human subject.

The porcupine has the duodenum very wide, somewhat resembling an additional stomatch. The remainder of the small intes-tines is narrow. The villi of the mucous membrane have the figure of thin conical scales, as in the human intes-tine, but more narrow and prominent. The cæcum is large, divided into two parts by three muscular bands. At the origin of this intes-tine, there is one of those faces much larger than the rest, projecting out of the line formed by the colon with the cæcum. This gut altogether has a good deal the figure of a feythe. The colon has some cells of a smaller size than those of the cæcum.

In the guinea-pig the cæcum is very capacious, and is in a degree curled when it gives origin to the colon, which is almost as wide as the cæcum for a little way, but afterwards gradually contracts to the dimensions of the small intes-tine.
The *paca* and *agouti* resemble the guinea-pig. The opening from the caecum in these animals is contracted by a valve. The colon of the *agouti* forms behind the liver many little concretial convolutions before it terminates in the rectum. The glands at the origin of the colon are very remarkable in the *paca*, forming a thick mafs.

In the *rabbit* and *hare* the small intestines are uniform in their size. They are villous, and have some longitudinal folds internally in the ileum. The caecum is very extensive. It has a conical figure, and exhibits regular contractions upon the surface, which correspond to a spiral fold that interrupts the cavity internally, like the spiral valve in the caecum of the *gric*. The colon is as wide as the caecum at its origin, but very soon contracts; it is faccated at first by three longitudinal bands, and afterwards by only one. The internal coat is smooth in the caecum, papililated in the first portion of the colon, and longitudinally rugous in the rectum.

The *squirrel* has a long cylindrical caecum with smooth papillæ. The *flying squirrel* has a similar intestinal canal, but the caecum ends in a pointed manner.

The *beaver* has a short dilatation at the origin of the duodenum. The caecum is of great size, elongated, and conic. The colon also is very wide at its origin. There are numerous constrictions and dilations throughout the great guts.

The *Pilobus macrurus* has the small intestines straight. The caecum is very voluminous, and divided externally by contractions, and internally by a corresponding number of angular folds. The colon is large at the beginning. The intestines of the *marmot* of the Alps are similar to the preceding.

In the *endrata*, or *musk rat*, the caecum is of a prodigious extent; it passes from the umbilical region to the left iliac; then into the right iliac, extending as far as the hypochondriac region of that side. The colon at its commencement is convoluted in a spiral manner.

The greatest part of the intestinal canal of the *cotar-rat* has a small diameter. The caecum is long and wide, with contractions. The colon is very wide at its origin; it diminishes afterwards, and is twisted in a close spiral manner for a great part of its length. The twisted part of the colon is distinguished by regular folds, which are visible from the outside of the gut. The coats of the whole intestinal canal are thin and transparent in this animal.

The intestinal canal in the *camposagot* (*mus arvalis*) resembles that of the *water-rat*.

The caecum is wide, short, a little curved, and without contractions, in the *black* and *Norway rats*; longer and narrower in the *common mouse*; elongated also, tapering at its extremity, and divided by contractions in the *field rat*. In the *Norway* and *black rat* the colon is at first straight, has thick coats, and some longitudinal folds internally; after which it is dilated, and exhibits, for some way, similar spiral traces to those of the *water-rat*: it then contracts again, and has but a small diameter in the greatest part of its extent towards the anus.

In the *mouse* and *field rat* the colon is wide at the commencement, but afterwards it becomes much contracted. There are oblique or spiral diææ, formed by the folds of the internal membrane.

The *bawler* has the small and great intestines of the same diameter, except where the caecum is formed. Both the ileum and colon open into a dilated part, which produces at one side several spiral turns, and at the other the caecum. This last is of considerable size, and divided into a number of facets by means of one band or cord, which runs along the concave side of this gut.

In the *male rats* the caecum is long and wide, and the colon spirally twisted. The *jerboa* has the caecum formed into three spiral turns.

Amongst the *edentata* there is a good deal of variety to be observed.

In the *three-toed ant-eater* the small intestines are very much puckered by the mefentery, by which the canal is irregularly contracted and dilated, like the great intestines of many animals. The large intestines of this animal form a short, wide, smooth canal; and on each side of the termination of the ileum in this great gut, there is a little process or appendix, with a contracted neck and bulbous head. These appendices correspond in situation to the caeca of birds, with which classes of animals the toothless quadrupeds are allied in many parts of their structure and economy. The caeca of the *ant-eaters* are too small to serve as reservoirs for their food; they communicate with the great intestines by a small orifice, as does also the ileum.

In the *exchaca* the small intestines are about half the width of the great; they have villi, but no valves upon the interior surface. The mucous glands are numerous, and particularly plain from being of a black colour. The caecum is single; it is a short, straight, blunt process.

In the *ormihirapocast* the duodenum is wider than the rest of the intestinal canal, which gradually diminishes to the caecum. This part is a long narrow process or appendix. The great intestines grow wider the nearer they approach the anus. The internal membrane in the small intestines is formed into numerous prominent lamiæ, somewhat like those of fishes; and in the beginning of the great intestines it produces some longitudinal folds.

The *long-tailed manis* has no caecum: the commencement of the colon is distinguished by an increase in the width of the intestine, and the thickness of its coats. There is no caecum likewise in the *fagelins*, or *flor-tailed manis*.

There is no caecum in the *armadillus*, but the great intestine is thicker and wider than the rest of the canal, from which it is separated by a contraction: the small intestines are much puckered and folded by the manner in which the mefentery is attached to them.

The *tardigrade* quadrupeds have the small intestine gathered into irregular dilatations by the mefentery. There is no caecum. The great intestine is distinguished from the small by a sudden dilatation, and a valve internally at the part where the colon commences. The irregular form and contractions of the small intestines, in some of those animals which have the colon short, and want the caecum, are designed apparently to answer the same purposes that a capacity in the great intestines does in other animals.

The *Cape ant-eater* has a short oval caecum.

The *bovid quadrupeds* are remarkable for the capacity of their great intestines. Amongst the *multungulata*, the *elephant* has the colon so large as to cover a great part of the abdominal viscéra; it is folded from side to side, and lies in the front of the other intestines: it is faccated in two rows on each side. The caecum is also very large, and thrown into faces or cells by three muscular bands. The small intestines have an uniform diameter. The ileum terminates by a circular vascular opening in the colon. The internal membrane of both the small intestines and the colon is pliated transversely; in some places it projects so as to form valves; in the rectum the folds are longitudinal. The surface of the internal men brane in the small intestines is covered with fine short papillæ. The coats, more particularly the muscular ones, are very thick.
Mammalia.

In the one-bored rhinoceros the cæcum is very wide, and divided into two parts, as is the colon still more plainly, at least at one part; but the most curious part of the structure of the intestines in this animal is to be observed in the inner coat. In the first portion of that part of the bowel which enters the pylorus and the ducts of the hepatic and pancreatic glands, the mucous membrane forms little projecting longitudinal folds, in the form of segments of a circle. In the next portion of the same part of the gut, these folds become more transverse in their direction, and assume a triangular figure. A little beyond the inferior of the biliary ducts the lining changes to a more numerous, compressed, and irregularly lobed. Farther on is the internal coat a kind of papille, lengthened into filaments, pressed the one against the other, especially about the middle of the length of the small intestine. The extremities of some of these processes are bithil. The inner surface of the cæcum has only the rugae that correspond to the face. The laminae of the outer coat are renewed in the colon; the folds are transverse, and grow larger as they come nearer to the rectum, between which gut and the colon the last lamina forms a valve.

The Cape cow has very singularly formed cæcum and colon; the first of these is a large irregularly shaped bag, which is pucked upon the sides by two longitudinal folds. The ileum opens into it by a projecting contracted orifice, and near the same place the colon arises: there is a valvular fold at the aperture of the colon. This intestine is at first longitudinally and greatly dilated; the inner coat of this portion is smooth, and irregularly plicated, as in the cæcum. The part of the canal succeeding the dilatation is small, has thick parietes, and the inner coat with waved folds, which are at first longitudinal, but afterwards become transverse in their direction. Beyond this portion the colon grows wider, and then becomes irregular in its shape and diameter; it has broad longitudinal folds internally. There next succeeds another enlargement of the colon, from the sides of which arise two pyramidal or cone-shaped processes, which pass in the direction contrary to that of the rest of the gut, in the same manner as the cæcum of birds, to which they bear a considerable resemblance. The colon, after furnishing these two appendices, makes several spiral turns upon itself, and some convolutions in the belly, and terminates in the rectum. This last intestine has thicker coats than the colon, and has in part longitudinal folds internally.

Amongst the birds, the ox has no folds in the interior of the small gut, except in the duodenum, where there are some transverse rugæ or pliaits. The villi have the figure of fine f description of the intestine, according to Cuvier; but we may observe, this structure is by no means uncommon in mammalia. The cæcum is not large: it is first contracted, then dilated, and terminates in a bulb. The inner coat is without rugae, except where it is narrow, and there we find some longitudinal rugæ: the colon is without folds of the inner coat: the rectum has thicker coats; and the inner surface furnishes longitudinal folds, and, very near the anus, some circular ones. The goat has a much larger cæcum in proportion than the ox.

The duodenum of the lama is wide at the commencement, forming an oval sac; the other small intestines are pucked by the mesenterie. The cæcum has a conical shape, and no contractions: the internal membrane of the small intestines has some transverse folds; that of the colon longitudinal ones. In other respects the intestinal canal of the lama resembles that of the ox, as does also the alimentary canal of the other ruminants without horns.

The great intestines are much more capacious in the horse, ox, &c. than in the ruminating quadrupeds; more particularly the cæcum, which is of a prodigious size. This gut is nearly as wide as it is long; and when the excrementitious parts of the food are allowed to accumulate in it and the colon, the abdomen has that tumbid appearance which is seen in oxen and in horses, that are fed only upon hay or straw. The colon begins with a dilatation, not much inferior in size circularly to the cæcum: it is doubled upon itself, and in its course through the abdomen it forms other curves or arches. The great intestines are drawn up into folds; there are large in the first portions of the colon. For a more detailed account of the intestines of the bovise, we shall refer the reader to the anatomy of that animal in this dictionary.

It is said, that in the morse (trichecus rofinorum) the cæcum is situated in the left side of the abdomen. There is no other instance of the kind in mammalia, except in those of transfusion of the vitamina. The cæcum in this animal is very inconsiderable, resembling a mere knob of the intestines. Both the small and great intestines have very nearly the same diameter.

In the southern lamanin the cæcum has a very peculiar figure: it forms the segment of the outline of a circle, or has a crescentic appearance. The ileum communicates with the middle, from which also the colon arises. This intestine is wider at first than the cæcum, and forms some close convolutions; it afterwards proceeds as a slightly twisted canal, and becomes again enlarged near the rectum, which last gut is wider than the colon.

The cetaceae are stated by Cuvier to want the cæcum; but Hunter, however, affirms that it exists in the piked and large whale-bone whales. In the genus delphinus there is certainly no dilatation corresponding to the cæcum: the last intestines are distinguished by their having a smaller diameter, and thicker muscular coats. In the porpoise the internal membrane forms some longitudinal folds, which are not very evident in the small intestines, and decline in the colon and the rectum. The grampus has transverse and longitudinal folds, which produce in some degree the appearance of meshes: these are most plain in the duodenum, and gradually diminish until they disappear. For about ten inches above the anus, the intestine is lined with a thick white cuticle. All the cetaceae, we believe, have the termination of the rectum covered with cuticle, and contracted in size. In the piked whale the inner coat of the duodenum has longitudinal rugæ, at a distance from each other, which receive lateral folds: these decline in the other intestines, and appear to correspond with the meshes of the grampus. The duodenum in the baleena whale swells into a large cavity, which might be called an additional stomach, if it were not that the hepatic ducts terminated in it. The whole of the intestinal canal in this species nearly has the inner coat forming faces or cells, which are again subdivided into smaller cells. These open, or have their mouths directed towards the anus, or in the course of the food through the canal.

The cetaceae, as also all other animals that inhabit exclusively the water, never have any flatus in their intestines. The sperm whale, however, produces a curious excrement, which is called ambergris. This substance is sometimes found floating on the surface of the seas that are frequented by these whales, and at others is taken from their great intestines. When whales are in a healthy state, their excrements are liquid, and of a black colour; but when sickly, the faeces are solid, and accumulate in such quantity in the intestines as to produce a tumour of the abdomen. It is in these cases that the ambergris is obtained from the whale.
Mammalia.

... themselves: it is found in the great intestines, about from two to fix or seven feet from the anus. When taken out, it has the same smell and the black colour of the fluid fixes; but after exposure to the air, it becomes harder, whiter, and acquires its peculiar odour. The pieces of ambergris are of various sizes, from half an ounce weight to 100 lbs. or more. Dr. Sweder relates that one piece weighed 182 lbs., and another 150 lbs., which was worth 500l. The ambergris is found largest and purest in the male cubs. Mr. Hornby found that human faces, by being long digested, acquired so strong a smell of ambergris, that the vessel was obliged to be removed out of the laboratory.

Plate V. of the Anatomy of Mammalia, represents the most remarkable varieties in the form of the intestines. Fig. 1 is the caecum and appendix vermiformis of the orang-outang; a, the ileum; b, the cul-de-sac, which takes the place of caecum; c, the colon; d, the appendix vermiformis. Fig. 2 shews the same parts in the phascolomys. The appendix is seen to communicate with the gut by a valvular opening. Fig. 3 is the origin of the great intestines in the lemury macaco: a, the small intestine; b, the colon; c, e, the long convoluted vermiform process, corresponding to the caecum. Fig. 4 is taken from the ornithorhynchus paradoxa: a, the small intestine; b, the colon; c, e, the straight appendix, which has been considered analogous to the vermiform. Upon the same side of the gut a number of black specks are visible, which are produced by mucous glands, they appearing of a dark colour in this animal. Fig. 5, exhibits the caecum and parts adjacent in the rabbit: a, the small intestine; b, the caecum; c, the colon. The figure being drawn from a dried preparation, the course of the spiral membrane is seen through the coats of the great intestines. Fig. 6, represents some coils of the small intestine, and the commencement of the great intestine, with a portion of the latter in the three-toed ant-eater: a, the small intestine, very irregularly formed; b, the great intestine; c, e, the two curious caeca peculiar to this animal. Fig. 7 is intended to shew the caeca in the Cafe cavy: a is the ileum; b, the cul-de-sac, corresponding to caecum from which the colon arises; c, the colon doubled upon itself at its origin. Fig. 8 represents the two additional processes which are produced by the great intestine of this animal: a, a, are some of the spiral turns of the colon at this place; b, b, the two sharp processes, resembling the caeca of birds; c, the continuation of the gut, after it has furnished these two caeca.

Lever.—This vefus is, in proportion, rather less bulky generally in mammalia than it is in man. It is usually divided more deeply into lobes, and these are also, in many species, more numerous. The division of the liver into several, almost distinct lobes, has been chiefly observed in the beasts of prey, and an opinion has been entertained by some, which was first advanced, we believe, by Monroee, that it was necessary, on account of the sudden and extensive flexions of the spine in these animals when running. Cuvier has inferred the number of lobes that are found in a great many species, from which we have composed the following table.

The lobes of the liver in mammalia, from being more distinct, are thinner in their form, and have sharper edges than in the human subject. Differences in the figure of this viscus are, however, immaterial, as they do not affect its functions.

The intimate structure of the liver is essentially the same in man and mammalia. The last branches of the efferent terminate in both in the same manner, and give origin to the excretory ducts.

The chief varieties in the biliary system of mammalia are produced by the number and situation of the trunks of the hepatic ducts, and the absence of the gall-bag.

The gall-bag is not found in the following instances: viz., many of the feline grade order, as the common rats and mice; the baukeeper, the mus luscinus, mus minutus, mus agrarius, mus mongaric, mus phoxus, mus forswita, mus acrodea; in the Hudson's Bay porcupine (hydridus donstica); all the tardigrade mammalia; amongst the many-hoofed quadrupeds, the elephant, the rhinoceros, the dama, and the pears. Of the ruminants, the camel, dromedary, and buffalo; all the folideaps; the northern lamantin; and the cetacea, according to Hunter, although Cuvier only states the porpoise and dolphin as wanting the gall-bag.

In some mammalia there is a dilatation in the course of the bile to the intestine, which may answer some of the purposes of the gall-bag. This dilated part is most remarkable in the elephant, on account of the numerous divisions in it. Upon the biliary duct entering the coats of the duodenum, it becomes enlarged into an oval sac, which is irregularly divided interiorly: some of the septa are placed nearly transversely, but in such a manner as to produce the effect of a spiral valve. They create four principal divisions: two other septa placed at the separation of the biliary duct of the first, in the longitudinal direction, form as many more pouches. There is at last, a small cell which proceeds the four principal ones, and which opens into the biliary duct of the head. It receives the orifice of the pancreatic duct upon its side, and that of the biliary duct in the direction of its axis. This orifice of the bile and pancreatic juice opens into the intestine by a moderately small orifice.

In the horse, the cat, &c., the biliary duct becomes very much dilated before it reaches the duodenum. In the northern lamantin the hepatic duct likewise is greatly enlarged, and receives the pancreatic duct before it passes into the intestine.

We have observed that the biliary duct of the grampus enlarges, before its termination, in what has been called the fifth stomach. The same has been noticed by Hunter in the ruminants generally.

Vol. XXII.
**Mammalia.**

In the *echidna* there are three hepatic ducts joined to the cystic, near the neck of the gall-bag. The cystic is large, and appears to form the ductus communis.

In the *ornithorhynchus* there are two hepatic ducts which end in the cystic in the same manner.

The *elephant* has nine or ten branches from the liver; these form three trunks, which unite again, and make but one. It is inserted into the duodenum, and there suffers the remarkable dilatation previously described.

In the *fowl* one hepatic duct joins the cystic near the neck of the bladder, the other at some distance from it.

In some species the hepatic ducts terminate directly in the body or neck of the gall-bag. This has been particularly remarked in the ox and *sheep*, in which animals there are several short ducts leading from the liver chiefly into the neck of the gall-bag, resembling what is found in some fishes. A similar structure has also been described in the *cows*, *dogs*, *hedge-hogs*, and *hams*; but in these animals the hepatic ducts rather should be considered perhaps as entering the origin of the cystic duct than the gall-bag itself. In the *vampire bat* there is but one hepatic duct.

It terminates in the commencement of the cystic. In all these cases the cystic duct must be considered as supplying the place of the ductus communis choledochus. The design of the hepatic ducts opening into the body or neck of the gall-bag, is obviously to produce a more concentrated fluid of the bile by retaining its progress into the intestine; but it is difficult to explain why this effect should be necessary to animals in whom the organs of digestion, and the quality of the food are so very different.

The existence of a gall-bag, whether the bile be conveyed directly into it, or by regurgitation through the same duct that carries the cystic bile out again, has necessarily the consequence of increasing the peculiar properties of the bilious fluid; it being found that all secretions, when accumulated in elevators, become more concentrated by having their aqueous parts absorbed. It would seem that the presence of cystic bile is required more especially to carnivorous animals that have a rapid digestion, as the gall-bag is only wanting in vegetable eaters, if we except the *cetacea*.

The distance from the pylorus at which the bile is poured into the intestine, was formerly considered as determining the digestive powers of the animal, it being supposed that the biliary duct opened nearest the pylorus in the most carnivorous quadrupeds. A further knowledge of comparative anatomy has shown that no general conclusion of this kind can be drawn. There is great variety, even amongst animals nearly allied in other circumstances, with respect to the situation of the orifice of the biliary duct in the duodenum. Cuvier states that it is nearer the pylorus in the *fistigata* quadrupeds generally, than in other mammals, and at the same time the farthest removed in the *kangaroo*, which belongs to the same order.

In Plate VI. of the *Anatomy of Mammalia*, fig. 1, represents the face into which the biliary and pancreatic fluids are poured in the *elephant*: *a* is the hepatic duct, formed by two branches, which are composed of nine or ten lesser ones; *b*, the pancreatic duct which passes to the cellular receptacle of the bile; *c* is that receptacle laid open, in the cavity of which the septa and apartments already described are to be perceived; *d*, the parietes of the duodenum. *Fig. 2.* exhibits the receptacle of the bile and pancreatic fluids in the *ostrich*: *a*, the biliary duct; *b*, the pancreatic duct; *c*, the external form of the receptacle; *d*, a portion of the duodenum.

Pancreas.—In most mammals this viscus has lobes, branches, or processes, which make its form different from that of the human subject.

In the *orang-outang* the pancreas resembles, in its figure, the same gland in man. It has an irregular form in the *Barbary ape*. In the other *monkeys*, the end towards the right side is divided into several processes.

In the *moles*, *hedge-hogs*, *raccoons*, and *bears*, there are two branches or processes in the right end of the pancreas. The *badger* has it bent into an arch. In the *ferreus*, the left end is separated into two forked processes.

The *cat* genus has the pancreas composed of two irregular shaped lobes, the smaller one accompanies the duodenum from before backwards. The larger lobe is situated transversely. The *dog* has the gland formed nearly in the same way. The *martin* (philylea* philylea*) has the pancreas doubled upon itself, so as to resemble, according to Cuvier, an overthrown figure of G, thus %.

In the *cervera gazella*, and *cervera zibethica*, this gland is a thick, compact, broad band, which reaches from the duodenum to the spleen.

In the *bears*, the pancreas is long and thin, and accompanied by the convolutions of the duodenum. In the *water rat* the pancreas has three long thin branches.

The *echidna* has several branches or processes.

The pancreas of the *elephant* is long and narrow, and without any offsets; it is said to be 6 feet long.

In the *ox* this gland has the figure of a lozenge.

The pancreas of the *boar* has an irregular figure, and three processes.

In the *fowl* the pancreas has dilated lobes.

The *northern lamanin* has two branches to the pancreas.

In the *cetacea*, at least the *genus* *delphis*, there is an irregular shaped pancreas, consisting of some roundish lobes matted together. The gland is small, in proportion to the size of the animals.

However the form of this gland may differ in the various genera of mammalia, the organization is uniformly the same in all, and does not differ from that of the human pancreas.

As the pancreas of mammalia has frequently branches or lobes, the excreatory duct is often found made up of several others.

The *orang-outang* has the duct formed as in man, and ending in common with the ductus communis choledochus. The pancreatic and biliary ducts are in the other *monkeys* united in some species, and distinct in others.

The *dog* has commonly two pancreatic ducts, one united with the common biliary duct, and the other passes into the duodenum, a little distance farther on. In the *cat*, the biliary and pancreatic ducts enter together. The *panther* has them separate, and the duct of the pancreas penetrates the intestine after the other. The biliary and pancreatic ducts unite, however, generally in the *carinivorus* quadrupeds.

They are dilated in the *porcupine*, and enter the intestine at some distance from each other. They are also remote in the *bears*. In the *marmot* the ducts are separate, but enter the intestine near each other. The *flying squirrels*, *kangaroos*, and many other *fistigata* mammals, have but one orifice for the biliary and pancreatic ducts.

In the *elephant* the pancreatic duct has two principal branches, one opening into the beginning of the dilated part of the biliary duct, and the other passes into the duodenum at a little distance.

In the *elephant*, the pancreatic ducts are commonly united.

In the *boar* they are separate, although close to each other.
MAMMALIA.

In the northern lamantin, and in the genus delphinus, these ducts are united.

If one may judge from the variety that is to be observed, with respect to the infection of the biliary and pancreatic ducts, both as to their conjugation, and the distance of their orifices from the pylorus; these circumstances are unimportant in themselves, and have very little concern with the functions of the pancreas or liver.

In fig. 5, Plate IV. of the Anatomy of Mammalia, the letter $b$ indicates the pancreas of the porpoise. In Plate VI. fig. 3. exhibits the curious form of the pancreas in the mar- tin (mustela foina).

Spleen.—The situation of this organ is as nearly as possible the same in all mammals. It is always attached to the great or left end of the stomach, when the latter is a simple cavity; and when it is composed of more than one cavity, the spleen is connected with the first stomach, or that in which the cardia terminates. Thus, in the ruminating quadrupeds, the spleen is placed on the left side of the paunch, and in the cetacea upon the first cavity, or that which is the receptacle of the food in those animals. It is retained in its situation by reflections of its peritoneal coat, and is likewise connected by its blood-vessels with those of the first cavity, or that of the greatest end of the paunch.

The form of the spleen is very variable, and is likewise subject to a change of bulk, and, in a degree, of figure, according to the different states of the disposition or fulness of the stomach; it being well known that the spleen, from its spongy structure, is easily comprized by the adjoining visera.

Cuvier has inferred the figure of the spleen, as he found it in several species. We shall extract the following from his "Anatomie comparée."

The monkey kind differ much with respect to the shape of this organ; thus it is triangular in the long-armed ape, the gibbons, the baboon, the femia apes, the orang ape, and the thynus, &c. It is broad posteriorly, and divided into two lobes in the Chinese ape, and Barbary ape. It is long and narrow in the swelling monkey, and in the ring-tailed macaque, the lemur mongoz, and the lemur macaco. It is broader posteriorly than before in the tardigrade lemur. It is very long, and has the figure of a triangular prism, in the bowloing baboon. In the lemur tarus, the spleen has the figure of an irregular leaf, at the end of the stomach.

The carnivorous quadrupeds generally have this viscus long and narrow, prismatic or flattened. It has a similar figure in the badger, the mole, the porcupine, hedgehog, &c.

In the galapiteles variegatus, and Virginian opossum, it is triangular. In the brown phalanger it is in three lobes, and has a similar figure in the Mexican opossum, and the marmoset (dietphila murina).

The spleen is large and oval in the weasel.

This organ is triangular, broad, and flat, in the kangaroo rat, water rat, and guinea-pig. Very long, very narrow, and thin in the great kangaroo; long and narrow in the normet, common rats, and hares. The figure of the spleen is said to vary in different individuals of the porcupine.

The echidna has three branches to the spleen. It is larger than the stomach in the ornithorynchus, and feline.

The spleen is very long in the elephant and hog; broad and flat in the rhinoceros; of a similar form in the danae.

It is round and flat in the hog; thin and oval in the gazelle; flat, large, and fibrous in the hanna. It is broad and thin in most of the other ruminating quadrupeds.

The boar has a flat triangular spleen.

The most remarkable deviation of structure is found in the cetacea. The porpoise and delphin have, according to Cuvier, seven small round spleens of various sizes, from the bulk of a chestnut to that of a grain of corn. We have counted but five spleens in the porpoise. It is probable they vary both in number and size. They are scattered over the first stomach in the course of its blood-vessels, from which they receive their branches. In the granum we did not observe these small spleens, but found a long series of a spongy substance, which appeared to be the pulp. We do not wish, however, to speak positively, as it was pale and clearer in its texture than the spleens of other animals, and the parts filling this were so much injured in being taken out of the animal, that we could not satisfactorily make out their connections. This stripe was two feet long, and about one inch broad for its greatest extent. Towards the root it becomes gradually wider, and where it appears to originate, it is three inches broad. Hunter states the spleen in the whales to be very small.

The variations as to bulk are not very material in the spleens of mammalia; the herbivorous quadrupeds appear to have the organ largest, and perhaps the cetacea should be considered as having the smallest spleen.

The colour of this viscus is generally deeper in mammalia than in the human subject.

No satisfactory account has yet been published of the internal situation of the spleen in mammalia. As far as our observation extends, the organization is essentially the same in this class of animals as in man. In the spleen of the ox, sheep, boar, and hog, &c., the cellular structure described by Malpighi and Stukely is more apparent than in man, or the small quadrupeds; and the ramifications of the blood-vessels upon these cells is discoverable. Mr. Home relates that he saw these cells very distinctly when in a distended state. He says that the roots of the splenic vein arise from the outside of the cells at right angles to their circumference, like roots. When the injection has not been very minute, they are seen to arise at so many points of the capsule: but when the injection has got into smaller branches, their number is so much increased, that they appear to form plexuses round the cells. Mr. Home also found invariably that the grains described as glands by Malpighi, and called corpuscles by Cuvier, are distinct cells, which contain a fluid, when the stomach had received an unusual quantity of liquors. This fluid was evaporated by puncturing the cell, when their membranous coat became visible. Mr. Home further ascertained, that the trunk of the splenic vein, compared with that of the artery, was in the proportion of five to one in its fibre, by which it appears that the veins of the spleen exceed the size of its arteries in a greater degree than is observed in the other organs of the body. Much, however, remains to be done in order to explain the anatomy of the spleen. To us the cells have appeared of different sizes, and to have a very free communication with each other, by which the organ, particularly towards the surface, resembles a good deal the texture of a sponge. We are doubtful whether the cells have coats proper to themselves, or whether they are not formed by the interstices of the parenchymatus substance. The blood-vessels appear to communicate with the cells only by their ultimate and most minute ramifications. Cuvier states that the texture of the spleen is very loose in the ornithorynchus, and that its vessels are much developed.

Fig. 5; Plate IV. of the Anatomy of Mammalia, gives a view of some of the spleens of the porpoise upon the first stomach, as pointed out by the letters $b, b_{1}, b_{2}$. 

Peritoneum and its Pouches.—This membrane has the same structure in mammalia as in man; but the reflections of it, which form the omentum, and the envelopes of the intesti-
telinal canal, differ considerably in their figure and extent in some quadrupeds. The form and extent of the mesentery, mesocolon, and mesorectum, depend upon the length and convolutions of the small and great intestines, and may be in some measure calculated from the previous description of the intesinal canal. The tubes of these parts are precisely the same as in man.

The great omentum varies in length in different mammalia, but in most of them it is longer than in the human subject. In some species it not only covers the front of the intestines, but extends into the pelvis, and is reflected forwards the length of the rectum. This reflection of the omentum is attached to the bladder, rectum, mesorectum, and to the sides of the peritoneum. The omentum is thus extended in many species of monkey, but the length of this membrane does not correspond with the agreement of the animals in general structure. Species nearly allied have it very different; for instance, in the brown bear, it does not pass below the middle of the abdomen, and in the racoon and badger it reaches to the pubis.

The layers of the omentum have not always the same origin and connections as in man, which arise from the want or the preference of the transverse mesocolon. There is no omentum to the colon, or appendices epiploicae in the carnivorous mammalia.

The ruminating quadrupeds have the cavity of the principal omentum very large. It includes the four stomachs, the duodenum, and the pancreas.

The fat, which is deposited between the layers of the omenta, is found in all mammalia, but in greater quantity in the herbivorous than in the carnivorous tribes.

Some of the herbivorous quadrupeds; for instance, the Alpian and Poilb marmots, the ocellus (mus citellus), the fat squirrel (myopus glis of Gmelin), and the jerboa, have lateral omenta in addition to those of other mammalia. These arise from the loins, cover the sides of the abdomen, sometimes even coming as far as the middle of the belly. About the period of hibernation, these processes of the peritoneum become, as well as the other omenta, loaded with fat, which is expended during the time that the animals remain torpid. The use of the lateral omenta is, therefore, sufficiently obvious, and yet it is very extraordinary, that they should be wanting in other species that sleep during the winter, some of whom also are nearly allied to those above mentioned; as, for instance, the garden squirrel (myopus nictita), the common dormouse (myopus myladarum), &c.

Ab sorbent S ystem.—This part of the anatomy of mammalia so much resembles what has been discovered in the human subject, that there has been no inducement to investigate it minutely; we, therefore, solely pass over the detailed account of the absorbent system of this class of animals.

The chief varieties which have been observed, relate to the number and situation of the absorbent glands, and the form of the thoracic duct.

The glands are most numerous, generally speaking, in quadrupeds than man: they are also commonly larger. The mesenteric glands are perhaps in most quadrupeds afflicted together into one or more masses; besides these masses, there are often some distinct glands in the mesentery. It is at the root of the mesentery that the glands are congregated into the chief mafs. They are connected with each other by means of cellular substance, and present an unequal surface externally. The assemblage of the mesenteric glands was mistaken for a pancreas by Professor, and have ever since retained the name of pancreas Aëllii. In the bear, the mole, the brown phalanger, &c., there is only one mass. The cat kind, and perhaps all the digitigrade quadrupeds, have one principal mass or cluster at the root of the mesentery, and near this some smaller ones. Cuvier states them to be the same in the dolphin. The pancreas Aëllii is very large, and of an inelated figure in the seal. There are two masses of the mesenteric glands in the weasel.

In the flying lemur, the common rat, and the cloven-footed quadrupeds, the glands are dispersed over the mesentery. We have found them so likewise in the granpus. It is probably the same in the other cetacea. The cellular structure of the absorbent glands is very apparent in the bose, aff, &c.

A very singular structure has been described in the mesenteric glands of the abode by Mr. Abernethy. He represented them as forming round bags, about the size of an orange; these bags contained a limy fluid, which was apparently a secretion of their own. The bags not only terminated in these bags, but formed a plexus upon their surface. The blood-vessels likewise ramified upon the coats, and communicated with the cavity of the bags, so that a waxen injection passed into it. We feel inclined to consider the cysts described by Mr. Abernethy on the mesentery of the abode as a morbid structure, as we have found nothing of the same kind in those cetacea we have dissected, and as it has not been observed by Hunter, Cuvier, Blumenbach, or any other comparative anatomist, as far as we know.

The thoracic duct has generally in mammalia a considerable dilatation of its origin, or a large receptaculum chyli. The bulk and course of the thoracic duct are liable to vary amongst individuals of the same species, more particularly in domestic quadrupeds. Sometimes there is an annular dilatation at the upper part of the thoracic duct in the dog, which has been represented by Vana Bils as a conical structure, which he called the receptaculum tortiform. The thoracic duct is double in some quadrupeds. It is so in the dog. Cuvier describes the duct in the dolphin as being complicated, and at last terminating in two branches, which open beside each other into the jugular veins. Mr. Home found in the sea otter the receptaculum chyli large, and the thoracic duct composed of two tortuous branches, which make many convolutions and communications with each other, and terminate separately.

Mr. Bracy Clarke has stated, that he found the thoracic duct of the bose forming several lateral communications at the lower part with the lumbar veins. (See Anatomy, Veterinary, in this dictionary.) We cannot, however, help doubting the accuracy of the observation, as this fact would form so extraordinary an exception to the fyllem of absorption, as it has been proved to exist in all the higher classes of animals.

Doubtless there are many varieties in the form of the thoracic duct, and the distribution of the absorbent vessels in mammalia, which have not yet been observed: but as they probably would not throw any light upon the function of absorption, they are of but little importance.

Heart.—This organ in mammalia corresponds in all material circumstances with the heart of the human subject. It is in every instance enclosed in a pericardium, notwithstanding Blainius, Peyer,Harder,Tozzetti, &c. have reported that this membrane is wanting in the hedgehog, Blumenbach accounts for these anamolies having made such a miscon from the thimose of the pericardium in the hedgehog; but to us this membrane has appeared not to be unusually thin, confusing the fyllem of the animal.

The position of the heart in the body is rather different from that of man. It is situated more in the direction of the animal's body, and rests rather upon the sternum than the diaphragm. We ought to except from this observation the
the heart of the *Carangius*, which is placed obliquely in the breast, with the point turned towards the left side, as in man. It must have been from the dilatation of the veins that the cavities of the heart first received the names of right and left, which are not strictly applicable to their situation in the human subject.

There are some differences in the relative size of the cavities of the heart, and in the thickness of the parietes of the right and left ventricles in *mammalia*, which are pointed out by Cuvier. He has also described some variations in the form of the valves. As these are unimportant, we shall refer the reader to Cuvier's "Anatomic comparée," tom. iv. for the details. It is necessary to state that the valve of *Euallium* is not found to exist in certain species; as the *lion*, the *bear*, and the *perezius*. It is strong and muscular in the *ficul.

In the *elephant* this valve is spiral, and is continued for the length of the supraventricular parietes of the ventricle, with the left and posterior extremity of another broad semilunar valve, which separates the orifice of the right and anterior venae cava from the cavity of the appendix of the auricle.

There are two superior, or more properly speaking anterior, venae cavae in the *elephant*; one left, the other right. The first opens into the sinuses of the auricle, near the mouth of the ventricle. The same is observed in the *perezius*. The *kangaroo* has also two superior or anterior cavae. Mr. Carli has shown that the *hybernating quadrupeds* have the superior cava divided into two trunk; the left palaeus over the left auricle of the heart, and opens into the inferior part of the auricle near to the orifice of the inferior venae cava. In some of the *ruminating quadrupeds*, and in the *pig*, there are two small flat bones at the origin of the aorta from the heart. It has been supposed that they supported the aortic valves. See C. J. Keuchen de Officulis et Cordibus Animalium.

A very common error, with respect to the anatomy of the heart, is the supposition that the quadrupeds which inhabit the water, and the *cetacea*, have the foramina diachora much unclosed, that the two auricles communicate. The opinion has received some support from this communication being actually found to exist in a very few instances. Blumenbach relates that he was prefent with the heart of a *wal*, in which not only the foramen ovale, but the ductus arteriosus remained unclosed. Seger found the ductus arteriosus open also in the same animal. (Ephem. Nat. Car. I. 1. an. 9.) The foramen ovale has been seen in an open flat twice by Mr. Home, in the *sea otter*. In the other numerous dilatations which have been made by the most expert anatomists of the *diving quadrupeds* and the cetaceae, the heart has been observed to possess the four cavities separate, as in man and the other mammalia. Our own experience is sufficiently abundant to enable us to conclude that any communication between the cavities of the heart in these animals is not a natural or necessary structure. That it may occasionally exist is not improbable, and that these animals may be particularly liable, from their habits, to such malformations of the heart, seems also not unlikely; but it would be absurd to found an opinion upon the observation of a fact so well known to be the general rule. We might further add, that the foramen ovale is frequently found more or less unclosed in the human subject, without having occasioned any embarrassment or peculiarity in the pulmonary circulation during the life of the person. We have observed, that it is even more commonly imperfectly closed than otherwise in the human subject. In most dead bodies that we have examined, we could at least pass a probe obliquely from the right into the left auricle.

The otter has been reported to have three communications between the auricles; but these were nothing more than the foramina Thibetica, perhaps in an enlarged state.

The external form of the heart is in some species elongated, in others broad. The point is blunter or rounder in some than others, but these varieties do not merit a particular notice. In the *laminaria* the figure of this organ is, however, very peculiar. It is much broader than it is long. The ventricles are actually separated half way from their end, so that there are two points or apices to the heart.

**Arteries.**—The structure of these vessels is perfectly similar in man and *mammalia*. They consist of the same number of coats, and in general have a similar relation in their diameter and the thickness of their parietes. The quadrupeds that inhabit rivers or the sea, and the *cetacea*, are distinguished by a large size of their blood-vessels, in proportion to that of the entire bulk, or the size of the other organs of the body. In some *cetacea* the principal trunks have a diameter nearly equal to that of the intestinal canal. The branches of the blood-vessels also in these animals are very large in proportion to the trunks from which they arise. The circulation appears to be much less free in aquatic animals than others, and hence the great size of the vessels and the accumulation of blood in *fishes*, which circumstances are also to be observed in a less degree amongst those mammiferous animals that live in the water. It seems to us, that the arteries of the *cetacea* *mammalia* have thinner coats than in other animals of the same class, according to the size of the vessels.

The *pulmonary artery* in the *cetacea*, however, has nearly as strong coats as the aorta.

The chief varieties to be noticed in the arteries of *mammalia* are the different origins of the trunks; the greater size of particular vessels; and the plexuses that are formed in certain species.

The *aorta* in the *ruminating quadrupeds*, the *horse*, the *rhinoceros*, the *hog*, the *pecari*, and probably in other animals not yet discovered, divides almost immediately upon its origin into two large trunks. One of these, which is the smaller, proceeds upwards, or more properly forward, in the body of a quadruped; and it corresponds to the right of the aorta, and furnishes the same branches. The other trunk goes backwards, and takes the place of the descending aorta.

The first branches of the *aorta* have different origins in *mammalia*. In the *maron* and *guinea-pig*, the arch furnishes only two primary branches. One of these, with the carotids, and then ends in the right subclavian. The other is the left subclavian artery. Sometimes the first of these branches very soon separates into two others, one of which is the left carotid, and the other produces the right carotid and subclavian. In other cases, the first of the primary arteries of the aorta furnishes a branch which divides into the two carotids. The remainder of the artery is the right subclavian. This last mentioned distribution exists in the *lion*, *dog*, *cat*, and *bear*.

In the *dolphin*, each of the two primary branches of the arch of the aorta furnishes the arteries of the head, and inferior extremity, on its proper side. The *fis* has three principal trunks from the arch of the *aorta*: the first is the common trunk of the right carotid and subclavian, the second the left carotid, and the left subclavian.

The *elephant* has three branches from the arch of the aorta also. The lateral vessels are the two subclavian arteries. The middle one divides into the two carotids.

The *goat* has the aorta divided, as already described, into the ascending and descending, or the anterior and posterior, more properly called. The anterior divides into three branches:
branches; the left subclavian; the right; and a trunk that forms the two carotids.

The anterior aorta of the horse soon bifurcates into two branches; the trunk of the two carotids and the right subclavian arise from one branch; the other terminates in the left subclavian.

The inferior thyroidal artery is not commonly in quadrupeds a branch of the subclavian, but of the carotid higher up. This distribution arises from the length of the neck, removing the thyroid gland far from the usual origin of this vessel.

In the apсидom, the kangaroo, and as it would appear in all the mammal quadrupeds, the brachial artery divides very high up into the ulnar and radial arteries; in some instances as high as the middle of the humerus. The ulnar is a large vessel, and passes through a hole formed in the internal condyle of the os humeri, and proceeds from the back of the arm to the front, where it is distributed in the usual manner. Cuvier states that the brachial artery forms several branches for the supply of the portion of the fin corresponding to the fore arm in the dolphin. The very remarkable plexus which the brachial artery furnishes in the tardigrade quadrupeds, will be noticed hereafter, along with the other arterial plexuses.

Dunherton has described in the feeding or phlebior auris of the porc a large dilatation, which appears to have been an aneurism. Typhon found in the same animal three dilatations in the course of this vessel. They were divided into cells. These enlargements were probably also a morbid structure, as they have not since been observed by other anatomists.

There are some varieties to be noticed in the branches of the celiac and mesentric arteries. In the cat the celiac sends off a branch to the right renal capsule, previous to its supplying the hepatic, the coronary of the stomach, and the spleen. In the porcupine the celiac divides into two branches; one furnishes the artery of the spleen, and a large branch to the pancreas; the other gives the hepatic and coronary.

The two mesentric arteries are always found; but when there is no marked distinction of great and small intestines, the one corresponding to the inferior mesenteric is very small. This vessel is almost exclusively distributed to the rectum in the bear. In the ruminating quadrupeds the primary branches of the superior mesenteric artery are numerous. They do not consequently form such frequent anastomoses as exist commonly. The inferior, or, as it should be called in quadrupeds, the phlebior mesentric artery, is small in these animals, and almost confined to the rectum. The remarkable anastomosis between the two mesenteric arteries on the colon is not found.

In the fox, the left kidney receives two arteries from the aorta, and the right only one, according to Cuvier. This not improbably may have been a variety.

The middle artery of the fractum, which is so inconsiderable in man, is often very large in mammalia, as it conveys almost the whole of the blood to the tail. In the kangaroo, bear, lion, dog, &c. it has been observed not to arise from the aorta, but to be furnished by a short short trunk proceeding from the bifurcation of the aorta, which also in these canes sends off the fora iliacus and the hypogastric arteries. The artery of the tail is as large in the kangaroo as the internal iliac. This vessel is of great magnitude also in the opossum. It runs along the under surface of the tail, protected by a number of small bones, which are attached to the caudal vertebrae, to near the extremity of the tail, and form by their opposition a sort of triangular conduit, similar to that including the termination of the aorta in the tail of fishes.

The artery of the tail might properly be considered the continuation of the abdominal aorta in the cetacea; it sends off a great many branches which anastomose with each other, and unite again in a small branch under the two last caudal vertebrae.

The primary iliac arteries frequently do not exist in the elephant-legged quadrupeds, the cet and dog kind, the bears, the kangaroo, &c. The external iliacs are formed by the bifurcation of the aorta, and the internal iliacs arise from a common trunk, as already mentioned. They are much smaller than the external iliacs, and separate into two principal branches, which send off the customary arteries of the internal iliac, except the ilio lumbalis, which comes in these infinances from the external iliacs.

In the sal the ilie-lumbales arise from the aorta before the primary iliacs are produced.

In the cetacea there are no arteries analogous to the external iliacs. The aorta sends off arteries which correspond to the internal iliacs, which only supply the bladder and genital organs.

We shall now notice the different plexuses which the arteries form in mammalia.

In the digitigrade quadrupeds, some of the ruminants, &c. the branches of the carotid, which go to meet the biliary artery, form so remarkable a plexus, that it was called by the older anatomists reta meridiales. These branches of the carotid are suddenly divided into an immense number of small vesseis, which are twisted and united together like a plexus of nerves. These plexuses fill up the hides of the feline turcuses, and afterwards reproduce the two branches that, unite with the biliary artery, establish what is called the circle of Willis. It is not known in how many species the reta meridiales exist; it was formerly supposed to be universal in mammalia. The Purinian dissectors do not find it in the monkey, and Cuvier says it does not exist in the elephant and beaver.

Mr. Carile has mentioned a similar plexus of the carotid artery near the jaws in the lion, ox, and sheep.

We have observed in the grampus a very intricate plexus of vessels around the articulation of the lower jaw. We did not ascertain whether the vessels were arterial or venous; they appeared to be both, and were lost in the appearance of ligamentous cells.

The intercostal arteries in cetacea form a very remarkable plexus. It appears to be made by the convolution of one vessel, which measures several hundred feet in length.

The arteries of the spinal marrow also in cetacea, are converted into a close plexus throughout the greater part of the spinal canal. In the grampus, the section of the fifth of the spinal marrow exhibits a number of the orifices of these vessels all round it.

But the most interesting arterial plexuses, are those described by Mr. Carile in the limbs of the slow-moving animals. In all these, as well as the tardigrade lenius, as the flotta, the axillary and diae arteries produce a plexus of undulating branches, which vary in number according to the species. Mr. Carile describes the trunks of the arteries as being expended in the formation of the plexuses; but we have ascertained that the trunk of the vessel is continued beneath the plexus, in the same manner as in the plexus of the anterior tibial artery in birds where the trunk is scarcely diminished. The vessels composing the plexus in the anterior extremity of the lenius tardigrades amount to 23. In the inguinal fascicles there are 17. These vessels have the same size throughout their course, and occasionally anastomose with each other.

The brachial and inguinal plexuses are larger in the great American flotta than in the tardigrade lenius. In the first Mr. Carile counted 42 vessels, and computed from the bulk that there...
there might have been above 30 more concealed in the middle of the fasciculus. He reckoned only 34 in the thigh, and those of the first series were larger than the rest. The plexus of the axillary artery in the two toxoc fleshy is very inconsiderable, and disappears in the upper part of the humerus, although in the other innerves it reaches to the elbow. The inguinal plexus also in this animal contains but eight vessels, which soon begin to ramify in the usual arboraceous form.

In the lori (lemur gracilis) there are brachial and inguinal plexuses, the vessels of which appear to form fewer anastomoses than in the other animals. From the agreement in the distribution of the arteries in the limbs of the slow-moving animals, it is impossible not to admit Mr. Carliole’s supposition, that this peculiar arrangement of vessels is necessarily connected with the flow operation of the muscles in the quadrupeds, although we cannot perceive why such a connection should exist.

The rete mirabile has evidently the effect of regarding the current of the blood to the brain, which may be more necessary to quadrupeds, from the frequent low position of the head, than in man and the monkey, where this plexus does not exist.

It is difficult to account for the intercostal, spinal, and mammary plexuses of the cetacea, unless we suppose that they serve as reservoirs of the blood, or rather prevent an accumulation of blood in larger vessels, which might arise from their continual residence in the water, and frequent suspension of their respiration.

In Plate VI. of the Anatomy of Mammalia, fig. 4. represents the rete mirabile of the carotids in the calf, somewhat above the natural size; a, the saphenous, a little pared away, to show more plainly the plexus, b, on each side; c, c, are the carotid arteries; d, the basilic. Fig. 5. of the same plate, is to show the axillary plexuses of the tarsih grade lemna; a is the trunk of the axillary artery; b, the plexus; c, c, the arteries of the fore-arm reuniting their proper form. Fig. 6. exhibits the plexus of the iliac artery in the same animal; a, the trunk; b, the plexus; c, c, different vessels for supplying the leg. Fig. 7. shows the axillary plexus in the three-toed fleshy; a is the sub-clavian vein; b, the trunk of the artery behind the large veins; c, the remarkable plexus which the artery forms; d, the median nerve. Fig. 8. represents the brim of the pelvis and groin of the three-toed fleshy, with the plexus of the inguinal artery; a is the bifurcation of the aorta into the two iliacs; b, a part of the internal iliac muscle; c, part of the bony margin of the pelvis, leading down to the pubis.

Veins.—These vessels agree in general exactly in mammalia with those of the human subject. Even where the arteries deviate in their origin from what is observed in man, the veins pursue the ordinary course.

We have already mentioned that there are two superior or anterior veins in the porcupine, elephant, kangaroo, and the hibernating mammalia. Mr. Carliole has marked, that, in addition to the cave forming two trunks before approaching the heart in the quadrupeds that remain torpid during the winter, there are also two trunks to the vena vaeno, which each open into the superior cava, on its own side of the thorax. He likewise remarks, that the intercostal arteries and veins are particularly large in those animals. Mr. Carliole wishes to infer from this distribution of the venous trunks, that it is necessary, on account of the languid circulation that is carried on when the animal is torpid; but we believe it is vain to attempt the explanation of the phenomena of hibernation by the anatomical structure of the animals concerned. The habit of retiring to rest during the winter is common to animals whose anatomy is extremely different, and if the diminution of action of torpid animals were to depend upon any particular organization of their vascular system, it would interfere with their perfect circulation at other feasons. Hibernation is accompanied by a suppression of functions, not a different mode of exercising them.

In the seal the inferior vena cava is dilated into a large sinus, as it passes the liver, into which five large hepatic veins enter. This dilatation may be either the consequence of the animal living in an element in which its respiration, and consequently free circulation is so often interrupted, or it may be an original provision of nature, to relieve the right side of the heart, when the current of blood through the lungs is impeded during the moments the animal is under the water.

A similar contrivance seems to exist in the borese. There is a dilatation of the jugular vein behind the jaws in this animal, which may serve to relieve the brain from the pressure of the venous blood during the time this animal is feeding. The ruminating quadrupeds do not require a provision of this kind so much as the bores, as they often eat lying, and generally ruminate so.

The veins of the viscera appear to be provided with valves in some mammals, like those of the members in man. According to Haller, there are valves found at the origin of the branches of the mesentric and hemorrboidal veins of the bores; and they have been observed also in the fleshy veins. They exist in the pulmonary veins of the dog and sheep. Most probably they may be found in many other instances, where they have not yet been observed.

The texture of the coats of the veins is apparently the same in man and in mammalia. Cuvier says he found the proper membrane to tear, like felt, into long silky filaments, in the axillary vein of the elephant, which he considers an example of the structure of this coat generally.

Vital Temperature.—That degree of heat which an animal sustains most commonly, or when not exposed to extremes of external temperature, we have called the natural standard. The standard heat of mammalia is several degrees higher than in man, although still below what is found to be the natural temperature of birds.

The thermometer, when introduced into the rectum or urethra of a man, (for the standard can only be ascertained in the cavities,) rises to 97°.

The following experiments were made by Mr. Hunter, and showed the difference in quadrupeds.

The bal of the thermometer in every case we are told to speak of Fahrenheit’s scale being introduced into the rectum of a healthy dog, the quicksilver rose to 100° exactly. The cuef of the dog was opened, and a wound made into the right ventricle of the heart. Immediately on the bulb being introduced, the quicksilver rose to 101°.

A wound was next made into the substance of the liver, and the instrument being introduced into it, rose to 102°. It was next introduced into the cavity of the flank, where it stood exactly at 101°.

The thermometer was introduced into the rectum of an ewe, and the quicksilver rose to 99°.

When inserted into the rectum of a rabbit it stood also at 99°.

Doctor Martine, in his Effays upon Thermometers and Heat, states that the temperature of the surface of the body is from 100° to 102°; or sometimes 103°, or a little more, in ordinary quadrupeds, as dogs, cats, sheep, oxen, fowes, &c. in which he is certainly incorrect. We have been led to ascertain the usual temperature of several quadrupeds, previous to making different experiments that would be irrele-
rant to our present purpose, if related here; but we may state that we have always found the heat of the cavities of the body to be about 97°, 100°, or 101°, when the quadrupeds were placed in a medium natural to them, and that of the surface of the body, two, three, or more degrees, according to circumstances, below that of the interior of the body. In quadrupeds, generally, we conceive the standard temperature should be stated to be 102°.

The heat in cetacea we should suppose to be equal to that of quadrupeds, or perhaps higher. The quantity of oil interposed between their internal parts and the water would seem to be sufficient to prevent the abstraction of heat, and that circumstance, joined with the want of evaporation from the surface, might even tend to exalt the temperature of the interior part of the body. Boerhaave considered the heat of cetacees to be the same as in quadrupeds, but he rates it in both too low. Mr. Richer found the blood of the porpoise to be as warm as the blood of land animals. Du Ham. Htlt. Ac. Sc. P. M. 157, and Mem. de l’Acad. des Sc. 1666—1668. Dr. Martine relates that he found upon trial the heat of the skin of the sea-calf (phoca vitulina) to be near 102°, and in the cavity of the abdomen it was about a division higher.

We may safely conclude from the facts before us, that the standard temperature in all mammalia surpassed the human by a few degrees. In what manner can this fact be explained? Should it be attributed to there being less evaporation from the skin, or the natural integuments of mammalia being better calculated for retaining the vital heat? We do not pretend to answer these queries, but we shall observe that although the natural clothing of an animal evidently tends to preserve its temperature from the influence of external cold, it does not seem capable of giving a higher standard. We cannot believe that the standard of a bear could be altered by depriving the creature of its fur.

Mammalia have, both from their usual coverings, and the high natural standard, great powers of reticulating the effects of external cold. Many of them are exposed to great extremes of temperature in the northern climates, in which they suffer more than birds, from sleeping on the ground. Mr. Hunter failed to freeze a dormouse, when surrounded by a freezing mixture, until he wetted its hair with water. And in another experiment, a mouse which he placed in an atmosphere as low as 13° above 0 during an hour, had not its heat diminished more than 10° at the diaphragm, and only 18° in the latter.

Like all other animals, however, which possesses a high standard, when this is brought very low in mammalia they perish. When in a torpid state they suffer a great reduction of their natural temperature, with the flame impurity as the more imperfect animals. Thus, in an atmosphere of 26°, a torpid hedge-bog was only 30°, although the same animal, when roused, was exposed for two days to the same atmosphere, and the internal heat, as tried by the rectum, did not sink below 93°.

Lungs.—These organs have their general figure regulated, in some degree, by the shape of the thoracic cavity. In those species which have the chest short it is commonly wide in proportion, and the convexity of the diaphragm is not considerable; and, on the contrary, where the thorax is long, it is often narrowed and diminished in the longitudinal direction, by the diaphragm being very convex, or projecting far into the chest. In the rhinoceros, horse, elephant, and woolly rhinoceros, the diaphragm pales up into the thorax, far beyond the margin of the ribs, so that it receives a part of the abdominal visera. The volume of the lungs is, therefore, still preferred in due proportion to the size of the animal, notwithstanding the external form of the chest might sometimes make it seem otherwise.

The lungs of mammalia are commonly divided into a greater number of lobes than those of the human subject, although there are some species which have them less so, or even not separated into lobes at all. The number of the lobes of the lungs is not conformable to any natural classification of mammalia, but varies even amongst individuals of the same species.

Cuvier has given in his “Anatomic comparison,” tom. iv, a very full table of the divisions of the lungs of mammalia by lobes and fissures, from which we shall select the following account.

In the orang-autang, there are three lobes in the right lung and two in the left, as in man.

The long-armed ape has four in the right, and only a fissure in the left. The rest of the monkey genus have commonly four lobes in the right, and two in the left lung; in some of these there are fissures.

The lemurs have four or three lobes to the right, and two or three in the left lung.

The flying lemur and the common bat have the lungs undivided, except by fissures. The great or tarsate bat of Edwards, has four lobes in the right, and three in the left lung.

The plantigrade mammalia have generally four in the right, and two or three in the left. The common hedge-bog has, however, four in the right lung, and no division of the left.

In the digitigrade there are four lobes in the right, and three or two in the left.

The marsupial quadrupeds (except the kangaroo-rat) have the left lung undivided, or slightly so, by one fissure. The phascolomyys has no lobes, but two fissures in the right lung. The kangaroo-rat has four lobes in the right lung, and two in the left. The Virginia opussum has three in the right lung; the other species of didelphis have either three lobes, or two and a fissure to the right lung.

The faguro quadrupeds have most commonly the right lung divided into four lobes, and the left is frequently entire. When the left lung is divided, it is usually into two lobes; but in the Hudson’s Bay rat there are four lobes, and in the jerboa three. The porcupine has six lobes to the right lung, and five to the left.

In the edentata there are two, three, or four lobes to the right lung, and either two or none in the left.

In the elephant and rhinoceros, both the right and left lungs are without lobes. The dama has two fissures to each lung. The wild boar has three lobes in the right lung, and two in the left. The Siamigo has four in the right, and two in the left lung.

The ruminating quadrupeds have generally four lobes in the right lung, and two in the left. The llama, however, has the left lung only divided by a fissure.

In the felipeds there are no lobes to the lungs of either side.

The seal has two lobes in the right lung, but none in the left. The humant is without lobes.

The cetacea have not their lungs divided into lobes. Some of the mammalia are said to have the lungs adhering to the parietes of the chest. The elephant is reported to be an infanct of this kind, and Tyron has also flated it to be the case in the web-footed and cetaceus mammalia. In those species we have examined the lungs have been free, as in the human subject. In the cetacea the coats are strong, and the lung altogether feeds firm and fleshy. Hunter states, that the lungs of cetacea poffes to much elati-
city, that they are of themselves sufficient to express the air from their cells. He also represents the air-cells as being smaller than they are in quadrupeds.

The intimate organization, which consists in the distribution of the arteries, veins, and the air-tubes, is perfectly the same in all mammals and in man.

**Bronchial Gland**—The use of this part not being established by anatomists, it cannot have a proper place assigned to it according to any physiological arrangement. We shall, therefore, describe it next to the lungs, from its contiguity to these organs in the body, without endeavouring to show any connection between the functions of the bronchial gland and respiration.

The size of the bronchial gland is greater in the human subject than in any other animal. In proportion to the entire bulk, there is very little difference observed in mammals, except in the kangaroo, which has a particularly small bronchial gland.

This gland is composed of two lobes, as in man; but they are sometimes quite unconnected with each other, as in the bat. In some species of rat, the elephant, the dama, the galapagos, and the seal. Moll commonly the two lobes are composed by one or sometimes two thin stripes, which pafs over the front of the trachea.

The form of the lobes varies in different species. They are broader above than below in the bat, elongated in the planigrada, long and flattened in the cat kind generally, still longer and cylindrical in the genus siviera. In the planigrada the lobes are elongated, and not quite cylindrical, being thicker above than below. The figure of the gland varies in the ruminants. It is round and tolerably large in the Lama, longer in the ox, sheep, and antelope.

In the galapagos the gland is but little elongated, and situated far below the larynx.

Hunter denied the existence of the thyroid gland in the cetacea, but Cuvier asserts that he found it very distinctly in many porpoises and dolphins, consisting of two parts supplied to the trachea, opposite to the superior, or rather anterior edge of the larynx. We have not perceived it in the porpoises or grampus, perhaps from not seeking it far enough in the interior of the body.

In man and the monkey the cellular substance forms the thyroid gland closely to the sides of the trachea, but in the other mammals this connection is looser. It is so much so in the rabbit, guinea-pig, and some other of the planigrada quadrupeds, that the thyroid gland is movable.

The internal structure of the thyroid gland appears to be the same in man and mammals. The observations that have been made upon it in the elephant have tended to explain its organization, as from the size of the animal the gland is large. It is surrounded by a thick aponerous, in the substance of which the thyroid vessels divide before they penetrate the gland. Each lobe of the gland is composed of about thirty lobules having a firm texture, and separated by peculiar cells, which are made by an extremely fine membrane. These cells are but slightly connected with each other, and with the lobules which surround them, so that they appear to serve only as the foundation for the smallest ramifications of the vessels that enter the gland. It is by means of these vessels, rather than the cellular tissue, that the different lobules are joined together.

According to Stellker, the northern lapland has the thyroid gland very large; it contains two fluids, differing from each other in colour and consistence. The external part of the gland is composed of a number of very small grains, and of a fluid resembling milk in colour and consistence, and having a sweet taste. There is a membranous sac in the middle of the gland, containing a thick and rather bitter fluid. It seems to be secreted by the grains, and deposited in the sac.

The existence of cells so plainly proved in the thyroid gland of these large animals, seems to justify the opinion entertained by some anatomists, that the cellular structure observed in bronchocele is produced by the natural cells of the part becoming enlarged.

It is a remarkable circumstance, which may throw some light upon the functions of the thyroid gland, that it only exists in man and mammalia. Cuvier seems inclined to consider a round cellular gland placed before the heart in the pentar as analogous to the thyroid of mammalia. It does not seem probable, however, that an organ should be wanting in birds, and re-appear in certain animals of a class one flep farther removed from mammalia.

**Kidney and Urinary Bladder.**—The position of the kidneys in the abdomen is different in man and mammalia, inasmuch as the latter commonly have the right kidney higher than the left.

The kidneys of mammalia usually possess the figure of the human. In the cat kind, the coati, the armadillo, the gazelle, &c. they are more or less round. In the ruminating quadrupeds, the paca, the hog, and the porcupine, &c. according to Cuvier, they are long-shaped. The lama has them nearly cylindrical. They are short and triangular in the boar.

In man and some mammals the kidneys before birth are in separate lobes. In those mammals that inhabit, or frequently visit, the water, and in a very few others, these glands preserve the Definitely lobulated appearance during life. The original lobules can, however, be always perceived, and reckoned from the number of their papillae. They may be injected also with different coloured fluids, and not occasion any confusion, although they are confluated into one mass.

The elephant is one of the animals which have lobulated kidneys. They are, however, not much divided, there being only four lobes to each in this animal. The texture of the elephant's kidneys is soft, and the disintegration of the cortical and medullary substances is not plain. There are three papillae, and as many infundibula, which join together without forming a pelvis.

The kidneys of the ox are still more divided than in the elephant, having from 23 to 30 lobes.

It is in the otter, bears, seals, and cetacea, that the lobulated structure is most distinct. The lobes are numerous and small in proportion, according to the succession of these animals. Thus, in the otter there are ten lobes to each kidney; in the beaver there are from 50 to 60; the seal has 120 to 140; and in the porpoise, dolphin, grampus, &c. there are upwards of 200. In the cetacea, the lobules or glands of which the kidneys are composed, are particularly distinct and small in proportion to the size of the viscous. They are connected almost entirely to each other by means of their vessels alone, in the manner of a bunch of fruit, and have a good deal of motion upon one another. In the other animals they are more preferred in their proper situation, and in contact with each other by means of their cellular substance. No satisfactory physiological reason has yet been given for the kidneys being divided into numerous distinct glands in certain animals and not in all. It has been conjectured that this structure was in some way connected with the habit of diving, on account of its being met with in all the aquatic mammals; but, as we have before stated, it is
not peculiar to them. Like many other peculiarities of structure it must remain unexplained, until it be investigated by experiment.

The number of papillae indicates both the original and the actual number of lobes that compose the kidney. There is but one papilla in the tame, and the cat; in the squirrel, the hare, the guinea-pig, the dog, many and many other of the feline and canidae. There are two in some cats, three in the elephant, four in the cobold, and live in the hyena. In the otters, bears, sea-fated and cetaceous mammalia, each separate lobe has its proper papilla.

The papillae regulate in a certain degree the number of infundibula. When there is but one papilla the infundibulum is commonly absent, being co-formed with the cavity called the pelvis of the kidney. This is particularly to be seen in the car, the dog, the armadillo, etc., in which the medullary substance that forms the papillae does not project into the cavity, but is flat or sometimes hollow: therefore, the cavity which receives the urine, and is the origin of the ureter, cannot send off any processes or funnel-shaped reflections of its membrane. The pelvis of the kidney in these cases is not visible on the outside.

The lobulated kidneys have a calyx or infundibulum to each of the glands that compose them. They unite to form trunks of vessels, which make at last something like a pelvis for the ureter to arise from in the bears, otters, and seals. In the cat there is no pelvis; the ureter is formed by the junction of some branches from the anterior infundibula, and receive the branches of the other infundibula afterwards, without forming any dilatation corresponding to the pelvis.

The renal arterias and veins do not enter at one place always; this is occasionally seen in man. The adlipsa arterias also are of various sizes, but in the lobulated kidneys, the vessels penetrate the organ at the nearest place, instead of passing in preference at the fissus, or the part where the excretory ducts come forth.

The veins of the kidneys in the cat kind have their principal trunks and branches running in an arborescent form upon the surface. They receive the branches from the internal part of the gland, as the sinues of the dura mater collect the blood from the brain.

The intimate structure of the kidneys in all mammalia appears to be the same as in the human subject.

The chemical composition of the urine appears not only to vary considerably in animals resembling each other, but even to differ in the same animal at different times. In this way one may account for the disagreement in the analysis published by the French and English chemists.

The urine in the camel, according to Mr. Brande's experiments, is composed as follows:

<table>
<thead>
<tr>
<th>Component</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Water</td>
<td>-4</td>
</tr>
<tr>
<td>Phosphat of lime</td>
<td>-6</td>
</tr>
<tr>
<td>Muriat of ammonia</td>
<td>-8</td>
</tr>
<tr>
<td>Sulphat of potash</td>
<td>-15</td>
</tr>
<tr>
<td>Urat of potash</td>
<td>-6</td>
</tr>
<tr>
<td>Carbonat of potash</td>
<td>-3</td>
</tr>
<tr>
<td>Urea</td>
<td>-4</td>
</tr>
</tbody>
</table>

Mr. Brande found the following component parts in the urine of the cow:

<table>
<thead>
<tr>
<th>Component</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Water</td>
<td>-65</td>
</tr>
<tr>
<td>Phosphat of lime</td>
<td>-3</td>
</tr>
<tr>
<td>Muriat of potash</td>
<td>-15</td>
</tr>
<tr>
<td>Sulphat of potash</td>
<td>-6</td>
</tr>
<tr>
<td>Carbonat of potash</td>
<td>-4</td>
</tr>
<tr>
<td>Urea</td>
<td>-4</td>
</tr>
</tbody>
</table>

But from Rouelle's examination, it consists of carbonat of potash, sulphat of potash, muriat of potash, urea, and benzoic acid. Both these chemists agree that potash is the only fixed alkalii in the urine of the cow.

The urine of the rabbit, according to Vaquelin, is composed of the following parts: carbonat of lime, carbonat of magnesia, carbonat of potash, phosphat of potash, phosphat of lime: muriat of potash, urea, gelatin, and sulphur.

The same chemist found that the urine of the guinea-pig, the domestic cat, the dog, and the horse, contain carbonat and muriat of potash, but not any phosphat, nor the uric acid.

From these examinations it would appear that soda and its combinations do not form any part of the urine of the camel, cow, guinea pig, and rabbit.

In the urine of the boar the following component parts have been discovered by Fourcroy and Vaquelin:

<table>
<thead>
<tr>
<th>Component</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Carbonat of lime</td>
<td>-11</td>
</tr>
<tr>
<td>Benzoat of soda</td>
<td>-9</td>
</tr>
<tr>
<td>Muriat of potash</td>
<td>-9</td>
</tr>
<tr>
<td>Urea</td>
<td>-7</td>
</tr>
<tr>
<td>Water and mucilage</td>
<td>-940</td>
</tr>
</tbody>
</table>

Mr. Brande found the urine of the boar to contain the following salts, viz. carbonat of lime and of soda, phosphat of soda, muriat of soda, benzoat of soda, and phosphat of lime, which parts amounted to about 4th of the urine.

The urine of the as, according to the same chemist, is mucilaginous, but at the same time transparent. Like that of the boar, it changes vegetable blus to green, but depoits no carbonat of lime. It differs in composition from that of the boar, by containing a much greater relative proportion of phosphat of lime and urea: it also contains carbonat, sulphi, and muriat of soda, and there appeared to be a small quantity of potash, which is probably united to muriatic acid. He did not discover any benzoic acid.

It deserves to be remarked, that the urine both in the boar and as is destitute of ammonia.

The urine of quadrupeds appears to have generally more confidence in than man. It feels particularly acrid or mucilaginous in the boar, as, and cow.

Fig. 1. Plate VII. of the Anatomy of Mammalia, exhibits the lobulated kidney of the boar.

The urinary bladder exists in all mammalia, and resembles, in general very closely, that of the human subject. Its muscular coat is particularly strong in those quadrupeds: it is most strikingly so in the carnivorous fencers, and a few herbivorous quadrupeds. The sacculi of the bladder are,
in these instances, very thick, and generally contract the bladder when the animals die; by which it is supposed to have a smaller cavity than it really possesses during life. In the large graminivorous quadrupeds the muscular coat is generally weak, and hence the great dilatation that the bladder admits in these animals by inflation.

The bladder of the *cob* diva and the *oriluchorkysenus* terminates in a long neck or tube, which opens by a small foramen into the cloaca, as in the *tortois*.

The ureters and vasa deferentia open close to each other into this tube, before the bladder. The urine, therefore, must return, or regurgitate into the bladder, in the same manner as in the *tortois*.

This fact is displayed in fig. 5, Plate VII. of the Anatomy of Mammalia. The letter *g* indicates the tube; *h, i* are the orifices of the ureters before the neck of the bladder; *b* is the opening of the tube into the cloaca; *k* is the urinary bladder.

**Renal Capsules.**—The French academicians have stated, that these parts are deficient in the *canis*; *fog*; but this appears to have been a mistake, as no influence of their being wanting in mammals is mentioned by other writers.

The relative situation of the capsules to the kidneys is nearly the same as in man. Sometimes they adhere to the kidneys, but, almost constantly, the right is attached to the vena cava.

The magnitude of these bodies differs very much according to the species, besides the variations depending upon age, which seem to be less in man; and in the *guinenfig* the capsules are even larger in the adult than the fetus.

The relative bulk of the renal capsules to the kidneys is as great in the *monkey* as in man. Cuvier found it to be 1 to 16 in the *varied ape* (*simia mono*), and as 1 to 12 in the *man"*. He found it to be 1 to 12 in a young *bowling baboon*.

In the *digitigrada*, Cuvier found the renal glands to be

\[
\frac{1}{3} \text{ the size of the kidneys in the *tiger*}, \quad \text{and in the *lynx* the } \frac{4}{12} \text{th}
\]

They are the \( \frac{4}{12} \text{th} \) in the *hedge-hog*; \( \frac{1}{12} \text{th} \) in the *kangaroo*; but the other *digitigrada* in general have the renal capsules large. In the *guinenfig* they are in the proportion to the kidneys of 1 to 5; they appear to be larger in some of the *rat* genus, in which they equal the \( \frac{4}{12} \text{th} \) of the kidneys during the whole life of the animal.

The *opossum* has them only amounting to the \( \frac{1}{12} \text{th} \) of the size of the kidneys.

In the *horse* they are the \( \frac{4}{12} \text{th} \).

Cuvier found the renal glands smaller in the *cat* than in any of the whole class. This animal has then only the \( \frac{4}{12} \text{th} \) part of the size of the kidneys.

The form of the renal capsules is very various, but corresponds, in some degree, with that of the kidneys; thus, when the latter are lobulated, the capsules are commonly so also.

In the *ruminating* and *solid-footed* quadrupeds, these parts resemble the renal capsules of the human subject, being flat and triangular.

In the *elephant* they are long, conic, and have their base turned backwards, and divided into twelve round lobes.

In the *peca* and the *percutia*, they are elongated and cylindrical. In these, and a great many mammals, they resemble very exactly the kidneys. In the *cat*, and the *diana*, they have a sinus like the kidneys.

In the *fain* and the *citaceae*, they are flat and triangular, but divided into many lobes, which coalesce in the centre.

The lobules are more separate in the *citaceae* than in the *fain*.

The structure of the renal capsules is the most interest-

ing part of their history, but it is involved in some obscurity. The vein which collects the blood of the capsule commonly forms a dilatation in the centre, which seems to have been sometimes mistaken for a peculiar cavity. Cuvier, however, has described three little pouches in the renal gland of the *elephant*, which he found to be covered with a very delicate, smooth, white membrane, that exhibited no orifice of any blood-vessels. This membrane appeared to be moistened with a clear mucous fluid. The bottom of one of the pouches had a little hole, which communicated with a fourth pouch, occupying the internal and posterior lobe of the capsule.

The appearance of two substances composing these glands is generally the same in mammals as in man. The external or yellow portion of the capsule appears to correspond with the cortical substance of the kidneys. It is of a brighter colour generally in animals than man, and is often so thick as to occupy more than the half of the gland. Cuvier says, that it is composed of fibres or tubes situated in a perpendicular direction relative to the renal substance. This last is soft, and of a deep brown colour.

In the *cat* three substances have been observed: one grey, which forms the nucleus. It is encompassed by a stripe or thin layer of a brown coloured substance; and external to this there is another thin layer of a bright yellow colour.

The same distinctions of substances exist in the *guinenfig*, the *rat*, and some other *faiigradae* quadrupeds, or rather a division into five substances, according to J. T. Meckel, who reckons every shade of colour as a distinct substance composing this gland.

It is remarkable that in the *elephant*, which has the cortical and medullary substances of the kidneys indistinguishable, the two substances of the renal capsules are so like, which marks the great analogy and connection which exist between the kidneys and these bodies. This is still further shown by the renal capsules having an uniform colour and substance in birds, which want the distinction of cortical and medullary substances in their kidneys.

Plate VII. of the Anatomy of Mammalia, and fig. 5, shews the relative magnitude and form of the renal capsule and kidney in the *common rat*. \( a \) is the capsule to the kidney. Fig. 3. of the same plate, exhibits a section of the renal capsule of the *rat*, in order to expose its different coloured substances: \( a \) is the central substance; \( b \), the intermediate one; \( c \), the cortical or external substance. Fig. 4. is a section of the renal capsule of the *ox*, to exhibit the cavity in the interior; \( a \), the vein of the capsule; \( b \), the cavity.

**Glands for peculiar Excretions.**—The motif of these in mam- mals are situated in the neighbourhood of the anus, or the external parts of generation, and secrete an odorous fluid, the natural use of which appears to be that of a defence against hostile animals. Nevertheless, many of the products of the excretory glands are employed by mankind as perfumes, or as medicines. There appears to be a very considerable resemblance amongst these excretions of quadrupeds, not only in their colour and consistence, but their effects upon the fomentations of other animals. The faecid matter furnished by the *pole cat*, and the *eivet* or *myth*, are extremely offensive to many individuals of the human species, and are probably universally disagreeable to beasts, except those that furnish them. All these odorous excretions likewise have a similar effect upon the nervous system, though differing in the degree of that effect.

In several quadrupeds, besides the small follicles which furnish the feecious matter of the prepuce, the colour of which is rather calculated to invite the opposite sex than to disgust other animals, there are two glands of considerable
size on the sides of the penis, which are conglomerate and formed of different lobules united together, and producing a common excretory duct, which opens within the prepuce either of the penis or the clitoris. These are very remarkable in the rat tribe, in whom they are large, flat, oval masses of granular bodies.

Cuvier ranks the apparatus which furnishes the effer amongst the glands of the prepuce, but they are much larger than would be necessary for the secretion of a substance to be used merely on the penis or clitoris. They are situated under the integuments, between the pubis and the common aperture of the anus and prepuce, which exists in the beaver. The number of these glands is apparently four; but there are two others involved in the lower face. The two first glands are conjoined together, and have, when thus united, the figure of a heart. Their internal coat is smooth, thin, and of an ash colour, streaked with some white lines. They contain a cavity internally, the parietes of which are thick, and formed into irregular folds or wrinkles, upon which a grey odorous sublance is found to adhere. The ash colour of the external coat is derived from the inner one. These two glands or pouches measure across about two inches in each direction. Where they are applied to each other, there is an aperture of communication between them of an inch in size. Both glands discharge their contents into the prepuce by a single orifice.

Underneath these there are two others, which are distinct, and have the figure of a pear, somewhat flattened. They are two inches and a half long, and about ten lines broad. There are placed, between their coats, a number of small glandular bodies, each of which contains a cavity, in which there is a fluid secreted, that is strongly odorous, yellow, unctuous, and combustible.

At the lower part of these pear-shaped pouches the third pair is found. They are about fourteen lines in length, and fix in breadth. They are full of a fluid, which is yellower than the contents of the other glandular faces, and has also a different smell. These pouches have likewise little glandular bodies on their surface, similar to those of the second pouches. The membranes of the two lower pair of pouches are intimately united to each other. Both these pairs open into the common aperture of the anus and prepuce. An ancient error prevailed with respect to the effer, or the cavity of the beaver, and the species of the old anatomists believed that it was taken from the testicles. Some absurd stories also are told of it; such as the beaver pressing this sublance out with its paw, and eating it to create an appetite, &c.

The apparatus for the secretion of the mulk in the mabelus mascliferus, is perfectly similar in structure to that above described in the beaver. The pouch containing the mulk is situated under the skin of the abdomen. Its figure is oval, and it is hollowed below into a groove, in which the penis comes forth; its parietes are apparently membranous, but the inner surface presents many irregular folds. The pouch has a small orifice, which is at the fore-part of the prepuce. The membrane surrounding it contains some febaceous follicles. Between the pouch and the skin of the belly there is a flaky sublance, apparently glandular. The mulk does not exist in the females, nor in the young males.

The antelope guturafa has also been described by Pallasis as possessing a similar membranous pouch to the foregoing, but it does not contain the mulk. Most of the antelopes have a pouch at the side of each nipple, formed by a fold of the skin, which contains an oily, odorous matter.

The inguinal glands of the hare appear to belong to the clafs of tho.se of the prepuce. They are small oval bodies; their orifices are on two demi-lunar spots of the skin, which are deprived of hair, and are situated on each side of the prepuce of the penis, or of the clitoris.

Thee glands, which Cuvier has called the anal, are capable of furnishing the most powerful of the odorous excretions. They are thees which afford the sublance called caviot, and those offensive discharges of others of the tanal tribe, the effluvium of which scarcely any animal can bear to approach. Thee anal glands are two pouches of a round or pear-shape, the coats of which are glandular. The interior of the face is lined apparently by the continuation of the skin. They are the reservoirs of the odorous matter which is discharged by a large opening from each face, usually into a cell or cavity formed by the integuments either around the anus, or in the neighbourhood of it. There are peculiar muscles for compressing these bags. Bartholinus figured four muscles; the French academicians found but three; one which passed across from one pouch to the other, and two muscles which arose from the itchium; each came to be joined to its antagonist at the middle of the two pouches, and was fastened to the pouch over which it went to make this conjunction. Cuvier merely represents some saecula, which crosses between and surround the pouches. The odorous matter found in the caviot bags is of a yellow colour, and resembles oil in composition and consistence. It has the smell of mulk.

Thee kinds of anal glands are met with in many of the digitigrade and folitigrade quadrupeds, and felid tribe; Blumenbach also attributes them to the opifimus. There are three of these pouches in the marmot, but smaller than the usual size; they open upon the edge of the anus, in the centre of three papillae which project from the anus when the animal is excited.

In several quadrupeds, besides the flank bags above described, there are numerous small glands placed in the parietes of a large cell or cavity, which the integuments form either around the anus or in the neighbourhood of it, or, in rare instances, in other parts of the body. These frequently make a part of the excretory apparatus already described, but they exist also without the anal faces, or flank bags.

In the civet, this cavity is situated between the genital organs and the anus; it opens by a longitudinal slit, the edges and intide of which are furnished with long hairs, that stand inwards. The inner surface of the cavity is grooved in the transverse direction.

The glandular cavity of the ichneumon surrounds the anus; the internal surface of it exhibits a great number of foramina along the margin. These are the orifices of the follicular glands, which are each about the size of a small pea, and lie upon the external part of the parietes of the cavity. They furnish a thick, yellow, oily fluid. On the superior part of the circumference of the anal cavity there is a triple row of little conglomerate glands, which secrete a whitish matter, and have larger openings than the preceding glands. This cavity further receives the contents of the large glandular faces above described. The anal cavity is compressed by the usual sphincter ani.

The guinea-pig has a square shaped cavity below the anus. It is much puckered internally, and receives the product of two febaceous glands, which has a peculiar smell.

The anal cavity in the hyena has a narrow transverse opening. This slit, says Cuvier, leads first to two lateral pouches, which are the central cavities of two glandular masses composed of lobes and lobules. These two pouches communicate with two other glands, of which the lobules are more detached, and are even assembled around a central cavity, in which their excretory canals terminate, and which opens into
Mammalia.

into the first pouches, as we have mentioned. There issued from the left anterior pouch a yellow-brown matter, although that in the right held a grey matter, as well as the two posterior pouches.

In the badger there is a transverse fissure between the anus and tail, which is the mouth of a cavity, the parietes of which are furnished with a number of small glands, that secrete into it an unctuous fluid. It is this which the badger mixes with its urine, and with its tail throws against its afflants.

The pecari, or Mexican hog, has a large gland or pouch situated under the skin of the back. It is composed of lobes and lobules, the excretory ducts of which terminate in a single orifice in the back. This gland furnishes an odorous matter, and must be removed immediately after the animal is killed, it is said, to prevent the flesh being tainted with the smell.

There is a gland under the skin of the temple in the elephant, which secretes a viscid fetid matter, and should be ranked with those just described, though placed in a different situation. It has an oval shape, and is interiorly of a red, fungous structure. The fluid it secretes flows off by a canal, which descends obliquely from behind forwards, and opens midway between the eye and the ear. The parietes of the canal resemble the skin. The fluid of this gland is less abundant in females than males; in the latter it is very copious when the animal is in heat. After death it becomes like wax.

In the antelope and deer there is a cell near the inferior and internal part of the eye; it is covered internally by a continuation of the skin, and is lodged in an excavation of the superior maxillary bone. The parietes of this sac are provided with febeanous follicles which secrete a thick, black, unctuous substance. These faces open by a slit. They have no connection with the lacrymal gland, or the tears, as has been supposed, but seem to belong, whatever may be their use, to the clavus of glands at present under consideration.

The sheep, and several of the cloven-hoofed quadrupeds, have glandular cavities in the feet. These are covered with hair internally, and have an excretory duct, which opens at the junction of the toes. When this is obstructed from wet weather, it occasions ulcers in the sheep.

In fig. 6, Plate VII. of the Anatomy of Mammalia, there is a view of the three different kinds of anal glands in the ichneumon. The letters o and p indicate the pyriform faces; q, q, are the small glands which are upon the outside of the two-thirds of the cavity that surrounds the anus; these furnish the yellow unctuous fluid; r, r, are the conglomerate glands, situated farther in upon the anal cavity, and which secrete the whitish matter. Some mucular fasciculi are seen to pass between and surround the anal glands o and p, by which their cavities are compressed, and their contents forced into the common cavity that includes the anus, and receives the secretions of the three orders of anal glands in this animal.

Ornament employed in the Exercise of the Generative Functions.

Male Parts of Generation—The penis is a more complex organ in many mammalia than in man. The peculiarities in its formation do not correspond with a similarity of general structure in different animals, but are often perfectly specific, which seems to be defied in some measure, to prevent that promiscuous intercourse which the blind appetites of some animals might lead to.

The penis has its figure and magnitude in many cases determined by the presence of a bone in it. The ox penis, by giving firmness and shape to the member, renders the corpora cavernosa and the glands less necessary: we accordingly find these parts diminished in these species which possess a bone in the penis.

The os penis has been found in some species of monkey, but not in others: in most of the bat kind, in the bear, the badger, the raccoon, the esgel, the ichneumon, the otter, the dog kind, except the byvens, the cat kind, the badger, and several of the genus mus, the seal, the true subbies amongst the cetacea. It is denied to the lamnites by Cuvier, but Blumenbach states that it exists in the whale. We posse a preparation of an os penis, which we have every reason to suppose belonged to that animal. It is two feet long, thicker than the thigh-bone of a man, and as solid as ivory, except at the root and where the skin is attached, at which places it is somewhat spongy in its texture. Camper is said to have a preparation of this bone, which had been fractured, as he supposed, during coteion, for the penis of this animal is not exposed to injury unless when erected.

The os penis is grooved in the lower surface for holding the urethra in the dog kind. It ends in a hook in the swelat. It is curved into the form of an S in the racon. In the squirrel, it is spirally twisted at the extremity. It is large, rounded, and terminates like a club in the swelat.

This bone forms the principal part of the penis in the bear, otter, raccoon, badger, dog, and esgel; but in the bats, cat, ichneumon, and most of the rat kind, it is small, and serves as an accessory part to the corpora cavernosa.

The direction and attachment of the penis are different from what is observed in man; none but the quadrumanus, the elephanto, and the armadillo, have the penis pendulous, or at all times projecting from the body, and covered with a skin proper to itself. In the other genera, the penis, when employed, is concealed more or less in a sheath formed by the skin of the abdomen. In the carnivorous and the large herbivorous quadrupeds, the sheath of the penis opens forwards, near the umbilicus. When the penis is long in these, it forms curves or folds upon itself in the sheath. According to Cuvier, the penis of the elephant makes, when retracted within the sheath, the curves of a double italic S.

These quadrupeds which have the penis fixed in this manner under the belly, have two additior muscles to the sheath: they arise from below the aponeurosis and the sheath of the abdominal muscles by several fasciculi, and having joined their fasciculi, are inserted into the floor of the anterior part of the sheath. These draw the sheath forwards upon the belly. There are also two muscles for retracting or opening the sheath, which come from the first caudal vertebrae: they terminate in the digitigrada, either upon the external part of the corpora cavernosa, or upon the os penis; and in the ruminants they are inserted upon the sheath of the penis. In the former these muscles must bring back the penis itself.

In the folipeds, the retractor muscles accompany the inferior part of the urethra, and are lost in fasciculi that are distributed upon the muscle which covers this canal. In these animals Cuvier thinks the retractor muscles restrain the elongation of the penis when it is erected, and contribute to withdraw it into the sheath.

These muscles appear to be supplied in the elephant by the levatores of the penis, to be described hereafter.

In some of the folipeds quadrupeds, the penis comes first as far forwards as the anterior brim of the pubes, and then turns back, the orifice of the prepuce being near the anus. But in most of the folipeds, and in the egglans, the
the penis goes backwards from the time that it comes out of the pelvis.

Several quadrupeds have been observed to void their urine backwards. It was, therefore, thought by the ancient naturalists, that they also copulated in the same direction, but later observations have proved the contrary.

The figure of the penis is very various in mammals. It is determined either by the size and shape of the os penis, when that bone exists, or by the form of the glans, and the thickness of the corpora cavernosa. The penis is slender in the bear and cloven-fisted quadrupeds. It is thick and long in the sheep, the elephant, and the lamantins; thick and conical in the porpoise and rhinoceros; thick, conic, and flat in the dolphin; nearly cylindric in the minkes and lewurs; short in the opusian, and most of the felibratoris, the dytii-gradus, and the fel; long and cylindric in the hedge-hog; twisted like a fowc in the squorly, and bent like an S in the racoon.

The corpora cavernosa are commonly formed of two distinct branches arising from the ifichum, as in man, and after wards joined apparently into one body; but the interior division of this part of the penis by a septum is often less distinct in mammalia, and sometimes is wanting. It is incomplete in some species of monkey and in the lemurs. It is totally wanting in the bear and the badger. It is also absent in most of the many-hoofed quadrupeds: the elephant and rhinoceros, however, have it. The fuid and cloven-hoofed quadrupeds and the cetacea want a septum between the corpora cavernosa. In these cases the ligamentous lamine arise from within the circumference of the united cavernous bodies, and meet in the centre.

The corpora cavernosa in the opusian arise by two long small branches, which are only connected to the ifichum by means of the mufcles called the erecturus penis. They unite without any septum, and then branch into two, in order to form the bend penis of these animals.

In the kangaroo there are at first four corpora cavernosa, which unite to form a conical-hapled penis. The urethra runs in their centre. They are composed by a muscular involvement. The direcor mufcles of the penis, or ischiocavern?s, serve to connect two of the roots of the corpora cavernosa to the ifichum. The two other roots are enveloped by a mufele which takes the place of the accelerator urinae, or bulbocavernosus.

The interior of the corpora cavernosa, during the erection of the penis, has been described by Cuvier in the elephant, and the other large quadrupeds, as being composed of the branches of the veins anastomosing frequently with each other, so as to form a close and inextricable plexus, resembling cells. We have discovered the fpongy part of the urethra to be composed of ramified vefcles in men and quadrupeds, but we have not been able to satisfy ourselves, that the corpora cavernosa are made in the same way.

The first membranous portion of the urethra is in proportion to the rest of the canal, commonly longer in mammalia than in man. The monkey kind have it short and almost entirely enveloped in the prostatic gland; it is particularly long in the hedge-hog, opusian, kangaroo, civet, and the cat kind, in most of which it is more than half the entire length of the urethra.

The part called verumontanum, on which the femail ducts terminate, contains in the elephant and some others a deep cell. There are frequently other folias of the membrane which form longitudinal eminences besides the verumontanum; and in the marmots there are twelve prominent folds, which go off on each side of the longitudinal projection.

The second portion of the urethra in the cloven-hoofed quadrupeds and the hog, has a cul-de-sac at its origin, or at that part corresponding to the bulb. This eaccum receives the semen and the fluid of Cowper's glands. In the squirrel and marmot, the dilatation in the bulb merely receives the ducts of Cowper's glands, and is continued into a narrow canal, which opens into the urethra as far forward as the middle penis.

The fpongy texture of the urethra in the opusian and phalopomus, all the marfiptal quadrupeds, and in the water rat, arises in two branches distinct from each other, and inclosed in their proper mufcles. There is also some appearance of two branches to the bulb in the camel.

There is a large corpus spongiosum in the large herbivorous quadrupeds, and a small one in the carnivorous, more particularly the siter, bear, &c. It is scarcely apparent at the part of the urethra which runs along the os penis.

The corpus spongiosum, as already mentioned, is composed of an intricate plexus of veins. This is very evident where it forms the glans penis of the hog, in which the vefcles are very plainly seen. They likewise communicate with a vast mafs of veins upon the durium of the penis in this animal, which increase the bulk of this member very much when they are dilated with blood during erection.

The glans penis varies very much in mammalia, both with respect to form and the nature of its integuments; even the animals of the same genus do not agree in these respects.

The glans of some monstes, as those with prehensile tails, forms a large tubercle, like the head of a mulinoon. In the baboon and aper it is oval, and split into two tubercles at the end where the urethra opens. In the Chines ape there are several tubercules, which produce a singularly formed glans.

In the ring-tailed facaus, (lemur catta), the glans is thick behind, but merely covers the os penis at the end. It is covered with horny spines, which have their points turned backwards.

The vesperiffio ferinaus has two tubercles or bulbs upon the sides of the glans. The inferior surface forms a fort of edge, and is clothed with flesh-like processes.

The hedge-hog has a piece of cartilage upon the top of the glans.

In the racoon the os penis has two tubercles at the end, which give the same form to the glans.

In the cat kind the glans is conic. The point is made by the os penis which projects beyond the orifice of the urethra. In molt of this genus, the glans is armed with reflected sharp hard spines. Cuvier says they are few in the lion, and molt numerous in the Mre.-sian cat (felis parda/is).

In all the long-bodied or vermiform quadrupeds, and in the badger, bear, and racoon, the glans takes the form of the os penis.

In the dog genus, the back of the glans forms a very remarkable bulb of the shape of a mushroom, the base of which is posterior. It is composed of venous cells, which are only dilated when the penis is erected, and is compressed behind the glans, there being two large trunks of veins running backwards, which carry off the blood from the bulb. It is by means of this apparatus that the penis of the dog is retained in the female organs, seemingly against his will. The splanhcter of the vagina suffers a spasmode contraction, and compresses the veins behind the bulb, and thus maintains it in a state of dilation. To obviate the effects of compulsion upon the urethra, that part of the canal is bulged in a groove of the os penis. The femen of the dog fades in jets for some time after he has turned off, as it has been napposed, in consequence of his wanting vehicle for inlet.

In the opusian kind, the glans is necessarily bifid, as the corpora
The two branches of the glans penis are short, and are directed outwards in the Virginian opiffum, but in the Mexican opiffum and the marmote (didolhia margin), they are long, and grooved upon the inner side so as to form a perfect canal when they are applied to each other. This canal forms a continuation to the urethra.

The phallicornes has the glans penis forming four lobes at the end: the urethra opens in the centre.

The kangaroo has a long, taper, sharp-pointed glans, formed chiefly by the corpora cavernosa. The urethra emerges near the end of the penis from the united corpora cavernosa, acquires the spongy coat, and ends in a kind of face, which has its orifice under the point of the glans.

The formation of the glans, as well as all the other parts of generation, is singular in the saltigrade mammae.

In the guinea pig the orifice of the urethra is in a flat oval penis; and behind and below it there is a cell, to the bottom of which are attached by their base two long, thick horns of a horny substance: the glans and surface of this pouch are covered with hard scales. When the penis is erected, the point of the penis, after passing out the horns, or horns, of the head, and forming a projection preceding considerably the orifice of the urethra. The glans is drawn in again by two fasciculi of muscles, which arise from the two crura of the corpora cavernosa, and pass under the bulb of the urethra, to which they are also attached. They furnish two tendons that run along the under part of the penis, and are inserted on the outside of the face or pouch already mentioned.

The glans of the agouti is still more curious. It has a pouch similar to that above described, and horny scales upon the surface; and in addition to these, two horny plates upon its sides, which adhere to the glans by one edge, and have the other edge notched like a saw.

The alpine marmot has the glans conical, and ending in a fine point, which is formed by the os penis. The urethra opens on the right side of this point, and on the left there is a small deep cell.

In the common rat there is the appearance of a second prepuce at the end of the glans, when the penis is not erected: this is produced by the edge of a cavity that encloses the penis. This bore came forth by pressure, and exhibits upon each side two little carilaginous appendages, in the form of wings. The urethra opens under this extremity, and has upon the inferior edge a valve formed like a gutter.

The other species of the genus mus have the glans constructed upon the same plan: its surface is armed with papillae, or with fine hairs, as in the hamster.

The dormice have a conical and sharp-pointed glans: the urethra opens at the end. There are two cells at its base.

In the elephant the glans is at first cylindrical, as the rest of the penis: the lips of the orifice of the urethra open to each side.

The glans of the rhinoceros has a singular formation: it is divided at the end like the mouth of a bell, in the centre of which there arises a peduncle, shaped like a mushroom, with a broad, flat, oval surface, upon the inferior edge of which the urethra opens.

In the boar and, many of the ruminating quadrupeds, the glans is taper and pointed, and has a buffer upon its side, in which the urethra terminates. The ram has it oval, with a transverse fissure at the end. The orifice of the urethra is at the left side of the slit, and near it there is a long slender process of a tendinous substance. The glans of the cow is, which is long and taper, ends in a hard appendix, which is bent transversely from left to right, by which its edge is turned forwards, and the point to one side.

The sipuleus have a cylindric glans, which contains a cavity or large cell, that is found to have a quantity of a brown oily substance, for defending the glans from the irritation of the urine, and lubricating the end of the penis. This secretion appears to be similar to that of the glands surrounding the glans in other animals, but is in greater quantity in the boar than in them. There is a second cell, according to Mr. Clarke's description, which is smaller than the first, and separated from it by a membranous partition: it nearly surrounds the urethra, which opens at the end of a pyramidal eminence of the glans.

The northern lamanina has the glans and all the penis similar to that of the boar, according to Cuvier, except the existence of a bone; although he denies that the lamanina have an os penis in another place.

The glans of the porpoise is broad at the base, diminishes suddenly, and ends in a slender point, at which place the urethra opens. In the dolphin it is broad, conic, and flat. The canal of the urethra runs distinctly along its under surface, and opens at its extremity.

The muscles of the penis are commonly more numerous in mammalia than the human subject.

The erectores penis, or, as they are more properly called by Cuvier, ischiocavernosus, do not materially differ from those of man, except in the marsupial quadrupeds: they, however, vary with respect to strength. Cuvier has observed them to be particularly thick in the boar; they are weak in the boar; and are divided in the elephant into four distinct slips. In the opiffum tribe these muscles form an oval mass round the roots of the corpora cavernosa, which in these animals are not attached immediately to the bones of the pelvis. The bulbous enlargement of the muscles is made of several layers of concentric fibres, which surround and compres the long roots of the cavernous bodies. The origin of the muscles is from the ischium by tendon.

The accelerator urina (bulbo-cavernosus of Cuvier) varies generally in thickness, in proportion to the difficulty of ejecting the urine and semen, as depending upon the structure of the urethra. In the boar this muscle is not confined to the bulb, but forms a layer of transverse fibres, which cover the urethra the whole way to the tip.

The bulbo-cavernosus consists of two portions in the rats, or all the marsupial animals, the elephant, and the camel. In the first two tribes, these cover the branches of the bulb, and also extend to the corpora cavernosa and pelvis: they are, therefore, not strictly muscles of the urethra in these animals. The bulb of the urethra is single in the elephant and camel, notwithstanding its muscle is double.

The bulbo-cavernosus, in some instances, has no effect upon the urethra; the contents of that canal being expelled by a strong layer of muscle that surrounds the first portion of the urethra. Thus two the marmot and squirrel, the bulbo-cavernosus compresses the col-de-fac of the urethra, into which the fluid of Cowper's glands is poured; and in the echidna, this muscle constitutes rather a thin layer, which surrounds both the glandular Cowperi, and performs no other office than that of expelling the fluid from these bodies.

Many mammalia have a muscle for raising and retaining the weight of the penis. It has been described in the bullet as composed of two thick fleshy portions, arising from the arch of the pubis; its tendon is extended along the back of the penis; and towards the extremity it becomes incorporated with the corpora cavernosa. In the liver, marmot, coyp, &c. it is twisted backwards, in order to give the
the proper direction to the penis during coition. This
muscle is remarkably large in the elephani; it is attached to
the pubes by two distinct flabby portions, and partly to the
roots of the corpora cavernosa; they proceed upon the
dorsum of the penis, and their tendons uniting into one, it
runs in a strong ligamentous fascia to the end of the penis.
There is no muscle of this kind in the bos, which is the
reason that manual assistance is given to that animal in
cooition.

In the bear, racoon, the dog, &c. there is a small muscle
arising from each of the roots of the corpora cavernosa,
and conjoined by a middle tendon, which is inserted into the
back of the penis under the pubis. This muscle compresses
the dorsal vein in the sinea callitrix, in which animal the
middle tendon is not found.

In the bisalata there is a muscle on each side, which arises
from the tuberousity of the ischium, and ascends obliquely
inwards, and is inserted into the bulbous part of the urethra.
It brings the bulb downwards and forwards, and contributes
as Cuvier thinks, to elongate the penis.

The artries and veins of the penis are similar in mammalia
and man, except where there are pleurales formed, as al-
ready described.

The nerves of this member are flated by Cuvier to be very
large. He discovered that they formed in the elephant a
net-work upon the veins of the back of the penis, in the
same manner as they have been observed to do on ar-
teries.

The ornithorhynchus and echidna seem to form a link be-
tween mammalia, birds, and reptiles, with respect to their
anatomy. Their alliance with the two last mentioned clas-
ses is decidedly shewn in the structure of the organs of
generation.

These two anim. have a spur upon the heel of the male,
for the purpose of holding the female during copulation.
The spur contains two small bones or phalanges; one is
very short, flattened, and joined to the astragalus; the
other is long and pointed, and serves as the mould of the
horny spur, in a manner similar to the spurs of eetax.
There is no other influence in mammalia of the male poiffelling
any prehensile organ, exclusively designed to be employed
during coition.

The penis of the ornithorhynchus and echidna is attached to
the margin of the cloaca, as in birds and reptiles. It is
covered with the continuation of the lining of the cloaca,
and is composed interiorly of a plexus of blood-veffels, which
become more close and intricate towards the extremity of
the penis. This plexus makes up the whole bulk of the
organ; it is only surrounded by a fibrous sheath, and the in-
teguments already mentioned. There is no urethra in the
penis of these animals; that canal terminating short of it, as
will be presently shewn. The penis is nearly cylindric in its
form, and short; it terminates in the echidna, in four emi-
nences or proceffes, which are hollowed out in the centre,
like cups. These correspond to the glans of other mammalia,
and no doubt are endowed with a greater sensibility than
the root of the organ. Cuvier thinks the concavities of
these eminences or papillæ are unfolded during erection.
In the ornithorhynchus paradoxus the penis terminates in two
papillæ, which have denticulated edges; and the surface of
the penis is more rough and wrinkled than in the echidna.

The erection of the penis in these animals is accomplished
by the dilatation of the vascillar structure of the interior part
of the organ, and by the contraction of the splanchnèr muscle
of the cloaca. The penis is retracted by a particular muscle,
which arises from the splanchnèr ani, and passes along the
under surface of the penis, and is attached to its extremity.
When retracted, it is received into a sac.

The urethra in these animals is simply a musculur canal,
continued from the bladder to the under part of the cloaca,
into which there is a small round tube, not quite at the ex-
tremity of the urethra; that canal terminating in a port of
cul-de-sac. The vasa deferentia open into this canal at
the neck of the bladder. There is a layer of muscle or
fibres arranged obliquely, and meeting upon a middle line,
like the constrictors of the pharynx, which accompanies the
rectum and urethra together, and affolls the muscular coat
of the urethra in ejecting the semen and urine into the
cloaca.

There are two small oval bodies, containing each a cavity,
from which there departs a long excretory duct to the side
of the cloaca when it opens. These glands appear to cor-
respond to Cruiver's.

The margin of the anus is furnished with a row of well
marked follicular glands, similar to those described in birds.

The teffilces are originally formed and situated in the
lunbar region, next the kidneys, in all mammalia, and in
man. In some of the former they remain in that situation
during life, as influences of which we may mention the
ornithorhynchus, the echidna, the elephant, the dama, the nee-
topoda or foul tribe, and the cetace. These animals are con-
sequently without a sertum and cremaster muscles. The
telilces are retained in their proper situation by peritoneum,
in the same manner as the other abdominal muscles.

In a number of mammalia the teffilces leave the loins, and
are placed behind the opening of the abdominal ring, which
is so large that these bodies can easily pass backwards and
forwards through it, as occasion may require. The teffilces
have been observed to come out of the abdomen in this man-
er, particularly in the sefnon for pairing, in the baj, was,
ferrens, hedges-hog; in many of the marine tribe, as the com-
mon rats, banfler, musk rat; and in the guinea-pig, porcupine,
beaver, squirell, &c. In these animals the paffage from the
abdominal cavity to the tunica vaginalis is permanently open,
and of great width.

The situation of the telilces is subject to vary in mam-
mla, when they are on the outside of the abdomen: thus
they are they sendued in a single fagle or sertum, behind the
penis, in the quadruman, the d糍grada, and many plasti-
grada. The sertum is long, and suspended before the
pelvis, and wants the septum sertui, in the opossum kind,
the kangaroo, and phaloxomy. The sertum forms two distinct
pendulous bags in the bare, jebbon, and most of the cloven-
footed in the solid-hoofed quadrupeds.

The figure of the telilces varies but in a few species from
that observed in man. The racoon, hedges, and elephant,
have these glands of a globular form; and in the splitipodo-
and cetaceous tribes they are very much elongated.

The magnitude of the telilces is remarkably great in the
mole and in the salsigrada quadrupeds, being even more con-
iderable than that of the kidneys. In thfe, and in several
other quadrupeds, the telilces become much larger at the
season for procreation than they are at other periods.

The interior structure of the telilces in man and mammalia
is essentially the same. In most of the latter that have been
examined, the tubuli seminiferi are in separate packets. In
the greater number of the salsigrada, however, they are
distinct from each other, and are very large. In the ram,
the seminiferous tubes have been observed to be very dilute,
and to have a peristome or undulating course.

In several quadrupeds the real structure is clearly seen of
the part called corpus Hypogean. It is not a canal, nor does
it poises the structure described by the older anatomists; but is formed by the testes, and tubes like a ligamentous strie or band along the testicle, from which the lanina or fibres that pass downwards and separate the seminiferous tubes of this gland arise. The principal arteries also of the testicle are supplied by this band.

The epididymis is very large in the faligraga and the elephant; in most of the former and in the opifhion tribe, it is nearly attached along the back of the testicle, but is free, except at its origin.

The vesica deferentia have thinner parietes in those animals that retain the testicles always in the abdomen, than in those instances where they occasionally pass into the scrotum, or are always outside the belly. They likewise proceed less directly to their termination in the urinary passages; thus in the elephant, the echidna, the dæmon, and the anti-cater, their course is very tortuous.

Very frequently the vesica deferentia become thicker, or are dilated before their termination. In the otter and seal, and in many of the faligraga, as the bare, easy, beaver, hamster, and the rat tribe, these tubes acquire strength, and in the faligraga juft mentioned, they are also wider as they pass behind the bladder. In the bear, badger, and raccoon, their coats are much thicker, and the two vesica deferentia touch each other, and appear as one canal, but do not really communicate. In the elephant, the vesica deferentia, where they pass beside the vesicule seminales, are dilated into globular faces, the surfaces of which adhere to each other. The vesica deferentia of the horse are dilated to about the size of the human thumb, for five or six inches before their termination. This dilated part consists of a number of cells, resembling those of the corpora cavernosa of the penis, which, when pressed, pour out a milky fluid. Mr. Bratty Clarke states, that the vesica deferentia run in the centre of these cells, with each of which they communicate by small pores. See Anatomy of the Horse in this dictionary.

There is a similar dilatation in the vesica deferentia of the ram, in which there are transverse lamina that form a mesh work.

The vesica deferentia are still more dilated in the buffalo than in the ram or horse. They are not divided into cells or meshes, but there are little cavities that secrete a fluid. They are dilated also in the other ruminants. The design of this structure seems to be to add a peculiar secretion to the semen before it passes into the urethra.

Cuvier mentions a curious variety in the course of the vas deferens, from the scrotum into the pelvis, in the chinese monkey (fusia fusia). In this animal, that canal does not pass through the abdominal ring, but through the anal arch, and ascends between the internal and external oblique muscles to join the cremaster muscle near the ring.

In a very few instances, the two vesica deferentia have but one opening into the urethra. In the badger they terminate in a cul-de-sac, which contains the verumontanum.

The vesiculae seminales are wanting in the following mammals, viz. in all the plantigrada, except the coatis and the hedge hog; in all the digigrada; the genus didelphis, the ornithorhynchus, and echidna; the cloven-hoofed quadrupeds; in the seal tribe, and the cetacea.

The vesicule seminales are nearly similar in the monkey and the human subject.

In the wapiti, but they are large, and form three convolutions. The first third of their canal is without cells or reticulation, and opens into a round body which is situated upon the neck of the bladder, and has the interior divided by membranous lamina into a great number of cells, which are found filled with a seminal fluid. This cellular referent orifice also receives the vasa deferentia, and has two small openings into the urethra. The remainder of the tube of the vesicula is cellular, as usual.

In the common bats they are round white faces, with a simple cavity; their coats are glandular.

In the hedge-hog, the vesiculae appear as bundles of convoluted tubes; usually four in number on each side of that part of the urethra which contains the verumontanum; each of these bundles of tubes ends in one tube, which either opens separately, or conjointly, with that of some of the other bundles or parcels in the verumontanum. These different bundles or vesiculae, when taken together, exceed in bulk that of the two testicles of the hedge-hog.

The vesiculae of the guinea-pig are two long conical tubes, becoming much thinner towards the extremity: they have some dilatations in their second half.

In the agouti they are also large tubes, and have some smaller branches.

In the marmot of the alp the vesiculae are small; their cavity is very intricate, and their coats glandular. They are similarly formed in the bobœ, according to Pallas; but he describes the vesicula of the puffle (wus cîthâs, Pall.) as being composed of a little puckered tube, which adheres to a mass formed of smaller tubes.

The rat tribe have the vesicula seminales enormously large, particularly during the season of procreation. They project even beyond the pelvis. They are membranous globules, conical in their figure, but twisted, and having their cavity rendered unequal by dilatations on their convex edge.

The common hare and rabbit have one face in place of the vesicula seminales. This is of a considerable size, and of a rectangular figure. The external corners are sometimes extended from the body of the face, and represent the two vesiculae. The coats of the face are membranous, except in the two-thirds of their superior side, which are very thick and glandular, and similar to the substance of the prostatic gland. The opening of this face into the urethra is single.

In the kpus puflîus, gaotone, and alpinus of Pallas, the vesicule are two, and separate, as in other animals.

In the squirrel the vesiculae are small, wrinkled, convoluted tubes, with glandular coats.

In the dæmon, according to Cuvier, the vesiculae are very large and ramified.

The rhinoceros has the vesicula making two tolerably large bladders: their cavity is irregular, from a number of dilatations on their exterior side.

In the boar, the vesiculae are remarkably large, and composed of lobes and lobules which contain cells interiorly, that communicate with each other. All the lobes pour out their contents through a common canal, which opens in the verumontanum. The vesicula seminales of the elephant are very large. Their figure is nearly oval, there being a contraction which separates the top from the rest of the face. The internal surface of the top and middle portions is provided with irregular columns or projections of the internal membrane of the vesicula, which is much thicker towards the top or end of the face than elsewhere. The vesicula are furnished with a muscle for expelling their contents in this animal. It arises from the neck, and extends as far as the middle part of the face, its fibres spreading as they proceed.

In the horsæ and civis, the vesiculae are two long membranous bladders, like portions of an intestine. They are wider at the end or fundus than the neck, which ends in a large excretory canal, that opens into the urethra by a common orifice with the vas deferens.
Mammalia.

Some anatomists have supposed that the prostate glands of the eleven-footed quadrupeds were the vesiculae feminales. The only part corresponding to the vesiculae in these animals, is a ligamentous bridge extending between the ends of the two vasa deferentia, and serving to unite the bafes of the prostate glands. This ligament has been observed in the ram, the ox, &c. But in the fallow deer, the place of the ligament is taken by two little capsules, which appear to be glandular, and their cavity to lead to the verumontanum, by the same orifices with the vasa deferentia.

The parts supplying the place of the prostate gland, are very different in their structure and number in different genera of mammalia. The termination of the prostatic duct or ducts also is various; they are found to open into the origin of the urethra, or throughout its extent, or towards the end of that canal. In some of the salpingidae, in the hedge-bog, and in the mole, the parts corresponding to the prostate glands are described by Cuvier as a distinct series of glands, which he, calls vesiculae accessoriae, on account of their having a structure similar to that of the vesiculae feminales, and because they are observed to enlarge during the season of procreation; but their being found in those animals which have not prostate glands of the usual structure, and yet are remarkable for the magnitude of all the genital organs, would lead us to receive these vesicular bodies as analogous to the prostate glands of other mammalia; we shall therefore describe them as such in the proper order of the animals to which they belong.

The prostate gland in the monkey tribe is similar to that of the human subject, except that it is somewhat different in shape. In the mandrill, there are some additional lobes to the prostate.

This gland in the lemurs has two offsets, which surround the excretory ducts of the vesiculae feminales. There are two in the lemurs tarsius, which form distinct tubercles before the vesiculae upon the sides of the urethra.

In the vampire bat, the prostate is simple, as in man and the monkey; but in the common bats, this gland consists of a great number of lobules.

In the bear, the tubular of the prostatic appears to be confounded with the enlargement of the united vasa deferentia.

In most of the veriform quadrupeds, as they are called, such as the weasel, and in the otter, this gland appears like a flap upon the urethra. In the ichneumen, however, it is of a considerable size.

The hedge-bog, as before observed, is one of the animals which has the prostate formed of a number of tubes. It has four bundles of these tubes, which are smaller than those of the vesiculae feminales, and arranged parallel to each other, branching into still smaller tubes.

In the mole, this gland is also composed of a mass of tubes, ramified and convoluted upon each other. During the season for copulation, these tubes enlarge so much, that they form a bundle, according to Cuvier, of a greater bulk than the urinary bladder.

In the agouti and guinea-pig, the prostate is formed of ramified and convoluted tubes. The former animal has these tubes ending in vesicular processes.

The rat tribe and lagomys have also tubular prostates, and in addition to them have two glands, which are attached to the inner surface of the vesiculae feminales. They are composed chiefly of one tube.

In the other salpingidae, the prostate gland is a single mass, often divided posteriorly into two lobes.

The prostate is single also in the digigrade and pedimanous quadrupeds, as far as they have been examined.

In the boar, it is divided into lobes, and there is besides a layer of glandular substance, which surrounds the origin of the urethra.

The elephant has four prostate glands, which are small in proportion to the other parts of generation. They are of different sizes with respect to each other. Some muscular fibres are spread over them which serve to prevent their secretion. Each gland contains one principal cavity, with which smaller cavities communicate: these left fill the indistinct lobes that are seen upon the glands externally. The chief cavity of each gland produces a duct, and these ducts terminate separately at the hobo of the verumontanum.

The eleven-footed quadrupeds have two prostates posessing the same cellular structure as those of the elephant. The lobes are still more indistinct in the ram and bull.

There are four prostate glands in the four-footed order. The two first are paler, and have larger cavities than the others. They are covered with muscular and tendinous fibres, which are extended to them from the vesiculae feminales and the bladder. The ducts from this pair of glands have many orifices in the urethra. The second pair of prostates are situated towards the end of the membranous portion of the urethra. They are enclosed by muscular and tendinous fibres. They have each twelve ducts, which open by as many orifices, arranged in a row in the urethra.

The felid tribe have the same form of prostate as that described in the otter.

The cetacea have the prostate in a single mass, and cellular internally, as in the human subject, &c. The muscle which surrounds it is very strong.

The glands called Cowper's are much larger, and consequently of more importance, generally, in mammalia than in man. They are wanting in some genera, and present in others closely allied to them. These glands, therefore, as well as the vesiculae feminales and prostatic, are not subject to any general rule, or regulated, either as to their existence or magnitude, by the anatomical rank or character of the animals. Cowper's glands are not found in the bear, raccoon, hedge-bog, mole; and are wanting, according to Cuvier, in all the planigrade, except the ichneumen; in the dog genus; the veriform quadrupeds; in the hare and rabbit; in many other of the eleven-footed tribe; the boar and ass; in the seal, and in the whale tribe.

These glands become larger than in man, in proportion to the size of the animals, in the quadrumanous and chiropterous mammalia.

They are also very large in the cat and rat; of a still greater size in the hyena. The muscle that surrounds them in these animals is very thick.

In the ichneumen, the glands of Cowper are very remarkable. They are covered by a layer of muscle, and each of them is besides inclosed in a musculo-tendinous sac. Each gland consists of a number of vesicles, which communicate with each other, and furnish a single excretory duct, that runs along the lower part of the urethra, and terminates by a distinct opening in the bottom of the cell at the end of the penis, in which also the urethra itself finishes. These glands have an egg shape, and are of great size.

In the marsupial animals there are several Cowper's glands, and it is remarkable that they are not wanting in this tribe, although the other glands are in force of the genera. The Mexican and Surinam Opposum (didelphis cupidollin, d. orientalis), the phoscolemys, and the great kangaroo, have fixed Cowper's glands. The kangaroo, rat, and Virginian Opposum, have four. In all these animals they are composed of tubes which lie in the longitudinal direction of the glands.

In the echidna, there is a gland analogous to Cowper's
on each side of the cloaca. They are small oval bodies, containing a narrow cavity internally, from which a long duct proceeds. It passes through the constrictor muscle of the cloaca, and goes to join the little canal by which the urethra opens into the cloaca. These glands are surrounded by a very strong muscle, which urges their fluid out when occasion requires.

The *squirl* has two large vessels, cone-shaped, and coiled upon themselves. The top of these has thick glandular coats, and is divided, interiorly, into a number of little cells. The glands both open into a cavity in the bulb of the urethra, which is continued into a canal that extends to the bend of the penis when it opens into the urethra. The *alpine marmot* and the *bobcat* resemble the *squirl* in the structure of their Cowper's glands.

The *bear* has these glands in the form of long flattened cylinders. Their substance has a firm texture; it contains small cells, which open into larger ones, and they again join to form a common cavity, from which a canal proceeds to open at the side of the urethra, within the bulb. Their muscle has oblique fibres. The glands of Cowper are very large in the *elephant*, in proportion to the prostates, as before-mentioned. They have an irregular form, as if lobulated. There is a distinction of two portions to be observed: the first is situated next the bulb of the urethra, and is small: it is divided internally into cells, which are of different sizes, the smallest being external, and the larger opening at last into a common cavity in the centre of this part of the gland, which furnishes a duct to join the principal duct that comes from the rect of the gland. The larger portion of the gland contains two central cavities, each give origin to a duct. These two ducts concur to form the principal duct above-mentioned. It proceeds, for some way, in the parietes of the urethra, before it opens into the canal. The glands of Cowper have a very thick muscle in this animal; the fibres of which are collected upon a tendon that is attached to each side of the corpora cavernosa.

In the *camel*, the glands of Cowper resemble, in figure and size, pigeon's eggs; their texture is close; and their single excreta duct terminates within the bulb of the urethra. The same structure is observed in the other cloven-hoofed quadrupeds which possess these glands. The muscle for compressing them in this tribe is very strong.

The figures which illustrate the male organs are found in Plates VI. and VIII. of the *Anatomy of Mammalia*.

Fig. 7, in *Plate VII.*, exhibits the os penis of the dog: a points out the groove in which the urethra is inclosed for some distance. Fig. 8, of the same plate, is a view of the os penis in the squirrel. Fig. 1, in *Plate VIII.*, shews a transverse section of the penis of the *kangaroo*, in which the canal of the urethra, as indicated by a, is seen in the middle of the united corpora cavernosa. Fig. 2, of the same plate, is a similar section of the *kangaroo's* penis nearer the end, in which the urethra is seen to be gaining the side of the penis. Fig. 3, of the same plate, is a longitudinal section of the penis of the *dog*, after the cellular structure had been injected with quicksilver, dried, and emptied: a, the glans penis; b is the bulb behind it; c, the trunks of the veins going backwards from the bulb, which are compressed by the sphincter vaginae of the female during the coitus. Fig. 4, is a view of the penis of the *guinea-pig*: a shews the glans, armed with horny scales; b are the hooks that come forth from the pocket in which the urethra terminates; c, c, the muscular falciculi that retract the pouch. Fig. 5, is the penis of the cat: a, the glans furnished with reflected horny spines. Fig. 6, of this plate, represents the male organs of the *kangaroo*: s is the urinary bladder; q, the ureters; r, the vasa deferentia; p, the first part of the urethra, which is inclosed in the prostate gland; a, b, and c, are the three glands of Cowper, on each side; d, d, are the two branches of the bulb of the urethra, each enclosed in its proper muscle; e, e, are the two branches of the corpora cavernosa, inclosed by their muscles; that on the right side is laid open longitudinally to expose its interior, and the fection of the muscle; g is a portion of the sphincter; and k is a portion of the levator ani muscle; i, the rectum; l, the anus; a is the pointed glans of the penis. Fig. 6, of *Plate VII.*, exhibits the male parts of the *ichneumon*: a is the bladder; b, b, the ureters; c, c, their orifices in the neck of the bladder; d, d, are the vasa deferentia; e, e, their orifices in the urethra; f, f, f, the different lobes of the prostate gland; h is Cowper's gland of the left side exposed, the muscular sac in which it is inclosed being laid open; i, the opposite gland, covered with its muscle; k is the excretory duct of the left Cowper's gland; l, an opening seen at the lower part of the glans penis, which leads into the cell where both the urethra and excretory ducts of Cowper's glands terminate; m is a part of the ichineumonous muscle of the right side; n, n, the rectum, at the lower part of which the anal glands are seen, which are already described and referred to under the head of the excretory glands in this article. Fig. 7, of *Plate VIII.*, exhibits the male organs of the *phal Tablet ura*, (dolichotis vetunea Shaw): a, the urinary bladder; b, b, the ureters; c, c, the vasa deferentia; d, d, the teats, of which the one on the left has the tunica vaginalis slit open; k, the first portion of the urethra; l, l, the branches of the corpora cavernosa enclosed in their glands; m, m, the branches which form the bulb of the urethra, covered also by muscle; n, o, two of the glands of Cowper, seen on each side; the third are concealed by the branches of the bulb of the urethra; q is the glans penis; r, r, the retractor muscles; s is the rectum. Fig. 5, of *Plate VII.* is a view of the organs of generation in the male *elephant*: a, a, the singular termination of the penis in this species; b, the body of the penis; c, the cloaca; d, d, the rectum, slit open and divided, to shew the canal which conduces the urine and semen to the cloaca; f is that canal laid open; f, f, orifices of glands; c, c, Cowper's glands; g, a portion of the body of the animal, its opening into the urinary canal; h, h, the vasa deferentia; e, e, the epididymis of each side; m, m, the testicles. Fig. 8, in *Plate VIII.* represents one lobe of the vesicular feminalis of the *hedgehog*, which is seen to be composed of convoluted tubes. Fig. 9, of the same plate, shews the single vesicular feminalis of the hare; a, the penis; b, the urinary bladder; c, the vesicle, with its two horn-shaped procceses. Fig. 10, is a view of one of the lobes of the prostate, or, as Cuvier calls it, accessory gland of the *hedgehog*.

**Female Organs of Generation**—The orifice of the *vulva* is not provided, in mammalia, with either the external or internal labia. It is a simple fissure in most cases, taking the direction of the body. The *kyona*, however, has this flat placed transversely. In the *falsigrada*, the orifice of the vulva is circular, and in many of them, and in the *marfpal* animals, it is surrounded by a sphincter, common to it and the anus.

The *vulva* is not a mere entrance to the vagina, as in the human subject, but forms most commonly a canal of some length, proceeding the true vagina. In the *prehensile-tailed*, and other *American* species of *monkey*, this canal is, according to Cuvier's observations, as long as the vagina. In the *bear*, it is even much longer. In some cases, however, the vulva is little more than the aperture of the vagina. It has been observed to be so in the *lemur*, the *agouti*, *paca*, and *guinea-pig*. In the *baboon* also, it is a very shallow cavity.

I. I. 2
Mammalia.

The internal surface of the vulva has usually slight rugae, which disappear upon the part being stretched. In the tiger they are oblique in their direction, and very small. They are transferrable in the *hippocæa* and the *hyena*, in which they are numerous, fine, and undulating. The *gauan* has the interior of the vulva smooth. There are glands analogous to those of Cowper, the ducts of which pass into the sides of the cavity of the vulva. These glands are remarkably large in the *cat* genus and *mar Sophia* tribe of mammalia. They are composed of a muscular investment.

The clitoris of mammalia is of various figures, sizes, and structures.

Its situation in all quadrupeds is necessarily the reverse of that in the human subject: the part of the vulva next the pubis being the lowest in all animals whose flattation is on four legs.

The clitoris is situated farther in where the vulva forms a canal, than in other cases. In the *bubon*, and in the *rat* tribe, the clitoris is situated externally to the vulva; in the latter animals, the *ilia* before the vulva forms a projection, which serves as a sort of prepuce to the clitoris, at which place also the urethra terminates; there are, therefore, in the rats three apertures in succession: the orifice of the urethra, the opening of the vulva, and that of the anus.

The clitoris of quadrupeds so generally resembles the penis of the males in the same species in form and structure, that it has been supposed they were similarly constructed in every instance. There are, however, exceptions to this rule: the clitoris in the *quadruped*, the *cow*, and the *dog*, wants a bone, although there is an os penis in these animals.

The shape of the clitoris is frequently greater in proportion than in the human subject; it is particularly so in the *monkeys*, *lemurs*, most of the *divers* grade and *altrigra* grade quadrupeds. It is very long, and curved upon itself, in the *bear*. In the *mar Sophia* mammalia, which have a *bipennis*, the clitoris is also double.

The prepuce of the clitoris sometimes forms a deep sac, in which the latter is nearly concealed, as in the *dog* genus. This prepuce is furnished with numerous februeous glands, like those of the penis, and in the *rat* kind they are extremely large.

The orifice of the urethra is found pretty uniformly upon the extremity of the inferior part of the vulva; it is, consequently, often much deeper seated in mammalia than in the human subject.

In the *prose* and other species of the new continent, the urethra opens in the pubes, in a furrow of a straight fold, extended from the hymen. Sometimes this canal is found to open in a slit between two tubercles, or folds, of the inner membrane of the vulva, which are sometimes extended upon the sides of the groove on the back of the clitoris, to conduct the urine out. In other cases, the urethra opens in the middle of a papilla. This orifice is in the bane of the clitoris in the *osoua* and *paca*; but in the *lemurs*, properly so called, and the *bibi*, the urethra passes along the back of the clitoris, and opens near its end.

A general opinion has prevailed that the hymen is peculiar to the human subject, which seems to have arisen from supposing this part to be formed for the sole purpose of proving the virginity, and, consequently, the purity of the mind in the female of the human species. Similar obstructions, however, to the congref of the lexes, are found in a considerable number of mammalia, and probably exist in many other species that have not yet been examined for this circumstance.
The **Mammalia**.

other in the *tardigrada*, and in the *edeniata*, the canal which conduces to the uterus in these orders being extremely short.

The **uterus**, in a few tribes of mammalia, possesses the same triangular form as in the human subject; inch is the cæsa in the tardigrade quadrupeds, the *aeo-eaters*, the *pangolins*, and the *armadillos*. It is nearly similar in the monkey kind, but in thefe the body is more round, and the neck is distinguished from the rest of the uterus by a contraction.

In all the remaining orders of mammalia, except the *marsupial* animals, the body of the uterus is more or less prolonged on each side, and forms what have been called *cornua*. The extent of these lateral divisions is, in many instances, very considerable; they often reach into the loins, in which cases the broad ligaments of the uterus are much spread out, and in the large quadrupeds there are mucosal fibres placed between their lamina. According to Cuvier these form different fasciculi in the *cows*, one of the *frongell* of which extends from the ovary to the neck of the uterus. It approximates these parts, but for what purpose is not known. Besides these there are some transverse fibres, which go from one side of the uterus to the other in the third of their length. The round ligaments also possess, in general, mucosal fibres. The division into cornua is less marked in the *lemur* than any other genus. They have the uterus rather formed into two lobes than cornua.

The neck of the uterus is very short in some species; in the *agouti*, the *paca*, and the *guinea-pig*, it can scarcely be said to exist, and in the *hare* and *rabbit* there is no part corresponding to the neck, but the two branches or cornua of the uterus open immediately by two distinct orifices into the vagina.

In the *ornithorynchus* and *echidna* there is no neck or body, properly speaking, to the uterus. The organ consists merely of two large convoluted tubes, which terminate by two distinct orifices in a common canal, which leads from the bladder to the cloaca, and appears to serve altogether the purpose of the vagina. The frict portion of these tubes is the widest. This corresponds apparently to the cornua uteri. The succeeding part is the most contracted; but terminates in a wide mouth that seems to supply the place of the Fallopian tubes, which are wanting in these animals.

It is probable that the uterus is formed in the *marsupial* animals is very peculiar. There are parts corresponding to the cornua, and to the body of the uterus, and in addition to these, two lateral canals. The cornua are oval cavities continued into small canals that extend to the ovaries, and are the Fallopian tubes. The oval cavities have been generally considered as the dilatations of these tubes, but Cuvier affirms that they are very distinct from the small parts of the canal which are really the Fallopian tubes. The openings of the cornua into the part corresponding to the body of the uterus are separate from each other, and are guarded by valvular folds. The body of the uterus is a straight canal, which is widest at the fundus, or the part that receives the horns, and becomes gradually less capacious as it approaches its termination, which is in the vagina, close to the orifice of the urethra. The body of the uteri is a single cavity in the *kangaroo*, *phalangers*, and *phalanger*; but in the Virginian *opossum*, the *wombat*, and *kanguroo*, the uterus is double, or consists of two cavities. Mr. Bell has described these in the *wombat* as having a pyramidal form. The right was considerably the largest, being about the size of a pullet's egg.

It should be observed, however, in this instance, that the right uterus was gravid. From the fundus of each of these uteri there was a Fallopian tube, nearly three inches long, which terminated at the ovarian. This tube had no dilatation at its junction with the uterus, which appears to confirm Cuvier's opinion of the dilatations in the *kangaroo*, &c. answering the purposes of the cornua uteri. The double uterus of the *wombat* had a common neck half an inch long, and of considerable breadth and thickness, which however had two orifices in the vagina. In the Virginian *opossum*, the two cavities of the uterus are formed by a longitudinal septum of the part corresponding to the body, and each of these cavities has a separate opening into the vagina. In the *kangaroo*, *phalangers*, and *phalanger*, there is but one opening from the uterus into the vagina, which is flattened by Mr. Home to be fo small in the virgin *kangaroo* as to be scarcely discernible.

By comparing the number and situation of the communications of the uteri in the vagina, with the form of the male organs in the *marsupial* mammalia, it will be sufficiently plain that the female passages, as in other cases, into the uteri directly, and not by the circuitous course of the lateral canals, as have been supposed.

The lateral canals arise in the *kangaroo* from the fundus of the body of the uterus where the cornua terminate, and in the *wombat* from the posterior surface of the common neck of the two uteri, near its junction to those uteri. The canals describe a semicircular curve, and terminate in the vagina, on each side of the orifice or orifices of the uteri.

The use of these lateral canals it is difficult to explain. It has been observed, that the ovum of the *marsupial* animals had no connection with the parietes of the uterus, but were involved in a species of jelly, which has been supposed to supply the nourishment of the fœtus. Mr. Home has conjectured that the jelly is secreted by the lateral canals, because they become fluit towards the vagina, enlarged throughout, and maintain a free communication with the uterus after impregnation. We are not, however, sufficiently acquainted with the history of gestation in these animals, to determine whether the changes in the canals subsequent to impregnation, may not be required for other purposes than the secretion of the jelly found in the uterus.

The uterus has but rarely, in mammalia, that projection around its orifice which is called the *os thUCE* in the human subject. Most commonly the os uteri is a transverse slit at the end of the vagina, and so much on the lower part of that canal, that the superior parietes form a cell or cul-de-sac above it. In the *porcupine* the os uteri has no flight a prominence, that it appears as an opening of the inferior part of the vagina. In the *bear*, *cow*, and others, the vagina makes a projection which tends to obstruct the paffage into the uterus.

The **structure** of the uterus is the same in the *monkey* and the human subject; but in the other mammalia the parietes are thin, and generally composed of layers of red muscle, superadded to the internal membrane, and external coat in the same manner as the alimentary canal is formed. These muscles are particularly plain in the double uterus of the large quadrupeds. There is a transverse layer of muscle upon the cornua covered by a thin layer of longitudinal fibres. The neck of the uterus commonly has the transverse layer only. The principal thickness of the neck of the organ in the *cow* is, however, composed of a white hard texture, resembling the substance of the human uterus.

The internal membrane of the body of the single uterus, and of the cornua of the double uterus, usually exhibits longitudinal folds, but in the *cow* they are transverse, and inflected into each other.

The changes of structure which the uterus undergoes after....
impregnation will be described under the head of Ovum, History of, in viviparous animals, in the subfrequent part of this dictionary.

The uses of these changes will be more easily understood, by being contemplated in conjunction with the parts immediately connected with the embryo. We shall also refer the account of the mamma, and marsupial, or sucking pouches, for the same head, as these organs are likewise subservient to the dependent state of existence of the young animal.

In Plate IX. of the Anatomy of Mammalia, the structure of the unimpregnated female organs is exemplified. Fig. 1. represents the uterus, vagina, and vulva of the bear, a portion of the parietes of the two latter parts being removed, to expose their internal surface; a is the mouth of the vulva; b is the clitoris, half concealed in its preputial pouch; c, the internal surface of the vulva; d, the valvular fold corresponding to the hymen, under which the orifice of the vagina is seen; e, the vagina laid open; it is shorter than the vulva, and its longitudinal folds are crossed by grooves; f, the crucial slit that leads to the uterus; g, the body of the ovary; h, h, the two cornua. Fig. 2. shows the double uterus of the rabbit: a is the vulva opened; b is the clitoris; c, the vagina laid open; d, d, the orifices of the two uteri or cornua in the vagina. Fig. 3. exhibits the female organs of the ornithorhynchus paradoxus: a, the cloaca laid open; b, the vagina, or canal which receives the urine, and the two lateral tubes or oviducts; c, the opening into the bladder; d, d, the two orifices of the oviducts; e, e, the dilated parts of the ducts, which apparently correspond to the cornua uteri; f, f, the contracted portions of the ducts which represent the Fallopian tubes; g, g, the termination of the ducts, which probably supply the place of the infundibula of the Fallopian tubes. Fig. 4. is a view of the female parts in the kangaroo: a is the short canal corresponding to the vulva and vagina laid open; b is the clitoris; c, the meatus urinarius; d, d, the lateral canals arizing at the fundus of the body of the uterus, and terminating in the vagina; e, the middle canal which corresponds to the body of the uterus in other mammals; f, f, the dilated parts which Mr. Home has considered as belonging to the Fallopian tubes; but which Cuvier more correctly, in our opinion, calls the cornua of the uterus; g, g, the parts of the tubes which really represent the Fallopian; h, h, the ovaries; i, i, the ureters.

If we except the formation of the tubes which correspond to the Fallopian in the marsupial mammalia and the ornithorhynchus, and the echidna, there is scarcely any peculiarity to be remarked in the Fallopian tubes in mammalia. Blumenbach states that they are found to be convoluted, sometimes fo to form a knob, as in the pygmy (sminia fosivans), and in the opossum. The imbriated extremity of the tube is constructed like a funnel in the rabbit, &c.

The ovaries of mammalia possess the same structure, as to all material circumstances, with those in the human subject. The figure of these bodies is frequently more round in their shape than in woman. In general, the vessels containing the ova are buried in the substance of the ovaries, as in those of the human species; but in some quadrupeds they are found near the surface, so that the ovaries appear tuberculated; this has been observed in the pig, the swine, and in the opossum, the ovary of which is entirely made up of the vessels. The most unusual form of the ovary is in the hedgehog. The vesicula Graafiana are contained in capsules, which are distinct externally, but connected together by their foot-lics, somewhat like the raccusius vilitorum of birds.

The corpora lutea grow much larger than the cells of the ovary from which the vessels have been expelled, at least in some quadrupeds. We have observed them, in the sheep, to be composed of a solid, firm, fleshy substance, intercommunicated by membranous lines, somewhat like a carcinomatous tumour, and to be about the size of a small cherry.

Fig. 5. Plate IX. of the Anatomy of Mammalia, exhibits the ovary of the hedgehog, which appears like a cluster of ova bound together. Fig. 6. represents a portion of the ovary of the sheep, from which an ovum had been recently discharged: a is the vacant cell. Fig. 7. is another portion of the ovary of a sheep, in which the deposit above described had been made in a cell, after the ovum had left it: a is the section of the substance of the ovary; b is the section of the new substance, or, as it is called in other cases, the corpus luteum.

Bones.—The skeletons of mammalia exhibit many important peculiarities, not only as compared with that of the human subject, but with each other. This class has great varieties in the modes of locomotion; and consequently in the organs by which these are effected. In all the deviations in the mechanism of the skeleton, the quadrumanous tribe seems to be the model. Thus, the parts which constitute the arm and hand, or are necessary to make a prehensile member, are found in those that employ the extremities for walking, flying, or swimming, in a greater or less degree obliterated, changed, or concealed; although the members have so different a form externally. The long tail also seems to be the model from which the short coccyea of some mammalia and of man is the deviation.

The interior composition of the bones of mammalia is generally the same as in man. Their texture is most close and dense in the small quadrupeds. We have observed the bones to be particularly hard and fragile in the kangaroo, but this might have been from the manner in which they had been prepared. The bones of the cetacea exhibit very plainly the fibrous structure, it being more loosely arranged than in the terrestrial mammalia. In the long bones, the fibrous fibres can be easily separated, and the cells of the spongous bones are exceedingly evident. Both in the feet and the cetacea there are no large medullary cavities in any of the bones. The texture of the bones in these animals has the effect of rendering them lighter than those of other mammalia; and therefore better suited to locomotion in the water. The vertebrae of the whale tribe, especially those towards the end of the tail, are much more dense in their structure than the other bones. All the cells of the bones in those animals are filled with fluid oil.

It has been attempted to establish a regular gradation in the proportions of the magnitude of the cranium to that of the face amongst the different mammalia, with the view of fixing the relative size of the brain, and consequentl the degree of intelligence possessed by the animal.

Daubenton and Camper proposed measuring the relative size of the cranium, by superposing two straight interfering lines to be drawn upon the cranium and face. The angles which they exhibit in different species determine the relative bulk of these parts. Camper's method was the most accurate. He drew one line upwards, which touched the incisor teeth of the upper jaw below, and the greatest projection of the forehead above; this he called the facial line. The other line was superposed to pass along the lowest part of the cranium. It was taken in the plane corresponding to the external meatus auditorius and the floor of the nostrils, and was called the basilar line. The angle formed between these two lines determines, according to Camper, the differences of the crania of animals, as well as the national physiognomy of the various races of mankind.
Mammalia.

It is obvious, however, that the projection of the frontal sinuses in many of the large quadrupeds, especially the elephant, must, in a degree, interfere with the accuracy of this mode of measurement. The great size of the nasal cavity in some species, and the prolongation of the jaws in others, will also form exceptions to a rule founded upon this principle of measurement. Blumenbach states that about three-fourths of all the species of quadrupeds with which we are acquainted, whose crania differ extremely in other respects, have the same facial line.

Nevertheless it must be admitted, that the proportions which the cranium (as indicating the bulk of the brain) bears to the face, serve in general to determine the mental endowment of animals. It is strikingly proved by the monkey tribe, which most nearly approach the human subject in the form of the head, polishing so much more of the mental character of man than any other animal in the classes.

The following table will shew the number of degrees of the facial angle in several species of mammalia.

<table>

According to this table, the facial angle of the orang-outang does not differ materially from the human, the adult negro having it only 70°. In the European head it is 87°, a difference generally considered as accompanying a gradation of the intellectual powers in these races of mankind. This opinion is not a modern one, but seemed to have been entertained by the ancients, who always made the cranium, in the statues of their gods and heroes, project more than is observed in any human head. The facial angle of many of the antique statues is 100°.

Another method of arriving at the relative bulk of the cranium and face, is to measure and compare the area of each, after there has been a vertical and longitudinal section made of them. The area of the section of the European human cranium is four times as large as that of the face; the lower jaw not being included. In the negro, the cranium remaining the same, the area of the face is increased about 4th. In the Calmias only 3/4. In the orang-outang the proportion of the face is further increased. It is nearly equal to the half of the cranium, in the other monkeys and the digitigrade quadrupeds.

In the other orders, the area of the face is generally larger than the cranium. The bare and marmot have it 3d larger. It is nearly twice as large in the cloven-footed quadrupeds; still more than double the size in the porcupine; nearly three times in the hippopotamus, and almost four times the size in the horse.

The cetacea have the face so much flattened, in consequence of wanting the nasal cavity, that it does not admit of a fair comparison with the cranium.

These modes of measuring the cranium only indicate the extent of its circumference in one direction. In order to arrive at the real bulk of the cranium, or of its contents, it would be necessary to make a vertical section from one side to the other, and a transverse section, so as to detach the upper half of the skull from the lower, as is done for the division of the brain; or, what would be still more satisfactory, to weigh the brain, first having ascertained the variations in the weight of a given bulk of brain in different species, if any do exist.

The number of bones composing the cranium in mammalia is frequently different from what is found in man. In some species certain bones remain during life in separate pieces, while in others, the futures that are always found in the human cranium are to early obliterated, that two, three, or more bones are consolidated into one.

The quadrumanous, and all the bovid mammalia, have freely the sphenoid bone in two parts. The future of the middle of the os frontis is found in the digitigrada, saltigrada, the hog, tapir, hippopotamus, rhinoceros, seal, and mors. In the cloven and solid-footed quadrupeds it exists for a considerable time. The bone containing the cavity of the tympanum is divided by a future from the rest of the temporal bone in the cat, dog, and civet genera; the saltigrada, the ruminants, solipeds, seal, lamantins, and cetacea.

In the cetacea the parietal, occipital, and temporal bones are united together; although the sphenoides is long, distinct, and even divided into several pieces.

All the futures of the cranium are very soon obliterated in the elephant.

The bones of the cranium in mammalia have not always the same connections with each other as in man. Even the orang-outang, whose head bears so strong a resemblance to the human, does not agree in this respect. This animal, as well as many other species of monkey, has the temporal wing of the os sphenoides very narrow, and not extended to the parietal bone; the temporal bone is partially joined to the frontal. The jocko has the temporal bone articulating by its squamous portion immediately with the os frontis, the temporal a of the sphenoides not being connected with either the frontal or parietal bones. In the sapajous, or monkeys with long prehensile tails, the parietal bone is articulated with the os male. In the bowing baboons, and the digitigrade quadrupeds, the bones of the cranium have the same connections as in man.

In all the saltigrada, the armadillos, pangolins, and sloths, the sphenoid does not articulate with the parietal bone; but in the anti-eater these two bones are extensively connected.

In the ruminants the os sphenoides has the same connections
The occipit is round in the anti-eater and cetacea; it is smooth and without processes in the mole.

The elephant has the occipit nearly square, and the condyles at the posterior extremity. There is no occipital prominence, but a depression in place of it, containing a longitudinal ridge for the insertion of the ligamentum nuchae.

The mufloid process belongs to the occipital bone in all mammals, except the monkey, in which it is an appendix of the os temporis, as in man. This process in the apes, and most of the monkey kind, is nearly obliterated. Most of the digitated quadrupeds want the mufloid process, and merely have a slight protrusion from the projecting part of the cavity of the tympanum; or this cavity itself supplies the place of the mufloid process. The cavv, bog, guinea-pig, the cloven and folved-feeted quadrupeds, &c. have a long triaoidal process behind the cavity of the tympanum.

The position of the foramen magnum is remarkably different from that of the human subject; it removes from the under part of the head, even in the monkey tribe, and in the true quadrupeds is found at the posterior part of the cranium, and situated so, that the edge, which is posterior in man, is directed obliquely upwards. This edge is in some quadrupeds turned directly upwards, or, as in the alpine marmot, is even turned more forwards than the other edge of the hole. The relative position of the occipital foramen was employed by Daubenton to determine the gradations of the cranial peculiarities of different animals. He drew one line from the edge of the hole, which is posterior in man, but superior in most quadrupeds, as already mentioned, through the lower edge of the orbit; another line was taken in the direction of the foramen itself, beginning at its posterior edge and touching the articular surface of the condyles. The angle formed by the intersection of these two lines, was considered by Daubenton as indicating the variations of form and magnitude of different crania. It has been objected to by Blumenbach, upon the fame ground that he disapproved the facial angle of Camper, namely, its not expressing all the variations that exist.

The fquamous portion of the temporal bone, as already noticed, is much less extensive in mammalia, even in the orang-outang, than in man. The principal part of this bone, as it appears externally in many quadrupeds, is the zygomatic process. The petrous portion of the os temporis will be described along with the other parts of the organ of hearing, to which it properly belongs.

The zygoma is not merely formed by the junction of the processae of the temporal and malar bones, but has an intermediate piece of bone in the ater, opifsum, beaver, guinea-pig, &c. Cuvier also mentions a particular bone which supplies the place of the zygomatic angle of the os male in the green ape, but which bone is soon anchylofed with other malar.

The zygoma is remarkably broad in the opifsum and the kënguroo.

In the mole, it is a straight process, not much thicker than a needle.

In the cetacea, at least the genus delphinus, the zygoma is a very slender osseous bar.

In proportion to the extent and strength of the mifereter muscle, the zygoma forms a curvature in an upward direction, and when this muscle is less considerabe, the zygoma is either horizontal, or makes a convexity downwards. The zygoma is universally arched upwards in the carnivorous quadrupeds. The faltigrada have the convexity downwards, and in the cavv and the paca, it even extends below the dilance of the molar teeth.

The
The zygoma of the *fus aethiopicus* is nearly horizontal, but is extremely broad and thick, and forms all the broad part of the cheek under and before the eyes.

The curvature of the zygoma outwards, which gives it the proper name of an arch, depends upon the magnitude of the temporal muscle which presses under it. We, therefore, find the zygomatic arch very wide in all the carnivorous tribe of quadrupeds, and particularly in the cat and *canis*, upon which depends the round shape of the head of the tiger, leopard, cat, &c. in a great measure.

The large herbivorous quadrupeds, in general, have the zygoma but little arched outwards. It is the same in most of the *cetacea*.

The zygoma is quite straight in the mole, and in the cetacea.

It is not found to form an arch outwards, of any consequence, in the *dentata*. In the *Capo ant-eater* it is perfectly straight.

In the pangolins and *American ant-eaters*, the zygomatic arch is incomplete; the latter animals have merely two tubercles in place of the processes, which usually form the zygoma.

The zygomatic arch, also, is not complete in the *flabell*. The os makes terminates posteriorly in two angles; the one superior, which extends above the zygomatic processes from the os temporalis; the other inferior, which presses obliquely downwards, and is unattached.

We shall describe the *ebonoid bone*, more particularly, under the head of the organ of smelling, by which its use will be more apparent.

The large fossæ, or depressions upon the inner surface of the base of the cranium, are shallow in proportion as the animal is removed from man.

Even the *bowling-bahoons* have the posterior and intermediate fossæ, and the *fella tureica*, in the plains of Asia.

Many quadrupeds want the *fella tureica*, as the *digitigrada*, and molt of the *sphigriada*. In the *cavy*, the *rhinoceros*, and the *eleven-footed* quadrupeds, the part having the situation of the *fella tureica* is even depressed, instead of being elevated.

Some of the spiny ridges on the internal part of the cranium, are often more eminent in mammalia than in man.

In the greater number of the carnivorous species, there is a thin projection of bone from the petrous portion of the os temporalis, which prevents the tenement of the cerebellum. It is usual to say that these animals have a bony tenement, and to suppose that it is necessary to defend their brain from concussion, during the rapidity of their motions, which does not seem probable, as something of the same structure is found in other species whose movements are slow.

The limits between the middle and posterior fossæ of the cranium is formed in the *pangolin* by a large vertical ovoid septum, with an oval hole in the middle.

In the *rhinoceros*, the part corresponding to the posterior clinoid processes is not attached to the base of the cranial, but extends like a bridge from one middle fossa to another, while the depression that is in place of the *fella tureica* communicates under this bridge with the coniform processes of the occipital bone.

The *foramina* upon the infide of the cranium are often less distinct, and consequently less numerous in mammalia than in man.

The *optic foramina* are close together in the *agouti*, being only separated by a thin ovoid plate. They are united into one hole next the foramen in the *bore*, the *four-toed ant-eater*, and the *elephant*. The *chevrotain* (moofbua) has but a single optic foramen, which is divided by the vomer.

The *fibula*, or *superior orbital fissure* in the *orang-outang*, is similar to that of the human subject; but in almost all the other mammalia it is nearly a round hole. In many of the *sphigriada*, and the *rhinoceros*, *elephant*, and *hippopotamus*, it is incorporated with the foramen rotundum. They are also confounded in the *crowned and footed* quadrupeds.

The *foramen rotundum* in the monkey is marked with a furrow for some time before it leaves the cranium. This hole is very large, and most of an oval than a round shape in the *digitigrada* quadrupeds.

The *foramen ovale* of the *bear*, *cat*, *crust*, &c. is defended at the external edge by an oseous lamina. The *bear*, *badger*, *flea*, and *vampire bat* have this foramen united into one with the foramen rotundum.

The *foramen ovale* is thrown into one with the anterior *foramen lacera* in the *cavy* and *porcupine*. In the *ten-band* armadillo, and the *four-toed ant-eater*, it is confounded either with the foramina lacera, which are united, or with the foramen rotundum, which is thus rendered very large, and of an oblong form. It is confounded with the anterior foramen lacera in the *elephant* and *hippopotamus*. It is very large in the *ruminating quadrupeds*, and does not exist as a separate hole in the *sphingida*.

The *foramen lacera anterior* is not found in the monkey kind, the *digitigrada*, the *squirrel*, and the *ruminating quadrupeds*.

It is very wide in several of the *sphigriada*. It is confounded with the *posterior foramen lacera* in the *armedillo*, the *hippopotamus*, and *sphingida*.

The canals *cardiidus* is much shorter and left tortuous in the *digitigrada* than in man. There is no canal in the *sphigrida*; the *cardiid* passing immediately through the foramen lacera. In the *hippotamia* the *cardiid* canals are lost in the foramina lacera.

The *foramen lacera posterior* is a very small round hole in the *pangolin* and *flabell*; and in the *elephant* it is very large. In the two first of these animals the anterior condylid foramina is remarkably large; and in the last there is no hole before the condyles, which shews the connection that exits between these two foramina.

The *foramen lacera posterior* is confounded with the anterior in the *rhinoceros*; and the *anterior condylid hole* is very large. There are sometimes two condylid foramina on one side, which are united into one.

The two tables of the cranium are in general less distinct in mammalia than in man, or appear to be more perfectly offifet; but in the *elephant*, the magnitude of the cranium depends in a great measure upon the separation of the two tables, between which are interpolated a number of large cells of a very irregular figure, which are filled with air instead of medullary substance, and communicate with the *ethalchian tube*, and by that means with the external air. The cellular structure of the cranium in the *elephant* is similar to that found in the head of the *owl*, and designed in both to produce an increase of bulk, without an additional weight.

The *bones of the face* differ very much in this class, both in their forms and connections, from those of man, in consequence of the great prolongation of the jaws, and the lateral position of the eyes, in most mammalia.

The form of the upper jaw arises in a great degree from the preence of two bones, which are placed between the two offa maxillaria. These have received different names, such as *intermaxillary and labial bone*; or frequently they are called the *os incisivum*, from the circumstance of their holding the incisor teeth, when they exist: they are called *alo* or *M in latere*.
MAMMALIA.

palati by Blair, and os maxillare interior by Vitel. The intermaxillary bones have been considered by some anatomists as forming a division between all mammalia and man; but they have not been found in several species of monkey; and Fischer, who wrote a treatise on this subject, states that he did not find an intermaxillary bone in the three-toed sloth, and in the bornea-bone bat; but he admits that the bone might have been broken off, at least in the fossil. Cuvier says that the sloths have very small intermaxillary bones. Vic d'Azir has ascribed these bones to the human subject, considering the small transverse fissure, seen within the incisor teeth of the human fetus, as the future connecting the intermaxillary bones or bone with the upper jaw; but all other anatomists deny the intermaxillary bones to man.

These bones vary much in different species, with respect to form and size. They are small in some of the digitigrada quadrupeds, in the rhinoceros, and in the sloth; although Cuvier states they to be large in the lamantin. They are particularly large in the spheniscus, in which they make the whole front of the upper jaw, and contain the large upper gnawing teeth of these animals. They are large also in the elephant, hippopotamus, porpoise, and phiaster macrocephalus. In the omnivorous these bones exit, although there are no incisor teeth; and the form of the jaws is so very peculiar, resembling in this animal the bill of a duck. The intermaxillary bones consist of two hook-shaped pieces, united by a broad cartilage.

The proper maxillary bones contain all in mammalia the posterior teeth of the upper jaw. These bones contribute more than any other to the composition of the face; even in the monkey tribe they begin to be prolonged, and assume something of the figure they possess in the true quadrupeds.

In the chiroptera, digitigrada, plantigrada, and pedimanus mammalia, the natal procees of the maxillary bones become so broad as to separate the orbits sufficiently, to give them a lateral position. The spheniscus have these bones carried so far back by the great size of the intermaxillary bones, that they form a considerable portion of the orbit, the palatine bones having but little concern in the composition of it.

The maxillary bones of the sloths also extend to the orbit.

In the ant-eaters these bones are very long and narrow, resembling a portion of a cylinder; but they do not contribute to the formation of the orbits.

The maxillary bones of the tapir pass backwards, and make the floor of the orbits: they also extend to the orbit in the rhinoceros.

In the hippopotamus these bones have no share in the orbit; they are very strong inferiorly, in order to accommodate the superior tubs, which are placed in them, and not the inter-maxillary bones.

The daman has the inferior surface of the orbit formed by the superior maxilla: it makes a small part of it on the ruminants.

In the lama they the maxillary bones constitute the bafe of the orbit, and afterwards extend a considerable way behind it.

In the cetacea they are much elongated, and reach to the very end of the flattened front of these animals: they ascend upon the side of the blow-hole, and cover that part of the os frontis which forms the arch of the orbit.

The malar bone, in a great number of mammalia, is large in proportion than it is in man, and does not articulate with either the orbitar procefs of the os frontis or the phehnoide, but merely forms a part of the zygoma and the lower margin of the orbit. In these cases, the frame of the orbit is incomplete at the posterior part, and communicates with the fossa for lodging the temporal muscle. It is thus with the chiroptera, digitigrada, plantigrada, salpinglada, pedimanus, edentata, and molongulata. In the spheniscus the os malle is placed in the middle of the zygoma; the superior maxilla supplying the anterior zygomatic processes, in place of the malar. The temporal fossa is completely thrown into one cavity, in the rhinoceros and elephant.

The frame of the orbit is completed externally by the union of the malar and frontal bones; but there is an opening behind this from the orbit into the temporal fossa.

The natal bones are commonly prolonged, in proportion to the other parts of the face in mammalia. In some of the monkey tribe they are united into one bone, which is very narrow. In the long-prel-tailed monkey the interface between the orbits is very narrow, and posteriorly merely forms a septum.

These bones are elongated in the true quadrupeds, and most fo in the spheniscus, whose external nare open immediately above the incisor teeth.

In the hog, the tapir, hippopotamus, and the rhinoceros, the natal bones are not conjoined with the jaw at their anterior extremity, but form a distinct process, which stands out above the intermaxillary bone. This process sustains the procefs of the tapir and hog, and the horn of the rhinoceros, or the anterior one when there are two, as in the hi-cornis.

The procefs which supports the trunk of the elephant is still more unlike the common natal bones.

The natal bones of cetacea are two small tubercles implanted in the os frontis.

The boehmiyal bone is sometimes wanting, as in the ele-phant: in other instances it is remarkably large, in the ant-eater, the opifllum, the ruminating quadrupeds, especially the aardvpe. It advances a little upon the cheek in the flying lemarr.

According to Cuvier, the ethmoid bone has no share in forming the orbit in the chiroptera, digitigrada, plantigrada, and pedimanus: its place is supplied by the orbitar procefs of the palatine bones, which are very large in these animals.

The palatine bones also constitute, in the long-natal edentata, the lower part of the surface of the depression corresponding to the orbit. The grayroid procefs also are produced by two lamina, which are continued with the offa palati, and which, having joined each other inferiorly, prolong the canal of the nare to the foramen magnum of the occiput.

In the above description of the bones of the upper portion of the face, we have anticipated most of the circumstances respecting the natal and orbitar sofs.

It should be mentioned, that the hog has two small peculiar bones, situated between the point of the offa nati and the corresponding intermaxillary bones. The serve to strengthen the finout, and are therefore called by Cuvier the bones of the finout.

The natal sofs, although always opening nearer the front in quadrupeds than in man, are liable to vary with respect to their situation. In the spheniscus the external nare are quite at the end of the finout, as already mentioned. In the elephant, the natal sofs are at about an equal distance from the top of the cranium and the edge of the alveol. In the finot, they are directed upwards. They are far forwards in the mare. In the cetacea, the openings into the blow-hole, which
which correspond with the nasal sofla, are immediately before the os frontis, and open upwards and backwards.

We have already mentioned the figure of the margin of the orbit in several species. In the cetacea there is a sofla corresponding to the orbit, although the eye of these animals is surrounded only by the soft parts. This sofla has a semi-
circular roof, formed by the os frontis; but it is quite open below, down to the lower jaw.

The spheno-maxillary fissure is shorter in all the monkey tribe than in man; it is contracted to the shape of a hole in the long-prehensile-tailed monkeys, and is closed altogether in the bounding baboon. In the other mammalia, which have the orbitar and temporal region united, it does not exist.

The sub-orbital foramen is fingle in most mammalia, as in man; but in some there are two, or three, or more holes under the orbit; in which cases they are small. There are, according to Cuvier, two in the orang-outang and the pre-
prehensile-tailed monkeys, three in the common monkeb and Barbary afes, four or five in the ribbon-tailed ape and hair-tipped ape. There are three or four holes in the cetacea. From the position of the orbits in these beings being low, the maxillar bones are above them, and contain the holes correspond-
ing to the full-orbitar.

The sub-orbital foramina are large in most of the subinfar quadrapeds, for the transmition of the great nerves that are distributed to those parts. In the eay, agouti, porcupine, and many of the rat tribe, they are prodigiously wide; and in the jerboa, nearly equal in size to the orbits themselves.

The greatest deviation from the human subject, with respect to the foramina of the face, is to be observed in the foramen incisivum. This hole is small and single in the orang-outang and chimpanzees, but enlarges a little in the other species of simia. There are two foramina very distinct from each other in almost all the other mammalia: they are remarkably large in the fotaligrada and cloven-hoofed quadrapeds; in the bale they even exceed the extent of the solid part of the palate.

It is single and large in the tapi, rhinoceros, borsa, and tamani; it is very oblitered in the morse; small and far from the alveolar procfs of the jaw in the dugong; and wanting altogether in the cetacea.

Peculiarities of the lower jaw are to be found in its composition, general form, direction of its ascending ramin, and the figure and relation of the condylar and coronoid procefses.

The inferior maxilla remains, during life, in two pieces, united by cartilage or ligament at the front, in most mammalia. These are anchylofed together, as in man, at an early period, in the monkey kind, the vammyre, and several other bats, the phacogeri (manis tetradactyla), and the elephant.

The two inferior maxillary bones are united into one very foorn; also in the many-roofed and solid-footed quadrapeds, and in the morse and tamani.

The general figure of the lower corresps with uniforml with that of the upper jaw, already described. In the fotaligrada it is commonly a little shorter than the upper jaw, on account of the inferior inciodor teeth being foom. In the armadillo and four-toed monkeb, the two sides of the jaw approach each other, and form a very acute angle at their symphysis.

The ornithorhyncbus has the two pieces of the jaw joined to each other before their termination, and then bifurcate again. In the cebus the extremities are again joined; they are thin, flat, and round, or spoon-shaped.

The lower jaw of the elephant is rounded in the front, and resembles the human jaw more than could be supposed, from the general outline of the head in each.

The ofendering ramus of the lower jaw forms nearly a right angle with the body of that bone as in man, in the bave, cat, bbebe-beg, squirrel, hare, bonar, sanguvea, and molt of the fotaligrada, rhinoceros, elephant, &c.; in line, in most mammalia; but the mechanical operation of the jaw depends upon the situation of the condyle on which this bone moves, and the coronoid procefses by which it is chiefly moved, with respect to the body of the bone.

The condyle projects commonly back beyond the line of the angle formed by the body, and the ascending branch of the jaw. The more it is out of this line, or, in other words, the more the condylar procefses approaches to the continuation of the body of the jaw, the more disadva-

This procese is small in the mole. In the lemur and the digitigrada it is large, and passes up into the temporal sofla, its point flanding higher than the zygomata, and than the condyle, consequently the power of the temporal muscle is diminished, but the disadvantage of the position of the coronoid procefs is more than counterbalanced by the enor-

This procese is small in the mole. In the lemur and the digitigrada it is large, and passes up into the temporal sofla, its point flanding higher than the zygomata, and than the condyle, consequently the power of the temporal muscle is diminished, but the disadvantage of the position of the coronoid procefs is more than counterbalanced by the enor-
of the lower jaw forms a perfect hinge, and only permits the separation of the lower from the upper jaw in the direction downwards. This is particularly to be observed in the badger, where the glenoid cavity has a projection before and behind, by which the condyle is partially inclosed in the joint; it even remains so after the parts are macerated, and the ligaments and cartilages are destroyed.

In the monkey, the condyle is transverse, and a little oblique; the glenoid cavity is wide and shallow, and permits a degree of retraction, protrusion, and lateral motion of the lower jaw.

The freedom of motion in different directions is increased in the other quadrupeds, and is most so in the ruminating and grazing tribes. In the latter, the figure of the condyle is exactly opposite to that of the carnivorous quadrupeds. It is a very thin oval tube, the length of which is from before backwards. The glenoid cavity is larger than the condyle, and so little concave, that the jaw has a very free lateral motion.

In the elephant, the condyle is short and round; the glenoid cavity, in place of being concave, is elevated in the middle. There is another condyle formed by the base of the zygomatic processes; a joint, thus constructed, enables the animal to protrude and retract the jaw in a peculiar manner.

The glenoid cavity of the hippopotamus is situated behind the zygomatic processes, in such a way as would seem to prevent any protrusion of the jaw.

In the rhinoceros, although the surface of the glenoid cavity is nearly flat, it is bounded posteriorly and internally by a long process, which must restrain its horizontal motion.

The articular cavity of the tapir has posteriorly an oblique process which opposes the lateral motion of the jaw.

The condyloid surface in the ant-eater is plane, situated at the posterior extremities of the jaw. There is no glenoid cavity, but an articular surface corresponding to that of the jaw. In the other edentata, the condyle is a distinct eminence, smooth upon the surface, and applied to a similar surface of the zygomatic processes, which supplies the place of the glenoid cavity.

The condyle of the cetacea is round, and very little eminent. The surface corresponding to the glenoid cavity is adapted to the figure of the condyle; they are united together, not merely by ligaments externally, but the articulating surfaces furnish many ligamentous bands, which consolidate the joint, and preclude every other motion of the jaw except that downwards.

The os hyoideum of mammalia differs from that of the human subject with respect to the figure of the body of the bone, the relative magnitude of the cornua, and the existence of an additional ossicle piece in place of the styloidal ligament. This latter is found in all the genera, with the exception of the monkey tribe: it is usually a long, slender bone, and is sometimes articulated in a particular depression situated at the place corresponding to the styloidal process of the os temporis. In other cases it does not reach so far as the cranium, but is connected to it by ligament or cartilage.

The cornua, which are called the large, in the human subject, are often consolidated with the body of the os hyoideum, and those called the small cornua are sometimes very large. Cuvier has treated of all the varieties of the os hyoideum, at great length, as he has of all the parts connected with the organs of deglutition or of voice. We shall notice some of the most remarkable deviations in the conformation of the os hyoideum, from its structure in the human subject, and refer the reader to Cuvier's "Anatomic comparé" for details of the less important circumstances.

The os hyoideum of the orang-outang and chimpanzee resembles, almost exactly, the same bone in man. In the other monkeys, the body of the bone is broader, and either square or triangular. In the common monkeys with long tails, not prehensil, the bare-tipped monkey, and the baboon, it is convex in the front, and forms a sort of cavity upon the internal surface.

In the bounding baboon this bone is very remarkable: it forms a bony flap under the root of the tongue. The planes of the face are thin and very elastic; they furnish a number of thin projections internally, by which the face is divided into several irregular shaped apartments. This face communicates posteriorly by a canal with the larynx. It is, therefore, subervient to the functions of that part, and enables the animals that possess it to produce that loud cry for which they are so distinguished.

The os hyoideum of the digirigrala is composed, in general, of slender pieces: the body is cylindrical, and nearly straight. The anterior cornua are longer than the posterior: they are formed of two pieces; the second is sustained by the styloidal bone. This latter is usually larger than all the other parts of the os hyoideum; the end next the temporal bone is broad, and covered with an articular surface.

The os hyoideum of the opaluma is flat, and nearly square: the cornua are joined to the angles: the large cornua are very broad at their base, and bent anteriorly, and end in a point: the small cornua are longer, cylindrical in their form, and enlarged at the posterior extremity.

In the falsigrala, the form of the os hyoideum is cylindrical in general, and the branches vary in their shape; in some genera they are broad; in others, narrow and slender. The beaver has a strong long oval process desending from the inferior edge of the body of the os hyoideum. The anterior cornua are small and cartilaginous. Several of the other falsigrala have also a process or projection from the body of the bone.

The os hyoideum has a peculiar structure in the echidna hyrrix. The body is formed of a flat, straight piece. The extremities of its anterior edge sustain the anterior cornua, which are cylindrical, directed forwards, and composed of but one piece. The styloidal bone descends almost perpendicularly to meet these cornua. The posterior cornua are arched; they are broad, flat, and articulated upon the sides of the body of the bone. The end of the posterior edge is convex, and is attached to a second piece, which descends parallel to the first as far as behind the body of the os hyoideum, where it is joined to the one of the opposite side. Two other pieces are added to these, about the place of their junction, and separate from them upon the s.
The number of vertebrae that compose the different regions of the spine of mammals are subject to great variety, with the exception of those of the neck, which are the same number in man and all mammals, besides the three-toed sloth, which has nine cervical vertebrae. When the neck is remarkably short, as in the whale tribe, the bodies of the cervical vertebrae are very thin, and a certain number of them consolidated by anchylosis into one bone, in which the distinctions of their original number and their processes can barely be seen.

The following table of the number of the vertebrae in the other parts of the spine, besides the cervical, is extracted from Cuvier's "Comparative Anatomy," and will render any further observations upon the numbers unnecessary.

Table of the Number of Vertebrae in Mammiferous Animals.

In all 66
The cervical vertebrae of the monkey tribe resemble those of the human subject, except that their spinous processes are stronger and not forked. They are very long in the species of baboon called pong, in consequence of the large projecting face of this animal requiring an extensive attachment for the muscles, which raise and support the head.

In the digitigrada the spinous processes of the second vertebra are very high, and extends upwards, or rather forwards, upon the atlas, and backwards upon the third vertebra. The transverse processes of the atlas are very large and flat on the front and back. These two vertebrae are altogether large. The pendent portion of the head, in most of the digitigrada, makes the existence of strong muscles necessary for its support; the ligamentum nuchae is not large in this family of quadrupeds. The short muscles at the back of the head contribute to the opening of the mouth of quadrupeds, and therefore should be strong in this carnivorous tribe.

The cervical vertebrae have no spinous processes in the mole and ferret. They appear, especially in the middle of the neck, as simple rings of bone, which admit of as free a motion upwards as in any other direction; their ligamentum nuchae is ossified in parts.

In the ant-eaters and armadillos the bodies of the last six cervical vertebrae are large and compressed. They are consolidated to each other by anchylosis. All the edentata have a gutter in the anterior part of the bodies of the cervical vertebrae, in which the odophagus is placed.

In the camel, camelopard, and other quadrupeds with long and flexible necks, the spinous processes are small, or almost obliterated. In the short-necked ruminants, as the common cattle, the transverse processes form two angles or double transverse processes. In both the ruminants and folivora the bodies of the cervical vertebrae have a longitudinal ridge along the upper front.

The large quadrupeds, in consequence of the great weight of their heads, have that peculiar elastic substance which is called ligamentum nuchae of a great strength. In the boar, the attachment of this part to the dorsal vertebrae is two hands broad. It is also connected by processes to some of the cervical vertebrae. In the elephant it is of an enormous size, and is invested into a fossa at the back of the occipital bone.

In the porpoise and dolphin, the two first vertebræ are ossified together. In the grampus, the first three or four are anchyloped, and in the cachalot (physeter), the fix last are united into one mass, and the bodies of the five middle vertebrae are reduced to an extreme thinnest.

The dorsal vertebrae want spinous processes in some species of bat, and in others there are little tubercles in the place of the spinous processes. In all this genus the canal for lodging the spinal marrow is very wide where it pales through the dorsal vertebrae.

In all the long-necked and heavy-headed quadrupeds, the spines of the dorsal vertebrae are remarkably large and long, particularly in the elephant, camel, camelopard, and boar. The size of the spinous processes in these animals is necessary for the attachment of the ligamentum nuchae.

The dorsal vertebrae of the whale tribe have at first the articular processes at the root of the transverse, and towards the ninth vertebra there are only the superior ones; for at this distance these articular processes turn backwards to the base of the spinous processes next the head, and form a kind of groove, which receives the preceding spinous process.

In the lumbar vertebrae there is great variety with respect to number, as is shown by the foregoing table. When a quadruped is distinguished by a long body, it is usually found to be occasioned by the number of the vertebrae of the joints. The spinous processes are long in the dog and cat genera, and have an inclination towards the head. This likewise takes place in some degree in the monkey kind.

The motion of the lumbar vertebra is more or less restrained in most quadrupeds, by the external side of each posterior articular processes having a point directed backwards, so that the anterior articular processes of the next vertebra is received between two prominences.

The transverse processes are very large in the ox, borse, &c.; but are particularly so in the whale tribe, for the purpose of affording a surface for the attachment of the great muscles which move and guide these animals the figure of fishes. There is a gradual change of form and size in the vertebra of the posterior portion of the spine in the cetacea, but no marked distinction in the lumbar, facetal, and caudal vertebrae.

The breadth of the sacrum in man evidently arises from the erect position of his body. The few mammalia that occasionally stand upon the posterior extremities, as the monkey and bear, have it broader than quadrupeds in general. In these it is an elongated triangle, and is the continuation of the spine. This bone has large lateral processes at its anterior extremity in the borse.

The spinous processes are usually more eminent upon the facrum in quadrupeds, than in man or the monkey. They nearly join to form a high sharp ridge in the rhinoceros, and many of the bifulca. This crest is very remarkable in the mole.

The vampire bat is the only example in mammalia of a total want of tail or caudal vertebrae. The facrum of this animal terminates in a long point.

The vertebra of the tail are usually very numerous in mammalia. Those next the facrum have the same processes as the vertebra of the other portions of the spine, and form a canal for holding the modulla spinalis. The vertebra towards the extremity of the tail want the spinal canal, and have only small eminences or tubercles in place of the transverse or spinous processes. Those animals that employ their tail in swimming, as the cetacea; in building, as the beaver; or for propulsion by leaping, as the kangaroo, have the processes of the caudal vertebrae large and strong. The beaver has the breadth of the tail increased by the size of the transverse processes, and has also inferior spinous processes, which are larger than the superior, for the purpose of giving attachment to the great muscles by which this animal's tail is forcibly depressed. The transverse processes only disappear very near the extremity of the tail in the cetacea.

In those quadrupeds that make much use of the tail, there is generally found a series of small double bones upon the under surface of the joints of the vertebrae, from the third or fourth to the seventh or eighth. In the cetacea they are very remarkable, and designed to perform the same offices as the inferior spinous processes of fishes' tails. They are sometimes anchyloped in pairs; but, generally, their edges touch, and each pair forms a sort of inverted Gothic arch somewhat similar to the inferior caudal spines of fishes.

Those that have prehensile tails, as one division of monkeys, have upon the inferior surface, and at the base of each body of the caudal vertebrae, two little tubercles, between which the flexor muscles of the tail pass.

The ribs of mammalia, both the true and the false, are very various with respect to number. They appear, however, to be not fewer in any instance than twelve, the number found in the human subject: as will appear by the following table, extracted from Cuvier's "Comparative Anatomy."

</table>

The ribs are thick and broad in the large herbivorous quadrupeds, which are employed as beasts of labour; the strength of the spine, and its capability of sustaining great weights, depending very much upon the size of the ribs, and the figure they give to the trunk of the body. In all the quadrupeds that protect themselves by rolling the head and extremities under the belly, when attacked by other animals, the ribs are remarkably strong, and close together. This conformation is to be observed in the common hodge-hog, but much more in some of the edentata, as the armadillo and the anteaters. The two first ribs of the armadillo are exceptionally large in proportion to the others, and in the two-toed anteater the ribs are so broad, that they overlap or rest upon each other, which gives this animal a greater security than it could derive from having the paires of the thorax formed of one piece of bone.

The ribs of the ornithorhynchus paradoxus and echidna lyriena are curiously formed. The fixing true ribs are each composed of two pieces united by an intermediate cartilage, like the ribs of birds; the piece connected with the spine is longer than the other. The false ribs of these animals terminate in broad, flattened, oval plates, which are connected together by elastic ligaments.

The ribs have a curvature upon their sides in those quadrupeds that want clavicles than in the others. Those with clavicles have a chest shaped more nearly like the human, but in the quadrupeds which never use the anterior extremity as a prehensile member, the chest is flattened or narrowed upon the sides, especially towards the sternum. The cetacea, however, notwithstanding they have no clavicles, have a cylindric thorax, or one rather wider from side to side, than from above downwards.

The sternum in mammalia differs from the human generally in being longer in proportion to the body, being a rounder and narrower bone, and composed of a greater number of pieces.

The orang-outang and the pongo have a flat broad sternum like man, but in all the other monkeys it is narrow, and composed of several or eight bones.

In most quadrupeds it projects a little forwards beyond the line of the first rib, but in the mole this projection is very extraordinary; it passes forwards for almost as great a distance as the bone makes a part of the chest. This anterior portion is compressed upon the sides; it is like a plough-share, and fulfills upon its sides the clavicles; by this structure the anterior extremities of the bone are carried forwards under the neck, occasioning the appearance of a want of neck, and the animal is enabled to excavate the earth for the admission of its body by the fore foot with extraordinary rapidity.

The anterior end of the sternum is curiously formed in the bats; it is enlarged into the figure of a 'Y', the superior branches of which pass over the ribs and are joined to the clavicles.

The hog has the sternum narrow anteriorly, and large behind.

In the cetacea, the sternum is short, thin, and even broader in proportion to its other dimensions, than in man.

The clavicle is a bone required for the motions of the anterior extremity in the outward or inward direction. It exists necessarily, therefore, in all animals that employ the arm as a prehensile or mechanical member, or as a wing. There is a perfect clavicle in all the monkey tribe, the cheiroptera, the opossum family; in the mole, ferrets, and hedges, amongst the plantigrada; in the squirrels, rats, beaver, porcupine, and kangaroo in the aramhili and anteaters in the bats, &c.

The destrich, and some of the falcigrada, have an imperfect clavicle, (as cheirouculare of Vig d'Azir.) This is a short bone suspended merely by the muscules, and not attached either to the sternum or the clavicles.

The clavicle is entirely wanting in the quadrupeds which employ their anterior extremities for progressive motion, as all the booted quadrupeds, the donam, the cavy, the pangolin, and in all the cetacea.

The clavicles of the orang-outang resemble those of the human subject.

In the bat, they are remarkably long and strong.

The clavicle has an extraordinary thickness in the mole: It is nearly square, being more broad than it is long.

In the two-toed anteater, this bone has the figure of a rib.

In the fleas, the clavicle has a process from the extremity next the sternum, which forms nearly a right angle with the axis of the bone.

The scapula exists in all mammalia, but its posterior angle is most elongated in those species which have the most complicated motions of the anterior limbs or the arms.

It is in the monkeys and lemurs a triangular bone, of which the inferior or posterior edge, and that next the spine, are larger than the anterior side, but no so much larger as they are in man.

The cheiroptera or flying mammalia, have the edge of the scapula next the spine very long, and the posterior very acute.

The body of the scapula in the hodge-hog is narrow, and the edge next the spine not extensive, but the whole is considerably elongated.
In the *mole*, the scapula is a long narrow bone, which does not exhibit the distinction of supra-spinous and infra-spinous surfaces upon the back; there being no spine—except near the posterior margin, and before the tubercle which corresponds to the acromion. The scapula of the *mole* lies parallel to the vertebra, and resembles a good deal both in form and position the same bone in *birds*.

In quadrupeds generally, the edge of the scapula next the spine is rounded, and the posterior angle thus rendered blunt. The spinous process of the bone is situated about the middle of the body, or even lower.

In those quadrupeds that want clavicles, the acromion scapulae is not so prominent as when the bones exist, and there is another process which points backwards almost perpendicular to the spine. This process is also found in the *hedgehog* and *opossum* which have clavicles. In the *hare* the recurrent process is very long.

The coracoid processes of the scapula is commonly wanting in those that have only the rudiments of clavicles, and more constantly where these bones do not exist.

In the *ruminants* and *fossil-footed* quadrupeds, the scapula has neither acromion, coracoid, nor recurrent processes. The *cetacea* have a thin flat scapula. The edge next the vertebra is round and broad, so that the whole bone has much the figure of a saw. In the genus *delphinus* the spinous process is near the cervical edge of the bone, and does not form an angle with the infra-spinous surface, of which it forms the continuation. The supraspinous fossa has a deep concavity, which appears to arise from a deficiency in ossification.

Above the humeral angle, there is a projecting plate continuous with the spinous process, which appears to correspond with the acromion. In the other genera of the *whale* tribe, the supraspinous fossa is fluted by Cuvier as being leaf-like.

The humerus of *Mammalia* varies in length and thickness, and in the elevation of its processes.

This bone is longer in the *bat* and the *tarchigrade* quadrupeds, in proportion to the rest of the anterior extremity, than the humerus of the human subject. In quadrupeds, generally, however, it is much shorter. Those that have the metacarpal bones long, have the humerus fo short, that it is concealed in a great measure by the muscles of the limb and the skin of the thorax, from whence the ancient anatomists fell into the error of supposing, that the elbow was turned forwards in quadrupeds, the joint of the carpus being mistaken for that of the elbow. It is cumbrous with people ignorant of comparative anatomy, still to mislead the part corresponding to the wrist in quadrupeds the elbow.

This bone is also very short in the *cetacea*, and has a large spherical head.

The shortell humerus, and the thickest with respect to its length, is found in the *mole*, which animal is distinguished by many peculiarities in its skeleton. It has besides a very singular form. The two ends of the bone are so much expanded and changed from the usual appearance of these parts, that they are with difficulty recognized. There is a small process which takes the place of the head of the bone, and is articulated with the scapula. There is another articular surface, apparently corresponding to the great tuberity, which also forms a joint with the clavicle; between these two the top of the humerus is deeply hollowed. The crest of the little tuberity is so large, that it resembles a square placed vertically, with the linea alpea at top. The body of the bone is bent towards the top, so that the part which forms the joint with the ulna points directly upwards; by which means the elbow of this animal stands above the shoulder, and the palm of the hand is turned outwards. This formation of the arm enables the *mole* to throw the earth to each side when it buries itself.

The humerus of the *bear* is considerably enlarged at the condyles. It has also a large transverse processes, at about the distance of one-third from the top.

In the *hog*, *tapir*, and *rhinoceros*, the humerus has the great tuberity divided into two parts. The linea alpea also of the *rhinoceros* terminates in a very high tubercle.

Something similar exists in the *bears*.

The *bisphora* generally have the great tuberity very high, and the linea alpea prominent.

In mottl quadrupeds, the great tuberity is elevated above the head of the humerus, and in those mammals that employ the upper extremity for other purposes than walking, the bone of the fore-arm exist differently, and preserve nearly their proper proportions, as in man. But in the true quadrupeds, the *ulna* declines in size, and becomes in some a mere appendage to the radius, which is the principal bone of the fore-arm in most quadrupeds. The existence of two bones in the fore-arm is only necessary on account of the motion of supination. Where the supine slate of the member would be inconvenient in the progression of the animal, we find the ulna either anchylosed to the radius, or entirely absent.

The *ulna* in the *orang-outang* resembles that of man. In the *monkey tribe*, generally, the coronoid processes of the *ulna* is narrower, and the bone is more compressed than in man. The articular surface of the radius also is deeper. There is often a hole found in the cavity at the back of the humerus, which receives the olecranon.

In the *digigrada*, the olecranon is compressed, and projects more backwards; and the coronoid processes is diminished before. In the *dog* there is a little cavity in the end of the radius, for the reception of the external process or keel head of the humerus, and a ridge for the furrow that divides it from the anterior part of the pulley, by which the rotation of the radius is a good deal restrained.

In some of the *fahigrada*, as the *cavy*, the *bear*, the *rat*, and others, the coronoid processes of the *ulna* is entirely obliterated, and the radius covers the front of the articulation. The head of the latter bone forms a hinge-like joint, having a cavity for the keel head of the outside of the humerus, and a ridge for the anterior part of the pulley, that is occupied in man by the coronoid processes of the *ulna*.

In the *rhinoceros*, the *tapir*, and *hog*, the *ulna* is entirely behind the radius. They move as one bone upon the pulley of the humerus. The keel head of the latter bone is quite effaced inferiorly. The *ulna* and radius of these animals are notwithstanding different, but still are incapable of rotation.

In the *elephant*, the coronoid processes is divided into two ridges with hollow surfaces, which revolve upon the projecting parts of a single hinge. Between these the head of the radius is placed. It is small, and furnished by the external ridge, and the middle channel of the hinge or pulley: for as it is oblong, it cannot turn upon it. The lower part of the radius is directed towards the inner side of the leg, which is therefore always in the pronated position. The inferior head of the *ulna* is larger than that of the radius, which Cuvier says does not occur in any other animal in this whole class.

In the *crowned* and *fossil-footed* quadrupeds, the *ulna* is united immovably to the radius almost throughout its whole length. This union is obvious after a certain period, so that they might be considered as one bone. They form together a hinge-like joint, with the pulley on the end of the humerus, which does not admit of any rotatory movement.

Where the anchylosis is incomplete of the two bones in the
Mammalia.

The birds, there is a short figure to be seen between them. This exists above and below in the camelopard, frog, and gazelle: only at the upper part of the bones in the horse, sheep, and ox, and is not perceived in the camel and dromedary; but in all these animals the original distinction between these bones is marked by a furrow or groove.

All the hoofed quadrupeds have the anterior extremities permanently in the state of pronation; that is, with what is called the back of the wrist turned forwards.

In the bat and galagocephalus, there is only one bone in the fore-arm, or at least a mere flatiform rudiment of the other. This single bone Blumenbach has called the ulna, and Cuvier the radius. The latter is certainly the proper appellation.

The motions of the anterior extremity, as a wing, require the part corresponding to the fore-arm to be constantly in a state of pronation.

In the mole, the olecranon is very long, and terminates in a transverse plate: the whole ulna is very thin. The edge of the head of the radius is prolonged under the little head of the humerus, and seems to be incapable of rotation.

The position of the fore-arm and hand of the mole is singular. The elbow, as before observed, is turned upwards; the palm of the hand outwards, and the thumb downwards. This is pronation carried to an extreme, which is the most suitable position of the hand for its peculiar office in this animal of scooping out the earth.

The foal, instead of the concavity for surrounding the pulley of the humerus, has upon the ulna one surface, which forms a joint with the humerus, and another oblique one for the radius. This last has a large head, the inner edge of which runs in a pulley. The body of the radius is very broad downwards.

In the lama and uroa, the radius and ulna are anchylosed together at both ends.

In the cetacea, the bones of the fore-arm are placed close to each other, but not united by osseous substance: they are flattened, and connected intimately with the humerus and the carpus by ligaments and cartilage, that they have none of the motions of a regular articulation. They merely admit of a degree of flexion, forwards and backwards, sufficient to communicate the necessary pliancy to the fin.

The number and the figure of the bones composing the carpus differ from what we find in the human subject, and amongst the different tribes of mammalia themselves.

In the monkey tribe there are nine bones in the carpus, which is one more than in man. According to Tyfon, however, there are but eight in the orang outang. The pisiform bone of these animals is elongated, and appears like a heel when they walk upon all fours, or use the anterior extremities as feet. Certain ossified points of the tendons passing into the hand, have been mistaken for supernumerary bones in the monkey kind.

The flying squirrel is mentioned by Blumenbach as possessing a very curious flat-pointed bone on the outer part of the carpus, connected to that part by two small round bones, and inclosed in the lateral expansion of the integuments.

In many carnivorous quadrupeds, the scaphoid and lunare are united into one. The car has at the radial edge of the carpus a little supernumerary bone, similar in figure to the pisiform bone of the human subject. The real pisiform of the digitigrade is long, and serves as a sort of heel to the forefoot. The os magnum is very small towards the back of the carpus. Those that have the thumb imperfect have also the trapezium much diminished. The serus guila has this bone also small, and a lylly-shaped process below the os scaphoides.

The mole has nine bones in the carpus, and an additional bone which resembles the blade of a scythe in its figure. It depends on the radial side of the hand, the surface of which it is designed to extend, in order to fit it for shovelling back the earth when this animal burrows.

Amongst the digitigrade, the hare has nine carpal bones. The beaver, marmot, squirrel, and rat tribe have the scaphoid and lunar bones formed into one. These animals likewise have, like the digitigrada, a supernumerary bone, which is often larger than the pisiform. In the jerboa and marmot, it bears upon it another supernumerary bone. In the furofupina there is an additional carpal bone, attached to the os unciniforme, between the os pisiforme and the metacarpal bone of the small toe. The cavy and guinea-pig have one bone for the scaphoid and lunar; and the latter animal has a small supernumerary carpal bone.

The two-toed ant-eater has six bones in the carpus. There are seven in the pangolin. There are eight found in the nine-banded armadillo.

The three-toed sloth has but five carpal bones.

The elephant has eight bones. The os pisiforme is lengthened, and the other bones of a wedge shape.

In the rhinoceros the trapezium does not exist, but there are two supernumerary bones; one on the edge of the scaphoides, and the other upon the os unciniforme.

In the other many-boned quadrupeds the trapezium is very small.

In the cloven and solid-footed quadrupeds the carpal bones are narrow. The first tribe have, in general, four bones in the first row, and two in the second. The folipedes have four in the first and three in the second row.

In the cetacea the bones of the carpus are flat-shaped, and intimately united to each other by cartilage and ligament: We have found the carpus of the grampus to contain a greater proportion of cartilaginous substance than of osseous, the bones appearing like spots of effusion in the centres of malleus of cartilage. The surface of the carpus in cetacea is smooth on both sides. There are five carpal bones, three in the first row and two in the second.

The metacarpus confits of the same number of bones as the fingers, or, as they are more commonly called, toes, in quadrupeds,) perhaps without exception; it being understood, that the pollex is not reckoned amongst the number of fingers, for it is a quection amongst anatomists, whether the first joint of the thumb, in the human subject, should be considered as a metacarpal bone, or as a real phalanx. We believe it is the latter, which opinion seems to be supported not only by analogy of structure in mammals, but in birds.

The cloven and solid-footed quadrupeds have been cited as giving examples of a difference in the number of the metacarpal bones and the digit. This difference, however, is more apparent than real. The cloven-footed have, it is true, but one bone in the metacarpus after a certain age, which is called the cannon bone (gamba of Vegetius), but this bone is originally composed of two parallel pieces, which are formed into one by a curious process. The two sides of the pieces that are applied to each other are rendered thinner by being absorbed; these are next portions of the sides removed, leaving holes between the cavities of the two pieces; and ultimately the fides in contact disappear, forming a common medullary cavity, and a single bone, which remains grooved at the line of the junction of its original parts.

The cannon bone of the folipedes is composed of three pieces; the two lateral are slender and flatiform, and are called, very appropriately, the flat bones. These have been considered analogous to the metacarpal bones of digit which do not

Vol. XXII.
MAMMALIA.

exst, but they should rather, perhaps, be viewed as the rudiments of both metacarpal bones and digits. In other cases where there are vestiges of digits, they appear as five-fingered bones.

The length of the metacarpal bones depends upon the activities of the anterior extremity. When it is employed solely for progression, as in the true quadrupeds, the metacarpus is very long, but when used as a prehensile member, the part is proportionally shorter.

Cuvier states, that in the three-toed sloth there are three metacarpal bones united into one at their base, and that there is a rudiment of a fourth bone added to them.

The metacarpal bones of cetacea, from contributing to the formation of a fin, are much flattened.

The digits of the quadrumanous mammalia, and all those with claws, are five in number. In the horse, the pollex is free in its motions, and capable of being brought opposite to the other fingers, which constitutes one of their most striking resemblances to man.

Even in the monkey tribe, however, the thumb is shorter and smaller, in proportion to the other fingers, than the thumb of the human subject; and a particular species of monkey, the simia paniscus, has it imperfect, and concealed beneath the skin.

The digigrada have the thumb parallel to the rest of the toes; in many it is short, and in the hyena it is nearly obliterated, confining only one phalanx. In the cat genus, there is a peculiar structure of the two last phalanges, by which the claws are thrown upwards in the extended state of the toes. The design of this appears to be, to avoid the blunting of the claws against the ground. The last phalanx but one is three-sided, having an inferior and two lateral surfaces; that on the infide appears in some degree twisted and hollowed out. The phalanx, which is terminated by the claw, is, of course, hooked at the end, but at its base, nearer the root of the claw, in a fort of hood or sheath. The posteriour part of the phalanx rises almost vertically, and is only articulated at its most inferior part. Beneath the joint there are two appendices, in which the muscles which bend the phalans are inserted. These also bring the point of the claw forwards and downwards. The same muscular power which puts the toes into a flex position, thus serves also to urge downwards the points of the claws into the prey of these animals. When the claws are retracted, the last phalanx is received by the lateral depression on the radial side of the second.

The pollex is short in the bear, beaver, and jere. It is more diminished in the squirrel, cat, porcupine, paca, and agouti. It is nearly lost in the civet, rivera, guinea pig, etc.

Amongst the edentata the thumb is obliterated in the great and the four-toed anteaters. Both it and the little toe are lost in the three-toed sloth. In this animal the three perfect toes are often incorporated at their roots with the metacarpus. When they form a joint with the metacarpal bone, it is such a one as does not permit any lateral motion. The phalanges themselves likewise are articulated with each other by hinge-like surfaces, which only admit of flexion and extension. Another peculiarity of this animal is, the last phalanx being the long one.

In the two-toed anteater and two-toed sloth, the thumb, fore, and little finger are the different parts.

The multituberculata have either four or five toes. In the elephant there are five perfect, but they are nearly enveloped in the skin of the foot. There are but three perfect in the rhinoceros. The hya has but two perfect and two imperfect.

The tapir and hippopotamus have four perfect, and the rudiment of a thumb.

The cloven-hoofed have two perfect, and in some two imperfect toes.

The full-hoofed have one perfect and two imperfect. By imperfect toes, or digits, are meant those little horrid excrecences which do not reach the ground, but are placed at the back, and are sometimes covered with nails or hoofs, and contain under the skin the proper bones of a toe.

The most remarkable deviations from the usual structure are found in the flying and aquatic mammalia. The very extensive wings of the bat are supported upon the elongated phalanges of the four fingers, the thumb being short, and armed with a hooked nail at the extremity.

In the foal and lamb our toes are elongated a good deal, and spread out, that the hand may the better perform the office of annar. In the cetacea the digits are rather elongated, and are much flattened. They are conjoined with the metacarpus and each other by cartilaginous surfaces, that do not permit any motion beyond the gentle waving one of the fin, in which they are concealed. The digits are close together at their bases, but spread a little further towards their extremities; but they are all bound together by means of the ligamentous substance which supports and strengthens the different parts of the fin.

The affa inornata are more elongated and narrow in mammalia generally than in man, and not opening so much forwards. Those mammals have the callousities on the buttocks, have the tuberousities of the ischiun very large, and spread out.

In the vampire bat, the tuberousities of the ischiun and the extremity of the sacrum are consolidated together by ankylosis, of which there is no other example in this whole clafs. The pelvic bones are less elongated in the bats, generally, than in quadrupeds.

The digigrada have the abdominal surfaces of the ischiun turned towards the spine, and so much narrowed, that the dor- sum of the bone is not larger than the neck. The concavity is all upon the external surface. The crista of the ischiun is so short, that it bears no resemblance to that part in the human subject. The form of the pelvic bones is nearly similar in the plantigrada and foliigrada quadrupeds, with some exceptions. In the mole, the affa inornata are nearly cylin- dric; they are long, and lie almost close to the spine: the cavity of the pelvis is so very narrow, that it can only receive the rectum, the organs of generation and bladder being placed externally to it. The bear and kangaroo have the affa pubis not united by cartilage, but are ankylosed together.

In the cephalus tribe and the kangaroo, the brim of the pelvis has but little extent, and there are two additional bones, the ufe of which is to support the abdominal pouch. These bones stand up from the edge of the pubis on each side of the symphysis. They are, at least in the kangaroo, of an elongated, tapering figure. They are connected with the
The pubis by ligament, which allows the free extremities of the bones to be moved up and down upon the belly. These bones exist also in the ornithorhynchus.

The tardigrada have the ossa ili broad, with a large circular pubis. The opening of their pelvis is, therefore, very wide, and but little oblique. In these animals, and the armadillo, pangolin, and anteaters, the tuber ischi is placed near the sacrum, and in some cases they are even offished together. In the anteaters, the ossa pubis have no symphysis, but are separate from each other, in which circumstance they resemble the bones of the pubis in birds. It is worthy of remark, that we discern the most frequent analogies of structure between the toothless tribe of mammals, and the other classes of animals.

In the ruminating quadrupeds the surface of the ileum, which in the human subject is internal and anterior, has a contrary aspect, being turned towards the spine. The ischiatric notch excavates the ileum deeply. In the ox, buffalo, and other strong-backed ruminants, the anterior part of the ileum is very large. The spine of this bone, and the tuberosity of the ischium, are discernible under the integuments, and produce that ragged outline of the rump of cattle.

The dorso of the ileum is very large in the boar, as in some of the ruminants, and the neck of the bone is very short: in both, the external surface of the ileum is concave.

In the elephant, the surface of the ileum next the belly is hollowed; the crista is round: both the anterior portion of this bone, and that which unites with the ilium, are very large, and the latter most so. The rhinoceros has a similar pelvis, but the posterior branch of the ileum is less in proportion.

There is a similitude in the pelves of the swimming quadrupeds, as the seal, otter, &c. they are long and narrowed.

In the cetacea there are two bones on each side of the anus. They are conjointed by cartilage before that aperture. These bones have a good deal the figure of two flat short horns united at their root. The ends of the horns are directed towards the spine, and correspond to the ossa ili; near the root there are two small conical projections which supply the place of the ischium of each side, and the conjointed parts of these bones represent the pubis. These bones are suspended in the flesh, and have no connection with the spinal column, and do not form any cavity; they, therefore, properly do not constitute a pelvis. Their use is to give attachment to the penis and clitoris, and some of the muscles of the testicles. Cuvier states, that the pelvic bones of cetacea are not united to each other, but we have found them as above described in the grampus.

The os femoris, in the monkey tribe, resembles the same bone in man. It, however, is smoother and rounder, having scarcely any lines affinis upon it.

In quadrupeds, generally, the femur has a shorter neck, and the great trochanter is less eminent, and the bone altogether is shorter in proportion to the other parts than in man. The femur is particularly short in the quadrupeds that have a long metatarsus, as the cattle and the horse. In these the bone is enveloped so much by the flesh of the buttock, that the part which is really the leg is commonly called the thigh. This bone is also remarkably short in the swimming quadrupeds, as the otter, beaver, and seal. In the last, Cuvier says the articular extremities make more than half its length. The bone does not appear to be quite so short, according to our observation.

Some quadrupeds possess a hook-shaped process upon the external side of the femur. It has been observed in the canis, rhinoceros, armadillo, and beaver. It is the termination of a prominent ridge of the bone about the middle. In the rhinoceros this uniciform process and the great trochanter are much prolonged, and close again, so as to have a hole between them and the body of the bone.

The bones of the leg are very similar in the monkey kind to those of the human subject. In some species the tibia is a little bent anteriorly, and more round in its shape.

In the boar the fibula is a delicate bone. The position of the bones of the leg is changed in these animals. The thighs are directed backwards, by which means the fibular, or external side of the leg, is situated internally.

The tibia in the bear is a little bent forwards: the anterior lab-of the external, and the surfaces for articulation with the femur are placed far back.

The position of the fibula is posterior in the falipræs.

In the opus agnus tribe, the long-tailed manis, the armadillo, and the opossum, the fibula is large and curved outwards, by which some space is left between it and the tibia.

The fibula has a singular formation in the wombat, which has been described by Mr. Brodie. It is proportionably larger, he says, than in other animals. At the upper extremity it is broad and has two different articulating surfaces; the anterior of which is joined to the tibia, and the posterior to a small bone of a pyramidal shape, which is connected to the tendon of the external head of the gastrocnemius muscle, like a femoral bone. The lower extremity of the fibula is large, and forms about half of the articulating surface for receiving the tarsus. An inter-articular cartilage is here interpolated between the tibia and fibula, and there is another between the fibula and the tarsus. The fibula has a flight degree of motion on the tibia at its upper end, and a half rotatory motion on it at its lower end. Mr. Home supposes, and we think with great probability, that this rotatory motion of the bones of the hind leg is designed to enable the animal to bury itself in the ground.

The fibula in many quadrupeds declines in size, and is anchylosed with the tibia, in which there is an analogy between it and the ulna in the fore-arm.

It is united to the tibia for about the lower third in the male. It is connected to the tibia the whole length postero-irly in the dog. It is ossiffed with the tibia at the inferior third of the bone in the rat kind. The fibula is flat, and united throughout by ossification with the tibia, in the elephant, the rhinoceros, and the dog. There is merely a rudiment of the fibula in the boar, which is anchylosed with the top of the tibia after a certain age.

In the eleven-footed quadrupeds, there is a small bone situated on the external edge of the astragalus. It forms the external malleolus, and is the only vestige that exists of the fibula in this tribe of animals.

The bones of the tarsus, and metatarsus, are analogous in their varieties to the carpus and metacarpus of the fore-arm of the same animals.

The bones of the tarsus, and metatarsus, are really hands; the metatarsal bone of the great toe is, therefore, shorter than the rest, and capable of being moved outwards. The projection of the os calcis, which forms the heel, and is so useful to some quadrupeds in walking, is also diminished in these animals, with the exception of the Batavius, onza. There are other peculiarities in their tarsal bones. The articulation of the astragalus with the bones of the leg is so constricted in the monkey tribe, that the foot rests more on the external side than what is called the bottom; a position of the member well adapted for its being employed in climbing, but unfavorable in walking.

In the lunus tarsus and lunus calcis, the os calcis and sesamoid.
phoides are extremely elongated, by which the foot assumes the appearance of a hand and fore-arm.

In the opipium tribe, the afragalus is very small, and articulated almost exactly between the tibia and fibula. The P'viginiua eopifumi has a little supernumerary bone upon the edge of the first cuneiform bone.

The os calcei is of a considerable length in the common bat. It has a tyle shape, and is included in the membranes of the wing at that part. In the vamypere bat, the part of the bone that forms the heel turns under the foot.

The os calcis is much elongated in the sfaligrada, particularly in the kanguro, in which the bone of the heel lands back a considerable way from the tarus. The beaver has the os scaphoides in two pieces; one is placed before the afragalus, and the other at the internal side of that bone. There is a flat supernumerary bone upon the inner edge of the tarus. A similar structure exists in the marmot. The scaphoides is divided also in the porcupine and paca, but the supernumerary bone is wanting. In the sfquirrel it is divided, but the inner portion is small. In all this order of quadrupeds, the scaphoides forms a tubercle in the sole of the foot. This, in some species, is very long, as in the jerboa of the Capé, &c. Many of the sfaligrada, that have only three or four toes, have some small bones, which are the rudiments of those that are deficient.

In the three-toed sfesh the tarus consists of four bones, the afragalus, os calcis, and the two cuneiform bones. There is a depression in the superior part of the afragalus for the articulation with the lower end of the fibula, which is of a cone shape. Upon the inner side of the afragalus there is a convex articular surface, which rolls upon the outer side of the end of the tibia. The confluence of this part of joint is, that the foot of the animal cannot be bent or extended in the usual direction, but from the outside inwards. The os calcis is articulated with the afragalus by a single tubercle, which is received into a depression of the latter bone, which also facilitates the lateral motion of the foot.

The elephant has the tarus and metatarsus both very short. In the dog there are three cuneiform bones, but in the tapir and rhinoceros only two.

In the eleven-footed order, the cuboidea and sfaphoides are united together, except in the camel. There is a small bone on the outside of the afragalus, and articulated with the os calcis, which takes the place of the fibula, and corresponds with the one described in the fore-foot as supplying the ulna. There are only two cuneiform bones in this tribe, and even they are ankylosed in the camelopard. The metatarsus is formed of two pieces before birth, as the metacarpus.

In the boas the metatarsus, as in the eleven-footed tribe of quadrupeds, is called the cannon bone. It has, like the metacarpus of the same animal, two sfles upon its sides, which are the rudiments of the metatarsal bones, and plangents of the second and third toes.

In the jerboa (mus jugita) and the mus Jaculus, the three middle metatarsal bones are ossified together, like the common bone of the eleven and solid-footed quadrupeds.

The orders of quadrumanous and pedimanous mammalia, as before-mentioned, have the power of moving the great toe in the manner of a thumb. Cuvier thinks the aye-aye, or Madagasgare sfquirrel, can do fo likewise.

The number of the toes on the posterior feet of quadrupeds varies from five to one. The great toe, or pollex, is the first that disappears.

Some of the sfaligrada have the great toe diminished, and a few, as the sai and dog genera, have it entirely obliterated.

Among the sfaligrada there is considerable variety in the number of the toes, and the size of the great toe when it does exist.

Many of the edentata and the tardigrada receive specific names, according to the number of their toes, which in these are always less than five. In the armadillos the great and little toe are shorter than the rest.

Among the many-footed quadrupods, as they are called, the elephant has five toes, the hog four, and the tapir and rhinoceros three.

The sfipidae have two perfect toes upon the cannon bone, and two imperfect.

The sfipeda have one perfect and two imperfect; the latter are merely flyloid processes.

It is hardly necessary to observe here, that the position of the toes gives the name to two orders of mammalia. Their number, and their sustaining the animal in walking, or not, determine the character of several natural tribes of this class. The titles we have used for the orders of mammalia throughout the present article, are of themselves explanatory of their foundation: for more full information, see the article Classification.

In Plate X. of the Anatomy of Mammalia, there are figures given of the three most dissimilar skeletons found in the class. Fig. 1. is a front view of the skeleton of the bat, which is taken as the example of a flying species. Fig. 2. represents the skeleton of the mole, the mechanism of which is the more curious found among quadrupeds. Fig. 3. exhibits the skeleton of the porpaje, as an instance of the aquatic tribe of mammalia. In each of these figures, familiar letters are employed to indicate similar parts, but when any of these parts are out of view, or do not exist in the skeletons, the corresponding letters are of course omitted: a is the lower jaw; b, the upper jaw; c, the inter-maxillary bone; d, the malar bone; e, of na; f, lacrymal bone; g, sphenoid bone; h, temporal bone; i, os frontis; j, pia-rletal bone; k, occipital bone; l, cervical vertebrae; m, dor-fal vertebrae; n, lumbar vertebrae; o, facrum; p, caudal vertebrae; q, supernumerary bones on the lower surface of the tail; r, sterneum, which is singularly formed in the bat and mole; s, ribs; t, the clavicle, enormously thick in the mole; u, the acapula, greatly elongated in the mole; v, the humerus, short in the porpaje, almost square in the mole; x, the ulna, with an enormous olecranon in the mole; y, the radius, which makes the single bone of the fore-arm in the bat; z, the carpus; 1, the metacarpal bones; 2, the digits, prodigiously elongated in the bat; 3, the supernumerary bone of the hand in the mole; 4, the os innominatum; the bones corresponding to the pelvis are very singular in the porpaje; 5, the femur; 6, the tibia; 7, the fibula; 8, the tarus; 9, the metatarsal bones; 10, the digit of the posterior extremity. There are no bones analogous to those of the pelvis in the porpaje.

Muscles.—The muscles of the head and face are formed upon different planes in man and mammalia. In the former, besides moving the eye-brows, ears, cartilages of the nose, and lips, they are designed to exhibit the various expressions of human sentiment. But in the latter, the muscles of these parts are almost exclusively confined to those motions which arise out of the mechanism of the organs of sense in different kinds of animals, and are consequently very different in their formation: thus, fone mammalia have the external ears greatly developed, others the nose, and others the lips.

The occipito-frontalis muscle exists in the monkey, dog, and other genera, without any remarkable variety, except that it is thinner.

The osseus grator supercilii also is found in these animals.

Mammals.
MAMMALIA.

Monkeys very frequently move the skin of the forehead, and brow, without however seeming to intend to express the same feelings which these actions indicate in the human species.

The muscles of the cheeks and lips, which give the principal expressions of countenance in man, are often weak and indistinct in mammalia, or rather replaced by a layer of muscular fibres, resembling the 
*pannis alius carnosi*.

In the monkey, the subcutaneous muscle of the face arises from below the orbit and the zygoma; it is continuous with the cutaneous muscle of the neck. It envelopes longitudinally the front, and terminates on the two lips, which it opens. Below this expansion of muscle the *buccinator* is very distinctly found, particularly in those species that have jaw-faces. There are also to be perceived a levator anguli oris, an orbicularis oris, and sometimes a *fistulatus* corresponding to the *zygomaticus*.

In the dog, the upper lip is moved by an expansion of muscular fibres which comes from the anterior angle of the eye, and spreads all over the upper lip, and by another little muscle which descends from the ala of the nose, near the septum in the middle of the lip. Beneath this layer there are found the *orbicularis* and *buccinator*. The lower lip is depressed by a very thin muscle.

The *ruminating* and *fold-footed* quadrupeds have the muscles of the lips large and distinct. In the *boof* Cuvier reckons seven of them; *orbiculari*, *diploper labii inferioris*, *buccinator*, a very large *zygomaticus*, the levator anguli oris, a *nasi* of the upper lip, and a subcutaneous expansion of fibres arising in the neighbourhood of the orbit, and spreading over the buccinator.

In the *bores*, in addition to these, with the exception of the two half, there are the *levator labii superioris*; the *pyramidalis* of Bourgelat, or *supramaxillo-nasalis magus* of Girard; a peculiar muscle for raising the angles of the lips, and a short muscle to each lip, that are called by Bourgelat *medius inferior*.

It is unnecessary to give any detailed account of these at present, as they are mentioned again, and are described under the *Anatomy of the bores* in this dictionary.

These animals require an extensive and varied action of the lips as organs of malversation, but the form of their face in other respects prevents their having much expression of countenance.

The muscles of the nose are subject to considerable variety in mammalia. In the monkey they appear to have their place supplied by the subcutaneous muscle already mentioned.

In the *dipitigrada*, of which we take the dog as an example, the *levator labii superioris* alaeque *nasi* is spread over the whole cheek, in a manner similar to the subcutaneous muscle of the monkey.

When the cartilages of the nose and the lips are prolonged together, to form a fount, the muscles have a peculiar form and arrangement.

In the *male*, the muscles which move the fount are eight in number, four on each side. They all arise from the bone, and extend each a long tendon to the fount. The two deepest and most muscular in the tendon to the superior part of the fount, upon which they unite and form a broad aponeurosis, which covers it for some distance. The two tendons that belong to the nasal superior of the muscles unite in a band upon the inner part of the fount. All the tendons are ultimately inserted into the elastic fleshly disk, which terminates the cartilaginous tube of the fount. In addition to these there is a small muscle that arises from the alveolar edge of the maxillary bone, and depresses the fount. There are annular muscular fibres surrounding these already described; these seem to be the continuation of the *zygomaticus*.

The muscles of the fount in the *boar* are similar to those of the *male*, but they are shorter, and arise from different places.

The first two come from the lachrymal bone: their tendons do not unite. The next four arise from the inferior jaw before the zygoma; the two last are small, and arise from the osa *nasii*: their tendons are not joined. There is also the circular muscle, as in the *male*.

The proboscis of the *elephant* is moved by a very complicated muscular apparatus, of which the best and latest description has been given by Cuvier, in the additions to the 5th vol. of his *Anatomo Comparad*.* It was composed from the defcription of two elephants.*

He divides the numerous muscles found in this organ into two principal orders; viz. those which form the body, or interior part of the trunk; and those which envelop it. The first order are more or less transversal, and intersect the interior part of the proboscis in various directions. The second have more or less of a longitudinal course, and that from the base to the point of the proboscis.

Cuvier again divides the longitudinal muscles into anterior, posterior, and lateral. The first arise from the anterior part of the os frontis, above the cartilages, and proper bones of the nose; they are a large semicircular one, which descends on each side as before the orbits. They form an innumerable multitude of fasciculi, all descending parallel to each other, and are contracted by tendinous intersections occurring at very short distances. The posterior division of the longitudinal muscles arise from the posterior surface, and interior edge of the maxillary bones. They form two layers, each of which is divided into a multitude of little fasciculi, which have an oblique direction. The fibres of the external layer are directed from above downwards; those of the interior take a contrary course, that is, from without inwards; and the fasciculi of the two layers, when they meet, form a middle line, which extends along the middle of the under part of the proboscis throughout its whole length.

Finally, the longitudinal muscles that make the lateral division form two pairs, of which the one is in some measure a continuation of the *zygomaticus*, or it might perhaps be rather considered as analogous to the nasal muscle of the upper lip; it comes from the commissure of the lips, and descends between the anterior and posterior muscles as far as the middle of the proboscis; it soon divides into several slips, which are inserted obliquely between the lateral fasciculi of the inferior muscles. The second lateral muscle is analogous to the *levator labii superioris*; it arises from the anterior edge of the orbit, and proceeds, becoming broader, to be spread over the root of the preceding.

Blair has considered the *zygomaticus* as a continuation of the first of these lateral muscles; and because the *maxillo-mandibularis* is attached to the zygoma also, in consequence of the want of the mallei process, Blair thought that these three muscles were but one, and therefore pretended that the depressor of the proboscis came from the *internum*.

The use of the longitudinal muscles of the *elephant's* trunk is sufficiently plain. When they all act together, they shorten the whole proboscis. When those of one side act, the trunk is bent towards that side. The divisions and tendinous intersections of the anterior longitudinal muscles, enable the animal to put particular parts of the trunk into a contracted or bent state, whilst other parts are elongated, or even bent in a different direction, and thus the prodigious variety
There is also a muscle for depressing the nose; it is situated anteriorly.

The muscles which operate upon the nares of the _sereus_ are much more complicated than in the preceding, tribe. The false naefrils are dilated by a muscle which veterinary anatomists have called the _pyramidalis_. It arises from the upper jaw, near the anterior part of the _zygoma_, by a small tendon. Its felty part becomes broader, and expanded upon the convexity of the false naefril, and in the oboicircular oris. There is another false situated above the preceding: it arises from the maxillary bone near to the notch of the eonical part of the nares; it penetrates into the fold placed between the bone and the false naefril, and is inserted into a cartilaginous production of the inferior turbinate bone. The semilunar cartilage is made to approach the septum, and the naefril is dilated by a muscle which is common to both naerils: This is the _transversus_ of Bourgelat. It appears to be an extension of the oboicircular oris. Superiorly there are some fibres which arise from the nasal bone, and are inserted into the superior convexity of the false naerils; these are the _brevs_ of Bourgelat. There is another muscle called _maxillaris_ by Bourgelat, which arises from all the anterior part of the forehead, proceeds obliquely downwards, and divides into two branches. The external parts over the _pyramidalis_ is intermixed with it, and is inserted in the external convexity of the false naefril.

The _levator labii superiors_ also acts upon the naerils: it arises from the lacrymal bone. Its tendon moves with the outer side of the other to form an anepocele, which covers the end of the nose, and is inserted into the upper lip.

The muscles which move the external ear in quadrupeds are much more numerous than in man. In the description which Cuvier has given from the _horse_, _sheep_, _rabbit_, and _dog_, he reckons twenty-one, some of which are peculiar to certain quadrupeds only. He divides them into four classes: 1. Those which pass from the head or neck to the third cartilage of the ear of quadrupeds, which he has called the _feetum_. The 2d are those which arise from some of the parts of the head, or the _cervical_ ligament, and are inserted into the concha or its tube. The 3d clafs contains muscles which unite the _footum_ to the concha, or to the tube of the ear. The 4th clafs consists of those that extend from one part of the concha to another.

In the first clafs there are three muscles: the _vernico-\_feudalis_, the _jugo-feudalis_, and the _cervico-feudalis_. The first comes from the crown of the head, and draws the ear upwards and forwards. The second arises from the _zygoma_, and draws the car forwards and a little upwards; it is wanting in the _bare_ and _sheep_. The third comes from the _cervical_ ligament, and makes the one ear approach the other polieriorly: it is peculiar to the _dog_ and _rabbit_.

The second clafs contains several muscles.

1. The _vernico-auricularis_ arises from the vertex of the head, and is inserted on the concha, which it elevates and approximates to the other: it is peculiar to the _horse_ and _sheep_.

2. The _suprino-auricularis_ takes the place of the preceding in the _bare_ and _dog_. It arises from the superepharyngeal arch.

3. The _cervico-auricularis_ arises from the _cervical_ ligament, and is inserted upon the concha, which it pulls backwards and to the other _ide_.

4. The _occipito-aumalzatis_ talyes from the occiput to the concha, which it draws upward and backward: it is not found in the _bare_.

5. The _cervico-\_feudalis_ profundus passes from the _cervical_ ligament...
MANMALLA.

ligament to the tube of the ear, which it draws backwards: it is double in the horfe, and wanting in the bare.

6. The occipito-aureicularis rotator arifes from the occiput, and terminates in the concha, near its tube: it exists in all long-eared quadrupeds, and turns the ear upon its axis.

7. The parotid-aureicularis paffes from the parotid gland to the concha, near the tragus: it defcribes the ear, and is a muscle constantly found.

8. The jugo-aureicularis goes from the zygoma to the concha: it is large in the fheep, double in the dog and horfe, and does not exist in the bare.

9. The jugo-aureicularis profundus arifes from the posterior part of the zygoma, and is inserted into the concha, near the tube; it throns the tube.

10. The vertico-aureicularis rotator goes from the vertex of the head to the anterior part of the concha, near the tube: it rotates the ear, so as to bring the hollow part forwards and inwards.

11. The vertico-aureicularis profundus arifes along with the preceding, and is inserted into that part of the concha near the tube, which is inward when its concavity is directcd outwards: its ufe appears to elongate the tube of the ear. These ftill two muscles Cuvier only found in the horfe.

The third clas contains two superficial and one deep-fated muscle.

1. The feptalis anterior paffes from the lower edge and anterior angle of the fcutum, to the front of the concha: it turns the latter on its axis, and directs it upwards and forwards when horizontal. It does not exift in the dogs that have hanging ears.

2. The feptalis posterior has nearly the fame origin as the preceding; but is inserted into the back of the concha: it raises the concha. The bare wants this muscle.

3. The feptalis rotator is deep-fated, and arifes under the fcutum, and terminates behind the concha next the tube: it rotates the concauity of the concha towards the earth, and backwards, when it is horizontal. This muscle is doubfe in the bare.

The fourth clas of the muscles of the ear do not exift in the fheep; and there is only one of them in the horfe, which is the tragicus: it contracts the opening of the external meatus. It is found in the dog and bare.

In the bare there is a muscle which fhorts the tube: it is called by Cuvier tubo-belicus.

In the dog there is a muscle analogouf to thofe on the hells in the human fubjeét. Cuvier calls it plicator auris.

In the dog and horfe there are fome muscular fibres upon the back of the concha, analogous to the tranfeversus auris.

By means of the muscles above decribed, quadrupeds are enabled to give almost all poifible attitudes to the external ear, besides collecting the sounds which approach in various directions. The external ear is fometimes employed in exfufing the fentations of animals: thus, horses throw back their ears, when displeafed; and most quadrupeds fhew their fatisfaction by an erect poifion of thofe parts.

The muscles which move the jaws in mammalia are, except in fome of the fahigrada, the fame in number, and bore the fame names as thofe in man. They differ chiefly with refpect to their relative strength. This circumstance has been in a great meafure already explained, in describing the form and extent of the bones to which these muscles are attached.

As a general obfervation, it may be stated, that the mufifter and pterygoid muscles are largel in the herbivorous quadrupeds, and the temporal in the carnivorous.

In the ant-eaters, the poifion of the mufifter is very unfa-

variable to its acfion. The tubercle that supplies the place of the zygoma is anterior to the part of the lower jaw, to which the other extremity of the mufifter is affixed; consequently the fibres of the mufcule pass in a direcfion contrary to that in which their force is exerted.

In the mars typhlus, the temporal mufcle is very flrong, although it is thin in this tribe generally. The typhlus has it fo much extended as to be intermixed with the one of the oppofite fide, upon the upper part of the head.

The mole has the temporal muscles very thick and elongated, fo that their greatest extent is from behind forwards. They touch each other upon the crown of the head.

In the carnivorous digiigrada, especially the cat genus, the temporal muscles have to great a bulk in every direcfion, that they make up the chief part of the bulk of the head.

An additional mufcle on each fide, for raifing the lower jaw, has been difcovered in the fawy, and other fahigrada, by Mr. J. F. Meckel, which is defigned to aid thofe animals in their particular mode of comminuting their food. This muscle has received the name of mandibulo-maxillaris. In the fawy it commences as a thick mass, from the molt anterior part of the fuperior maxillary bone, proceeds backwards and downwards across the great sub-orbital foramen, which it fills, and changes there into a ftrong tendon, which defcends to the lower jaw, to be inferted on the outflde of the pterygoideus externus mufcle, oppofite the first molar tooth, that is, in the molt anterior part of the canal, in which the pterygoideus mufcles are inferted. These mufcles are generally familiar in the other gnawing quadrupeds: they are muscular throughout in the rats, in whom they are very ftrong. The action of the mandibulo-maxillaris mufcle has a direcf effedt upon the incifor teeth, or upon the extremities of both jaws; and hence the effedt of this mufcle in thofe fahigrada that gnaw hard fubftances. The mandibulo-maxillares are wanting in the bare and varmit, which live on soft herbs.

The digiigradic muscle, except in the monkey, is diftinctly formed than in man. The name of melo-maxillaris, impofed upon it according to the modern fystem of nomenclature, is pecufarily proper. It generally wants the middle tendon, which forms it into a mufcle with two bellies, or a digi- tricus. In the mandril (fonia mainon), the tendons of the mafioid portions of each fide become intermixed above the hyoïdes, fo that these two portions appear to make a digi- tradic mufcle.

In the digiigrada this mufcle has but one belly, and it is inferted into a procus at the posterior angle of the branch of the jaw.

In the fahigrada there are two portions.

This mufcle is wanting in the ant-eaters and armadillfs. These animals have their place supplied by a long fonder mufcle, that arifes from the middle of the top of the fternum, and is inferted at the inferior and middle part of the ramos of the lower jaw. This mufcle is called by Cuvier the fterno-maxillaris.

In the fahigrada the digiigradic is connected with the fterno-

hyoïdes mufcle.

* The ox has the middle part of this mufcle covered above and upon the internal cu.de by an aponeurofs, which gives attachment to a figure mufcle, that extends from one di-

gatrice to the other.

The muscles of the ox hyoidei exhibit to very flirking pec-

ularities, except in fome of the edentata.

The fterno-hyoïdes mufcles in the fio arife fo far within the fternum as the third piece compofing that bone. In the,
MAMMALIA.

Feet they arise from the first ribs, and are strengthened by a ligament from the little tuberosity of the humerus, which corresponds to the omohyoid.

The sterno-hyoides is narrow in those animals, to which Cuvier ascribes the sterno-hyoides as having an unusual origin.

The sternohyoideus and omohyoideus muscles are incorporated, and make a very large muscle in the dolphin. The sterno-hyoideus is only perforated by the digastric muscle in the muscles, as in man.

In the face the sterno-hyoideus is wanting; the hyoid bone is not connected with the cranium; and the middle portion of the digastricus adheres firmly to the body of the os hyoideus.

The mylo-hyoides is an active muscle in bringing forwards the hyoideus, when this bone is placed far back, and the jaw is much elongated.

The position of the os hyoideus being so near the sternum in the anteater, the muscles which act upon it have many peculiarities. There is a very small muscle which is analogous to the sterno-hyoideus: it arises from the middle and anterior part of the hyoid bone; it descends forwards and backwards, to be united to the edge of the genio-hyoideus. The mylo-hyoides is necessarily very long: it does not touch the os hyoideus, but its last fibres ascend to the base of the hyoid bone, to which they are attached and, more anteriorly, some of these fibres even ascend to be inserted into the transverse processes of the middle cervical vertebra. Thence which precede the last mentioned are inserted more internally, into the membrane of the bottom of the mouth. It is only the portion corresponding to the two anterior thirds of the jaw, that is attached to the edge of that bone. There is no middle tendinous line in this muscle, and all its fibres are transverse in their direction. The genio-hyoideus is a single muscle: it is attached to the angle of the chin by a very thin tendon, which extends to the opposite angles of the jaw, accompanying the middle of the mylo-hyoideus: its fleshy part commences there. It is very thin throughout, and is at first narrow, but it afterwards enlarges, and then is composed of two portions: it contracts again, before it is attached to the body of the hyoideus. The sternohyoideus muscles extend upon the sternum, as far as the middle of the bone.

In the echidna the mylo-hyoides is attached in a great measure to the palate membrane: the most dilated portion ascends upon the sides of the orifice. The sternohyoideus the mylo-hyoides has a tendinous line in the middle, from which the muscular fibres depart on each side, and proceed obliquely from behind forwards, and are inserted into the inferior border of the jaw. There is a second portion of this muscle, which appears to supply the place of the genio-hyoideus in this animal. Its fibres depart from the hyoideus and the base of the tongue, and advance more obliquely outwards, as far as the most dilatant part of the branches of the jaw, to the lower edge of which they are attached. The sterno-hyoideus is prolonged upon the sternum, as far back as the middle of that bone, both in the echidna and Erinaceus fuscus. It is difficult to conceive the use of the extension of the muscle in the latter animal. In the echidna and the anteaters it is subservient to the motions of their tongue.

The muscle called by Cuvier the stylo-mastoides is peculiar to mammals, in which it appears to exist pretty regularly. It is a small muscle, arises from the external surface of the masticatory process, and is inserted upon the internal surface of the temporal end of the hyoid bone. When the hyoid bone, as in the winter-boiled quadrupeds, has an angle prolonged posteriorly, this muscle is inserted into it, and moves the hyoid bone as a lever, and brings its lower end upwards and outwards. When the hyoid bone is not attached to the cranium, this muscle serves to uphold it.

In the paca, the stylo-mastoides seems to form a part of the digastricus, with which it descends to the os hyoideus, and is afterwards extended upon the sides of the pharynx, by which it supplies the place of the stylo-pharyngeus.

In the digitigrade, there is another additional muscle: it is thin, flat, and fills up a part of the interval of the two horns of the os hyoideus of the same side.

The muscles of the pharynx resemble those of man so much, that a description of them becomes unnecessary.

There is a pharyngeus proprius in the elephant, bear, &c. which has been already mentioned.

The stylo-pharyngeus has some peculiarity of direction and effect, in conformity of the horizontal position of the pharynx. It descends almost perpendicularly from the styloid process, or bone, upon the upper surface or sides of the pharynx, and it is only after it has passed under the constrictor muscles that it proceeds backwards along the pharynx. Its operation is rather to dilate the bag of the pharynx than to bring it forwards.

The peculiarities of the muscular structure of the tongue are more noticed in the first part of this article, where that member is described as an organ of mastication.

The subcutaneous muscles are much more remarkable in quadrupeds than the human subject. In the latter, they are weak, and confined to particular places; but in the former, almost the whole of the skin can be moved; and in those species that roll themselves up when they are in danger, the subcutaneous muscles are of great magnitude, and complicated in their arrangement.

The cutaneus or latissimus coli, (tibrapefaciæus of Cuvier) is inconsiderable in many quadrupeds. It is intermixed with some muscular fibres that lie under the skin of the face in the monkey kind, as already observed. In the marmot, this muscle has another place under it, which is thicker, and extends to the side of the head, and to the face and snout.

There is a cutaneous muscle upon the abdomen, and under the skin of the thighs of quadrupeds, which is inserted, along with the pectoralis major, into the humerus by one or two tendons. Before acting upon the skin of the lower surface of the body, it converges, with the actions of the pectoral muscle, in bringing the arms inwards, and in the true quadrupeds is a muscle of progression, by affixing to move the body forwards upon the anterior extremities. Cuvier gives the name of dermo-lumeralis to this muscle. In the racoon it is attached to the prepuce, which it retraces. Where it covers the belly of this animal, it is very thin. In the marmot this muscle covers the back as well as the under surface of the body: it is inserted into the arm by two tendons; the one with that of the latissimus dorsi; the other with the tendon of the pectoralis major.

Those animals that have the power of rolling themselves up, possess a number of curious muscles for the purpose. There are the most numerous and striking in the kedge-hog. In this animal there is a very extensive subcutaneous muscle upon the back of the body. Its fibres adhere closely to the skin of the back and the ends of the spines. The shape of the muscle is oval: the middle of it is thin, and has the fibres mostly arranged longitudinally; but around the edge they are thick, and have a circular direction, and resemble a sphincter muscle.

In the ordinary position of the kedge-hog, the dorsal muscle is contracted, and entirely carried upon the back; but when
MAMMALIA.

When the creature is coiled up, the longitudinal fibres of the muscle are so much relaxed, that it is capable of being extended over the top of the head, the tail, and posterior legs; after which the sphincter or marginal fibres are put in action, by which the whole body is inclosed, as it were, in a round bag.

There are several small distinct muscles which serve to connect this flabby oval expansion to different parts of the body, and which contribute to bring the head and limbs into their proper position, after they have been doubled up by the muscles situated upon the inferior part of the body. Two pair of these muscles arise from the anterior extremity of the oval muscle. They are inclosed into the narial and intermaxillary bones, and the lateral parts of the nose.

One pair of muscles arises from the posterior part of the oval expansion: they are broad, pyramidal, and inclosed by tendon into the flides of the tail, near its end. There are three distinct portions of the skin under the skin, upon the lower surface of the body. The first corresponds to the cutaneous colli; it arises from the top of the ilium, and is inclosed behind the ears. The second is posterior to this; it arises from the middle of the ilium; it fables over the top of the shoulder, and is inclosed into the oval or orbicular muscle of the back. These two muscles, with their fellows of the opposite side, produce the figure of two cones, having their points turned backwards, and the one being received into the base of the other. The third muscle covers with its fellow the surface of the abdomen. It is attached to the tail, the top of the thighs, the arm, and the dorsal muscles, by so many distinct slips or divisions. This muscle is analogous to the dermo-humeralis of other quadrupeds.

There are, besides those already described, some deep-seated muscles situated under the great oval one of the back. One arises from the posterior edge of the mctatus audenters, and proceeds backwards to be lost in the forepart of the orbicular muscle. Another arises from the last cervical vertebra, and is inclosed into the orbicular muscle. Underneath the great oval muscle there is a thin layer of transverse fibres: the anterior ones are attached to the inner and upper part of the humerus, and the posterior to the external process of the ventral or dermo-humeralis muscle.

When the orbicular muscle is entirely contracted, and carried upon the back of the hedgehog, it serves as the fixed attachment of the muscles, which go from it to the head, neck, and tail; and these parts are consequently raised or fulfilled by them; but when the animal wishes to roll itself up, it relaxes the orbicular muscle, and puts into operation the flexors of the head and limbs, by which they become fixed points, and all the straight muscles connected with the oval or orbicular muscle of the back are enabled to act upon it, and spread it over the body; and when the latter is brought over the head and tail, the margin of it contracts separately from the rest, by which even the head and feet of the animal are completely inclosed. The connection which the great oval muscle has with the roots of the spines of the skin, puts the spines into a state of erection in different directions, which renders the animal unapproachable at every point. See Himsly's account of the rolling up of hedgehog, printed at Brunswick, 1801, 4to.

The muscles that act immediately upon the ribs have no peculiarities in mammalia worth remarking.

The abdominal muscles are longer and narrower in mammalia than man. This depends, in some degree, upon the difference in the shape of the trunk, but not entirely, as...
Mammalia.

Caudales of Vic d'Azir, are situated upon the upper side of the tail. They arise, by fleshy slips, from the three or four last lumbar vertebrae, the sacrum, and from those caudal vertebrae that have processes. Small tendons pass off from the common mass opposite to the fleshy digitations. The first tendon is the shortest, and is inserted into the base of the first caudal vertebra. The second tendon to the next vertebra, and so on to the end. There are thirteen of these tendons. They enter ligamentous grooves or fheaths, which are connected together by a ligamentous web that incloses them in a sort of case. These muscles have the effect of directly raising the tail.

The intercoccgei (spinale. obliqui of Cuvier,) (lumbo-facrococcygei of Vic d'Azir), should be considered as the continuation of the inter-spinale muscles of the back. They cooperate with the last described in the elevation of the tail.

There are four pairs of muscles for depressing the tail.

The ilio-subcaudales (ilio-coccygei of Vic d'Azir) arise from the internal part of the ilium; form two long fleshy masses in the pelvis; and are inserted into one of the V shaped bones of the under surface of the tail. Sometimes they are inserted between the fifth and sixth of the bones, at others between the seventh and eighth.

The facro-subcaudales (furo-coccygei inferiores of Vic d'Azir) resemble exactly the facro-coccygei superiores, except that they are placed upon the opposite side of the tail. They arise from the sacrum, and from the transverse processes of the superior caudal vertebrae. Their tendons are long and numerous, and inclosed in a sheath, likethose of the facro-coccygei superiores. They begin in the long-tailed species to be inserted into the seventh caudal vertebra, and go on.

These muscles, with the superior coccygei, operate upon the tail, even to its point, and have exactly the opposite effects of each other. They are particularly employed in all the more delicate motions of the tail.

The subcaudales of Cuvier (inter-coccygei of Vic d'Azir) are situated under the middle of the tail. They arise at the articulation of the first and second caudal vertebrae. They are first inserted into the V shaped bone of the fourth, fifth, and sixth vertebra; then they further receive slight fleshy slips, which gradually diminish, and go on to be inserted into the base of each bone of the tail.

The pubo-subcaudales of Cuvier (pubo-coccygei of Vic d'Azir) arise broad and thin from the upper part of the pelvis, and proceed to terminate in points which are inserted into the processes or tubercles at the base of the fourth and fifth vertebra, upon the inferior surface of the tail. They bring the tail close to the body. These muscles are wanting in the raccoum.

There are two muscles on each side of the tail for producing the lateral motions of it.

The ilio-caudales of Cuvier (ilico coccygeus extenso of Vic d'Azir) arise from the internal surface of the ilium, and pass backwards over the transverse processes of the tail. In the racoon, it is inserted into the seven caudal vertebrae that succeed the third, by seven fleshy digitations. In the opusum, into the four first vertebrae of the tail. In the dog, it is the mere fip of flesh, and is inserted into the fourth vertebrae.

The intertransversarii pass from one transverse process to the other on each side, as far as they go. This muscle is similar to the one of the same name in the other parts of the spine.

It is scarcely necessary to observe, that the combined actions of these muscles, or their contractiof opposition to each other in different parts of the tail, are capable of communicating to this member all possible directions. The effects of this co-operation are strikingly displayed in the tails of certain monkeys, marsupial animals, ant-eaters, &c. in which this member is capable of performing most of the operations of a hand.

There are several peculiarities to be noticed in the muscles of the anterior extremity, particularly those of the shoulder and upper arm of quadrupeds.

The ferratus major has not only the digitated attachments to the ribs, but to some or all the transverse processes of the cervical vertebrae. In the dolphin, and probably in all species, this muscle has no attachment to the cervical vertebrae; the greater extent of the ferratus major appears to be required for progression on four feet.

The pectoralis minor does not exist in the digitigrade and hoofed quadrupeds. Another muscle supplies its place in the horse. This is united to the pectoralis major, and is in part inserted into the humerus. The pectoralis minor of the dolphin is narrow, and arises by one digitation from near the top of the sternum, and is inserted into the glenoid cavity of the scapula.

The levator scapulae is inserted into the spine of the scapula in the monkey, the digitigrade and foliggrade quadrupeds. In the dog and bear it arises from the first cervical vertebra only, and in the rabbit from the cuneiform processes of the caput, and has been called by Vic d'Azir acromio-humeralis. In the sheep it arises from the first cervical vertebra, and is inserted into the posterior part of the spine of the scapula. The levator scapulae is wanting in the horse. In the dolphin it comes from the first cervical vertebra, and its tendon is spread over the whole external surface of the scapula.

The trapexius and ferno-cleido malafoideus are generally confined with each other, or with one of the other muscles of the neck. In the carnivorous, and those foliggrade quadrupeds that have an imperfect clavicle, the clavicular portions of the ferno-cleido malafoideus, and of the deltoide and of the trapexius, make but one muscle, to which Cuvier gives the name of mengo-humeralis, and which has been called by other anatomists communis capitis, pectoris, and brachi. The clavicular portion of the trapexius is distinct from the scapular portion; and the levator scapulae passes between them. In the bear, the anterior portion of the trapexius is again divided into two muscles, one of which sends a tendon to the top of the sternum. In the sheep, there is a muscle which arises from the maloide processes; it divides into two; one goes to the sternum; and the other is incorporated with the clavicular portion of the trapexius and of the deltoide.

In the horse there is a distinct ferno-malafoideus, but the cleido-malafoideus, levator scapula, and the clavicular portions of the trapexius and deltoide, are supplied by one muscle, which arises from the malafoide processes, and the transverse processes of the superior cervical vertebrae, and passes down the internal side of the arm to be inserted inferiorly. In the dolphin, the clavicular portion of the trapexius is wanting; the ferno-malafoideus of this animal is very strong, and there is another muscle external to it, which arises from the malafoide process also, and is inserted below the head of the humerus.

There is a muscle of the shoulder apparently peculiar to the rabbit: it is thin, and arises from the spine of the scapula, and is inserted into the clavicle.

The rhomboideus is a larger muscle in quadrupeds, in proportion, than it is in man. It is even in the monkey tribe extended to the occiput. The portion arising from the bull is distinct in the digitigrade quadrupeds, and is the muscle
Mammalia.

Muscle which has been called the lewator scapulae magnus. This portion of the rhomboïdes arises from the ligamentum nuchae in the horse, and has been called by the veterinary anatomists lewator scapulae proprius. The rhomboïdes has no division, and is a small muscle in the dolphin.

The supraspinals is of course wanting in those quadrupeds that have imperfect clavicles, or none.

We have referred the account of the muscles of the shoulder in the mole and bat for separate consideration, as the motions of the anterior extremity in these animals are so very peculiar.

In the mole, the ferratus major is extremely large, but simple in its form; it arises from only the last, cervical vertebra. The trapezius has no anterior origin; there are only two falciculi from the lumbar region to the posterior angles of the scapula, which would draw these bones asunder, if they were not bound together by a strong transverse ligament. The rhomboïdes is attached posteriorly almost entirely to this transverse ligament of the scapula, and anteriorly to the ossified ligamentum nuchae. The chief use of this muscle is therefore to elevate the head. The muscle corresponding to the occipital portion of the rhomboïdes arises from the middle of the head, has its fibres parallel to the cervical spine, and passes through the rhomboïdes, properly so called, to be attached to the transverse ligament of the scapula. This muscle operates with great power in raising the head, which is a necessary exertion to the mole in burrowing. This animal has two muscles to the clavicle: one of these Cavalier calls supraclavarius: it arises from the first bone of the sternum at the anterior angle of the great head of the clavicle. The other arises lower down on the sternum, and is inserted near the first.

In the bat, the ferratus major is situated before the pectoralis minor. It is only attached to the ribs, and is inserted into the inferior and external edge of the scapula. The supraclavarius is very large. The trapezius arises from the eleven first dorsal vertebrae, and is inserted into the triangular surface of the cervical angle of the scapula. The musculo mufcle is only attached to the sternum.

The musculo of the humerus appear all to exil in mammalia, but frequently under different conditions than in man.

The pectoralis major is commonly composed of several distinct fasciculi, or portions. In those species which have not a perfect clavicle, there is a portion of this muscle arising from the sternum, and inserted into the linea aspera, which, with the portion of the opposite side, makes a common muscle for both arms, to which Cuvier gives the name of ambibrachialis communis. It has the effect of croffing the fore-legs. In the sheep, there is a second common muscle, which passes from the sternum to the ulna, completely inclining the humerus with the trunk. It is designated to crofs the fore-legs, and has been called by the veterinary anatomists, in the horse, ambibrachialis communis. It should rather, perhaps, be considered a subcutaneous muscle than a portion of the pectoralis major. In the bat, the pectoralis major is divided into three distinct muscles. The last lies partly under the first. This is inserted into the great anterior tubercle of the humerus. The second is inserted above the first, behind the great tubercle; and the third muscle terminates upon the spine of the humerus. These muscles depref the wing in flying, and therefore require to be very strong.

The latissimus dorfi of the bat is a fleshy stripe from the spinous tubercles of the two last dorsal vertebrae.

The suprascapulae of quadrupeds have a different relative size to each other than in man. In the former, the supraspinatus is the larger muscle. In the cat, the supraspinatus is the muscle on the back of the scapula nearly obliterated.

In those species that want the clavicle, there is only the scapular portion of the deltoideus, the other part being, as before described, continued into the trapezius. There is a distinction of two parts also in the scapular portion, the acromial and infraspinous. In the horse, the acromial attachment is wanting, and the deltoid having the same direction as the infraspinatus, it is distinguished by the peculiar name of adductor longus brachii.

The coraco-brachialis consists of two parts in the monkey, bear, etc.; one of which extends the whole length of the humerus. In the bear, the inferior portion is inserted into the external condyle. When there is no conjoined process of the scapula, this muscle arises from a little eminence on the upper edge of the scapula.

In the dog, cat, rabbit, and horse, the biceps arises by one head, and is unconnected with the coraco-brachialis.

The muscles which move the humerus are of an extraordinary bulk in the mole. The pectoralis major is almost as large as the pectoral muscles of birds. It consists of five portions: four of these arise from the sternum, and are inserted into different points of the humerus; the fifth comes also from the sternum, and covers the whole surface of the humerus; the sixth is extended from one humerus to the other. The latissimus dorfi is also very strong; it is divided into two parts. The teres major is prodigiously strong. Upon these three muscles chiefly depend the rotation and the retraction of the anterior limbs of the mole, the motions by which it excavates the earth with such extraordinary force and rapidity.

The supinators and pronators of the fore-arm are not found in those species of mammalia which either have the ulna immovable, or obliterated. The cat and dog have the supinator brevis, but not the longus. The rabbit has only the pronator teres.

Monkeys, the cat, and bear, have the same number of flexors and extensors of the carpus as the human subject. In the eleven and solid-hoofed quadrupeds, the external radialis is inserted anteriorly into the base of the cannon bone, which it extends; this is the extensor radialis communis of Bourgelat. The radialis internus is the flexor internus of Bourgelat. The ulnaris internus is the flexor obliquus of the same author; it is inserted into the bone that corresponds to the os pisiforme. The ulnaris externus is inserted likewise into the same bone, and is called by Bourgelat the flexor externus. The muscle analogous to the ulnaris externus in the bat, arises from the os brachii, and from the radius as far as its middle. Its tendon is inserted into the upper and internal part of the carpus, which it abducts. The muscle corresponding to the ulnaris internus arises from a fleshy portion common to it, and the other muscles of the fore-arm, and is inserted into the external side of the first phalanx of the last finger. It adducts the carpus. The adductor pollicis has the same common origin, and sends its tendon obliquely across that of the ulnaris externus, and is inserted into the internal side of the carpus at the base of the thumb.

The extensor communis digitorum exists in all quadrupeds. Its tendons correspond to the number of fingers. The portion, which merely extends the little finger in man, is of greater size, supplies more fingers, and is more difficult in many mammalia. In the monkey and rabbit it has two tendons, and sends one to the fourth finger. In the dog and bear it furnishes a tendon also to the third and middle fingers.
The *cat* has two muscles in place of this division of the extensor communis. In the *claw-footed* cattle this muscle extends the outer toe, and the extensor indicis the internal.

There are two muscles in the *horse*: one is called by Bourgelat *extensor lateralis*, and by La Folle the *extensor of the posterior*. It tends the tendon to the side of the first joint of the toe.

The other muscle is situated between the preceding, and the one analogous to the *extensor communis*, of which it is considered by some anatomists as making a part.

The *indicator* has two tendons in the *monkey*: one of which goes to the middle finger; this muscle does not exist in the *rabbit*, the *follic* and *claw-footed quadrupeds*.

The *extensor brevis pollicis* is not found in the *cat*, *dog*, *bear*, and *rabbit*. The *extensor longus* tends a tendon to the first finger in the *bear*.

The *flexor longus pollicis* is wanting in the *monkey*, and its place supplied by a fifth tendon from the *flexor profundus communis*.

In the *dog*, the *flexor profundus* unites with the *flexor pollicis*, and the latter separates to go to the thumb. The *flexor profundus* tends a tendon to the thumb. In the *cat*, the *flexor profundus* consists of five distinct slips, and lends off as many tendons. The *flexor profundus* also lends a tendon to the thumb.

In the *rabbit*, the *profundus* furnishes a tendon to the thumb, but the *profundus* not.

The *flexors* furnish fewer tendons, of course, where there are fewer digits; for instance, they lend off but two in the *claw-footed*, and one in the *fossil-footed* quadrupeds. The *bat*, which has so many peculiarities of the anterior extremity, has only one *extensor* of the digit: its five tendons run along the back of each of the elongated fingers that sustain the membrane of the wing, to the extension of which they contribute. The *flexor communis* arises from the common mass of muscle upon the under side of the fore-arm; its delicate tendons unite with the *flexores proprii* of the joints of the wing. These last muscles are four in number; they form a flabby mass where they arise from the *carpus*; become connected with the tendons of the *flexor communis*, and are extended to the ends of the joints of the radius of the wing. Some short fibres arise from the *carpus*, and are inserted into the root of the *pollex*.

The *muscles* of the fingers are obliterated in the *catceca*.

The *muscles* of the *inferior*, or, more properly, posterior extremity, that arise within the body, are, in general, similar in man and mammalia. The *psoas parus* has been observed to be wanting in the *bat*.

The *bat* wants the *quadratus lumbrorum*, *psoas magnus*, *ilio-thigh internus*, *pyiformis*, *geminii*, *obturator internus*, and *quadratus femoris*. The *psoas parus*, is, however, very strong in this animal, and its aponeurosis broad; the *psoas* and *obturator internus* are long and slender. The *psoas* of the *dog* lends its tendon to the lower part of the *femur*. Quadrupeds, in general, have the *psoas magnus* and *ilio-thigh* more elongated in their figure than they are in man.

There is a striking disproportion in the *gluteal muscles* of mammals. The *external*, called in man *gluteus maximus*, is in all quadrupeds the smallest of the three. In the *horse*, it is little more than an aponeurotic expansion, and is called by Bourgelat the *gluteus minimus*. The diminished size of this muscle, proves that its chief use in the human subject is to move the pelvis upon the thigh, and to maintain the erect position of the body. In the *horse*, this muscle has, in addition to the thin flabby head from the *carpus* and back of the *ileum*, another thin slip from the top of the *ileum*.

The *gluteus medius* and *minimus* are found much larger in proportion in quadrupeds than man. The *medius* in the *horse* is very large: it arises from the *carpus*, all the membrane between that bone and the *ileum* and *femur*, and is inserted into the process of the femur that Courteau has been inclined to call a third trochanter. This muscle draws the limb backwards, as in the action of kicking. In the *bat*, the *gluteus minimus* descends almost perpendicularly from the *ileum* to the *femur*. This animal has but one *adductor femoris*, or head of the *tendo*: it goes from the symphysis of the *pubis* to the *femur*, about one-third from its top.

The shape of the thigh is rather flat in the true quadrupeds, and even in the *monkey* it is less round than in man. The muscles are thrown forwards and backwards, which is the most convenient position for progression on four feet. The great size of the muscles upon the internal part of the thigh of the human subject is not displayed, as anatomists generally rate, to bring the legs together, or to balance a horse, or, in case of shipwreck, the marts of the vessel, but in the ordinary progression, on two feet, to transfer the weight of the body from one side to the other.

The *fasciarius* and *gastrocnemius* are placed upon the anterior part of the thigh in the *dog*, *cow*, and *fossil-footed quadrupeds*. The *fasciarius* is called in the *horse* *adductor longus*. The *gastrocnemius* is large in all quadrupeds, and especially in the *fossil-footed* orders.

It is called by Bourgelat the *adductor brevis*. He gave the name of *gastrocnemius* to the *mucelle* corresponding to the *fasciarius*.

This last muscle, and the *femoromembranosus*, are inserted into the *tibia* by a broad aponeurosis, lower down than in man, by which means the hind legs are always, in a degree, bent, a circumstance favourable to progression on four feet, but very inconvenient in the erect position of the body. Even the *monkey* has this form of the limb, and for that reason, as well as others, cannot remain long standing, without supporting itself by the anterior extremities. In the *bat*, there is only one muscle which supplies the place of the *fasciarius*, *gracilis*, *femoromembranosus*, and *femoromembranosus*. It arises by two portions: the one from the *femur* and *iliac* part of the *femur*, the other from the *pubis* and *femur*. The *adductor femoris* passes between them. The common tendon produced by these two muscles is inserted below the head of the *tibia*, on what is the *femur-part* of the *leg* in the *bat*. This muscle bends the *leg*. There is but one muscle also for extending it, which arises from the upper part of the *femur*, and is a slender tendon, which is inserted into the *tibia*.

The muscles composing the calf of the *leg* are much smaller in mammalia than man, in proportion to the size of the animals. The *soleus* arises from the back of the *fibula*: it is peculiarly light in the *claw-footed* and *fossil-footed* quadrupeds.

The *tibialis anticus* is inserted into the anterior surface of the *tibia*.

The lower part of the *cannon bone* in those quadrupeds that have this bone.

The *tibialis posticus* of the *monkey* has a large *femur* bone in its tendon. In quadrupeds that want the great toe, the tendon is inserted into the *metatarsal* bone of the first toe, which it abducts or separates from the rest. This muscle does not exist when there are *cannon* bones.

The *peroneus longus* in the *monkey* adds the great toe to the others. The other *peroneal muscles* of the *monkey*, and of the quadrupeds with claws, resemble the same muscles of the human subject. The *rabbit*, however, is an exception. The *peroneus medius* lends a tendon to the *littl toe*. In the *claw-footed order*, the *peroneus longus* crofts below
below the joint of the cannon bone to be inferted into the first os cuneiforme. The tendon of the {\textit{medius}} extends to both the toes, and the {\textit{peroneus brevis}} does not exist. There is only one peroneal muscle in the {\textit{horsë}}; its tendon joins that of the extensor of the finge toe.

The {\textit{plantar}} mufcle, which terminates upon the os caleis in the human subject, is a {\textit{stronger}} muscle in mammalia; it supplies the place of the {\textit{flexor brevis digitorum peronatus}} in quadrupeds. It is continuous with the {\textit{plantar}} {\textit{flexor}} in the {\textit{monkey}}, from the defection of which animal this muscle probably received the name it bears.

In the {\textit{wombat}}, according to Mr. Brodie, there is a peculiar muscle of the leg. It is situated between the tibia and fibula throughout their whole length. The fibres have their origin from the inner edge of the fibula, and pass obliquely, inward and downward, to be inferted into the opposite surface of the tibia. The operation of this muscle is to bring the fibula forwards, and produce a degree of rotation on the tibia which turns the toes inwards. This muscle is opposed in its action by the one that corresponds to the {\textit{biceps}}, and which is inferted into the posterior part of the fibula. It brings the toes back into the straight line, but does not turn them outwards.

There are several peculiarities in the arrangement of the {\textit{flexor}} mufcles of the toes in the {\textit{monkey}}. The part of the {\textit{flexor brevis}} that goes to the first toe only is attached to the os caleis. The short flexors of the great and little toes resemble that of the human subject. The {\textit{flexor pollicis longus}} gives a tendon to the pollix, or great toe, and two perforating tendons to the third and fourth toes. The {\textit{flexor longus digitorum}} supplies two perforating tendons to the second and fifth toes. The three perforating tendons of the third, fourth, and fifth toes do not come from the bone of the heel, but have their fleshy fibres arising from the {\textit{flexor longus digitorum}}. The tendons of the long flexors are united together. The {\textit{accessory flexor}}, or {\textit{mattus cornu}}., has an anephraneous attachment to the tendon of the {\textit{flexor pollicis longus}}; and lends a strong tendinous band to the tendon of the {\textit{flexor longus digitorum}}.

The {\textit{flexor longus pollicis}}, when there is no great toe, has its tendon incorporated with that of the {\textit{flexor longus digitorum}}, as in the {\textit{dog} &c.}

The monkey has a long {\textit{adductor}} of the great toe; it is inferted upon the inner side of the external long pollicis.

The {\textit{extensor pollicis}} is wanting in those that have not the great toe, such as the {\textit{dog}} and {\textit{rabbit}}.

In the {\textit{eleven-toed}} quadrupeds, the inner toe has an {\textit{extensor proprius}}, which represents the external pollicis. This is wanting in the {\textit{horsë}}.

The quadrupeds that have cannon bones in place of meta-

The muscle corresponding to the short {\textit{extensor}} of the toes arising from the cannon bone, and inferted into the tendon of the long extensor.

\textbf{Plate XI.} of the Anatomy of \textit{Mammalia}, exhibits the mufcles which move the integuments of the \textit{bed, r-hog.} \textbf{Fig. 1.} is the "hedgehog" in the caled flat, and covered by the orbicular muscle, which is exposed by defection. \textbf{Fig. 2.} 

\textit{flew} the animal in the relaxed state: \textit{a} is the orbicular muscle contracted, and carried upon the back; \textit{b b}, its marginal part, resembling a fphincter; \textit{c c}, two mufcles going from the orbicular mufcle to the top of the head; \textit{d}, the mufcle of the left fide, which is one of another pair that extends from the orbicular to the head; \textit{e e}, the two mufcles from the orbicular to the tail; \textit{f}, part of the mufcle which corresponds to the cutaneous coli, fcin going to be attached behind the ears; \textit{g g}, a portion of the mufcle which comes from the middle of the ilerumn to the orbicularis; \textit{h}, the cutaneous mufcle of the belly; \textit{i}, the portion of the fame mufcle which passes over the shoulder to be inferted into the humerus. There are other deep-feated mufcles which connect the orbicularis with the body and neck, that are concealed by those indicated in this figure.

\textbf{Plate XI.} and \textbf{fig. 3}, is a portion of the trunk of an \textit{elephant}, cut in different directions, in order to expofe its ftructure. \textit{A} is the horizontal fection, in which are fewn the little transverse mufcles, \textit{a}, cut crofs-ways, and some others cut longitudinally (as indicated by \textit{b}); \textbf{B} is the vertical fection made lengthways, by which the nafl canal of the left fide at \textit{C} is divided. The little transverse mufcles are, by this fection, cut longitudinally at \textit{b}, and tranferly at \textit{c}. Some other little analogous mufcles are fewn in their length by \textit{d}; and \textit{e} points out the longitudinal mufcles of theプロセス, which antagonize thefe falt. \textit{D} is the vertical fection made crofs-ways. The little transverse mufcles are feen in their length, pulling in different directions, with refpect to the axis and circumference of the trunk, but always tranfverly. They are ftrong within the longitudinal mufcles of the trunk, which have been fewn divided crofs-ways by this fection, around the circumference of the trunk, as pointed out by the letters \textit{f f}: in this fection are feen also many veffels and nerves cut crofs-ways. Some large nerves, with blood-veffels accompanying them, are fewn running in the direction of the fection \textit{A}, as pointed out by the letter \textit{g}. \textit{C C}, are the two nafl canals which run in the interior of the trunk, somewhat nearer the lower furface than the centre.

\textbf{Brain.} This vificent is formed upon the fame plan in \textit{man} and \textit{mammalia}. The chief differences conftit in the figure and fize of the parts, in relation to each other, to the reft of the nervous fystem, or to the entire body.

The relation with refpect to bulk, between the brain and the whole body, has been generally confidered as determining the degree of intelligence posfessed by an animal. That the mental character fhould be indicated by the proportion which the organ of perception bears to the parts which exercise the other functions of life, feems to be almost felf-evident; and is conformable to common opinion and obfervation, with refpect to the intellectual powers of different individuals of the human species. Nevertheless it fhould be observed, that some differences must arise from the age and the degree of fatue of an animal, which cannot be fupposed to affect materially the powers of the mind, although they do the weight of the body.

A comparison of the weight of the cerebrum with that of the cerebellum, is another mode employed by anatomists for ascertaining the degree of intellect an animal enjoys, and is more accurate and precise than the preceding. In the inferior classes of animals, the diminution of the cerebrum in proportion to the cerebellum is very striking, and forms a very correct index of the gradations of intellect. But for the purpo{e of fixing the mental rank of the different tribes of mammalia, it is best to compare the brain with the medulla oblongata, or the nerves that arise in the cranium. This may be done, after the manner of Soemmerring and Ebel, by measuring the diameters of each at their thickest part. This last mode seems to flow, with tolerable accuracy, the intellectual endowment of the different genera of mammalia, except in the \textit{saukule} tribe, which have the brain so very broad in proportion to its length. The fame rule also serves to correct the conclusions that would be drawn from comparing the weight of the brain with that of the whole body, in some of the \textit{monkey} kind, and the very small quadrupeds, which have as large a brain in proportion to their body as man.
MAMMALIA.

In judging of the capacities of animals, we should carefully distinguish between the operations of intellect and of instinct. These are often mistaken for each other in animals, and, we believe, are more frequently confounded in the workings of the human mind than people in general are aware of. The brain is the seat of reflection, and of ideal knowledge: the nerves and organs of sense are but its agents; they are incapable of performing any intellectual operation of themselves. The perfection of the organs of sensation determines, however, in a great degree, the infinitesimal faculties of animals, independently of the influence of the brain. Indeed the intellectual and instinctive powers are found, like the organs upon which they depend, to exist in an inverse ratio to each other. Man, who has the highest mental character, has the brain largest, and the nerves smallest in relation to each other; and in the inferior classes of animals, whose actions are almost entirely governed by instinct, the nerves are uncommonly large, and the brain extremely small; and even in some genera hardly distinguishable.

To illustrate this subject, the following tables have been extracted from Cuvier's "Comparative Anatomy," vol. ii.

The
MAMMALLA.

The brain of the monkey resembles most closely that of the human subject; but it is nevertheless distinguished by certain differences, which form, as it were, the first steps in the gradations of structure in this organ.

The superior surface of the hemisphere is somewhat flatter in the monkey than in man; but in quadrupeds it is considerably flatter. In some of them also, as most of the digitiata, the anterior part of the cerebrum is much narrower than the posterior. The hoofed quadrupeds generally have the brain nearly oval in its circumference, as it is in man and the monkey.

In quadrupeds the middle lobes of the cerebrum are flattened upon the inferior surface, and the posterior lobes do not exit; consequently the cerebellum is not concealed by the cerebrum, as in man and the monkey.

The brain of the porpoise, dolphin, grampus, and most probably others of the whale kind, has a figure different from that of any other animal; it is rounded at every part. Its greatest diameter is across, yet it covers the superior part of the cerebellum; it has numerous and deep convolutions.

In mammalia, even in the monkey, the middle lobes of the cerebrum are larger, in proportion to the lateral ones, than they are in man. These lobes are of the same size of the others in the fijigrada.

The division of the external surface of the brain into convolutions takes place to a less extent in mammalia than in man. There are few convolutions in the monkey tribe, particularly in those with prehensile tails, which have the posterior lobes nearly smooth. The jacko and Barbary ape are exceptions, and have the posterior lobe separated from the others by a distinct tranverse fissure.

In the digitiata and plantigrada the furrows upon the surface of the brain are tolerably numerous, and are arranged in a regular order.

The fijigrada have no convolutions, properly so speaking, but very faint grooves; their brain is almost smooth upon the surface. There are deep convolutions on the brain of the hoofed quadrupeds, especially the cloven and hoofed-footed tribes.

The lower surface of the brain of mammalia is less unequal; the different prominences not projecting so much as in man.

The olfatory nerves of quadrupeds are of an enormous size, and contain a cavity which communicates with the lateral ventricles; they are composed of cinctuous subtiliim subtile exterally, and medullary internally. They were described by the early anatomists under the names of caruncula mammillares, or processus mammillati. They are found of the greatest size in the large herbivorous quadrupeds.

There are no olfatory nerves in the estuarous animals.

Except the peculiarities we have just mentioned, the origin of the nerves is the same in man and mammalia.

The lateral ventricles have less extent in all mammalia, except the monkey, than in man. That portion of their cavity which is called the posterior horn, or digital cavity, is only found in the monkey, in which the posterior lobes exist.

The tubercula quadrigemina become larger, in proportion as the animals are removed from man. They are of the greatest size in the fijigrada, bifidae, and fohpeda. There is a very singular proportion observed between the superior and inferior of these tuberci. In all the herbivorous tribes of quadrupeds, the nates, as they have been called, exceed very much in size the tyfls; and in the carnivorous quadrupeds, whether fijigrada or plantigrada, the inferior tubercles or tyfls are larger than the nates; from which it might be supposèd that the relative magnitude of these parts indicate the disposition of the animal. Cuvier flates, that the tyfls are three times the size of the nates in the dolphin.

But few observations have been made upon the comparative structure of the pineal gland. The gruity or earthy substance of this body has been discovered in the fallow deer (cervus dama) by Socemmerring; and in the goat by Malacare. It is not known in what number of quadrupeds the earthy matter exists in the pineal gland; it may be supposed, from its being found in the species above mentioned, which are lefs allied to the human subject in general structure than many others of this class, that the sandy matter would be met with generally in the pineal gland of mammalia.

The corpora condaudentia are small in the carnivorous quadrupeds; there is but one large eminence of this kind in the herbivorous tribes.

The other eminences and cavities of the brain of mammalia exhibit no peculiarities worthy of notice.

The ventriculum cerebelli, in many mammalia, is fuffused by a thin plate of bone, which projects from the inner surface of the cranium in one or three pieces.

In some infanes the ventriculum is a uniform bony partition, which leaves a quadrangular opening into the lower part of the cranium. This is the case in molt species of the cat and bear genera; in the marlin and in the coati (simia paniscus).

The fals, which divides the hemispheres of the cerebrum, is also fuffused upon a bony plate in the ornithorhynchus. Blumenbach flates, that something of the same kind exists in the skull of the porpoise; but the specimen to which he refers, appears to have been an irregular formation of the bone of the cranium.

The membranae of the brain do not exhibit any other peculiarities of much importance in mammalia.

The blood-vessels of the brain have been described already under the heads of Arteries and Veins in this article.

In Plate XII. of the Anatomy of Mammalia, fig. 1, is a lateral view of the external appearance of the brain in the rabbit. The anterior part of the cerebrum is seen to be smaller than the posterior. The middle lobes are flattened upon their inferior surface; and the posterior lobes are wanting: a, the cerebrum; b, the cerebellum; c, the medulla oblongata.

Fig. 2, is a view of the under surface of the anterior part of the cerebrum of the sleep; a, a, the olfactory nerves; one of which is laid open to expose its cavity, which is traced to the lateral ventricle, by cutting through the subdura of the cerebrum. Fig. 3, is a transverse section of the brain of the monkey: a, a, the corpora fritia; b, b, the thalamus nervorum opticorum; c, the cavities of the lateral ventricles laid open; d, d, the digital cavities; e, the nates; f, f, the telles; s, s, the pineal gland; b, b, the cut surfaces of the hemispheres. Fig. 4, is a view of the tubercula quadrigemina in the sleep: a, a, the nates; b, b, the telles; c, c, the surrounding portion of the brain.

Fig. 5, is a similar view of those parts in the brain of the dog, which are indicated by corresponding letters.

Nerves.—There is no part of the anatomy of mammalia in which there is so close a resemblance to the human, as in the distribution of the nerves. Where differences do occur, they are in general plainly referrible to the difference in the figure of the neighbouring parts, and not to any physiogical reason.

The first pair of nerves, or the olfactory, afford a striking exception to the foregoing observation. In all mammalia which possess them, except the monkey kind, they are large, hollow procercus of the anterior lobes of the cerebrum, the cavities
Mammalia.

eavities of which communicate with the lateral ventricles of the brain, as already described. This peculiarity of struc-
ture, however, does not appear to produce much effect upon them after they have passed through the ethmoid bone into the nasal cavity. The only difference to be remarked between the branches of the olfactory nerves of quadrupeds and those of man, is, that they are stronger, and more easily demonstrated in the former.

The second pair of nerves, or optic, have precisely the same structure in mammalia and man before their entrance into the globe of the eye. The medullary tubes of which they are composed, are more plainly shewn in the larger quadrupeds.

The third, fourth, and fifth pair of nerves, exhibit no pecu-
liarities.

The fifth pair of nerves shows some difference in its ramifi-
cation, and the ganglia it forms, although its distribution is, as nearly as may be, the same in mammalia and man. Cuvier has given some account of the three principal branches of the fifth pair of nerves, taken from dissections of the dog, rabbit, sheep, and calf.

According to Cuvier’s description, the first, or ophthalmic branch of the fifth pair, is divided within the cranium, but does not form its three branches until it arrives in the orbit.

The first, which is analogous to the nasal branch of the ophthalmic, is the largest. It is divided into five or six small nerves. Some of these pass through the vault of the orbit to the frontal sinuses; others, which are larger, enter the nasal cavity by the internal orbital foramen. They ascend in an osseous canal, and pass into the cranium by the large foramina of the cribiform bone, and pass down again through the ethmoidal foramina, to be distributed, as in man, to the pituitary membrane of the nose. These branches are very plain and easily traced in the cloven-footed quadrupeds: one of them seems to have been mistaken by Cuvier for a branch of the olfactory in the sheep. One or two of the branches into which the nasal divides, go to the levator palpebrae superioris. One of these twigs afflicts in forming the lenticular ganglion, which in the dog goes off two ciliary nerves that divide before they enter the eye, and in the calf it sends off four ciliary nerves. Finally, the nasal sends filaments to the obliquis inferior muscle, and the glandula Harderi.

The second, or frontal branch of the ophthalmic, is situated superior under the roof of the orbit. It divides into two nerves; one is external, and furnishes two filaments to the rectus superior and the levator palpebrae; the other is internal, and supplies the internal straight muscle of the eye, and goes off the frontal branch which passes through the superciliary notch, to be distributed to the integuments of the forehead.

The third, or lacrimal branch of the ophthalmic, furnishes a great number of filaments that are expended upon the lacry-
mal gland.

The fourth branch of the fifth pair, or the superior maxill-
ary nerve, when it arrives on the outside of the cavity of the cranium, becomes considerably enlarged. Its fibres seem to cross each other in such a manner, that the two branches which it soon after forms appear to be produced by opposite filaments: thus, the posterior, or sub-maxillary branch, seems to be composed of the anterior filaments, and the anterior or supra-maxillary branch of the posterior fibres. This dispo-
sition is very remarkable in the dog, but less so in the calf.

The supra-maxillary branch proceeds almost horizontally from behind forwards. Having reached the anterior and inferior parts of the temporal fossa, it divides into a great number of filaments: one bundle, which consists of four or five filaments, proceeds towards the spheno-palatine foramen. This faciculus then divides into two; one branch is sent into the nasal cavity, and furnishes a considerable nerve, which is spread out upon the fleshy substance of the palate. Sometimes, as in the calf, this branch separates from the trunk, even before it enters the spheno-palatine hole.

The other branch of the superior maxillary nerve, which enters by the spheno-palatine hole, passes into the body of the superior maxillary bone, detaches filaments to all the teeth, and goes out by the sub-orbital foramen, where it expands into a great number of branches, which supply the mucus, and integuments of the face, and anastomose with the branches of the facial nerve. The sub-orbital nerve and its branches are of a prodigious size in all mammalia with whirlers; in these animals its anastomoses are more intricate than usual, and from the net-work under the skin about the lips, the bulb of each whisker receives one or more large nerves.

There are some other filaments given off from the su-
perior maxillary nerve. The first is a small one, which, after anastomosing with a ganglion, passes into the substance of the temporal muscle, to which it gives branches. It afterwards perforates the orbit, and from thence goes into the nose. Another more remarkable filament arises from the spheno-palatine branch; it forms a ganglion, which is joined by the preceding nerve, as already mentioned, and several other twigs. A flat nerve proceeds from this ganglion, which appears to be the continuation of the nerve that formed it, although larger. It passes between the palate and the convexity of the pterygoid process, in the substance of the bone; amongst other branches it sends one down to the floor of the nostrils.

The third, or inferior maxillary branch of the fifth pair of nerves, produces, almost immediately after its separation, a pretty large branch, which is distributed to the parotid and maxillary glands. It afterwards divides into two other branches; one is internal, and is lost in small filaments in the muscles, and even in the substance of the tongue; the other is external, and gives a number of branches to the pterygoid muscles, and those of the cheeks and lips, on their way to the skin of the face on which they are lost, anastomos-
ing with the other facial nerves. The continuation of the superior maxillary nerve passes, as usual, into the canal of the lower jaw, supplies the teeth, and emerging at the foramen mentale, spreads in branches upon the soft parts in the neighbourhood.

In the calf, the inferior maxillary nerve, soon after leaving the cranium, divides into four branches.

The most posterior of these branches goes backwards, and below the condyle of the jaw, where it forms two branches; one is slender, and enters the parotid gland, to which it gives filaments, which anastomose with those of the facial nerve; the other takes the circuit of the jaw, and advances in the front of the mouth; it unites, as it passes along the cheek, with the middle branch of the facial nerve, from which it previously receives several anastomosing branches.

The next branch of the four is very long, slender, and follows the ramus of the jaw to be expended upon the buccinator muscle and the glands.

The third branch passes into the dental canal, and supplies the teeth as usual.

Lally,
Lately, the fourth branch is the lingual: it is strong and flat, and terminates in radiated filaments.

The facial nerve, commonly called the portio dura of the seventh pair, arises in the calf, according to Cuvier, by two roots; the one is really the portio dura: the other appears to proceed from a considerable ganglion of the posterior part of the par vagum, which is situated in a particular depression of the inferior surface of the bone of the tympanum: this root also appears to unite with the great sympathetic nerve, which has almost the firmness of cartilage. Two or three short filaments concour in the formation of this root. It afterwards becomes thicker, and paffes into the fissura Glabri to meet the other roots of the facial nerve, to which it transmits a filament, and continues to proceed onwards before and below the ear.

The magnitude of the branches of the facial nerves varies in mammals, but with respect to number, they scarcely differ from those of the human subject. In those quadrupeds that have large ears, the branch of the facial nerve, which unites with the first cervical pair, is of much greater size than ordinary. In the carnivorous kinds, also, the nerves going to the temporal muscle are particularly large, and in all mammals with whiskers, the branches that anastomose with the facial nerves of the fifth pair have a considerable size.

There is nothing peculiar to be observed with respect to the portio molis of the seventh pair, or the true auditory nerves.

The species that Cuvier had dissected for the par vagum, or pneumatic nerve, were the calf, dog, racon, hog, and the porcupine, in all of which, its distribution and ramifications bore the greatest resemblance to the same nerve in the human body. The connection it has with the facial nerve in the calf already mentioned, was the chief peculiarity observed.

The glossopharyngeal, and the hypo-glossal nerves, exhibit no deviation from their disposition in the human body, as far as they have been examined.

The hypo-glossal was found by Cuvier to have a blueish colour in the calf, until it arrives on the inside of the ramus of the lower jaw.

The sub-occipital and the cervical nerves also appear to be formed exactly as in man. They are of course in some quadrupeds larger in proportion than in others, on account of the size of the muscles on the neck. In the three-toed fheath, there are probably nine cervical nerves corresponding to the number of vertebrae in that animal.

The phrenic nerves differ in no respect from those of man.

The dorsal and lumbar nerves vary only in regard to their numbers, which may be reckoned by the vertebras. The nerves of the pelvis also exhibit no peculiarity in mammals.

The nerves which supply the tail are of some consequence in this class, and do not exist in the human subject. The following description has been given of them in the rabbit by Cuvier.

The first pair of caudal nerves comes out between the last piece of the fascrun and the first vertebra of the tail, and proceeds by the ischiatric notch. It divides into two branches, one of which is united to the ischiatric nerve, and the other continues to advance between the pelvis and the tail, until it enters a gland situated under the fifth pair of caudal nerves, where this branch terminates: but in its way thither it forms several anastomoses with the other caudal nerves, and gives off branches, by which there is a remarkable plexus formed, which Cuvier calls the caudal.

The first branch sent off by this nerve is distributed among the gluteal muscles. The nerve is afterwards joined on the inner side by a small filament, that seems to be derived from the second pair of caudal nerves, and on the outer side by three or four filaments, which make a plexus, from whence several branches go to the muscles; one, which is very considerable, and easily traced, is sent to the penis. Afterwards the third, fourth, and fifth pair of caudal nerves send filaments to the inner side of the branch of the first pair; then five or six branches are given off from the external side of the muscles of the penis, and those which arise from the ischium. Finally, the trunk of the first caudal pair terminates in the gland, as above-mentioned.

The great sympathetic, or intercostal nerve, has been described by Cuvier from disuctions of the wolf, racoon, porcupine, sheep, and calf. He found it to form a very remarkable anastomosis with the fifth and sixth pair of nerves. On entering the cranium through the foramen lacerum, the intercostal is distinct from the par vagum, and adheres very closely to the periosteum of the temporal bone. If the cord of the nerve be stretched, it is seen to be divided into fix or seven filaments, that form a close network. A few lines farther, these filaments approach each other, and become confounded into a ganglion, which, from its great firmness, appears like cartilage. Many filaments depart from this ganglion: some are short, and proceed to the nerve of the fifth pair: others are long, small, and are interwoven with the blood-veffels, so as to form a reddish-coloured plexus, which was considered by Willis as a little retex viable. The communication with the fixth pair is by means of this plexus, which surrounds the nerve on every side, and is hardly to be separated from it. There is not any remarkable anastomosis observed in the calf and ram.

The great intercostal, while passing through the foramen lacerum, detaches a filament to the cavity of the tympanum. At the same place also it is united with the eighth pair of nerves.

The superior cervical ganglion is formed some lines from the cranium. It has a reddish colour, and an elongated oval figure. It forms the same communication with the neighbouring nerves as in man.

In front of the last cervical vertebra the intercostal nerve forms a curve from within outwards, towards the first rib, on the head of which it joins the first thoracic ganglion. Several filaments from this curve go along the mediastinum to the pericardium: others form a plexus around the subclavian artery.

The first thoracic ganglion is a semilunar figure. Some filaments go off from one of its edges; the uppermost of which is sent to the vertebral artery, around which it forms a plexus, and appears to accompany the vessel into the cranium. The other filaments unite with the last cervical, and with the two first dorsal pair of nerves.

The concave edge of the ganglion detaches two or three filaments, which descend obliquely to the root of the pulmonary arteries, where they unite with the par vagum, to form the pulmonarv and inferior cardiac plexuses.

The intercostal, in its passage through the thorax, produces a ganglion upon the head of each rib, which is joined by a filament from each of the dorsal nerves.

The intercostal, on entering the abdomen, forms a single cord, which is the splanchnic nerve. It pafles into the middle, under the omentum, where it frequently separates into two cords, which are afterwards joined together again. From this fort of nervous ring, there arises either a principal trunk, or four or five filaments, which, uniting together near the celiac artery, form a ganglion, that is frequently of a femi- ....
lunar figure. The filaments that produce the thymachic, splenic, and hepatic plexuses, arise from the femoral ganglion, and correspond to the solar plexus. There are also filaments detached to form the renal plexus.

The intercostal, as it proceeds along the lateral parts of the bodies of the vertebrae, gives origin to ganglia of an elongated quadrangular figure: one of the superior angles of these receives the continued trunk of the nerve; the other the lumbar pair. The internal inferior angle sends a branch to the aorta, to concur in the formation of plexuses, which encompass each of the branches of that vessel. The external inferior angle furnishes the continuation of the trunk.

Except the variations above-mentioned, there does not appear to be any material difference between the intercostal or great sympathetic nerve in man and animals.

Scarce any peculiarity is to be perceived in the distribution of the nerves of the extremities in mammalia. The articular nerve is exclusively formed in the rabbit by the fifth cervical pair of nerves; only one of its filaments is derived from the axillary plexus.

The thoracic nerves are furnished by the axillary plexus. The median nerve, about the middle of its course, sends off a branch, which is analogous to the external cutaneous nerve.

The humeral nerve also, about the middle of the arm, gives off a branch, that appears to take the place of the internal cutaneous nerve: it supplies the extensor muscles of the elbow and the skin.

Both the origin and distribution of the nerves of the posterior extremity appear to correspond with what has been described in man.

Organs of Touch.—The general surface of the body in mammalia is better calculated for receiving external impressions than it is in any other animals, except those that have naked and soft skins, such as certain reptiles, and some of the inferior classes. The skin of mammalia is well supplied with nerves; the cuticle is thin, and the hairs, having their roots buried in the skin, rather facilitate than impede the sensibility of touch.

The cuticle has the same structure in man and mammalia. It is most delicate in the smaller quadrupeds, and in those that have their body well defended by other coverings, as very thick hair or spines. The cuticle is particularly thin in the pangolin.

It is dry, and consists evidently of scales, on the tail of the porcupine, rat, and others, &c., and upon the surface of the bodies of the pangolin and armadillo.

In the large many-hoofed quadrupeds the cuticle is thick, and is covered with small plates, that separate from it like scales. It sinks into the furrows of the true skin. On the foals of their feet it is very remarkably formed. It appears externally to be divided by deep impressions, nearly circular, with six or eight surfaces, some more regular, others less so, each of which contains an infinite number of small polygons, that are very irregular. These polygons, both large and small, correspond to furrows in the true skin, into which internal projections of the cuticle are inserted.

The cuticle of the cetacea is not thick in proportion to the other parts of the skin. It is free from folds or wrinkles: the surface of these animals being smooth, to facilitate their progress through the water. It is also bienioned with oil, which not only is of use in swimming, but prevents the maceration of the cuticle in the water.
