1819.
PUNISHMENT, a penalty imposed upon the commission of some crime or offence against the laws. It is essential to the nature of a law, that it import or declare a punishment to the transgressors of it.

Solon very justly asserted, that the two great stimulants of human action being hope and fear, a good government could not possibly exist without an equitable system of rewards and punishments.

The forms and manners of punishment are various in various countries and ages, and for various crimes; as treason, felony, adultery, parricide, &c.

There was a time, says Beccaria, when all punishments were pecuniary. The crimes of the subjects were the inheritance of the prince, so that an injury done to society was a favour to the crown, and the sovereign and magistrates, those guardians of the public security, were interested in the violation of the laws. Crimes were tried at that time in a court of exchequer, and the cause became a civil suit between the person accused and the crown. The magistrate then possessed powers that were not necessary for the public welfare, and the criminal suffered punishments different from those which the necessity of example required. The judge was rather a collector for the crown, an agent for the treasury, than a protector and minister of the laws.

Among the Romans, the pecuniary punishments were the mala est et conciatio. The corporal punishments were capitis diminutio, aque et igni interdictio, proscriptio, deportatio, relegatio, surca, crux, carcer, culeus, equidus, scula, gemonis, damnatio ad gladium, ad metallum, flagellation, talio, &c. which see described under their respective articles.

Among us the principal civil punishments are, fines, imprisonments, the flocks, pillory, burning in the hand, scotting, ducking, hanging, beheading, quartering, burning, transportation, &c.

The ecclesiastical punishments are, censures, suspensions, deprivation, degradations, excommunications, anathemas, penances, &c. The military punishments are, being shot, running the gantlet, riding the wooden horse, the bilboes, &c.

Among the Turks, &c. impaling, bastinadoes on the soles of the feet, &c. obtain. See Empalement, &c.

The right of punishing crimes against the law of nature, as murder and the like, is in a state of mere nature vested in every individual. Accordingly the first murderer, Cain, was so sensible of this, that we perceive him (Gen. iv. 14.) expressing his apprehensions, that whoever would find him would slay him. In a state of society, this right is transferred from individuals to the sovereign power; and thus men are prevented from being judges in their own causes, which is one of the evils that civil government was intended to remedy. The sword of justice is now vested by the consent of the whole community in the magistrate alone. Every punishment which does not arise from absolute necessity, says the great Montesquieu, is tyrannical; and this proposition is rendered more general by Beccaria, who observes, that every act of authority of one man over another, for which there is not an absolute necessity, is tyrannical.

Upon this principle, the sovereign's right to punish crimes is founded; that is, upon the necessity of defending the public liberty, entrusted to his care, from the usurpation of individuals; and punishments are just in proportion, as the liberty, preferred by the sovereign, is sacred and valuable. It was necessity that forced men to give up a part of their liberty, and it is certain, that every individual would choose to put into the public stock the smallest portion possible; as much only as was sufficient to engage others to defend it. The aggregate of these, the smallest portions possible, forms the right of punishing: all that extends beyond this is abuse, and not justice. The laws only can determine the
the punishment of crimes; and the authority of making penal laws can only reside with the legislator, who represents the whole society, united by the social compact. No magistrate, therefore, as he is one of the society, can, with justice, inflict on any other member of the same society, punishment that is not ordained by the laws, nor increase the punishment already determined by the laws. To the sovereign representing the society itself, who makes general laws to bind the members, it does not belong to judge, whether any individual has violated the social compact, or incurred the consequent punishment. In this case, there are two parties, one represented by the sovereign, who inflicts upon the violation of the contract, and the other is the person accused, who denies it. It is necessary then, that there should be a third person to decide this contest; that is to say, a judge or magistrate, from whose determination there should be no appeal. Judges, in criminal causes, says Baccarini, have no right to interpret the penal laws, because they are not legislators. The lawful interpreter is the sovereign, that is, the representative of society, and not the judge, whose office is only to examine, if a man have, or have not committed an action contrary to the laws. Many evils arise from the erring infallibility of arbitrary interpretation.

The lawgivers of punishing criminals, who are chargeable with offences against the laws of society, that are only "mala prohibita," and not "mala in se," is founded upon this principle, that the law by which they suffer was made by their own consent; it is a part of the original compact into which they entered, when first they engaged in society; it was calculated for, and has long contributed to their own security. This right, conferred by universal consent, gives to the state exactly the same power, and no more, over all its members, as each individual member had naturally over himself or others. Hence some have doubted how far a human legislature ought to inflict capital punishments for "pоборные offences;"—offences against the municipal law only, not against the law of nature; since no individual has, naturally, a power of inflicting death upon himself or others for actions in themselves indifferent.

With regard to offences "mala in se," capital punishments are in some instances inflicted by the immediate command of God himself to all mankind, as in the case of murder, by the precept delivered to Noah, their common ancestor and representative (Gen. xvi.), "whoso sheddeth man's blood, by man shall his blood be shed." In other instances they are inflicted after the example of the Creator, in his positive code of laws for the regulation of the Jewish republic, as the case of the crime against nature. But they are sometimes inflicted without such express warrant or example, at the will and discretion of the human legislature, as for forgery, for theft, and sometimes for offences of a lighter kind. None of these crimes are offences against natural, but only against social, rights. The practice of inflicting capital punishments, for offences of human institution, is thus justified by that great and good man, sir Matthew Hale (1 Hal. P. C. 13.) "When offences grow enormous, frequent, and dangerous to a kingdom or state, destructive or highly pernicious to civil societies, and to the great insecurity and danger of the kingdom or its inhabitants, severe punishment and even death itself is necessary to be annexed to laws in many cases by the prudence of lawsgivers." It is, therefore, as judge Blackstone observes, the enormity, or dangerous tendency of the crime, that alone can warrant any earthly legislature in putting him to death that commits it. It is not its frequency only, or the difficulty of otherwise preventing it, that will excuse our attempting to prevent it by a wanton effusion of human blood. For, though the end of punishment is to deter men from offending, it can never follow from this circumstance, that it is lawful to deter them at any rate and by any means; since there may be unlawful methods of enforcing obedience even to the justest laws. Every humane legislator, as the learned judge remarks, will be therefore extremely cautious of establishing laws that inflict the penalty of death, especially for flight offences, or such as are merely positive. Nor will it avail to allege that no lighter penalty will be effectual, because experience has not taught us that capital punishments are more effectual. Was the vast territory of all the Russias, it may be asked, worse regulated under the empress Elizabeth, than under her more fanguinary predecessors? Or has it been since, under Catherine II., less civilized, less social, and less secure? And yet we are assured, that neither of these illustrious princesses have, throughout their whole administration, inflicted the penalty of death; and the latter, upon full persuasion of its being useless, and even pernicious, issued orders for abolishing it entirely throughout her extensive dominions. But if capital punishments, says Blackstone, were proved by experience to be a sure and effectual remedy, that would not prove the necessity (upon which the justice and propriety depend) of inflicting them upon all occasions, when other expediency fail. This reasoning would, as we may justly apprehend, extend much too far. Were the evil to be prevented is not adequate to the evil itself, the preventive, a sovereign that thinks seriously can never reconcile laws that inflict death to the dictates of conscience and humanity. To shed the blood of our fellow-creature, says the learned and humane judge, is a matter that requires the greatest deliberation, and the fullest conviction of our own authority; for life is the immediate gift of God to man; which neither he can resign, nor can it be taken from him, unlefs by the command or permission of him who gave it; either expressly revealed or collected from the laws of nature or society by clear and indisputable demonstration. Blackstone, however, would not be underfoot to deny the right of the legislature in any country to enforce its own laws by the death of the transgressor, though some persons of abilities have doubted it. To this class of persons we may refer the ingenious writer already cited. The ulelefs profusion of punishments, which has never made man better, has induced Baccarini to enquire, whether the punishment of death be really just or useful in a well-governed state? What right, he asks, have men to cut the throats of their fellow-creatures? Certainly not that on which the sovereignty and laws are founded. The laws are only the sum of the settled portions of the private liberty of each individual, and represent the general will, which is the aggregate of that of each individual. Did any one ever give to others the right of taking away his life? Is it possible, that in the smallest portions of the liberty of each, sacrificed to the good of the public, can be contained the greatest of all good, life? If it were so, how shall it be reconciled to the maxim which tells us, that a man has no right to kill himself? Which he certainly must have, if he could give it away to another. The punishment of death is not authorized by any right; for no such right exists. The death of a citizen cannot be necessary, but in one case; when, though deprived of his liberty, he has such power and connections as may endanger the security of the nation; when his existence may produce a dangerous revolution in the established form of government. But even in this case, it can only be necessary when a nation is on the verge of recovering or losing its liberty; or in times of absolute anarchy, when the disorders themselves hold the place of laws.

If the experience of all ages be not sufficient to prove, that the punishment of death has never prevented determined men
PUNISHMENT.

men from injuring society; if the example of the Romans; if twenty years reign of Elizabeth, empress of Ruffia, in which she gave the fathers of their country an example more illustrious than many conquests bought with blood; if, says Beccaria, all this be not sufficient to persuade mankind, who always suspeét the voice of reason, and who choose rather to be led by authority, let us confult human nature in proof of this asserfion.

It is not the intenfeness of the pain that has the greaftest effect on the mind, but its continuance; for our fenfibility is more easily and more powerfully affected by weak but repeated impreffions, than by a violent, but momentary, impulse. The power of habit is universal over every fenfible being. As it is by that we learn to fpeak, to walk, and to fatisfy our neceffities, fo the ideas of morality are stamped on our minds by repeated impreffions. The death of a criminal is a terrible but momentary fpectacle, and therefore a lefs efficacious method of deterring others, than the continued example of a man deprived of his liberty, condemned, as a beafl of burthen, to repair, by his labour, the injury he has done to fociety. "If I commit such a crime," fays the Spectator to himfelf, "I shall be reduced to that miserable condition for the rest of my life." A much more powerful preventive than the fear of death, which men always behold in diftant obfcurity.

The terrors of death make fo flight an impreffion, that it has not force enough to withfand the forgetfulness natural to mankind, even in the moft effential things; especially when affifted by the passions. Violent impreffions surprife us, but their effect is momentary; they are fitted to produce those revolutions which infantly transform a common man into a Lacedemonian or a Perifian; but in a free and quiet government they ought to be rather frequent than ftrong.

The execution of a criminal is, to the multitude, a fpectacle, which in fome excites compaffion mixed with indignation. Thofe fenfiments occupy the mind much more than that fubtle terror which the laws endeavour to infpire; but in the contemplation of continued fuffering, terror is the only, or at leaft predominant fenfation. The severity of a pulfishment should be juft fufficient to excite compaffion in the fpectators, as it is intended more for them than for the criminal.

A pulfishment, to be fir, should have only that degree of severity which is fufficient to deter others. Now there is no man, who, upon the leaft reflation, would put in competition the total and perpetual lofs of his liberty, with the greaftest advantages he could possibly obtain in confequence of a crime. Perpetual flavery, then, has in it all that is neceffary to deter the moft hardened and determined, as much as the pulfishment of death: it has even more. There are many who can look upon death with intrepidity and firmness; fome through fanfaticism, and others through vanity, which attends us even to the grave; others from a desperate reolution, either to get rid of their mifery, or ceafe to live; but fanfaticism and vanity forfake the criminal in flavery, in obfains and fetters, in an iron cage; and defpair seems rather the beginning than the end of their mifery. The mind, by collecting itfelf and uniting all its force, can, for a moment, repel affailing grief; but its moft vigorous efforts are insufficient to repel perpetual wretchedness.

In all actions, where death is used as a pulfishment, every example furnophes a new crime committed. Whereas in perpetual flavery, every criminal affords a frequent and lafting example; and if it be neceffary that men fhould often be witnefles of the power of the laws, criminals fhould often be put to death; but this furnophes a frequency of crimes; and from hence this pulfishment will ceafe to have its effect, fo that it muft be ufeful and ufelefs at the fame time.

We fhall be told, that perpetual flavery is as painful a pulfishment as death, and therefore as cruel. To which we ansver, that if all the miferable moments in the life of a flav were collected into one point, it would be a more cruel pulfishment than any other; but these are scattered through his whole life, whilst the pain of death exerts all its force in a moment. There is also another advantage in the pulfishment of flavery, which is, that it is more terrible to the fpectator than to the sufferer himfelf; for the fpectator coniders the sum of all his wretched moments, whilst the sufferer, by the mifery of the prefent, is prevented from thinking of the future. All evils are increafed by the ima- gination, and the sufferer finds refoures and confolations, of which the fpectators are ignorant; who judge by their own fenfibility of what paffes in a mind, by habit grown callous to misfortune.

He who forefces that he muft pafs a great number of years, even his whole life, in pain and flavery; a flav to thofe laws by which he was protected; in flight of his fellow citizens, with whom he lives in freedom and fociety; makes an ufeful comparison between thofe evils, the uncertainty of his fuc- cefs, and the fhortnefs of the time in which he fhall enjoy the fruits of his tranfgreffion. The example of thofe wretches continually before his eyes, makes a much greater impreffion on him than a pulfishment, which, instead of correcting, makes him more obdurate.

The pulfishment of death is pennisious to fociety, from the example of barbarity it affords. If the passions, or the neceffity of war, have taught men to fhed the blood of their fellow creatures, the laws, which are intended to moderate the ferociaty of mankind, fhould not increafe it by examples of barbarity, the more horrible, as this pulfishment is usually attended with formal pageantry. Is it not abfurd, that the laws, which deteft and punifh homicide, fhould, in order to prevent murder, publicly commit murder themfelves? What are the true and moft ufeful laws? Thofe compacts and conditions which all would promife and obferve, in thofe moments when private interefte is silent, or combined with that of the public. What are the natural fenfiments of every perfon concerning the pulfishment of death? We may read them in the contempt and indignation with which every one looks on the executioner, who is neceffarily an innocent executor of the public will; a good citizen, who contributes to the ad- vantage of fociety; the instrument of the general fecurity without which as good fathers are without. What then is the origin of this contradiction? Why is this fenfiment of mankind indelible, to the scandal of reflation? It is, that in a fecret corner of the mind, in which the original impreffions of na- ture are ftrill preferved, men difcover a fenfiment which tellis them, that their lives are not lawfully in the power of any one, but of that necelfity only, which with its iron fceptre rules the univerfe.

What muft men think, when they fee wife magiftrates and grave muniflers of justice, with indifference and tranquillity, dragging a criminal to death, and while a wretch trembles with agony, expeeting the fatal stroke, the judge, who has condemned him, with the coldeft indefinition, and perhaps with no small gratifcation from the exertion of his authority, quits his tribunal to enjoy the comforts and pleasures of life? They will fay, 'Ah! thofe cruel formalities of justice are a cloak to tyranny, they are a fecret language, a folemn veil, intended to conceal the word by which we are sacrififed to the infatiable idol of deportifm. Murder, which they would repreff to us as an horrible crime, we fee practifed by them without repugnance, or renounce. Let us follow their ex- ample.
The punishment of crimes of violence must be left to the arbitration of the legislature, which should inflict such penalties as are warranted by the laws of nature and society, and such as appear to be the best calculated to answer the end of precaution against future offences. Some have recommended, and highly extolled for its equity, the "lex talionis," or law of retaliation; but judge Blackstone observes, that this can never be in all cases an adequate or permanent rule of judgment. Although there cannot be any regular or determinate method of rating the quantity of punishments for crimes, by any one uniform rule, applicable to all cases, and without ultimately referring to the will and discretion of the legislative power; yet there are some general principles, deduced from the nature and circumstances of the crime, that may afford some assistance in allotting to it an adequate punishment. One circumstance that serves in some measure to determine the nature and degree of punishment regards the object of it; for the more dignified in respect of rank, character, and influence, the object of an injury is, so much greater care should be taken to prevent that injury, and of course under this aggravation the punishment should be more severe. Accordingly treason in confining the king's death, is by the English law punished with greater rigour than even actually killing any private subject. Moreover, the violence of passion, or temptation may, in some cases, alleviate a crime; such is theft in case of hunger, contradicting with the fame crime committed through avarice, and to serve the purposes of luxury. Homicide, in consequence of sudden and violent resentment, is less penal than upon cool deliberate malice. The age, education, and character of the offender; the repetition (or otherwise) of the offence; the time, the place, the company in which it was committed: all these, and a thousand other incidents, may aggravate or extenuate the crime. Thus Demofthenes (in his oration against Midas) truly remarks the aggravations of the insults he had received: "I was abused," says he, "by my enemy, in cold blood, out of malice, not by heat of wine, in the morning, publicly, before strangers as well as citizens; and that in the temple, whither the duty of my office called me."

Farther, as punishments are chiefly intended for the prevention of future crimes, those should be most severely punished, which are the most destructive of the public safety and happiness; and, among crimes of an equal malignity, those which a man has the most frequent and easy opportunity of committing, which cannot be so easily guarded against as others, and which, therefore, the offender has the strongest inducement to commit; according to Cicero's observation (Pro Sexto Roscio, 46): "et sunt animadvertenda peccata maxima, qua difficillimum praecavendum."

We may also observe, that punishments of unreasonable severity, especially when indiscriminately inflicted, have least effect in preventing crimes, and amending the manners of a people, as such as are more mild or merciful in general, and yet properly intermixed with due distinctions of severity. Crimes, says Beccaria, are more effectually prevented by the certainty than the severity of punishment. The certainty of a small punishment will make a stronger impression, than the fear of one more severe, if attended with the hopes of escaping: for it is the nature of mankind to be terrified at the approach of the smallest inevitable evil, whilst hope, the best gift of heaven, hath the power of dispelling the apprehension of a greater; especially if supported by examples of impunity, which weakens or avarice too frequently afford.

If punishments be very severe, men are naturally led to the perpetration of other crimes, to avoid the punishment due to the first. The countries and times most notorious for severity of punishments, were always those in which the most bloody and inhuman actions and the most atrocious crimes were committed; for the hand of the legislator and the alarum were directed by the same spirit of ferocity; which, on the throne, dictated laws of iron to slaves and savages, and, in private, infligted the subject to sacrifice one tyrant to make room for another.

In proportion as punishments become more cruel, the minds of men, as a fluid rises to the fame height with that which surrounds it, grow hardened and insensible; and the force of the passions still continuing, in the space of an hundred years, the wheel terrifies no more than formerly the prizon. That a punishment may produce the effect required,
it is sufficient that the evil it occasions should exceed the good expected from the crime; including in the calculation the certainty of the punishment, and the privation of the expected advantage. All severity beyond this is superfluous, and therefore tyrannical.

There are yet two other consequences of cruel punishments, which counteract the purpose of their institution, which was, to prevent crimes. The first arises from the impossibility of establishing an exact proportion between the crime and punishment, for though ingenious cruelty hath greatly multiplied the variety of torments, yet the human frame can suffer only to a certain degree, beyond which it is impossible to proceed, be the enormity of the crime. The second consequence is impunity. Human nature is limited no less in evil than in good. Excessive barbarity can never be more than temporary; it being impossible that it should be supported by a permanent system of legislation; for if the laws be too cruel they must be altered, or anarchy and impunity will succeed. The excessive severity of laws (says Montesquieu, Sp. of Laws, b. 6. c. 13,) hinders their execution; when the punishment far exceeds all measure, the public will frequently, out of humanity, prefer impunity to it.

Thus also the statute 1 Mar. ft. c. 1. recites in its preamble, "that the state of every king confuits more assuredly in the love of the subject towards his prince, than in the dread of laws made with rigorous pains; and that laws made for the preservation of the commonwealth without great penalties, are more often obeyed and kept than laws made with extreme punishments." Happy had it been for the nation, says Judge Blackstone, if the subsequent practice of that deluded prince, in matters of religion, had been correspondent to these sentiments of her self and parliament, in matters of state and government. It may be farther observed, that fanguinary laws are a bad symptom of the distemper of any state, or at least of its weak constitution. The laws of the Roman kings, and the twelve tables of the decemvirs, were full of cruel punishments: the Porcian law, which exempted all citizens from sentence of death, silently abrogated them all. At this period the republic flourished: under the emperors severe punishments were revived; and then the empire fell.

We may further add, that it is absurd and impolitic to apply the same punishment to crimes of different malignity. Besides, a multitude of fanguinary laws (besides the doubt that may be entertained concerning the right of making them,) fungs likewise a manifest defect either in the wisdom of the legislative, or the strength of the executive power. Although it be much easier to extirpate than to amend mankind; yet that magistrate must be esteemed both a weak and a cruel surgeon, who cuts off every limb, which through ignorance or indolence he will not attempt to cure. Boccaccio therefore proposes to form in every state a scale of crimes, with a corresponding scale of punishments, depending from the greatest to the least, but if this idea be deemed romantic, a wife legislator will at least mark the principal divisions, and not assign penalties of the first degree to offences of an inferior rank. When men fee no distinction made in the nature and gradations of punishment, the generality will be led to conclude, there is no distinction in the guilt. Much as we may be difposed to admire and extol the excellence of the English law in a variety of respects, yet none can otherwise than regret the frequency of its capital punishments; inflicted by a multitude of sueceffive and independent statutes, upon crimes very different in their natures; and we cannot forbear paying our tribute of respect to Sir Samuel Romilly, whose talents and character far exceed our praise, and other legislators, who are laudably exerting themselves in simplifying and mitigating our penal code.

It is a melancholy truth, says Judge Blackstone, that among the variety of actions, which men are daily liable to commit, no less than 160 have been declared by act of parliament to be felonies without benefit of clergy; or in other words, to be worthy of infall death. So dreadful a list, instead of diminishing, increases the number of offenders. The injured, through compunction, will often forbear to prosecute: juries, through compunction, will sometimes forget their oaths, and either acquit the guilty or mitigate the nature of the offence; and judges, through compunction, will repel one half of the convicts, and recommend them to the royal mercy. Among so many chances of escaping, the ready and hardened offender overlooks the multitude that fudder; he boldly engages in some desperate attempt, to relieve his wants or supply his vices; and if, unexpectedly, the hand of justice overtakes him, he deems himself peculiarly unfortunate, in falling at last a victim to those laws, which long impunity has taught him to contum. Boccaccio, whose excellent essay we have often cited in this article, observes, that the more immediately after the commision of a crime, a punishment is inflicted, the more just and useful it will be. It will be more just, because it spares the criminal the cruel and superfluous torment of uncertainty, which increases in proportion to the strength of his imagination, and the sense of his weakness; and because the privation of liberty, being a punishment, ought to be inflicted before condemnation, but for as short a time as possible. Imprisonment, he says, being only the means of securing the person of the accused, until he be tried, condemned, or acquitted, ought not only to be of as short duration, but attended with as little severity as possible. The time should be determined by the necessary preparation for the trial, and the right of priority in the oldest prisoners. The confinement ought not to be clover than is requisite to prevent his flight, or to conceal the proofs of the crime; and the trial should be conducted with all possible expedition. Can there be a more cruel contrariety than that between the indolence of a judge, and the painful anxiety of the accused; the comforts and pleasures of an indolent magistrate, and the filth and misery of the prisoner? In general, "The degree of the punishment, and the consequences of a crime, ought to be fo contrived, as to have the greatest possible effect on others, with the least possible pain to the delinquent." If there be any society in which this is not a fundamental principle, it is an unlawful society; for mankind, by their union, originally intended to subject themselves to the least evils possible.

An immediate punishment is more useful; because the smaller interval of time between the punishment and the crime, the stronger and more lasting will be the association of the two ideas of crime and punishment; so that they may be considered, one as the cause, and the other as the unavoidable and necessary effect.

It is, then, of the greatest importance, that the punishment should succeed the crime as immediately as possible, if we intend, that in the rude minds of the multitude, the seducing picture of the advantage arising from the crime, should instantly awake the attendant idea of punishment. Delaying the punishment serves only to separate these two ideas; and thus affects the minds of the spectators rather as being a terrible sight, than the necessary consequence of a crime; the horror of which should contribute to heighten the idea of the punishment.
PUNISHMENT.

There is another excellent method of strengthening this important connection between the ideas of crime and punishment; that is, to make the punishment as analogous as possible to the nature of the crime; in order that the punishment may lead the mind to consider the crime in a different point of view, from that in which it was placed by the flattering idea of promised advantages. This ingenious writer closes his essay with the following general theorem, as the result of his previous reasoning. "That a punishment may not be an act of violence, of one or of many against a private member of society, it should be public, immediate, and necessary; the least possible in the case given; proportioned to the crime, and determined by the laws." Montesq. Sp. of Laws. Beccaria's Essay on Crimes and Punishments. Blackft. Com. vol. iv.

A valuable work, comprising the subject of this article, was presented to the public in the year 1811 by M. Dumont of Geneva. It was formed of detached materials, furnished by the papers of Mr. Jeremiah Bentham, and the whole is executed with such judgment in the arrangement of the matter, and so much vivacity and elegance as to the style of the composition, that M. Dumont appears more like an original author than an editor. This work would have afforded us many instructive and interesting extracts, if our limits had allowed our making that use of it, which it deserves. This, however, is the less necessary, as the reader may have access to the original treatise, viz. "Theorie des Peines et des Recompenses; par M. Jeremiah Bentham, Juristconseille Anglois; redigee en Francois d'apres les Manuscrits, par M. Et. Dumont de Geneve," 2 vol. 8vo. a Londres, 1811: or to the ample analysis of it in the Edinburgh Review, No 43. A brief account of its contents may, however, be gratifying to our readers. This work consists of two great parts or branches; the theory of penal legislation, and the theory of remunerative legislation. The first contains a systematical form all the principles that serve to regulate the choice of different modes of punishment and the apportionment of punishments to crimes. In the second are exhibited the principles upon which the lawgiver ought to proceed, when he holds out inducements either alone or attended with corresponding penalties, to influence the conduct of his subjects. The first book explains the general principles of the system, and opens with definitions and classifications.

Punishment, in its most general sense, is the infliction of some evil upon an individual, with an intention that he should suffer this evil, and with a reference to some act done or omitted. Punishment, in its legal sense, is the infliction of some evil, according to judicial forms, upon an individual convicted of some act forbidden by law, and with the intention of preventing the recurrence of such acts. Punishments, as well as crimes, are divisible into four classes, as they affect the person, the property, the reputation, or the condition of those upon whom they are inflicted. Those which affect the person, or corporal punishments, are subdivided into various species; they may be simple or complex afflicting, or retificatory, or active (e.g., compulsory labour) or capital. The other three classes are all private, afflicting the delinquent with loss or degradation. Hence arises another general classification of punishments, by dividing them into corporal and privative.

From this definition it appears, that the object of all punishment is the prevention of the offence in future, either by the same delinquent or by other persons in similar circumstances. The first end is accomplished in three ways: by taking from the offender the physical power of committing the offence; by taking away the desire; or by deterring him. The other, and principal object of the infliction, that of restraining others, can only be effected as far as the punishment is concerned, by the threat which it holds out of similar infliction. These objects, as they form the only just motives, constitute also the only justification of punishments. Although the direct and primary object of punishment is prevention, the civil magistrate, having provided for that object, has another duty to perform, which is to provide as far as possible for the reparation of the injury suffered through the crime committed.

The expense or cost of any punishment is, in the language of this system, the whole evil of every kind occasioned by it, including the suffering of the delinquent, the loss of his labour or life to the state, the pecuniary cost of his punishment; and, in short, every thing endured, paid, or foregone, in order to obtain the double preventive which the punishment is intended to administer. The gain or profit of the punishment consists in this preventive, or in the tendency of the punishment to secure it. A punishment may be termed frugal or economical which produces the desired effect with as little suffering as possible; and it may be termed costly or prodigal, when the same effect might have been produced by a smaller degree of suffering. The real value is distinguished from the apparent value, of the suffering: the former being the actual amount of that which is inflicted; the latter, the estimation of it which is exhibited, or otherwise made known to, and understood by the public. The expense of a punishment is equivalent to the real amount; the profit is in proportion to the apparent amount only; and hence are deduced these important maxims: 1. That, ceteris paribus, a punishment easily comprehended, is preferable to one of difficult apprehension. 2. That one which takes hold of the memory, is preferable to one easily forgotten. 3. That one which is as great or greater in apparent than in real amount, is preferable to one which is really greater than it appears to be: the excess of real amount being in truth so much thrown away, so far as regards the principal object, of general example.

The next subject of discussion comprehends the principles that ought to regulate the extent of punishment, for the prevention of crimes. These are contained in the following propositions. 1. The evil of the punishment must exceed the advantage arising from the crime; so that, generally speaking, the stronger the temptation to commit any crime, the more severe ought to be the punishment, subject to exceptions in extreme cases. 2. When the criminal act evidently indicates a habit or practice, the punishment should be proportioned, not to the gain derived from a single offence, but to the probable amount of profit flowing from a course of such conduct. 3. An addition must be made to the punishment, in order to compensate its want of certainty and proximity. 4. In cases where a temptation offers for the committal of different crimes, a more severe punishment should be denounced against the greater crime. 5. The more pernicious any crime is, the more safely may a severe punishment be ventured upon, for the chance of preventing it. 6. The nominal amount of punishment for the same crime, must often be varied at the discretion of the judge, according to the circumstances of the delinquent, in order to preserve the real amount of suffering.

The qualities of punishment, the consideration of which naturally succeeds that of the measure or quantity, are such as follow: it should be divisible; invariable, or certain; commensurable with others; analogous to the crime; exemplary; economical; remissible; that it should restrain the offender from doing harm; conduct to his reformation; yield a profit, in the ordinary sense of the word; be simple in its description;
PUNISHMENT.

description: and so far popular as to shock none of the established feelings or prejudices of the community. These qualities are, for the most part, understood as soon as they are mentioned. Some of them, however, undergo a more ample discussion than others. This is the case with respect to the qualities of analogy and popularity. One of the sources of analogy specified by Mr. Bentham is that of employing the same instrument or operation in the punishment, as the delinquent did in the crime, as, e.g. burning an incendiary who had committed any aggravated act of arson, by which lives were sacrificed as well as property. Another method is that of inflicting on the delinquent the same injury which he offered to the innocent person. A third consists in subjecting to punishment the part of the body with which the offender committed the crime. All these, in affecting the face with some disfigurement similar to disfiguring, where part of the offence was the use of a disguise. Other analogies also are enumerated. In discussing the popularity of punishment, the author advert to the prevalence of false feelings and prejudices, and he reduces the errors proceeding from these causes to four heads: as they concur in mistaken notions of liberty, decency, religion, and humanity. The author allows, however, that a lawgiver should, for a time at least, frame his institutions so as to humour even the caprices and errors of his people, when he finds them too deeply rooted and widely spread, to be overcome or disregarded. To any speculative arguments, founded upon false views of those different subjects, of course no regard should be paid—as to those fanatics in politics, religion, or sentiment, who would have no imprisonment because it violates liberty, or abolish capital punishments because they encroach upon the province of the Deity, or because they are painful to the feelings.

The author mentions four cases, in which punishment is wholly inept, and ought not to be inflicted: viz. where the crime being either imaginary, or unfelt for legislative interference, may be laid not to exist, and the punishment would be unfounded; where the punishment would be wholly insufficient on the delinquent, or others in the same circumstances, as in the case of idiots: where the means being sufficient to accomplish the end in view, punishment would be superficial: where more evil being likely to result from punishing the particular offenders than from letting them escape, the infliction would be too costly, as in the case of an extensive mutiny or rebellion.

We have already stated, that the author divides punishments into two great classes, corporal and privative; that he again subdivides corporal punishments into five kinds, and privative into three. 1. The first class of corporal punishments consists of punishments simply afflicting, denoting those which cause bodily suffering, with little attendant injury; and even those mortally simple, as the lafh, are accompanied with a certain disgrace by their public exhibition, which is an essential part of the process. Of the various kinds of simple infliction, our author gives the preference to the lafh, under certain modifications. 2. The second class consists of punishments complexly afflicting, or those in which the mere bodily suffering is attended with, or followed by, some other loss, either of personal comfort or reputation. These are subdivided into three kinds, comprehending those that are inflicted by deforming the person, which is done either by disfiguring, e.g. gr. burning in the hand; or dismembering, e.g. cutting the nose, or cutting the ear; by disfiguring a limb or organ, without destroying it; by mutilating or destroying the part. The third class comprehends retributive punishments, which prevent the offender from doing or enjoying something agreeable or useful to him. The restrictions thus imposed are of two kinds; simple prohibitions, and restraints upon loco-motion. The former are so limited in their application, that we need not particularly specify them; but the latter are divided into five kinds; viz. imprisonment, in the ordinary sense of the word; quasi-imprisonment, or confinement within the district to which the offender belongs: relegation, or confinement to some other district within the dominions of the state: local interdiction, or banishment from a particular district: banishment from the territories of the state, either indefinitely, or to some specific foreign part. Imprisonment, according to our author’s statement, in order to be equal, ought to place the offender, for a limited time, under the most complete restraint, instead of being long and flight. Mr. Bentham enlarges in the enumeration of the evils comprehended under this mode of suffering, of which some belong infalutably and necessarily to it: others such as are necessary, but most frequently accompany it; and others again such as arise from abuse of it. With imprisonment, he says, in certain cases, and always for a very limited time, may most advantageously be joined solitudes, darknese, and regimen. Our author, having exposed the absurd system of “prison-fees,” infers from his general principles that there ought to be three kinds of prison, adapted to the several purposes of simple detention, penitentiary confinement, and perpetual imprisonment. The first being only applicable to the case of insolvent debtors guilty of imprudence or extravagance, and of accursed persons kept for trial, should have no accompaniment whatever of rigour. The leading principle in distinguishing the two others is, that the subjects of the former are to enter again into society; while those of the latter, being for ever excluded from it, the exemplary nature of their sufferings should be the principal object of attention. The names of the three prisons, for these separate purposes, should be different, as well as their external appearance; and every thing which can seize hold of the imagination, without awakening sympathy, should be preferred, both in the construction of the perpetual prison, and in the situation of its inhabitants. 4. The fourth class of punishments comprehends those that are termed active or laborious. Punishments of this class, when examined by the rules already premised, are found to unite the greatest number of advantages with the fewest defects. In the discussion of this subject, the author directs our attention to what may be called the extreme case of mismanagement in this kind of punishments. Here he alludes to Botany Bay. The transportation of convicts to America, which preceded the present plan, with several disadvantages of great moment, was, upon the whole, infinitely preferable. It was grossly unequal, inasmuch as it became lervitude with exile to the poor, while it was only simple regulation to those who could pay for their passage. It was defective too in preventive power, the opportunities of escape being necessarily great. In both these particulars, the deportation now practised has the manifest advantage. All the convicts are equally under restraint, and their escape is much more difficult; but in every other point of view, it is either as bad, or a great deal worse. It is as little as possible exemplary: the disproportion between the real and apparent suffering, the excess of the former, is in truth a maximum. The community in this country fee a convict sent on a long voyage, to a fertile country, lying in a fine climate. This is the example. The reality is, that the miserable wretch, after rotting in the hulks for a year or two, is crammed with some hundreds of his fellows into a floating prison, or, it may be, a debt-house, in which, if he survives the ricks of famine, pestilence, mutiny, fire, shipwreck, and explosion, he is conveyed, through the

imagination.
PUNISHMENT.

Fiction of a ten months' voyage, to a life of alternate slavery and rebellion, where guilty or cruel excess succeeds exquisite suffering, without varying the uniform misery, or changing the prevalent character of the body; and all this passes at the opposite extremity of the earth's diameter, from whence it operates no more in any manner of way upon the inhabitants of England, than if it were paling in the moon. The tendency of discipline in the colony to reform the convicts, fupposing them to have arrived there, may easily be estimated. They are not separated from their companions in guilt; they have no better examples before them, no eyes to watch them. The partial historian of the rising rebellion, himself the chief magistrate, (Mr. Collins,) has supplied us with the details; and, in spite of his inclination to see every thing in the fairest light, he has painted, if the pages of a journal for sixteen years may be laid to paint, by far the blackest picture ever yet exhibited of human society. His book is a catalogue of crimes; it would be a record of convictions, but that perjury so universally prevails as to ensure the escape of all who are not taken in the fact. The vice at the root of all the rest, a rage for spirits approaching to frenzy, can neither be cured, nor deprived of gratification. Far from improving by their refuge there, it was only at the first establishment that any remission of unfavourable symptoms appeared. As soon as the first convicts had finished their period of servitude, their liberty brought along with it an influx of disorder and contamination, which each succeeding year seems to increase. If this system, then, prevents the delinquent from repeating his crimes, it is only by transferring the scene of their to a distant settlement, where it softens and augments them; and although, with reference to one part of the empire, this may be termed prevention, the legislator, whose care should embrace the whole, has no right to give it such a name. As to the pecuniary expense, by which so much evil is purchased, we find it in the parliamentary reports estimated at above a million in about ten years, or about thirty-eight pounds for each convict, besides the value of his labour. Last of all, the punishment inflicted is perfectly different from the one to which the sentence of the law has condemned the convict. Not to mention the detention before transportation, and the arrival sometimes when the term of punishment has nearly expired, the power of returning at its expiration is poiffessed by few men, and no women; while of the voyage some idea may be formed, from the average mortality between 1787 and 1795, being above one in ten; and from a jail fever, always a probable occurrence, on one occasion, in 1795, having carried off one hundred in three. If, in such a case, we could look to the settlement as a colonial speculation, we should find its gains in a similar proportion; but this estimate would be as superfluous after what has been said, as it would be foreign to the design of this inquiry.

In the work before us we have a general sketch of the author's plan of improvement upon this system, together with a view of its connection with the principles which he has unfolded, and of the prodigious advantages accruing from it. The "Panopticon" is distinguished by three leading properties. From the form of the building, and the disposition of the cells, the inspector can see each prisoner at all times, without being seen by them, and can direct them without leaving his post: the management of the establishment is carried on by contract, the government paying a fixed price for the whole expenses of each convict, and the contractor having the whole profit, as he has the entire charge and regulation, of the work to be performed, but allowing a certain proportion of the gain to the convict:

the contractor infures the lives and safe custody of the convicts; he is allowed yearly a certain sum for the deaths, as calculated from the common tables, and he pays the same sum for each death which actually does happen, and for every escape which takes place. If we mistake not, Mr. Bentham, by his contract with government, further engaged to pay so much for each prisoner who, after his discharge, should afterwards be convicted of any offence. The entire publicity of his accounts was another condition, and one upon which he himself insisted. The Panopticon was to be open at all times to every magistrate, and at certain hours to the public generally.

The most striking points of the comparison between both systems, as they are presented to us by the anonymous author of the article on the subject in the Edinburgh Review, are such as follow. The punishment is in the highest degree exemplary; it is all seen and understood; it appears much greater than it really is; the comforts of the convicts, in their intercourse with each other according to their improvement, and in the state of industry, and cleanliness, and wholesome regimen, for which they have exchanged their ordinary habits, being, however real, by no means such as strike the multitude of spectators, who only see confinement, compulsory labour, and ignominy. The reforming effects of the plan are equally manifest: the labour, to which they are in part allured by a fixed allowance of profit; the perfect temperance in which they live; the facility afforded of separating them into classes, according to their habits and behaviour; the means of easy instruction, both religious and other, which they give: all furnish as good a chance of reclaiming those unhappy persons who are not hardened in guilt, as from any such discipline can reasonably be expected. The preventive powers of the Panopticon are complete, while the convict remains in it; and although a relapse after liberation can only be guarded against by reformation, a contrivance is added to this establishment, admirably calculated to provide against the first dangers of the discharge: the convict is transferred to another place of mitigated confinement, where he is rather under inspection than in custody, and from whence he is gradually allowed wholly to withdraw. With respect to the cost of the plan, we may form some estimate of it from the terms of Mr. Bentham's contract. Each convict was to cost government 35l. 10s., including 1l. 10s. for the proportion of the expenses of building and ground. He was to provide a fund for indemnifying the parties injured; to allow the convicts one quarter of the profits of their labour; and, after the first trial, to make a reduction in the charge. Practical men, well versed in such matters, had no doubt that a very considerable reduction might have been speedily afforded; and that in a few years, the profits would entirely defray the expenses of the establishment to the state. While all manner of delays and difficulties were thrown in the way of this experiment: while wits and jobbers, or, as they termed themselves, matter-of-fact men, averse to theories, and deprecating novelties, were employed in running it down; trials were made in America of penitentiary houses upon similar principles, though in a much less perfect shape, and without some of Mr. Bentham's chief improvements. We have the most irrefragable testimony borne to their success, by the interesting narratives of the da de Rocheouault Liancourt and captain Turnbull: the one a perfon eminently skilled in the subject of prisons; the other a more practical observer, imbued with no knowledge beyond that of the naval profession. Both these very different witnesses concur in their statement of the salutary consequences of the plan; and if we wished to find a perfect contrast to the melancholy
mellancholy narratives of Mr. Collins, we could certainly
nowhere so well be suited as in the descriptions which the
French and English travellers have given us of the convicts

5. Capital punishments compose the fifth clas.
This clas consists either of simply infliction of death with the least
possible degree of suffering, or in accompanying the destruc-
tion of life with torment. The latter method, at one period
universally prevalent, and still known in most countries, is
happily almost abolished in the two most civilized nations.
In France, the Code Napoleon allowed it only in the cases of
parricide, and attempts against the sovereign’s life, where
the addition made to the punishment of death is cutting off
the right hand. In England, it is only in the case of high
treason that such augmentations are allowed: the punish-
ment of the law is no doubt barbarous in the extreme, but
in practice it is always remitted. All such cruelties have the
effect of inspiring pity in the spectators towards the crim-
inal, and of rendering criminals more hardened and sav-

The ingenious author of the critique on Mr. Bentham’s
theory, to whose analysis of the work we are so much in-
debted in the compilation of this article, agrees with him in
his objections to Beccaria, who maintains that a punishment of
longer duration is more terrible to the spectator. Clearly
there is none so dreadful as death. M. Dumont adds,
that its apparent suffering is greater than its real, which
applies only to the pains of it. On the other hand, it ex-
ceeds all others in some material defects; not only is it ex-
ensive, and beginning to become unpopular; it is quite
irremissible, and it is in the highest degree unequal, and in-
capable of division or apportionment. A very satisfac-
tory statement is given under this head, of the evil tendency of
frequent executions, of the kind of reasoning by which of-
fenders at the moment of temptation get rid of the fear of
death, and especially of the wide difference between encoun-
tering certain destruction, and yielding to impulses which
may lead to it. The evils arising from its being irremissible
are also ably expounded; yet we think the author has
neglected to consider how much of its horror consists in this
quality. It is manifest that no other punishment can utterly
exclude hope. In comparing capital with other punish-
ments, our author is disposed to give the latter the pre-
ference, almost to the exclusion of the former; chiefly be-
cause, however exemplary to men in general the infliction
of death may be, and how deep forever the impression it
makes on their minds, it has not the fame terrors for the
clas of men most likely to commit the worst offences, vi-
olent spirits and hardened delinquents. That its range shou-
d be extremely limited, we are willing to admit; but we
differ from him in the position, that for this clas of men,
perpetual confinement to hard labour would have more
terrors than death. The total extinction of life, without
chance of escape, pardon, or mitigation, ought still to be
denounced against the worst offences; and, by being con-
ined to those, will unquestionably become doubly terrible.
The evils arising collaterally from the abuse of this punish-
ment, are so ably pointed out by sir Samuel Romilly, that
our author abridges a part of the treatise before us, by re-
ferring to his tract.

The other great division of punishments in Mr. Ben-
tham’s theory, consists more peculiarly in privation. These
may be arranged in three clas, as they impose a for-
feiture of reputation, of property, or of condition. 1. Punish-
ments which affect a man’s reputation consist of appeals
to public opinion, and are those meaures which the law-
giver takes with respect to him, for directing that opinion
against him. The lawgiver may inflict punishments of this
kind, or rather may expose the offender to have them in-
flicted, either by simply denouncing, with the authority
belonging to his functions, that certain acts shall be deemed
infamous, or by treating the particular offender judicially in
a certain way. The latter is the mode used in modern
times; and it is practiced in different ways; by publication
of the offence;—by judicial admonition;—by inflicting punish-
ments of the other clas, corporal as well as privative, the
immediate object of which is not the destruction of repu-
tation;—by inflicting what may be termed quasi-corporal
punishments, the sole object of which is infamy;—by de-
gradation, or depriving the offender of his rank, natural or
conventional;—by discrediting him, or preventing his testi-
mony from being received. 2. The description of punish-
ments affecting property consists of those which are pecu-
niary, and which are quasi-pecuniary, as confiscation of lands, &c.
3. The forfeiture of condition, or status, though a clas of
great extent, theoretically speaking, is in practice reduced
within narrow limits. Marriage may be dissolved; children
may be bastardized; blood may be corrupted; the different
kinds of trust may be taken away; a person may be re-
duced to slavery; a community may be deprived of its
rights and privileges. Outlawry may also be referred to
this head.

There are other kinds of infliction, which every found
principle teaches us to avoid where it is possible, and to
diminish as much as possible, where, from the defects of all
human contrivances, they inevitably mingle themselves with
the legitimate modes of punishment. Our author’s syste-
arranges them in two clas; those which are misplaced, or
which fall upon other persons than the offender; and those
which are complicated, or present neither to the legislator,
the judge, the party, nor the public, any fixed and definite
idea. Those punishments that are misplaced, in the proper
use of the term, or which the legislator enacts with the
intention of punishing another person than the offender,
either along with him, or in his place, confit of four
kinds; viz. vicarious, where the offender escapes;—transfere,
where an innocent person is purposely punished who is con-
ected with the offender;—collective, where a body of
innocent persons suffer, in the punishment of the guilty
being among them;—and fortuitous, where an innocent
person suffers as well as the offender, though unconnected
with him. The only instance of vicarious punishments is
that inflicted upon the families and creditors of suicides
by the law of England. This, like all other absurd and un-
just laws, is evaded, in almost every instance, by perjury,
and the exercise of discretion in a sovereign. The example
given of transfere punishment is the corruption of blood,
the abridgment of which is ably exposed. The chief inflicts
of collective punishments are those in which corporations are
punished for the ‘faults of certain individual corporations;
proceeding which can never be justified. The well-
known examples of fortuitous punishments are taken from
the law of England. The most notable is the forfeiture
and efech of frehold property, in cases of attainder of
treason and felony, where the confiscation relates back
to the commissio of the offence, and all meane conveyances
are avoided; so that a man may commit a secret crime, and
fall his estate to an ignorant and innocent purchaser, in
whose hands the crown or the lord afterwards feizes the
estate upon the vendor’s attainder; and as his goods and
chattels are forfeited upon conviction, the only fund of
compensation is gone afo. Decendants are another infliction
of similiar injustice; and the punishment of incapacitating a
person from giving evidence, is manifestly one which may
be
strike more injuriously at parties wholly unconnected with the offender, than at himself; besides, that it is by no means inflected merely with the view of putting courts of justice on their guard against admitting a bad witnese; for it is often the punishment of crimes which have no peculiar connection with violation of truth.

Among the evils of complicated punishments, we may reckon, besides outlawry and incapacitation of giving evidence, excommunication and felony. Some gross abuses having occurred in the infliction of the punishment of excommunication, several distinguished persons have undertaken to substitute other procedure in its place; and Sir W. Scott brought a bill into parliament with this view, so that the evil is done away. The punishment of persons as felons, comprehends a number of infestions very different from each other, so that our author considers the punishing of a felon to be a vague and indefinite term. This comprehends two descriptions of punishment; the one capital, with forfeiture of lands and chattels; the other not capital, but confining in forfeiture of chattels, and the form of burning in the hand; to which, by special enactment, imprisonment, transportation, or indeed any other punishment, may be superadded. It must be acknowledged, that a much simpler and better manner of slating the punishment due to an offence would be, to tell at once of what it is to be conceived; and instead of enacting that certain offences are felonies, which specifies nothing, to prohibit them, and slates the precise infestions which shall follow the commissio

Punishment, in Theology. It has been disputed among divines, whether the punishment of the wicked in a future world be strictly eternal or not. For the arguments on both sides of the question, see Hell.

Punitive Interest, in the Civil Law, such interest of money, as is due for the delay of payment, breach of promise, &c.

Punk, in Natural History, the inward part of the excrecence or exuberance of an oak. It is used by the Indians of Virginia for medicinal burning, as the Exit Indians use moxa. Phil. Trans. No. 454. p. 1-11.

Punn. See Pun.

Puno, in Geography, a town of Peru, now annexed to the vicerealty of La Plata or Buenos Ayres, and capital of a district of the same name, called also Paucarcolla (not Pauarcolla, as it is misprinted in that article). It is a rich and populous town, situated on the W. side of the lake Titicaca, and containing some illustrious families, as well as a beautiful church for the Spaniards, and another for the Indians, who weave great quantities of coarse cloth, with which they supply the neighbouring countries. S. lat. 16° 20'. W. long. 70° 26'.

Punt, in Sea Language, a sort of oblong flat-bottomed boat, with a square head and stern, whose floor resembles the platform of a floating stage; and used by shipwrights for breaming, caulking, or repairing a ship's bottom. It is also used in some canals.

Punta, in Geography, a town of South America, in the audience of Quito, and jurisdiction of Guayaquil.

Punta, La, a town of Mexico, in the province of New Biscay; 40 miles N.N.E. of Durango.

Punta is also an epithet, distinguishing several capes, which are too numerous to be here recited; and this is the least necessary, as the principal of them occur under other appropriate titles.

Punta Entornada, a town on the N. coast of Spain. N. lat. 43° 34'. W. long. 7° 32'.

Punta del Guada, a sea-port and capital of St. Michael, one of the Azores, defended by a castle.

Punta de Tordera, a town and cape of Spain, on the coast of Catalonia. N. lat. 41° 38'. E. long. 2° 37'.

PUNTO DEL MONTE, a town of South America, in the province of Cordova; 15 miles S. of Cordova.

Punugga, a village of Bootan, situated in a deep hollow, and surrounded with mountains, for the most part covered with pines, along whose sides clouds are perpetually hovering. On the borders of this village are many large heaps of fir-leaves, which being left to ferment and rot, are used as excellent manure.

Pununagalur, a town of Bengal; 10 miles W. of Nattore.

Pununay, a town of Hindooistan, in the circar of Gohud; 18 miles E. of Raat.

Puolango, a town of Sweden, in the government of Ulea; 40 miles S. of Cajana.

Pupa, in Natural History, a name lately suffixed in the room of chrysalis or auroria, because many insects in this state resemble an infant in swaddling clothes; and all, except those of the hemiptera order, take no nourishment. See Entomology.

Pupigliio, in Geography, a town of Etruria; 10 miles N. of Pisa.

Pupil, Pupilus, in the Civil Law, a boy or girl not yet arrived at the age of puberty, i.e. under fourteen years of age for the boy, and under twelve for the girl.

While a minor remained under the direction of a tutor, he was called a pupil; after puberty, a curator being assigned him, he ceased to be called a pupil.

A tutor is obliged to pay interest for what monies of his pupil lie idle and unemployed. A tutor is allowed to do any thing for his pupil, but nothing against him.

Pupil is also used by way of extenuation, in Universities, &c. in the sense of alumnus, for a youth under the education or discipline of any one.

Pupil, in Anatomy, the round opening in the iris, by which the rays of light are admitted into the eye. See Eye.

Pupil, in Optics. It is observed, that as we are forced to use various apertures to our optic glasses, so nature has made a like provision in the eyes of animals, whereby to shut out too much, and admit sufficient light, by the changes in the aperture of the pupil.

The structure of the uvea and iris is such, that, by their aperture, the pupil is contractile and dilatable at pleasure, so as to accommodate itself to objects, and to admit more or fewer rays, as the object, being either more vivid and near, or more obscure and remote, requires more or less light: it being a constant law, that the more luminous the object, the smaller the pupil; and again, the nearer the object, the smaller the pupil; and vice versa.

This fact has been long ago noticed by optical writers. B. Porta, about the middle of the sixteenth century, in his treatise De Refractione, p. 74, observes, that the pupil is contracted involuntarily when it is exposed to a strong light, and opens of itself when the light is small. A similar observation was made by his countryman and contemporary, Father Paul of Venice. Galen, indeed, first observed the dilatation of the pupil of one eye, when the other was shut or loth, and the contraction of it, when the other was opened or recovered; and in this opinion he was followed by all naturalists and philosophers, till Fabricius ab Aquapendente, professor at Padua, by observing the eye of a cat, found
found that the pupil not only dilated and contracted itself, when one of the eyes was shut, but also when both were open. F. Paul found, from repeated experiments, that the pupil not only of cats, but also of men, and other animals, always contracted itself when the eye was exposed to a bright light, and again dilated itself when the light was faint and languid. This he always observed, as well when both eyes were open, as when one of them was shut. The same remark was made by Achiilinus, in a treatise published in 1522; and the fact was known to the Arabians, Rhazes and Avicenna. That the pupil of the eye is enlarged, in order to view remote objects, and that it is contracted while we are viewing those that are near, is a fact with which Scheiner, in the beginning of the seventeenth century, was well acquainted, and which he proved by experiments, and illustrated by figures. When a needle, or any small object, is brought near to the eye of any person, who looks attentively at it, the pupil, he says, is plainly seen to contract; and it as constantly expands whenever it is withdrawn.

This alteration of the pupil is effected by certain muscular fibres on the outside of the uvea, which arrive from nerves detached hither from the sclerotic. These fibres proceeding straight from their origin towards the centre, terminate in the orbicular limb or zone of the pupil, which consists of orbicular fibres, whereby the figure and space of the pupil are defined. The first, or longitudinal fibres, dilate the aperture of the pupilla; the latter, or orbicular ones, constringe it.

Some authors, however, attribute the motions of the pupil to the ligamentum ciliaire; and others think, that both this, and the fibres of the uvea, concur herein. Dr. Derham adds, that while the pupil opens and shuts, the ligamentum ciliaire dilates or comprizes the crystalline, and brings it higher to, or farther from, the retina, as the object is more or less remote.

There is no doubt that the change to which the pupil is subject is the effect of light upon the eye. Dr. Hartley, Obs. on Man, vol. i. p. 219, supposes, that the light which enters at the pupil has great efficacy in contracting both the greater and less rings of the iris, as may be concluded, he says, from the immobility of the pupil in a gutta serena; also because, on this supposition, the light which passes in at the pupil mutt, by contracting the less ring, become a check and guard against its own too free admission, which is agreeable to the tenor of nature in like instances. The retina, he observes, extends to the greater ring, and may send some nervous fibres to it, and even to the iris. Dr. Whytt also says, Essay on vital and involuntary Motion, p. 112, that the contraction of the pupil is not performed by the action of light upon the iris, but upon the retina; since whatever intercepts the rays of light, so as to prevent their reaching the retina, causes a preternatural dilatation of the pupil; because in a cataract, where the crystalline humour, being considerably opaque, intercepts a great part of the rays, the pupil loses a good deal of its contractile power. This author also observes, that the wideness of the pupil in a syncope, apoplexy, and confirmed gutta serena, shews that, in order to dilate the pupil to its largest size, no effort of the mind is necessary, but only the superior contractile power of the longitudinal fibres of the uvea, when its circular muscles is not excited into action by the stimulus of light on the retina. M. Mery informs us (Mem. Ac. Paris, for 1704) that, having plunged a cat in water, and exposing her eye to the strong light of the sun, the pupil was not at all contracted by it; whence he infers, that the contraction of the iris is not produced by the action of the light, but by some other circumstance. For he contends, that the eye in this situation receives more light than in the open air. M. de la Hire, in reply, endeavours to shew, (Mem. Ac. Par. for 1709) that fewer rays enter the eye under water, and that, in those circumstances, it is not so liable to be affected by them. Besides, it is obvious to be remarked, that the cat must be in great terror in this situation; and being an animal that has a very great voluntary power over the muscles of the iris, and being now extremely attentive to every thing about her, she might have her eyes open, notwithstanding the action of the light upon it, and though it might be very painful to her.

The figure of the pupil, in various animals, is wonderfully adapted to their various circumstances and occasions; in some, e. g. in man, it is round, that form being most fitted for the position of our eyes, and the various uses we make of them in all directions.

In others, it is elliptical or oblong; in some of which, e. g. the horse, sheep, ox, &c. the elliptis is transversely, and the sillure large, to enable them to see laterally, and even with a little light; and thereby both to gather their food the better in the night, and to avoid dangers on either side. In others, e. g. the cat, the elliptis is erect, and is also capable of opening very wide, and shutting very close, by means of the latter of which states, that animal can exclude all, but, as it were, a single ray of light, and so avoid all the inconveniences of the bright sun; and by the former, it can take in all the faintest rays, and thus avoid the inconveniences of the night: an incomparable provision for these animals, which are to watch and way-lay their prey both by day and night, to see upwards and downwards, to climb, &c. See Eye and Vision.

Pupil. Closurc of. A preternatural smallness of the pupil always renders the patient incapable of discerning objects well at night-time, and occasions a diminution of vision. The consequence of a complete closure of the pupil, a cafe termed synecrisis, is total blindness. Both these affections only differ from each other in degree, and they originate from the same causes. The most frequent cause is a violent inflammation of the eyes, particularly when such disorder extends to the iris, and arises at a period when the anterior and posterior chambers of the aqueous humour contain none of this fluid. This case principally happens after the extraction of the cataract. Here the inflammation constantly affects the capsule of the crystalline lens, so as to make it opaque, and at the same time adhere behind the pupil to the iris; a circumstance which is well deserving attention. Not unfrequently, however, a closure of the pupil takes place during ophthalmia, notwithstanding both chambers of the eye are full of the aqueous humour. Wounds of the iris sometimes cause this unpleasant occurrence, especially when they continue open, and do not heal. It is observed to be most frequently produced by such wounds as divide the radiated fibres of the iris transferly. These wounds, however, do not invariably remain open; sometimes they close, and then the pupil undergoes no alteration. Even when such wounds do not unite, a closure of the pupil does not always follow. In these instances, the natural pupil has been remarked to become closed, and the preternatural aperture in the iris to be widened, when the eye was exposed to the light; and, on the contrary, immediately the light was diminished, the pupil became dilated, and the other opening was contracted and closed. Wounds of the iris in the other direction, even when they remain dilated, often cause little or no diminution of the natural motion of the pupil.

It sometimes happens, that a greater or lesser portion of the iris is detached from the circumference of the cornea;
ternaturally dilated. In all such cases, the only indication is to endeavour to remove the original disease, of which the mydriasis is merely a symptom.

In the case where mydriasis is to be regarded as the only disorder, the complaint seems to depend upon a weakness or paralysis of the fibres which close the pupil. Here it is commonly the consequence of apoplexy, a blow on the eye, or a violent and sudden dilatation of the pupil, as, for example, sometimes happens in the extraction of a cataract. When the disease is of long standing, there is little hope of cure, whatever may be the cause from which the complaint arises. When it is recent, the pupil will sometimes regain the power of moving and contracting under the use of internal and external stimulating tonic remedies. The chief means of this class are, blisters applied to the eye-brows, ethe real oil rubbed into the skin around the orbit, electricity, emetic medicines in small and full doses, and other similar remedies, which are usually preferred for the relief of paralytic affection of other parts. When these means prove unavailing, the practitioner must be content with recommending a palliative plan, which will be presently noticed.

As the pupil naturally dilates in the dark, it follows, that when a person is kept a long while away from the light, a mydriasis is produced, the pupil becoming habituated to the expanded state, and losing the power of contraction. In most instances, it gradually recovers its motion after the eye has been for a certain time exposed to the light again. The light, however, must be allowed to get to the eye only by degrees, or else its sudden operation on the eye, in the expanded state of the pupil, would be apt to impair, or even destroy vision altogether. When the pupil does not recover its power of motion, the patient must be satisfied with resorting to palliative means. It has been remarked, that mydriasis is sometimes a congenital defect. All attempts at a radical cure must here be attended with extreme difficulty. When the light cannot be endured without inconvenience, the palliative plan is necessary. A blow on the eye sometimes tears the pupil. The rent most often remains open, and the patient is in the same state as if affected with mydriasis. Here, as the laceration cannot be repaired, the indication is to prevent, by palliative means, vision from being hurt by the too great strength of the light.

Through a preternaturally dilated pupil the light enters the eye in such quantity, that the patient is blinded. He not only sees things very indistinctly in light places, but he also runs a risk of being gradually entirely deprived of vision, in consequence of the too strong action of the light upon the eye. The prevention of such mischief is the object of the palliative treatment. By it the light which falls upon the eye is to be diminished, so that the patient may be enabled to see not only plainly and without inconvenience in light places, but also without any danger of losing his sight altogether. The usual means recommended for this purpose are, eye-shades, by which the light, coming principally from above, is kept from entering the eye; black veils over the face; green spectacles, which lessen the quantity of rays of light coming from objects which the patient is looking at; spectacles made with black cards, in the centre of which is left an opening of the size of the natural pupil. But the best and most proper means is a pair of tube-spectacles. This is a common pair of spectacles, which, instead of glasses, has adapted to its two rings two conical tubes, the bases of which are to be put towards the eyes, and the narrower parts towards the objects which are looked at. These tubes ought to be made of black leather, and they should be three or four inches long. Their diameter at the base must be equal to that of the circumference of the orbit; but their other ends need not be quite so wide. The edge of their bases is to be cut in such a way, that they will fit closely on the circumference of the orbit. The use of these tubes consists in their keeping off all the rays of light coming laterally, and only admitting those into the eye, which proceed from objects in the axis of vision. Every surgeon will be able, according to circumstances, to multiply and vary the contrivance here described. See Richter's Anfangsgr. der Wundartzneykunst, band 3, cap. 10.

PUPILLARIS Membrana, in Anatomy, a circular membrane, by which the pupil is closed during the greater part of utero-geisation. See Eye.

PUPILLARITY, or Pupillage, the state of a pupil; in opposition to puberty.

PUPPET, in Natural History. See Aurelia.

PUPPISOS, a name given by some authors to the forehead. The future in this bone is also called by many anatomists the futura puppis.

PUPPOLA, in Geography, a town of Sweden, in the government of Ulea; 45 miles S. of Ulea.

PUPULE, a name used by some to express the extremities of the fingers.

PUR, in Geography, a river of Russia, which runs into the Tazovskiia gulf. N. lat. 67° 40'. E. long. 78° 34'.

Pur autre vie, in our Law-Books, is used where lands are held for the life of another. See Occupant, and Tenant.

PURA Eleemosyna, pura alia, denotes a tenure, whereby the churchmen hold lands in Scotland, somewhat on the footing of the primitive clergy.

Pura Hasta. See Hasta.

PURALLA BAY, in Geography, a bay on the coast of Chili. S. lat. 42° 10'.

PURANA, the common name of a series of poetical romances, considered among the Hindoos as sacred works, the offspring of inspired writers, communicated for the instruction and benefit of mankind. They are ascribed, in their present form, to a celebrated man in the literary history of the Hindoos, whom they call Vyasa. (See VYASA.) He is supposed to have reduced an immense mass of inspired writings into eighteen works, and to have arranged them as they now appear. The following are the titles of these eighteen books, to which the common denomination of Purana is appertained when spoken of or referred to. 1. Brahman, or the Great One. 2. Padma, or the lotus. 3. Brahmaunda. 4. Agni, or fire. 5. Vihnu. 6. Garuda. 7. The transformations of Brahma. 8. Siva. 9. Linga. 10. Nareda. 11. Skanda. 12. Markandeya, or the immortal man. 13. Bhavihiya, or the prediction of futurity. 14. Matiya. 15. Varaha. 16. Kurma. 17. Vamana. 18. Bhagavata. Of these, the first four relate to cosmogony; the next nine to the attributes and powers of the Deity. The sixth is named after the vehicle or bird of Vihnu, called Superna, as well as Garuda. (See SUPERNA.) See Linga, for the mysterious symbol whence the ninth derives its name. Nareda, whose laws and history are detailed in the tenth, is a mythological son of Brahma. Skanda, the hero of the eleventh, is a name of Kartiya; see that article. The fourteenth and three following relate the histories of four of the principal incarnations of Vihnu the preformer, called Matsyavatara, Varahavatara, Kurunavatara, and Vamanavatara. Under these articles respectively will be found a brief notice of the outline of their histories. The eighteenth, called Sri Bhagavata, is the life of Krishna, (see KRISHNA), with
with which the poet Vyafa is popularly imagined to have crowned the whole series; though some reasonably assign them different composers; and the series is differently arranged and named by other authorities. Every Purana treats of five subjects. 1. The creation of the universe. 2. Its progress, and the renovation of the worlds. 3. The genealogy of gods and heroes. 4. Chronology, according to a fabulous system. 5. Heroic history, containing the achievements of demi-gods and heroes. Since each Purana contains a cosmogony, with mythological and heroic histories, they may, not unaptly, be compared to the Grecian theogonies.

A copy of, we believe, all the eighteen mythological poems, is preserved in the library of the East India House. It is estimated that the whole cannot consist of less than half a million of folios. Hitherto no translation of any of them, or of any considerable portion of either, hath been made from the original into any European language. They are, of course, written in the Sanscrit tongue. In some articles of this work a fanciful, or a brief outline of some of the Puranic tales, elucidatory of the character or subject under discussion, is occasionally introduced, and may perhaps give some little idea of the style of these extravagant poems. The reader, in this view, may consult the following, in addition to the other articles herein and thence referred to; Jambavanta, Kalpa, Karshagni, Krityika, Lissingawa, Lotos, Meru, Mun, Naksitra, Naramedha, Pavaka, Pavana, Pikeswari, Polleur, Prithu, &c. &c.

As to these extravagant, and not always decent, tales of the Puranas, the probability is that physical or historical facts are thus connected under a veil of allegory, carried through a series of poetical narratives and adventures, related of the personified attributes of the Deity. The facts are either forgotten, or unknown to the vulgar; but the fables remain, and are generally and commonly alluded to in composition and conversation. Taken literally, as the translations of divine or holy perfections, nothing (bathing the invention, imagery, and other poetical merits) can be more contemptible than these Puranic romances; but if we deire to extract the grains of ore that the mass may probably contain, we must be content to examine them as they are; and in case of failure, many inquisitive researchers will deem their labour not lost, in the invention and other poetical beauties abounding in these wild compositions.

We shall briefly give an abstract of the contents of two or three of the Puranas, whence a judgment may be formed of the others. The Agni Purana is entitled to have been delivered by Agni, or Pavaka, the god of fire. (See Pavaka.) It contains a great variety of subjects, and seems to have been intended as an epitome of Hindoo learning. The poem opens with a short account of the several incarnations of Vishnu, an enumeration of which, with a brief outline of their history, will be found in the article Vishnu of this work, and these thence referred to. It dwells, however, chiefly on the incarnations of Krishna and Rama. (See these articles.) Then follow a history of the creation; a tedious dissertation on the worship of the gods, with a description of their images, and directions for constructing and setting them up; a concise description of the earth, particularly of those places which are esteemed holy, with the forms of worship to be observed at them; a treatise of astronomy, or rather astrology; a variety of incantations, charms, and spells, for every occasion. One species of this is named mantra, under which article a sufficient account is given of them; computations of the periods called manvantara, kalpa, &c. (See Karpaka.) A description of the several religious modes of life called asrama, and the duties to be performed in each; rules for penance (on this head see Tapas); feats and fables to be observed throughout the year; rules for bestowing charity; a dissertation on the great advantages to be derived from the mystic word OM (under which article of this work the reader will probably find sufficient of mysticism), with a hymn to Varistha, of whom something occurs under that article. The next head relates to the office and duties of princes; under which are given rules for knowing the qualities of men and women; for choosing arms and ensigns of royalty; for the choice of precious stones; and a treatise on the art of war. The next head treats of worldly transactions between man and man, as to buying and selling, borrowing and lending, giving and receiving, &c. &c. Then follow certain ordinances, according to the Veda, respecting security from misfortunes, &c. and for the worship of the gods. Genealogies of the two races of solar and lunar kings, called Suryavansha and Chandravansha (see Surya); of the family of Yadu and of Krishna, with a short history of the twelve years' war, described in the Mahabarat. (See Mahabarat.) A treatise on the art of healing, as applicable to man and beast, with rules for the management of elephants, horses, and cows; charms and spells for curing various disorders; and the mode of worshipping certain divinities; on the letters of the Sanscrit alphabet; on the ornaments of speech, as applicable to oratory, poetry, and the drama; on the mystic signification of the single letters of the Sanscrit alphabet; a grammar and short vocabulary of that language. The whole of this defulatory work is divided into 353 short chapters.

The Siva Purana is sometimes called also, after one of the forms of his comfort, the Kalika Purana. (See Kalasa.) It is a mythological history of that goddes, including her adventures under various names and characters. Many of those names and characters are enumerated under the article Parvati, her more common name; and Mr. Moor has given an extract under Narindeha, which word means a man-sacrifice, the rites and ceremonies of that horrid offering being minutely laid down in this Purana. It is a curious and entertaining work, including as episodes several beautiful allegories, particularly one founded on the motions of the moon. See Moor's Hindu Pantheon.

The Vayu Purana, as one of those poetical romances is variously called, but which we have not the means at this present moment of ascertaining is attributed to the regent of wind Vayu, otherwise and more commonly called Pavana (see Pavaka); where the reason is furnished why the Purana is not called after that name. It contains, among a variety of other curious subjects, a circumstantial detail of the creation of all things, celestial and terrestrial, with the genealogy of the first inhabitants; chronological computations as to the grand periods manvantara, kalpa, &c. before spoken of; a description of the earth, as divided into islands, continents, &c. and its dimensions, and also of other planets and fixed stars, their distance, circumference of orbits, &c. &c. Under the article Pavaka, an extract is given from the Matyva Purana, directing how images or pictures are to be made of the god of wind. Most of the Puranas contain directions of that sort.

A brief notice of one other of these inspired works will suffice. The Nareda Purana is believed to have been delivered by the inspired Nareda, a mythological son of Brahma. Under the article Nareda, (see Hindu Pantheon) an account is given of him, with his genealogy, and the derivation of his name, from the Varaha Purana. Like the others, this poem opens with describing how heaven and earth rose out of chaos, but it treats principally of the unity of God, and as it spectrally is written with the Vaihnavia bias (see Vaih-
Pur, trigono-

Ferrara cardmal alfo in As (See was This mufl improve am he all and He on Mr. Geography, in attend improper the grammarian, effect kAva), Other ferver, in the proofs aiks clufxon could facts, defcefTor longer they to fubjecl they to the proofs were ever sufted to the public ; and whatever they were, they have not wrought conviction on the minds of all. Mr. Colebrooke, however, (Af. Ref. vol. v.) leaves us to infer that he thought them very inferior in point of antiquity to the age assigned them by his illustrious predecefor in the chair of the Asiatic Society. Mr. Wilford expressly says, that "the Puranas are certainly a modern compilation from valuable materials, that I am afraid no longer exit: an astronomic obervation of the heliacal rising of Canopus, mentioned in two of the Puranas, puts this beyond doubt." (Af. Ref. vol. v.) Mr. Bentley, after giving various reafons and calculations for the foundation of his opinion, says, "It must be evident that none of the modern romances, commonly called the Puranas, at leaft in the form in which they now fland, are older than 684 (now 1813, about 600 years), but that none of them are the compilations of ill later times." (Ib. vol. viii.) As far, indeed, as the eighteenth Purana, called Sri Bhagavat, is concerned, Mr. Colebrooke countenances Mr. Bentley's opinion. "I am inclined," he says, "to adopt an opinion supported by many learned Hindoos, who confider the celebrated Sri Bhagavata as the work of a grammairian, supffed to have lived about 600 years ago." Ib. (See Sri Bhagavat.) Be this as it may, the orthodox Hindoos have implicit faith in, and great veneration for, those celebrated poems, or " sacred histories," as they call them; and it is authoritatively aflemed, that "the Veda, the revealed fystem of medicine, the Puranas, and the code of Menu, are four works of supreme authority, which ought never to be shaken by arguments merely human. (See Menu.) There are, however, many individuals of all the four tribes of Hindoos, fewest certainly in that of Brah- mana, who correcpond with the Levites of Israel, who deny the divine origin of the Puranas, looking upon them in nearly the fame light as a rational critice of Europe may do.

Purangurrah, in Geography, a town of Bengal; 20 miles S.E. of Dhahabad.

Purari, a name of the Hindoo deity Siva; which see.

Purary, a name of the Hindoo deity Siva; which see.

Purbach, George, in Biography, an eminent mathematician and afebmon in the 15th century, was born at Purbach, a town on the confines of Austria and Bavaria, in 1423. He was educated at Vienna, where he manifested great talents, and took his degree of M.A. with great applause. He directed his attention principally to mathe- matics, and advanced in that science with almost incredible rapidity. For farther improvement, he visited the most cele- brated universities of Germany, France, and Italy. He found a particular friend and patron in cardinal Cusa, and he formed an intimacy with John Blanchini of Bologna, who adoring Purbach's extensive knowledge, and his ready method of communicating instruction, wished to pre- vail upon him to deliver lectures on astronomy at Ferrara; but Purbach preferred returning to Vienna, where he ob- tained the mathematical professorship in that university. About this time he received offers from Ladislaus, king of Hungary, to become his astronomer, accompanied with promises of liberal rewards and distinguished honours, which he declined.

The fame of Purbach, as a mathematical professor, was soon widely diffused, and brought numerous students to attend his lectures at Vienna. Among others was the celebrated Regiomontanus, who feured the esteem of his master, and was chosen the affiliant and companion in his labours. From this time they maintained an union of studies, in their endeavours to improve the different branches of mathe- matical science, and more particularly astronomy. This science they would, no doubt, have materially improved by their joint labours, had Purbach's life been prolonged. His first effay was to amend the Latin translation of Pto- lemy's Almagest. After this he wrote "An Introduction to Arithmetic," and proceeded to draw up another "On Gnomonics," or dialling, with tables suited to the difference of climates and latitudes. This was followed by a small tract "Concerning the Altitudes of the Sun," with a table, and "Astralabic Canons." After this he made solid spheres, or celestial globes, and not only explained their construction and uses, but added to them a new table of fixed stars, with the longitude by which every star had increa- sed, from the time of Ptolemy to the middle of the fifth century. He also invented various other instruments, among which was a "gnomon," or geometrical square, with canons, and a table for the use of it, which he lent to the archbishop Strigonia, who was himself a man of great erudition, and entertained a high opinion of Purbach. Our author made considerable improvements in trigono- metry; prepared tables of the fixed stars, and undertook to reform thofe of the planets, and constructed fome entirely new ones. When these tables were finished, he drew up a kind of perpetual almanack, chiefly for the moon, anfwer- ing to the periods of Meton and Calippus: also an alman-ack for the planets, or, as it was afterwards called, an Ephemeris for many years. He finifhed his "Theorie Novae Planetarum," (see Muller,) which was made a textbook in all the schools, and was commented upon by none of the moft eminent mathematicians. Purbach died in the 38th year of his age, in 1461.

Purbeck, Isle of, in Geography, a district in the Blandford division of the county of Dorset, England, is bounded on the west by Luckford lake; on the south by the British channel; and on the other side by the river Frome, and the bay of Pool. It is improperly called an iland, being in fact only a peninsula, as it may be entered from Earl Lilworth by an isthmus, between the head of Luckford lake and the sea. This district extends twelve miles in length, and varies from seven to ten in breadth. It
Purbeck Stone, the *fassum arenarium cinereum Purbeckense* of Da Costa, and *psalterium friabile albido fuscem* of Hill, is an alkaline sand-flone, which is hard and rough, of a disagreeable ahen colour, very heavy, and moderately hard, of a texture not very compact, but somewhat porous, and is composed of an angular grit, cemented together by an earthy spar: it cuts freely, and with a tolerable even or smooth surface, but will not take a polith. It will not strike fire with a flint, and burns to a white colour. The quarries of this flone are in the island of Purbeck, in Dorsetshire, whence it is brought to London in great quantities, and used in building, and for pavements. Its specific gravity is 2.68. There is also another kind of Purbeck flone, the *fassum fusco-albidum* of Da Costa, and the *sympsoium durifimum, splendidum albido-fusoeum* of Hill, which is alkaline, of a dull, disagreeable, pale, brownish, white colour, and is not capable of a polith, though it cuts to a very smooth surface: it is of a fine, close, compact texture, not quite deftitute of brilli-
ness, but full of spars of pure spar, and intimately mixed with vast quantities of small pectunculi, which are often faturated and filled with the fame substance; it is very heavy and hard, and water does not pervade its texture; it does not strike fire with a flint, and when burnt, acquires a clear ahen colour. This flone is brought from Purbeck, and used in building, pavements, &c. Hill informs us, that it is likewise found in man y other parts of the kingdom, and that there are large flates of it in Yorkshire. Da Costa's *Fossils*, p. 128–152.

Purbury, in Geography, a river of Hindoostan, which runs into the Chambul; seven miles W. of Suito-
pour, in the country of Agimere.

Purcar, a town of European Turkey, in Beffaria, on the Dniefer; 4 miles S.E. of Bender.

Purcell, Henry, in Biography, an English musician of more extensive genius than perhaps our country can boast at any other period of time, was born in 1659. His father, Henry, and uncle, Thomas Purcell, were both musicians, and gentlemen of the chapel royal, at the restoration of king Charles II. There is a three-part song in Playford's "Musical Companion," by Henry Purcell, which, being printed in 1667, when our great musician was but nine years old, must have been the production of his father. There is likewise a chant in the first volume of Boyce's *Collection*, p. 289, No. II, called the "burial chant," by Thomas Purcell, his uncle, who continued in the service of the chapel till the time of his death, in 1682. Though these compositions promise no great hereditary genius, they are mentioned here, as mankind is naturally curious concerning every thing that is connected with eminent person.

From whom Henry received his first instructions in music, cannot be very clearly ascertained. But his father dying in 1664, when he was no more than six years old, it is probable he was qualified for a chorister by Capt. Cook, who was master of the children from the restoration till the time of his death, in 1672. For, as Purcell was appointed organist of Westminster Abbey at eighteen years of age, he must have learned the elements of his art before his fourteenth year, at which time Pelham Humphrey, brought up in the royal chapel under Capt. Cook, was appointed his successor, as master of the boys. Purcell certainly continued to sing in the king's chapel, and to receive lessons from Humphrey till his voice broke, an accident which usually happens to youth at sixteen or seventeen years of age: after this, perhaps, he had a few lessons in composition from Dr. Blow, which were sufficient to cancel all the instructions he had received from other masters, and to occasion the boast inscribed on the tomb-stone of Blow, that he had been

"Master to the famous Mr. Henry Purcell."

But there is nothing more common than this petit larceny among musicians: if the first master has drugged eight or ten years with a pupil of genius, and it is thought necessary, in compliance with fashion or caprice, that he should receive a few lessons from a second, he infantly arrogates to himself the whole honour, both of the talents and cultivation of his new scholar, and the first and chief instructor is left to fingo, sic vos non vocis.

Purcell is said to have profited so much from his first lessons and clope application, as to have composed, during the time of his being a finging boy in the chapel, many of his anthems, which have been constantly sung in our cathedrals ever since. Eighteen was a very early age for his being appointed organist; that is, maestro di capella of Westminster Abbey, one of the first cathedrals in the kingdom for choral compositions and performance. It was not likely he would stop here: the world is, perhaps, more partial to promising youth than accomplished age; and at twenty-four, in 1682, he was advanced to one of the three places of organist of the chapel royal, on the death of Edward Low, the successor of Dr. Christopher Gibbons, in the same station.
After this, he produced so many admirable compositions for the church and chapel of which he was organist, and where he was sure of having them better performed than elsewhere, that his fame was soon extended to the remotest parts of the kingdom.

From this time, his anthems were eagerly procured, and heard with pious rapture wherever they could be performed; nor was he further long to devote himself totally to the service of the church. He was, very early in life, solicited to compose for the stage, and chamber, in both which undertakings he was so superior to all his predecessors, that his compositions seemed to speak a new language; yet, however different from that to which the public had been long accustomed, it was universally understood. His songs seem to contain whatever the ear could then wish, or heart could feel.

We have been assured by a very good judge of music, who was nineteen years of age when Purcell died, and remembered not only his person very well, but the effect which his songs had on himself and the public at that time, when many of them were first heard; and used to say, that "no other vocal music was listened to with pleasure, for near thirty years after Purcell's death; when they gave way only to the favourite opera songs of Handel."

The unlimited powers of this musician's genius embraced every species of composition that was then known, with equal felicity. In writing for the church, whether he adhered to the elaborate and learned style of his great predecessors Tallis, Bird, and Gibbons, in which no instrument is employed but the organ, and the several parts are constantly moving in fugue, imitation, or plain counterpoint; or, giving way to feeling and imagination, adopted the new and more expressive style of which he was himself one of the principal inventors, accompanying the voice-parts with instruments, to enrich the harmony; and even the melody and meaning of the words, he manifested equal abilities and resources. In compositions for the theatre, though the colouring and effects of an orchestra were then but little known, yet as he employed them more than his predecessors, and gave to the voice a melody more intercelling and impassioned than, during the seventeenth century, had been heard in this country, or perhaps in Italy itself, he soon became the darling and delight of the nation. And in the several species of chamber music which he attempted, whether fantasias for instruments, or odes, cantatas, songs, ballads, and catches for the voice, he so far surpassed whatever our country had produced or imported before, that all other musical productions seem to have been instantly configned to contempt or oblivion.

As many of his numerous compositions for the church, particularly those printed in the second and third volumes of Dr. Boyce's Collection, are still retained in the king's chapel, and in our cathedrals, we shall here acquaint the musical reader in what manner we have been affected by some of these productions, in a late attentive perusal of them.

It appears by Dr. Bayley's "Collection of the Words of Anthems used in his Majesty's Chapel Royal," that ten of Purcell's are still performed there; and in the late Rev. Mr. Mafon's "Copious Collection of the Words of such Anthems as are used in the Cathedral of York," that nearly twenty of his choral compositions are still sung in that choir.

Purcell's four-part anthem, "O God, thou art my God," (Boyce's Collection, vol. ii. p. 148.) must certainly have been one of his juvenile productions, before he had sufficiently refined his ear, or exercised his judgment; as there are many crude harmonies, and false accents in it, which in riper years he would not have tolerated.

Of his six-part anthem, "O God thou hast called us out," the first movement, in which there are many bold harmonies, is extremely elaborate, yet spirited and pleasing. The verse, "O be thou our help," is not only full of new and fine effects, but touching. By those who object not to the confusion in the words which arises from fugue and imitation, while the several parts are singing different portions of the same sentence, at the same time, the words will appear perfectly well accented and expressed.

The first movement of his full anthem in eight parts, "O Lord God of hosts," is a noble composition, alla Pura_ lifrma, in which all the laws of fugue are observed, and sometimes more, subjects, are preferved inviolate; the harmony, though bold, is, in general, chaste, and the effect of the whole spirited and majestic. The second movement is extremely pathetic and expressive; but, both in that and the last movement, he seems trying experiments in harmony; and, in hazarding new combinations, he seems now and then to give the ear more pain than pleasure.

The two-part anthem, "Thy way, O God, is holy," continues to be excellent music still, in the flow movements; the quick, however, seems somewhat antiquated, and the melody to these words, "the air thunders," &c. seem too light and dramatic for the church at any period.

The three-part anthem, "Be merciful unto me, O God," is admirable throughout. Indeed, to our conceptions, there seems no better music existing, of the kind, than the opening of this anthem, in which the verse, "I will praise God," and the last movement, in C natural, are in melody, harmony, and modulation, truly divine music.

The complete service of Purcell, in B flat, printed by Boyce, is a most agreeable and excellent piece of counterpoint, of which the modulation frequently stimulates attention by unexpected transitons, yet so softly a kind as never to give the ear the least uneasiness, till we come to the bottom of p. 170, and then the fame crudities of the sharp 3d and flat 6th, and flat 3d, 4th, and 5th, which we have already conferved in the works of Mr. Blow; which we hope, in spite of our partiality for Purcell, the organists of our cathedrals confpire not to change for better harmony.

These two or three combinations, like some words and phrases which Shakspear tried unsuccessfully to render current, have been rejected by posterity; and it is in vain to attempt at forcing them upon the public by the mere weight of authority. The ear will patiently bear very rough usage from an artist who in general makes it such ample amends; however, there are limits, beyond which it is unsafe to excrete cruelty of all kinds; and the auricular sense will be deadened, disguised, or rendered indifferent to music's powers, by too harsh treatment.

The "Benedicium," as well as "Te Deum," and all the rest of the service, must be extremely pleasing, in all other respects, to every ear sensible to harmony. The words are, in general, accented with great accuracy (except the contracting high f into a monolyllable, to which only one note is given); and the few points of imitation are fragments of agreeable melody. In p. 121 of Boyce's, the A♭ and A♭, at the word befree, in the Kyrie, are peculiarly beautiful, as are the 3rd with the 6th at "before all worlds," in the creed, and the close at "whom all things were made." The point at "throughout all generations," in the Magnificat, is what the Italians call ten tirato, well-worked. In the last line, however, of page 122, so many exceptional combi-
nations occur, that we cannot pass them over without a digma. Yet, upon the whole, the abilities of Purcell, as a profound contrapuntist, appear perhaps more in the course of this service than elsewhere; as he has manifested deep study and meditation in a species of writing to which it was not likely that his creative and imaginative genius would submit, having had the patience, as well as abilities, to enrich it with no less than four different canons, of the most difficult construction, as of two, three, and four in one, by inversion.

The superior genius of Purcell can be fairly estimated only by those who make themselves acquainted with the state of music previous to the time in which he flourished; compared with which, his productions for the church, if not more learned, will be found infinitely more varied and expressive; and his secular compositions appear to have descended from another more happy region, with which neither his predecessors nor contemporaries had any communication.

Besides the whole service, with three full, and six verse anthems, in Dr. Boyce’s Collection, there are nine verse and full anthems, wholly different, still sung in the cathedral at York. And in Dr. Tudway’s Collection, Britis Mufeum, there are besides a whole service in B flat, different from that in Boyce, eight full and verse anthems, different from all the rest, four of which were composed for the chapel royal of Charles II., and are accompanied with instruments. And still, exclusive of these and the hymns printed in the two books of “Harmonia Sacra,” in a manuscript bequeathed to Chrift-church college, Oxon, by Dr. Aldrich, there are two motets, and a “Gloria Patri” for four and five voices, in Latin, with seven psalms and hymns for three and four voices, by our fertile and diligent composer, that have all their peculiar merit, but of which some may, without hyperbole, be said to reach the true sublime of sacred music.

To enter into a minute examination of these, and his admirable Te Deum and Jubilate, composed for St. Cecilia’s day, 1694, would extend this article to too great a length; though they merit much praise as well as critical remark; for which, on the Te Deum we refer our readers to the ample account of him and his works, in Burney’s History of Music, vol. iii.

Purcell’s theatrical compositions, if we collect the number and excellencies of his productions for the church, and the shortness of his life, will surprise by their multiplicity as well as singular merit. Of those dramas which are called operas, and of which music and decorations were the principal allurements held out to the public, a detailed account is given in speaking of the origin and progress of the musical drama in England, previous to the use of the Italian language, music, and performers on our lyric stage. (See Masques, and Matthew Locke.) And of Purcell’s detached and incidental songs, dialogues, and scenes that were performed at our national theatre, or playhouse, the principal will be mentioned in speaking of his “Orpheus Britannicus,” or posthumous collection of his miscellaneous compositions. But before we enter on an examination of this work, it seems necessary to acquaint the reader, that the chief part of his instrumental music for the playhouse is included in a publication that appeared two years after his decease, under the title of “A Collection of Ayres composed for the Theatre, and on other Occasions, by the late Mr. Henry Purcell.” London, printed for Frances Purcell, Executrix of the Author, 1697.” These airs are in four parts, for two violins, tenor and bass, and were played as overtures and aét-tunes in our own memory, till they were superseeded by Handel’s hautbois concertos, and those, by his overtures, while Boyce’s sonatas, and Arne’s compositions, served as aét-tunes. In process of time these were supplanted by Martini’s concertos and sonatas, which were thrown aside for the symphonies of Van Maldere, and sonatas of the elder Stamitz. About this time, the trios of Campioni, Zanetti, and Abel, came into play, and then the symphonies of Stamitz, Canabich, Holtzbauder, and other Germans, with those of Bach, Abel, and Giardini; which, having done their duty many years very pleasantly, “slept with their fathers;” and at present give way to Vanhall, Boccherini, Haydn, and Pleyel. “Sic transit gloria mundi corum!”

Purcell seems to have composed introductory and aét-tunes to most of the plays that were brought on the stage during his time. The publication of these, in four parts, contains his music to the following dramas:

“Abelazer,” 1677. The music of this consists of an overture, and eight airs or tunes.

“The Infamy Queen.” The first movement of this overture is equal to any of Handel’s. There are likewise two or three trumpet-tunes, well calculated for the instrument, and a rondcado at the end, which would now seem new, if played in a concert by a good hand.

“Dioclesian, or the Prophets,” 1690. The instrumental music of this English opera given here, consists of an overture of two movements, the first excellent in the style of Luilli, and afterwards of Handel, with better fugues; prelude, accompaniment to a song, trumpet-tune, air, hornpipe, country-dance, and canaries.

“Amphitrition,” 1691. Overture and eight tunes.

“Gordian Knot untied,” 1691. Overture and seven tunes.

“Dilfressed Innocence, or the Princess of Persia,” 1691. Overture and seven tunes, all proofs of the author’s original genius.

“The Fairy Queen,” 1692. Two overtures and sixteen tunes of different kinds. No 1, an air, 4 in 2, is a very curious canon on two subjects; the first treble and bass performing one, and the second and tenor the other. There is as much accent and spirit in this composition, as if it were in free counterpoint.

“The Old Bachelor,” 1693. Overture and eight tunes.

“The Married Beau,” 1694. Overture and eight tunes, among which is a very agreeable air for the trumpet, a march, and a hornpipe, that are characteristic. This last is very much in the style of a Spanish fandango.

“Bondouca,” 1695. Overture and eight tunes, including “Britons strike home,” and “To arms,” in four parts.

These are the contents of this posthumous publication; but besides the music for these dramas, he composed overtures, aét-tunes, and songs, for “Timon of Athens,” 1678; for “Theodorus, or the Force of Love,” 1680; for Dryden’s “Tempest,” 1690; and for “Don Quixote,” 1694.

But few of Purcell’s single songs seem to have been printed during his life. He published the music to a masque sung in the tragedy of “Oedipus,” when it was revived in 1692. And “a musical entertainment,” performed Nov. 22, 1684, on St. Cecilia’s day, printed in score by John Playford, with a dedication to the gentlemen of the musical society, and particularly the stewards, written by Henry Purcell, composer of the music.”

D 2
There are several of his songs in Playford's Collection, called "The Theatre of Music, 1687, fourth and last Book," and though these are not in his best manner, they are more original and interesting than the rest. Among these, p. 55, "A new song to a Scotch tune," by our author, feems to us more pleasing and lafs than any of the Scotch tunes, or imitation of the national melody of the northern inhabitants of this island, that has been fine produced.

Page 62 of the same Collection, there is an admirable piece of recitative, in a truly grand style: "Amidst the shades," &c. But the collection of his peculiar vocal music, which did him the greatest honour, and long rendered his name dear to the British nation, was published by his widow two years after his decease, by the title of "Orpheus Britannicus." Here were treasured up the songs from which the natives of this island received their first great delight and imprefion from the vocal music of a fingle voice. Before that period we had cultivated madrigals, and fongs in parts, with diligence and fuccefs; but in all fingle fongs, till those of Purcell appeared, the chief effects were produced from the words, not the melody. For the airs, till that time, were as unformed and mis-shaped, as if they had been made of notes scattered about by chance, instead of being call in an elegant mould. Exclusive admirers of modern symmetry and ealeance, may call Purcell's tale barbarous; yet in spite of superior cultivation and refinement, in spite of all the vicifitudes of fashion, through all his rudeufes and barbarism, original genius, feeling, and passion, are, and ever will be, discoverable in his works, by candid and competent judges of the art.

To this admirable collection are prefixed seven copies of verses to his memory, at the head of which is an ode, written on his death, by Dryden, which was set by Dr. Blow, and performed at the concert in York Buildings.

There are few songs in the "Orpheus Britannicus," but what contain some characterific marks of the author's great and original genius. The melody, however, will at first feem to many at present uncouth and antiquated; but by a little allowance and examination, any one pofteed of a great love for music, and a knowledge of our language, will feel, at certain places of almost every song, his unfuperior felicity and passion in expressing the poet's fentiments which he had to tranflate into melody.

The favourite songs with Purcell's admirers in our youth, were the following; and upon a late attentive perusal of the book, they feem to have meritcd particular diftinction. "Cela has a thousand charms": the firft movement of this, like many of Purcell's fongs, feems only reactiva graced, or embellifhed with the fashionable volute, or flourifher of the times, which are now as antiquated as the curls of his own perrue, or the farbells and flows of queen Elizabeth. The second movement, however, of this fong, is plainfiant and graceful; and at "I should my wretched, wretched, fate deplore," is still new and pathetic.

"You twice ten hundred duties," opens with what feems to us the bleft piece of reactiva in our language. The words are admirably effracted throughout this fong, by modulation as well as melody. And there is a proprity in the changes of movement, which does honour to Purcell's judgment, as much as the whole composition to his genius. The change of style and sluggish motion given to the notes at these words, "from thy fleeping mantie rife," is a model of musical imitation and expression. The modulation is flill fo excellent, that the best modern mafters are obliged to adopt it on many of its great occasions.

Of the music to "King Arthur" we fhall say but little, as it has been lately revived, well performed, and printed. If ever it could be faid with truth of a compofitor, that he has deve\ nce fe\ ce, outstrip his age, Purcell is entitled to that praise; as there are movements in many of his works which a century has not injured, particularly the duet in King Arthur, "Two daughters of this aged stream," and "Fairest isles all isles excelling," which contain not a fingle passage that the bleft compofers of the preient times, if it prefted itself to their imagination, would reject. The dialogue in the "Prophetefi," "Tell me why, my charming fair," is the moft pleasur and ingenious of all the compositions of the kind which the rage of fashion produced during the five epoches. The firft part of "O lead me to some peaceful gloom," is truly elegant and pathetic." From rose bow's," is faid to have been set in his lail sicknels, at which time he feems to have realized the poetical fable of the fwan, and to have lung more fweetly as he approached nearer his dilfolution; for it feems to us as if no one of his productions was fo elevated, fo pleasing, fo expressive, and throughout fo perfect, as this. The variety of movement, the artiful, yet touching modulation, and, above all, the exquisite expreffion of the words, render it one of the moft affecting compositions extant to every Englishman who regards music not merely as an agreeable arrangement and combination of sounds, but as the vehicle of sentiment, and voice of passion.

There is more elegant melody, more elaborate harmony, more ingenious contrivance, in the motion and contexture of the several parts than in the works of many great compofers; but to the natives of England, who know the full power of our language, and feel the force, spirit, and shades of meaning, which every word bears according to its place in a fentence, and the situation of the speaker, or finger, we must again repeat it, this composition will have charms and effects, which, perhaps, Purcell's music only can produce.

"When Mira sings," is a duet that will ever be captivating, as long as the words remain intelligible; of which he has augmented the force, particularly at the end, by notes the moft felect and expressive that the musical scale can furnish.

"Loft is my quiet," another duet, which fills lives. And "Celebrate this festival," a birth-day fong for queen Mary, which is graceful and pleasing through all its old-fashioned thoughts and embellishments. "I'll fall upon the dog-star," has all the fire of Handel's prime.

"Mad Befs" is a fong, or rather a cantata so celebrated, that it needs no panegyric, or renewal of public attention, as every captivating English singer in our memory has revived its favour. The firit Mrs. Sheridan and Mrs. Bates never gave more exquisite delight by their admirable performance, than when they regarded their friends with this song. Beard, forty years ago, used to acquire great applause by finging Purcell's "Rody Bowes;" and Pafi, by her performance of "Mad Befs," in the concerts at Hichford's rooms, the Caflc, and Swan concerts, where Stanley was justly admired for his ingenious and masterly manner of accompanying them. "The Nature's Voice," is an enigmatic fong, seemingly on nature, in which Purcell has crowded all the fashionable passages of taste and vocal difficulties of the times. Indeed, he feems to have anticipated many fantastical feats of execution and articulation in which great performers have since raved; and this is the more wonderful, as the Italian opera was not eftahlished, or even attempted here, during the life of Purcell; whose decease preceded the arrival of Valentiini and Niccoli, the first great fingers imported from Italy, at leaft ten years.
"Blow, Boreas, blow," was in great favour, during our youth, among the early admirers of Purcell; but this seems now more superseded than any of his popular songs.

"Let Caesar and Urania live," was a duet in a birdbath ode, during the reign of King William and Queen Mary, which continued so long in favour, not only while those sovereigns jointly wielded the sceptre, but even when George III. had left his royal comfort, and there ceased to be a queen, or Urania, for whom to offer up prayers, that Dr. Green, and afterwards Dr. Boyce, used frequently to introduce it into their own and the laureate's new odes. This duet, like many other productions of Purcell, was built on a ground-bafe of only two bars, which are invariably repeated to different passages of the voice-parts that are in harmony with it, throughout the movement. The latter part of this duet is extremely beautiful, and does not seem at all to have suffered from the voluntary restraint under which the composer laboured.

The composing fongs on a ground-bafe, was an exercise of ingenuity, in which Purcell seems to have much delighted; but though it was as much a fashion in his time, as the composing madrigals on the subject of old tunes in the days of Jefquin, and variations upon those tunes in the days of Bird and Dr. Bull, in which they all manifested superior abilities, yet the practice was Gothic, and an unworthy employment for men poifelled of such genius and original resources. The Italians started this, as well as most other musical fashions; for it appears by the works of Tranquillo Merula, published 1635, that writing upon a ground-bafe was a favourite occupation with that capricious composer, as well as our ingenious countryman.

Judges of musical design, modulation, and expression, will meet with many places to admire in songs that have never been popular, yet have local beauties, and mark the superior powers of the composer; particularly in the "Signs for the death of King Charles II." In the "Dialogue in tyrannic Love," p. 158, there is a passage upon which the late Mr. Bach has constructed a favourite movement in one of his Quartets concertati.

"I attempt from love's sickness," is an elegant little ballad, which, though it has been many years dead, would soon be recalled into existence and fashion, by the voice of some favourite finger, who should think it worth animation.

"Let the dreadful engines!" this is the last song in the first volume of the "Orpheus Britannicus," of which, though both the words and music of the first movement are wild and bombast, yet the second and last differ o more for the graceful comic, as well as the tender and sublime fable of composition; and there are several passages in this cantata sufficiently gay and new for a modern burletta.

In 1702, a second, and more correct, edition, of the first volume of this work was published, with more than thirty songs that were not in the first impression; but, in order to make room for which, some of the former were excluded.

The fame year was likewise published a second volume of "Orpheus Britannicus," by Henry Playford, which he dedicated to the earl of Halifax. The song of this second volume, p. 4, beginning, "Ah! cruel nymph!" has great ingenuity in the first movement, and grace in the second. And the next air, "Crown the altar," seems the most pleasing of any that he has composed on a ground-bafe. "May the god of wit inflire," for three voices, is natural and pleasing, and the echo in the second part are very ingeniously contrived.

"Thus the gloomy world," accompanied with the trumpet, and violin alternately, is masterly, and well designed to display the truest and most brilliant tones of the trumpet, though but little is given to the violin, which so much better deferves employment, than an instrument of such false intonation as the trumpet.

Those that can relish good music of every age and country, and have no exclusive partiality to individuals of either, will find amusement in the performance or perusal of Purcell's "Four Seaons," in the "Fair Queen," which comprehend merit of various kinds.

"To arms, to arms," is an admirable military song, accompanied by a trumpet, which is so confined an instrument, that nearly the fame passages must be used in all ages, so that time has robbed this song of but little of its novelty. Indeed, the divisions of this air have been revived of late years, and are now as fashionable, in frivolous and unmeaning melody, as ever.

There are many excellent fongs in this volume; however, these and their peculiar beauties we must pass over, or our commentary will encroach too much on the limits of our biographical articles, as well as on the time and patience of those readers to whom the name and productions of our British Orpheus are alike unknown or indifferent. Yet we must observe, that there is a composition in Purcell's "Bac-
ducea," in which he has anticipated a species of dramatic music, which has been thought of late invention; the words are "Hear ye gods of Britain!" he has put in an accompanied recitative, a tempo, or aria parlante. The beginning, however, with the bass à pedale, has the true characteristic of recitative. Afterwards, when the bass is put in motion, the whole has the properties of an air, ingeniously and spirituallly accompanied by two violins and a base. Besides the true dramatic call of this composition, there are new harmonies hazarded, which we do not recollect having seen in anteror contrapuntials, at least of our own country.

We dare proceed no further in analyzing the works of our illustrious countryman, though it would afford us great pleasure, as we never look at them without seeing a merit very superior to that of any of his contemporaries out of Italy, and even there, only the vocal compositions of Carissimi and Stradella seem to surpass them in grace and elegance. Carissimi appears to have been his model in his bell recitatives, and Lulli in the world; and it is manifest that he was fond of Stradella's manner of writing, though he never pillaged his passages.

We must not quit his vocal music without an honourable and grateful memorial of his catches, rounds, and glees, of which the humour, ingenuity, and melody, were so congenial with the national taste, as to render them almost the sole productions of the facitious kind that were in general use for near four score years. And though the countenance and premiums bestowed of late years upon this species of composition, as well as modern refinements in melody and performance, have given birth to many glees, of a more elegant, graceful, and exalted kind, than any which Purcell produced; yet he seems hardly ever to have been equalled in the wit, pleafantry, and contrivance of his catches.

Of fifteen anthems, with symphonies and instrumental parts, with innumerable odes and miscellanies, we have room to say nothing, though much praise is due to many of them.

An abfund cufum prevailed in Purcell's time, which he carried to greater excels, perhaps, than any other composer, of repeating a word of one or two syllables an unlimited number of times, for the sake of the melody, and sometimes before the whole sentence has been heard. Such as no, no, no, —all, all, all, —pretty, pretty, pretty, &c. ad infinitum. But there is equal redundance and obscurity in the wfe which the Italians make at present of i, ii, iii, and ni, no, ni, in their fongs.

Purcell
PURCELL.

Purcell was so little acquainted with the unlimited power of the violin, that we have scarcely ever seen a becoming passage for that instrument in any one of his works; the symphonies and ricordanze to his anthems and songs being equally deficient in force, invention, and effect. And though his fantasias contain many ingenious, and, at the time they were composed, new traits of melody and modulation, if they are compared with the productions of his contemporaries, Corelli, they will be called barharous. But Corelli wrote for an instrument of which he was a great master: and who ever entirely succeeded in composing for one of which he was ignorant? When a great performer on keyed instruments confides to compose for the violin, upon which he has never been a good player, or the voice, without knowing in what good fingering conflits, the passages all come from the head, and none from the hand, except the hand of a harpichord player, which is ever unfit to suggest ideas either for a voice, or for any other instrument than his own. Such a composer for the violin must inevitably embarrass the player with perpetual awkwardnesses and difficulties without effect, which discover an utter ignorance of the finger-board.

If Purcell, by travelling, or by living longer at home, had heard the great instrumental performers, as well as great fingers, that arrived in this country soon after his decease, and had such to compose for, his productions would have been more regular, elegant, and graceful; and he would certainly have set English words better than it was possible for any composer to do, for our feelings, however great his genius, or excellent, in other respects, his productions. But Purcell, like his successor, Arne, and others who have composed for the playhouse, as always had an inferior band to the Italian opera composers, as well as inferior fingers, and an inferior audience to write for.

The diligent and candid Walcher, by not having afforded to Purcell a niche in his Musical Dictionary, feems never to have heard of his existence; but Purcell was so truly a national composer, that his name was not likely to be wafted to the continent; and the narrow limits of his fame may be fairly ascribed, not only to the paucity and poverty of his compositions for instruments, for which the musical productions are an intelligible language to every country, but to his vocal compositions being solely adapted to English words, which render it unlikely for their influence to extend beyond the foil that produced them.

We should, however, have known as little of Lulli, as the French or Italians of Purcell, but for the partiality which Charles II. acquired, by his long residence on the continent, for the arts and amusements of France. The first attempts at operas here, after the Restoration, were either in French, or on the model of those that were then in high favour at Versailles. And whoever is equally acquainted with the recitative, we had almost said the general melody of Lulli and Purcell, must perceive a strong resemblance. Purcell, however, having infinitely more fancy, and, indeed, harmonical resources, than the Frenchified Tufani, his productions now afford far greater pleasure and amuse- ment to a liberal lover of music, than can be found, not only in the productions of Cambert and Grub, whom Charles II. and to flatter his majesty, Dryden, patronized in preference to Purcell, but in all the noisy monotony of the rhapsodist of Quinault.

Let those who shall think Purcell has sacrificed the national honour by confounding his reverence for the productions of Italy, compare the peculiar productions of English musicians, from the death of queen Elizabeth to the year 1683, with those of Carissimi, Cesti, Stradella, and innumerable others of great abilities, and if they do not equally hate music and truth, they will admire Purcell's probity, as well as his genius.

Indeed, music was manifestly on the decline, in England, during the seventeenth century, till it was revived and invigorated by Purcell, whose genius, though less cultivated and polished, was equal to that of the greatest masters on the continent. And though his dramatic style and recitative were formed in a great measure on French models, there is a latent power and force in his expression of English words, whatever be the subject, that will make an unprejudiced native of this island feel, more than all the elegance, grace, and refinement of modern music if happily applied, can do. And this pleasure is communicative to us, not by the symmetry or rhythm of modern melody, but by his having fortified, lengthened, and tuned, the true accents of our mother-tongue; those notes of passion, which an inhabitant of this island would breathe, in such situations as the words he has to set deliberate. And these indigenous expressions of passion Purcell had the power to enforce by the energy of modulation, which, on some occasions, was bold, affecting, and sublime.

These remarks are addressed to none but Englishmen: for the expression of words can be felt only by the natives of any country, who seldom extend their admiration of foreign vocal music, farther than to the general effect of its melody and harmony on the ear; nor has it any other advantage over instrumental, than that of being executed by the human voice, like fallegri. And if the Italians themselves did not come hither to give us the true expression of their songs, we should never discover it by study and practice.

It has been extremely unfortunate for our national taste and our national honour, that Orlando Gibbons, Pelham Humphrey, and Henry Purcell, our three best composers during the last century, were not blest with sufficient longevity for their genius to expand in all its branches, or to form a school, which would have enabled us to proceed in the cultivation of music without foreign assistance.

Orlando Gibbons died 1625, at forty-four.
Pelham Humphrey died 1674, at twenty-seven.
And Henry Purcell died 1695, at thirty-seven.

If these admirable composers had been blest with long life, we might have had a music of our own, at least as good as that of France or Germany; which, without the assistance of the Italians, has long been admired and preferred to all others by the natives at large, though their princes have ufually foreigners in their service. As it is, we have no school for composition, no well-digested method of study, nor, indeed, models of our own. Instrumental music, therefore, has never gained much by our own abilities; for though some natives of England have had hands sufficient to execute the productions of the greatest masters on the continent, they have produced but little of their own that has been much esteemed. Handel's compositions for the organ and harpsichord, with those of Scarlatti and Alberti, were our chief practice and delight for more than fifty years; while those of Corelli, Geminiani, Albinoni, Vivaldi, Teffarin, Vercini, and Tartini, till the arrival of Giardini, supplied all our wants on the violin, during a still longer period. And as for the hautbois, Martinu and Fisler, with their scholars and imitators, are all that we have listened to with pleasure.

If a parallel were to be drawn between Purcell and any popular composer of a different country, reasons might be assigned for supposing him superior to every great and favourite contemporary musician in Europe.

Carissimi and Stradella, if more polished in their style, were certainly less varied, and knew still less of instruments, than
than our countryman. They had both, perhaps, more grace and regularity, but infinitely less passion and fire.

The elder Scarlatti was more rieberché and learned, but never so natural and effecting.

In Germany, if Keifer, during an active and much longer life, surpassed him in the number and excellence of his dramatic compositions, his productions for the church, could they be found, would, we believe, bear no comparison.

Lulli, both in his manner and in his productions, composed also more operas than Purcell, and was the idol of the nation for which he laboured; but though his overtures long served as models, even to Purcell, as well as to the composers of all the rest of Europe, and his music was performed by better fingers, and a more numerous band, supported by the patronage of a court, and all the splendour of ingenious and costly exhibition; it is easy to see that even his theatrical works are more monstrosities, monotonous, and uninteresting in themselves, than those of Purcell; but in relinquishing the stage, and stepping on holy ground, we should have found, even in France, during all his glory, and the enthusiasm he raised, none of his votaries who would attempt to put his sacred music in comparison with that of our countryman.

Rameau, the successor of Lulli in court and popular favour, and who had more learning and theoretical knowledge in the art, than perhaps any practical musician of modern times; yet, in pathos and expression of words and the passions, he was Purcell's inferior, even upon the stage; and in the church, he had no claim to celebrity.

Handel, who flourished in a less barbarous age for his art, has been acknowledged his superior in many particulars; but in none more than the art and grandeur of his choruses, the harmony and texture of his organ fugues, as well as his great style of playing that instrument; the majesty of his hautbois and grand concertos, the ingenuity of the accompaniments to his songs and choruses, and even in the general melody of the airs themselves; yet in the accent, passion, and expression of English words, the vocal music of Purcell is, sometimes to our feelings, as superior to Handel's as an original poem to a translation.

PURCHASE, Samuel, was born at Thaxted, in Essex, in 1577. He was educated at Cambridge, and was presented to a vicarage in his native county. This cure he resigned to his brother, and came to live in London, for the purpose of conducting the great work he had undertaken. The first volume folio appeared in 1613, under the title of "Purchas his Pilgrimage, or Relations of the World and the Religions observed in All Ages and Places discovered from the Creation unto this Present!" The other four volumes were published in 1625. To these the general title is "Hakluytus Posthumus, or Purchas his Pilgrims: containing a History of the World in Sea-voyages and Land-travels by Englishmen and others!" The name of Hakluyt is introduced, because Purchas became possessed of the papers which he left behind him. This great work, of which the object is to connect ancient and modern history, was well received, but probably involved the author in debt. He had been collated to the rectory of St. Martin's Ludgate, and was chaplain to Abbot, archbishop of Canterbury. He died about the year 1628, at the age of fifty-one. Biog. Brit.

PURCHASE, in Law, in its largest and most extensive sense, is defined by Littleton to be the possession of lands and tenements, which a man hath by his own act or agreement, and not by descent from any of his ancestors or kinred. In this sense, it is contradistinguished from acquisition by right of blood, and includes every other method of coming to an estate, but merely that by inheritance; in which the title is vested in a person, not by his own act or agreement, but by the single operation of law. (Co. Litt. 18.) Purchase, in its vulgar and confined acceptance, is applied only to the acquisition of goods, lands, tenements, or the like, by means of money, or some other valuable consideration.

What we call purchase, perquisitio, the feudists call conquest, conquenus, or conquerito (see Conquest); both denoting any means of acquiring an estate out of the common course of inheritance; and this is still the proper phrase in the law of Scotland. The difference, in effect, between the acquisition of an estate by descent and by purchase, consists principally in these two points.

1. That by purchase the estate acquires a new inheritable quality, and is descendible to the owner's blood in general, and not the blood only of some particular ancestor.

2. An estate taken by purchase will not make the heir answerable for the acts of the ancestor, as an estate by descent will. According to this legal significication of the word perquisitio, or purchase, it includes the five following methods of acquiring a title to estates, viz. escheat, occupancy, prerogation, forfeiture, and alienation, conveyance, or purchase, in its limited sense: under which latter head may be comprised any method in which estates are voluntarily resigned by one man, and accepted by another: whether that be effected by sale, gift, marriage-fettlement, devise, or other transmission of property, by the mutual consent of the parties. See the several articles, and Title.

Natural persons, incorporate persons, sole or aggregate, deaf, dumb, and blind persons, minors, and all reasonable creatures, may purchase, except in some cases; but some have capacity to purchase, and not to hold, as aliens, felons, &c.; and others have ability to hold or not to hold upon a purchase, at the election of themselves or others, as infants, and feme covertis. 1 Inft. 2, 3. 11 Rep. 77. 7 Rep. 17.

PURCHASE and value of land. See Valuation of Land, and Political Economy.

PURCHASE of rents. See Writt.

PURCHASE, in the Sea Language, has the same significication with draw in, at land. Thus, they say, the caplern purchaes space, i. e. draws in the cable space; and when they cannot draw or hale anything in with the tackle, they say, the tackle will not purchase.

PURCHASE is also a name given by sailors to any mechanical power employed in raising or removing heavy bodies, or in fixing or extending the ship's rigging. Such are the tackles, windlasses, caplerns, fcrews, and handspikes.

PURCHASE-Book, among Traders, is the name given to a book, which is a kind of journal, containing an account of all the purchases made, or things bought in the day.

PURCHASER, First, Perquisitor, in Law, denotes the person who first acquired an estate to his family, whether the same was transferred to him by sale or by gift, or by any other method, except only that of descent. See Descent.

PURCHASING of Estates, in Agriculture, the busineses of buying landed property. In order to perform this sort of bargain with propriety, and to the best advantage, attention is necessary to be had to a great variety of circumstances of different kinds, which respect the nature, quality, situation, condition, value, and conveniences of the property. See Valuation of Land.

But it is probably best done, when to any extent, by a surveyor or other person who is perfectly conversant with the nature of the busineses, and fully acquainted with the real
real value of landed property in the district where the purchase may be situated or met with.

It has been observed by Mr. Marshall, that there are two methods of making bargains of this kind, the one by public biddings, the other by private treaty or contract: in either of which, a certain degree of caution is common prudence. In the former, however, the conditions being fixed, an accurate valuation is the best safeguard; and, in the latter, among honest men little more is required.

In purchasing by private contract, the particulars which may be previously required to be furnished by the seller, are the quantities of the several pieces of the lands which are on fale, together with the maps, or rough drafts, of the same; the tenure under which they are held; some assurance as to the title of the seller; and his right of alienation; the tenancy under which the several farms are let; and, if on lives, the ages of the nominees; if for a term of years, the number which are unexpired; if at will, the notice with which the tenants have been served, if any have been given.

An abstract of the covenants under which they are let; particularly of those which relate to taxes and repairs, to the expenditure of produce, to the ploughing of grass-lands, &c. &c.

The existing rents and profits receivable; whether for tenanted lands, appurtenances, or abstract rights; with the estimated value of the demesne, and the woodlands in hand; together with the estimated value of the timber growing upon the estate on fale; as well as of the minerals and soils which it may contain.

The outgoings to which the estate is liable; the proposed time of the delivery of possession; the price and the mode of payment which are expected.

And next, it will be proper to let down the particulars of the instructions to be given to a surveyor, or other valuer, of the estate to be purchased. It will be right, however, to premise, that much, in this respect, depends on the probability of purchasing; and on the time which is allowed for making the estimate. In cases of fale by public auction, when there can be no certainty as to purchase, and where the time for valuation is limited, a rough estimate of each farm, and a general idea of the value of the timber and other appurtenances, may be all that can be prudently ascertained. But in a fale by private contract, where the refusal of an estate is granted, and time allowed for deliberation, a more minute investigation may be proper; especially where there is every reason to believe that a bargain will take place. For the fame report will not only serve as a guide to the purchaser, but will become a valuable foundation, on which to ground the future management of the estate. And for these and other reasons, a purchase by private contract is most to be desired by one who is not in the habit of personally attending public sales, and is unacquainted with the business of an auction room.

It may be noticed, that the particulars to be required from a surveyor, or surveyors, in these cases, are principally these: the rental value of each field or parcel of land, with the rate at which it lies, as to arable, meadow, pasture, or woodland; the value of the timber and other appurtenances: the characteristic, and the state of management of each farm or tenement, with the eligibility of the occupier; together with the state of repair of buildings, gates, fences, water-courses, and roads, the amount of the encumbrances and outgoings. And, lastly, the probable value of the improvements of which the estate may appear to be capable; whether by the several means that are commonly practised, or by new regulations and improved modes of agricultural management, that may admit of being introduced.

It is added, that these several particulars of information being procured, the subjects of treaty are few. The two statements having been duly compared, so that no misunderstanding can take place between the parties, the price, and the times and mode of payment, are the principal matters of agreement. A clear understanding respecting the custody of title deeds and the expences of conveyance, require, however, to be enumerated among the preliminaries of purchase.

In these transactions, it is also supposed, the business of negotiation is best carried on by letters, which become vouchers of facts. Whatever is done by interview, requires to be reduced to writing, and to be read by or to the parties before they separate, that no possibility of misconception may arise. And, added to these precautions, it is proper in large purchases, and when abstractions of intricate title deeds are to be made out, and examined, that a legal contract or memorandum of agreement should be entered into, for the mutual satisfaction and surety of the parties. This contract and the deed of conveyance, which is the instrument which is legally to transfer the property from the seller to the purchaser, may be said to conclude and ratify the business of purchase. And in this part of it, legal assent is essentially necessary; to examine existing deeds, and see that the seller has a legal right and clear title to the land, and a legal power to dispose of it; as well as to draw up or examine the fresh deed of conveyance, and see that it is sufficient to transfer the property legally and adequately to the purchaser.

PURCHASE, in Geography, a town of Spain, in the province of Andalusia; 60 miles N. of Grenada. N. lat. 37° 18'. W. long. 2° 30'.

PURE, something free from any admixture of foreign or heterogenous matters.

PURE Fire. See Fire.

PURE Hyperbola, in Conics, is an hyperbola without any oval, node, or conjugate point. See CURVE.

PURE Mathematics. See Mathematics.

PURE Proposition. See Proposition.

PURE Quadratics. See Quadratic.

PURE Refinements. See Resignation.

PURE Villages. See Villages.

PURE, or PURAN, in Geography, a town of Chili; 80 miles S.S.E. of La Conception.

PURBRAY, a town of Hindoostan, in Oude; 10 miles N. of Baharit.

PUREG, anciently Pura, once the capital of Gedroia (Mekran), and termination of the toilsome march of Alexander towards the frontiers of Caramania, is now a mean village.

PUREDRA, in Mythology, a name of Indra, the Hindoo regent of the firmament. (See INDRA.) The word is said to mean deputy of town, the Indian Jupiter having, in revenge for sacrificial flights or negligences, frequently, according to the Hindoo books, assumed that character. The ancient city of Ugeen, the capital of Malwa, was, according to tradition, destroyed by Indra. See UGEEN.

PURESIL, in Geography, a town of Hindoostan, in the ciear of Cicaco, 40 miles N.W. of Vizianagram.

PURETTA, a name given by some writers to the common shining black sand, used to throw over writing, and erroneously called by some steel-dust.

It is a natural mineral substance, found on the shores near Genoa, and in other places.
PURFLED, ornamental work, whether in stone or other materials, representing embroidery or lace work.

PURFLEW, a term in Heraldry, expressing eminences, peans, or any of the furs, when they compose a border found a coat of arms.

Thus they fay, heareth gules a border, purflew, vairly; meaning, that the border is vairly.

PURG, or FORG, in Geography, a town of Persia, in the province of Laristan; 60 miles N.E. of Lar. Lat. 28° 30'. E. long. 54° 40'.

Purgation, Purgatio, the act of purging, scouring, or purifying any thing, by separating and carrying off any impurities found therein.

Purgation, in Pharmacy, is the cleansing of a medicine by retrenching its superfluities; as taking the wood and seeds out of caffia, and the stones out of dates, tamarinds, and other fruits.

Purgation is also used, in Chemistry, for several preparations of metals and minerals, intended to clear them of their impurities; more usually called purification and refining.

The ordinary purgation of mercury is performed, by passing it through a chamois skin. (See Mercury.) Gold is purged by the coppel, cementation, &c. See Gold, Coppel, &c.

Purification, in other metals, is performed by repeated fusion, &c.

Purgation, Cathartia, in Medicine, the evacuation of the alimentary canal of its fecal contents, by means of substances which ferment its fibres, and excite them to a more active peristaltic motion. Purgation is also sometimes carried farther, and, by causing a copious discharge of fluids from the exhalent vesicles of the inner surface of the bowels, produces a considerable evacuation from the system at large. For an elucidation of the doctrine of purgation, see Cathartic.

Purification, in Law, is the clearing one self's of a crime, whereof publicly suspected or accused before a judge, called also judicium Dei.

Of these purgations there was anciently much use in England, especially touching matters of felony charged on clerks; and there is something of them still retained in the ecclesiastical court on suspicion of incontinency, &c.

Purification is either canonical or vulgar.

Purgation, Canonical, is that prescribed in the canon law, the form of which, obtaining in the spiritual court, is, that the party suspected shall take his oath that he is clear of the fault objected against him; and bring so many of his honest neighbours, not above twelve, as the court shall affign him, to swear, on their confidences, that they believe he swears truly.

The canonical doctrine of purgation, whereby the parties were obliged to answer upon oath to any matter, however criminal, that might be objected against them, continued till the middle of the 17th century to be upheld by the spiritual courts; when the legislator was obliged to interpose, to teach them a lesson of similar moderateness. By the statute of 15 Car. II. cap. 12. it is enacted, that it shall not be lawful for any bishop, or ecclesiastical judge, to tender or administer to any person whatsoever, the oath usually called the oath ex officio, or any other oath whereby he may be compelled to confess, accuse, or purge himself of any criminal matter or thing, whereby he may be liable to any censure or punishment. But this doth not extend to oaths in a civil suit; and, therefore, it is still the practice both in the spiritual courts, and in equity, to demand the personal answer of the party himself upon oath. Yet if in the bill any question be put, that tends to the discovery of any crime, the defendant may thereupon demur, and refuse to answer. Anciently, upon the allowance of the benefit of clergy, the person accused was delivered to the ordinary, to make his purgation, which was to be before a jury of twelve clerks, by his own oath affirming his innocence, and the oaths of twelve compurgators as to their belief of it. But now, by the Stat. 18 Eliz. cap. 7. this kind of purgation is also taken away; and the person admitted to his clergy shall not be delivered to the ordinary.

Purgation, Vulgar, being the most ancient manner, was by fire, or water, or combat: used by infidels, and by Christians too, till abolished by the canon law. See Ordeal, and Corned.

Combat, though now disused, may yet be still practiced by the laws of the realm, in cases where evidence is wanting, and where the defendant rather chooses combat than any other trial. See Combat.

Terris bonis, &c. redhabendis post Purgationem. See Terris.

Purgation, in Rhetoric, is used for that kind of defence which takes place when the accused person owns the fact, but denies that he did it with design, or with any bad intention.

Purgation, in Tragedy, is a term which Aristotle uses for the effect of tragedy on the mind.

That philosopher observes, that tragedy, by means of the terror and compulsion which it excites, purges passions out of the soul.

Indeed, Corneille adds, that tragedy frequently creates passions, instead of purging them; so that he takes Aristotle's purgation to be no more than a chimera.

Purifications, Menstrual, the cutamania or menes of women.

Purgative, or Purging-Medicine, a medicament, which evacuates the contents of the bowels by stool. See Cathartic.

Purgatory, Purgatorium, in the Romish church, a place where the just are supposed to suffer the pains due to their sins, for which they have not satisfied in this world.

It is by the mercy of God, the indulgences of the church, and the prayers of the faithful, that people are supposed to be delivered out of purgatory.

This doctrine of purgatory, which some derive from the Platonic fancies of Origen, the Montanists of Tertullian, pretended visionaries, and pagan stories, rhetorical flourishes, and doubtful expressions of the later fathers, and in which we may discern an obvious resemblance to the famous pagan doctrine, concerning the purification of departed souls by means of a certain kind of fire, was partly introduced, at least in the spirit of it, towards the close of the fifth century, and by Gregory the Great in the sixth century; but it was not, however, positively affirmed till about the year 1140, nor made an article of faith till the council of Trent. See Papists and Popery.

In Ireland is a place called "St. Patrick's purgatory," where, as the legend has it, at the prayers of St. Patrick, bishop of the place, there was made a visible representation of the pains which the wicked undergo after death, in order to deter sinners, &c.

Purgatity, in Geography, a town of Hindoosfan, in the circuit of Cicecole; 40 miles N.W. from Vizniagram.

Purge, in Medicine, a term frequently used for a dose of some purgative medicine.

Purging Ale, Butler's. See Ale.

Purging Grain, Oily, in Botany. See Sesamum.

Purging Nut, in Botany. See Jatropha.

Purging Thorn. See Buckthorn.

E. Purglitz.
PURGLITZ, or KRESSEN, in Geography, a citadel of Bohemia, in the circle of Rakonitz, where the royal treasures were anciently kept, and state prisoners confined; seven miles S.E. of Rakonitz.

PURGOT, a town of Hindooftan, in Coimbetore; 35 miles W. of Arcodelle.

PURGOW, a town of Hindooftan, in Bagiana; 25 miles E.N.E. of Balleen.

PURGSTALL, a town of Austria; four miles N. of Scheibis.

PURIFICATION, in Chemistry, &c. the act of purifying or refining natural bodies; or of separating the faces and impurities from them.

For the methods of purifying metals, gold, silver, iron, copper, tin, &c. see Gold, Silver, &c. and Refining.

For the purification of semi-metals, minerals, and other matters, as antimony, sulphur, camphor, saltpetre, &c. see Antimony, Sulphur, Camphor, &c.

Purification, in Pharmacy. See TRYING.

Purification, in Matters of Religion, denotes an offering made the priest by women riling out of child-bed, before they are re-admitted into the church.

By the law of Moses, a woman, after bringing forth a male child, was unclean forty days; after a female, eighty days; during which time, she was not to touch any thing holy, nor to go near the temple, but was to continue within doors, separate from all company, and commerce of others.

This term expired, she was to present herself at the temple, and at the door of the tabernacle, to offer a lamb, as an holocaust, and a pigeon or turtle; which the priest taking, offered to God, and prayed for her, that she might be purified.

This ceremony, which consisted of two things, an holocaust, and a sacrifice of expiation, was called פָּרָשׁוֹת הָרִם הַנִּנְיָא, purification, purgatio.

The holy Virgin, though, according to the fathers, exempt from the terms of the law, yet complied with it, and, at the time prescribed, went to the temple, and accomplished the law; in commemoration of which the church yearly solemnizes the feast of the Purification of the Virgin, on the second of February; called also the Feast of Candlemas.

Purification, The Feast of the, seems to be very ancient. It is ordinarily said to have been instituted in the time of Julian, in the year 342, and this on occasion of a mortality, which that year depopulated almost the whole city of Constantinople. Yet there are some, who imagine it to have been observed before, though in another manner, and on a different day from that fixed by Julian; viz. between the Circumcision and Epiphany. See CANDLES.

The same day is the presentation of our Saviour in the temple.

Purification, in Geography, a town of Mexico, in the province of Xalisco; eight miles S. of Compostella Nuova. N. lat. 19° 58'. W. long. 105° 46'.

PURIM, a solemn feast held among the Jews on the fourteenth and fifteenth of March, in memory of their deliverance from the conspiracy of Haman by Esther. See Esther.

This feast, which derives its name from the Persian word purim, q. d. lots, because it was by the casting of lots that Haman determined this time for the destruction of the Jews, is the Bacchanals of these people, which they celebrate with all manner of rejoicing, mirth, and jollity; indulging themselves with every kind of luxury, especially in drinking wine even to drunkenness, which they consider as part of the duty of the solemnity; because it was by means of the wine banquet (they say) that Esther made the king's heart merry, and brought him into that good humour, which inclined him to grant the request presented by her for their deliverance; and, therefore, they think they ought also to make their hearts merry, when they celebrate the commemoration of it. During this festival the book of Esther is solemnly read in all their synagogues from the beginning to the end, at which they are all to be present, men, women, children, and servants, because all shared in the benefit of the deliverance which Esther obtained for them. And as often as the name of Haman occurs in the reading of this book, the custom is for all to clap with their hands, and stamp with their feet, and cry out, Let his memory perish. Prideaux's Conn. vol. ii. p. 456.

PURITANS, in Ecclesiastical History. See Cathars and Novatians.

Puritans is also a term anciently used for the Calvinists of Great Britain, from their professing to follow the pure word of God, in opposition to all traditions, human constitutions, and other authorities.

The separation, whence this distinguishing appellation took its rise, commenced on the following occasion. Upon the accession of queen Mary, it was well known, that popery revived in this kingdom; the flatters of king Edward were repealed, and the penal laws against heretics were put in execution against the reformers. Many suffered at home; and others escaped the fury of persecution by seeking refuge in foreign countries. Some went to France and Flanders; some to Geneva; and others into those parts of Germany and Switzerland, where the reformation had taken place, and where the magistrates received them with great humanity, and allowed them places for public worship. The exiles were most numerous at Frankfort; and there that contest and division began, which gave rise to the Puritans, and to that separation from the church of England, which continues to this day. In the year 1554, some of the English fugitives settled in this city; and agreed to conduct their worship, without answering aloud after the minister, and without using the liturgy and surplice; to begin the public service with a general confession of sins, then to sing a psalm, after which the minister prayed for the divine affiaince, and next proceeded to the sermon; after sermon, a general prayer for all estates, and particularly for England, at the end of which was subjoined the Lord's prayer, and a rehearal of the articles of belief; then the people were to sing another psalm, and the minister to dismiss them with a blessing. Such was the order which they had unanimously adopted; and having chosen a minister and deacons, they invited their dispersed brethren to join with them. In the year 1556, Dr. Cox, afterwards bishop of Ely, came to settle at Frankfort with several of his friends; who interrupting the public service by answering aloud after the minister, and reading the whole litany, in violation of the agreement upon which the congregation was formed, overpowered the first settlers; and obtaining leave of the magistrates for the free use of king Edward's service-book, performed divine worship according to the rites that had been authorized by that prince; while others, who preferred the Genevan method of worship, as more pure and simple, left the city of Frankfort, and removed to Basil and Geneva. Thus commenced the distinction of Puritans and Conformists, by which the two parties were afterwards known. The former were called Conformists, on account of their compliance with the ecclesiastical laws enacted by Edw. VI. and the denominations of Nonconformists and Puritans were given to the latter, from their infilling upon a form of worship, more exempt from superflition, and of a purer kind than
than the liturgy of Edward seemed to them to be. Upon the accession of queen Elizabeth, the exiles returned to England, where each party strove to advance the reformation according to their own standard. The queen, with those who had weathered the storm at home, were only for restoring king Edward's liturgy; but the majority of the exiles were for the worship and discipline of the foreign churches, and refused to comply with the old establishment, declining loudly against the popish habits and ceremonies. However, the queen's party prevailed; and in 1559 a committee of divines was appointed to review king Edward's liturgy, who were instructed to strike out all offensive passages against the pope, and to make people easy about the belief of the corporeal presence of Christ in the sacrament. But no alterations were made in favour of those who now began to be called Puritans, from their attempting a purer form of worship and discipline than had yet been established; and whole sentiments in many points were agreed to, to be maintained by John Wickliffe, the first reformer. For they agreed with him in opinion, that in the sacrament of orders there ought to be but two degrees, prebendaries and bishops; that all human traditions are superfluous and sinful; that we must prudently and teach only the laws of Christ; that mystical and significant ceremonies in religious worship are unlawful; and that to refrain men to a prescrib'd form of prayer is contrary to the liberty granted them by God. The old festivals, with their eyes and the popish habits, were continued as they were in the second year of king Edward VI. In 1558 the act of supremacy was passed, in which there is a remarkable clause, that gave rise to the court of high-commission, which proved afterwards so oppressive; and in 1559 was passed an act for the uniformity of common prayer, and service in the church, and administration of the sacraments. The Puritans remonstrated against these proceedings, and complained, that the gross superstitions of popery, which they had looked upon as abrogated and abolished, were now revived, and even imposed by authority. Some required nothing less than that the church of England should be exactly modelled after that of Geneva; others only denied liberty of conscience, with the privilege of celebrating divine worship in their own way; but neither party obtained the object of their wishes. The queen, intent upon the suppression of this troublesome sect (as she was used to call it), permitted her enemies to employ for that purpose all the resources of artifice, and all the severity of the laws. The court reformers pleaded, that every prince had authority to correct all abuses of doctrine and worship within his own territories; the Puritans, on the other hand, whilst they disowned all foreign authority and jurisdiction over the church, could not admit of that extensive power which the crown claimed by the supremacy; apprehending it unreasonable, that the religion of a whole nation should be at the disposal of a single lay person. However, they took the oath, with the queen's explication in her injunctions, as retaining her majesty only to the ancient and natural rights of sovereign princes over their subjects.

Farther, the court reformers allowed, that the church of Rome was a true church, though corrupt in some points of doctrine and government; that all her ministrations were valid, and that the pope was a true bishop of Rome, though not of the universal church. But the Puritans affirmed the pope to be antichrist, the church of Rome to be no true church, and all her ministrations to be superfluous and idolatrous; they renounced her communion, and durst not suspend the validity of their ordinations upon an uninterrupted line of succession from the apostles through her hands. Moreover, it was agreed by all, that the holy scriptures were a perfect rule of faith; but the bishops and court reformers did not allow them to be the standard of discipline or church government; affirming that our Saviour and his apostles left it to the discretion of the civil magistrate, in those places where Christianeously should obtain, to accommodate the government of the church to the policy of the state. But the Puritans apprehended the holy scriptures to be a standard of church discipline as well as of doctrine; at least that nothing should be imposed as necessary but what was expressly contained in, or derived from them by necessary consequence, and, besides, they maintained that the discretion of the people was not lodged with the civil magistrate, but with the spiritual officers of the church. Farther, the court reformers maintained, that the practice of the primitive church for the first four or five centuries was a proper standard of church government and discipline, and in some respects a better than that of the apostles, which (according to them) was only accommodated to the infant state of the church while it was under persecution, whereas theirs was suited to the grandeur of a national establishment. Whereas the Puritans were for adhering to the Bible in the main principles of church government, and for admitting no church officers or ordinations, but such as are herein mentioned; and they apprehended, that the apostles, in establishing the first Christian church on the arithmetical plan therein observed in the Jewish sanhedrin, designed it as an unchangeable model to be followed in all times and places.

The court reformers also maintained, that things indifferent in their own nature, which are neither forbidden nor commanded in the holy scriptures, such as rites, ceremonies, habits, &c. might be settled, determined, and made necessary by the command of the civil magistrate, and that in such cases it was the indispensible duty of all subjects to observe them. But the Puritans insisted, that those things which Christ had left indifferent, ought not to be made necessary by any human laws, and that such rites and ceremonies as had been abjured to idolatry, and had a manifest tendency to lead men back to popery and superstition, were no longer indifferent, but to be rejected as unlawful. Nevertheless, both parties agreed too well in affording the necessity of an uniformity of public worship, and of calling in the sword of the magistrate for the support and defence of their several principles; which they made an ill use of in their turns, as they could grasp the power into their hands. The standard of uniformity, according to the bishops, was the queen's supremacy, and the law of the land; according to the Puritans, the decrees of provincial and national synods, allowed and enforced by the civil magistrate; but neither party was for admitting that liberty of conscience, and freedom of profession, which is every man's right, as far as is consistent with the peace of the government under which he lives.

In the year 1564, upon a report that the habits, enjoined on the clergy, were generally neglected, and also of attention to other imposed forms, the queen directed the ecclesiastical commissioners to consult some proper methods to reduce them to an exact uniformity; upon which they agreed on certain advertisements (as they were called), partly for due order in preaching and administering the sacraments, and partly for the apparel of ecclesiastical persons. To these advertisements certain protestations were annexed, to be made, promised, and subscribed by such as should hereafter be admitted to any office or cure in the church. The queen, though she would give no authority to the advertisements, which had occasioned much remonstrance and complaint, sifting out a proclamation in 1567, peremptorily re-
quir” uniformity in the habits, upon pain of prohibition from preaching, and deprivation. Parker, the archbishop of Canterbury, was violent and unrelenting; and by various methods of severity, harassed, flenched, and deprived many of those who persisted in the use of the habits. The suppliant ministers, finding that renewed applications to the queen and her counselors were ineffectual, published, in 1566, a small treatise in vindication of their conduct; in which they allege, that neither the prophets of the Old Testament, nor the apostles of the New, were distinguished by their garments; that a distinction of garments in the Christian church did not generally obtain till long after the riting of antichrist; that the garments against which they objected, had been abused to idolatry, forcery, and all kinds of conjurations; that they were an offence to weak Christians, an encouragement to ignorant and obdurate papists, and the use of them an affectation of returning to their communion; that at best they were only human appointments, subject to the apostle’s reproof, Col. ii. 20—22; that allowing them to be indifferent (which they did not grant), yet they ought not to be repented, because it was an infringement of the liberty with which Christ had made them free; and finally they urged the usage of foreign divines, who all condemned the habits, though they were not willing to hazard the reformation in its infancy, on account of them.

If, at this time, the habits and a few ceremonies had been left indifferent, both ministers and people would have acquiesced; but it was the compelling of these things by law that made them separate from the established church. Accordingly, in 1566, they came to a resolution, alleging it to be their duty, in their present circumstances, to break off from the public churches, and to assemble, as they had opportunity, in private houses, or elsewhere, to worship God in a manner that might not offend against the light of their conscience; and it was debated among them, whether they should use as much of the common prayer and service of the church as was not offensive, or resolve at once, since they were cut off from the church of England, to set up the purest and best form of worship, most consonant to the holy scriptures, and to the practice of the foreign reformers. The latter of these measures was concluded upon; and accordingly they laid aside the English liturgy, and made use of the Geneva service-book. However, it is necessary to observe, that though all the Puritans of these times would have remained in the church, if they might have been indulged in their habits and a few ceremonies; yet, they were far from being satisfied with the hierarchy. They had other objections besides those for which they were deprived; of which we shall here only join a summary. They complained of the bishops affecting to be thought a superior order to presbyters, and claiming the sole right of ordination, and the use of the keys; and assuming, in connection with their office, temporal dignities, titles, and employments. As long, however, as the English bishops pretended to derive their dignity and authority from no other source than the laws of their country, and pleaded a right, merely human, to the rank they held in the church and state, the controversy was carried on without excessive animosity and zeal; but the flame broke out with redoubled fury in the year 1588, when Bancroft, afterwards archbishop of Canterbury, ventured to affirm that the order of bishops was superior to the body of presbyters, not in consequence of any human institution, but juris divina, or by the express appointment of God himself. Farther, the Puritans excepted against the titles and offices of archdeacons, deans, chapters, and other officials, belonging to cathedrals, as having no foundation in scripture, or primitive antiquity, and intruding upon the privileges of the prebys ters in the several dioceses. They complained of the exorbitant power and jurisdiction of the bishops and their counselors in their spiritual courts, as derived from the canon law of the pope, and not from the word of God, or the statute law of the land. They lamented the want of a godly discipline, and were uneasy at the promiscuous and general access of all persons to the Lord’s table. Though they did not dispute the lawfulness of the forms of prayer, provided a due liberty was allowed for prayers of their own composition before and after sermon, yet they disliked the frequent repetition of the Lord’s prayer in the liturgy, the interruption of the prayers by the frequent repetitions of the people, some passages in the office of marriage, as With my body I thee worship, and in that of burial, as In fear and certain hope of the resurrection to eternal life, pronounced over the word of men, if not excommunicated, &c. They also objected against the reading of the apocryphal books in the church, while some parts of canonical scripture were omitted; and though they did not dislike the homilies, they thought that no man should be ordained a minister in the church who was not capable of preaching and expounding the holy scriptures. They disapproved of several of the church festivals or holidays, as having no foundation in scripture, or primitive antiquity; and they disallowed of the cathedral mode of worship; nor did they approve of musical instruments in the church service. Finally, they scrupled conformity to certain rites and ceremonies, which were enjoined by the rubric, or the queen’s injunctions; as the sign of the cross in baptism, baptism by midwives, or other women, in caes of sickness, and the mode of churching women; the use of god-fathers and god-mothers, to the exclusion of parents from being fireties for the education of their own children; the custom of confirming children, as soon as they could repeat the Lord’s prayer and their catechism, by which they had a right to come to the sacrament, without any other qualification, and the imposition of hands, as a sign of the divine favour, which seemed to them to imply a sacramental efficacy in this ceremony; kneeling at the sacrament of the Lord’s supper, which they considered that Christ gave it to his disciples rather in a pollic of sealing than of adoration; that it had no foundation in antiquity; that it had been grossly abused by the papists to idolatry in their adoration of the host; and that, if the pollic were indifferent, it ought not to be imposed as a necessary term of communion; nor did they approve of administering either of the sacraments in private, even in cases of danger; bowing at the name of Jesus; giving the ring in marriage, which they considered as derived from the papists, who made marriage a sacrament, and the ring a sign of facred sign or symbol; the prohibition of marriage during certain times of the year, and the licensing it for money; and, lastly, the wearing of the surplice, and other vestments to be used in divine service.

In points of doctrine there was, at this time, no difference between the Puritans and Conformists; and if we add one article more to the preceding, we shall have the principal heads of controversy between the church of England and the Protestant Dissenters, at this day; viz, the natural right which every man has to judge for himself, and make profession of that religion he apprehends most agreeable to truth, as far as it does not affect the peace and safety of the government under which he lives; without being determined by the prejudices of education, the laws of the civil magistrate, or the decrees of councils, churches, or synods. See Protestant Dissenters.

Towards the latter end of queen Elizabeth’s reign, there arose a party, which were first for softening, and then for overthrowing,
overthrowing, the received opinions concerning predestination, perseverance, free-will, effectual grace, and the extent of Christ's redemption. The clergy of the episcopal church began to lean towards the notions concerning these intricate points, which Arminianism propagated some time after this; while on the other hand, the Puritans adhered rigorously to the system of Calvin. Several episcopal doctors remained attached to the same system in the reign of James I. &c. and all these abettors of Calvinism, whether episcopal or presbyterian, were called doctrinal Puritans. At length, according to Mr. Fuller, (Church Hist. book ix. p. 97. book x. p. 1000.) the name was extended to rigmatize all those who endeavoured in their devotions to accompany the minister with a pure heart, and who were remarkably holy in their conversation; so that a Puritan was a man of severe morals, a Calvinist in doctrine, and a Non-conformist to the ceremonies and discipline of the church, though he did not totally separate from it.

Queen Elizabeth was violent in her opposition to the Puritans through the whole course of her reign; and besides the ordinary courts of the bishops, erected, as we have already observed, a new tribunal, called the court of high-commission, which suspended and deprived men of their livings, not by the verdict of twelve men upon oath, but by the solemn determination of three commissioners of her own nomination, founded not upon the statute law of the realm, but upon the canon law; and instead of producing witnesses in open court to prove the charge, they assumed a power of administrating an oath ex officio, by which the prisoner was obliged to answer all questions the court should put to him, though never so prejudicial to his own defence. If he refused to swear, he was imprisoned for contempt; and if he took the oath, he was convicted upon his own confession.

During the reign of James I. from whom the Puritans expected more indulgent treatment, they were treated with great severity, and many of them were obliged to leave the kingdom, and retire to Holland; and from thence considerable numbers migrated to America in the year 1620. All were Puritans, in the estimation of King James, who adhered to the laws of the land in opposition to his arbitrary government, though otherwise ever so good churchmen. These were called Puritans in the large; and those who scrupled the ceremonies, and adhered to the doctrines of Calvin, were Church Puritans, who, though comparatively few, yet being joined by those of the other classes, became the majority of the nation. The success which attended the first emigrants, who settled in that part of America afterwards called New Plymouth, engaged great numbers of Puritans, who groaned under the oppression of the bishops, and the severity of a court, by which this oppression was authorized, to follow the fortunes of these religious adventurers; and this produced a second emigration in the year 1629, which gave birth to the second grand colony, commonly known by the name of the Massachusetts's Bay. The colony of Connecticut was formed by emigrants of the same classes in 1636, and that of New Haven in 1637, who fled from the persecution of Laud, and the oppressions of the star-chamber and high-commission courts. Afterwards, when the Puritans were not allowed to transport themselves to New England, many of them removed, with their families, into the Low Countries.

After the reformation of Charles II. in the year 1662, the name of Puritans, says bishop Burnet, was changed into that of Protestant Non-conformists, who were subdivided into Presbyterians, Independents, Anabaptists, and Quakers. At this time a public law, called the Act of Uniformity, was enacted, by which all who refused to observe the rites, and subscribe the doctrines of the church of England, were entirely excluded from its communion. From this period until the reign of king William III. the Non-conformists were in a precarious and changeable situation, sometimes involved in calamity and trouble, and at other times enjoying some intervals of tranquillity and certain gleams of hope, according to the varying spirit of the court and ministry, but never entirely free from perplexities and fears. But in the year 1689, their affairs took a favourable turn, when a bill for the toleration of all Protestant Dissenters from the church of England, except the Socinians, passed in parliament, almost without opposition, and delivered those who could comply with the conditions it imposed, from the penal laws to which they had been subjected by the act of uniformity, and other acts passed under the house of Stuart. For the present state of the toleration, see Toleration. See also Corporations Act and Test. Neal's Hist. of the Puritans, in 4 vols. 8vo. paufim.

PURITY, in Oratory, is one of the constituent parts of elegance, and denotes the choice of such words and phrases as are fitted and agreeable to the use of the language in which we speak. Grammarians reduce the faults which they oppose to it to two sorts, which they call barbarism and obscurity; the former of which respects single words, and is an offence against etymology, and the reproach of it is incurred by the use of words entirely obsolete, or by new formations and compositions, from simple and primitive words in present use. The latter respects the construction of words, and is an offence against syntax; to which Dr. Campbell adds a third class of faults, under the denomination of impropriety, which is an offence against lexicography, the business of which is to assign to every word of the language the precise meaning or meanings which use hath alligned to it. This impropriety occurs both in single words and in phrases. Dr. Ward recounts the principal things that vitiate the purity of language. It often happens, he says, that such words and forms of speaking, as were introduced by the learned, are afterwards dropped by them, as mean and forlorn, from a seeming barbarism contracted by vulgar use: and it is common to language, with all other human productions, that it is in its own nature liable to a constant change. (Hor. Art. Post. v. 68.) We must, therefore, no less abdote from antiquated, or obsolete words and phrases, than from forlorn ones. On the other hand, we should refrain from new ones, or such, whose use has not yet sufficiently established, at least among those of the best taste. Besides, any mistake in the sense of words or their construction, is opposed to purity: for to speak purely is to speak correctly. And farther, a distinction ought to be made between a poetic diction, and that of prose writers: for poets in all languages have a sort of peculiar dialect, and take greater liberties, not only in their figures, but also in their choice and disposition of words: so that what is a beauty in them, would often appear unnatural and affected in prose. Ward's Or. vol. i. p. 382, &c. Campbell's Phil. of Rhet. vol. i. p. 409, &c.
that the manner in which these woodlands are occupied is
exactly the same as that of many of the royal forests, with
the exception of the right of pillage, and for that reason
much more productive and beneficial. See Woods and
Royal Forests.

PURITY, in Building, those pieces of timber that
lie above the rafters on the inside, to keep them from fink-
ing in the middle of their length.

PURLUE, Purlieu, or Pouralle, formed from the
French pur, pure, and lieu, place, is all that ground near any
forest, which, being added to the ancient forest by our kings,
was, by perambulation, granted by some of their successors,
fevered again from the same, and made purlieu, i.e. pure
and free from the laws and obedience of the forest.

A purlieu, or pouralle, is defined a circuit of ground ad-
joining to the forest, and circumfered with immovable
boundaries, known only by matter of record; which com-
pas of ground was once forest, and afterwards was dis-
afforested by the perambulations made for severing the new
forest from the old.

Purlieus, or pourallees, commenced after the manner fol-
loving. King Henry I. at his accession to the crown in
1154, took so much delight in the forests of this kingdom,
that, not being contented with those he found there, though
many and large, he began to enlarge divers of them, and to
disafforest the lands of his subjects nearly adjoining to the same.

His successors, Henry II. and Richard I., far from in-
trenching or reddening any thing, made still further encroach-
ments: and thus did the lands continue till the 17th year of
John; at which time, the grievance being grown
unglorious, and generally felt by all degrees of people, divers
noblemen and gentlemen besought the king to grant, that
they might have all those new afforestellations made by his
predecessors aforesaid, and by himself, disafforested again;
and the king, after much solicitation, was at length pre-
vailed on to subscribe and seal such articles concerning the
liberties of the forest, as they then demanded; being, for
the most part, such as are now contained in the Charter of
the Forest.

Hereupon choice was made of divers noblemen, &c. to
the number of twenty-five, who were sworn, with others
their affiltes, to see the said liberties, so granted, and con-
firmed by the king, to be in every point observed.

But, before any thing was done to the purpose, king
John died; and king Henry III. succeeding, fresh solici-
tations were made to him who, for the better accom-
plishing of the said disafforestemt, ordered inquisitions to be
taken, by substantial juries, for severing all the new
forests from the old; upon which, two commissioners were
sent to take those inquisitions; in virtue whereof, many
great woods and lands were not disafforested, but were
improved to arable lands by the owners thereof. After
this charter was made and confirmed, some of those new
afforestellations were perambulated, and proper inquisitions
taken, and the certainty was determined by matter of re-
cord, which, taken, the old, and which the new: though it
appears, that the greatest part of the new disafforestellations
were still remaining during the life of king Henry III.

Under Edward I. fresh petitions and solicitations being
bet on foot, three bishops, three earls, and three barons,
were at length appointed to see those perambulations per-
formed and continued; who caused them to be made ac-
cordingly, and inquisitions to be taken thereupon, and re-
turned into the court of chancery; and all those that were
ancient forest to be meared, and bounded with irremovable
boundaries, to be known by matter of record for ever.

Those woods and lands, that had been newly disafforested,
the king likewise caused to be separated from the old, and
to be returned into the chancery by marks, meres, and
bounds, to be known in like manner by matter of record for
ever.

Thus it appears how the purlieus, or pourallees, had
their first beginning; for all such woods and lands as were
disafforested by Henry II. Richard I. or king John, and, by
perambulations, severed from the ancient forests, were, and
yet are, called pourallees. of d. woods and lands severed from
the old forests, and disafforested by perambulation; pouralle
being the same as perambulatio, in Latin.

But, notwithstanding such new disafforestellations were dis-
afforested by perambulation, whereby the same became
pourallees, or purlieus; yet they were not thereby so disaffo-
rested as to every man, but that they do, in some sense, continue forest till as to other. For, by the words of
Charta de Foresta, if the king has disafforested any woods or
lands of his subjects, to the damage of the proprietors,
they should forthwith be disafforested again; that is, only
as to those persons whose woods and lands they were; who,
as the proper owners thereof, might fell and cut down their
woods at their own pleasure, without any licence from the
king; as also convert their meadows and pâtures into til-
lage, or otherwise improve their ground to the best advan-
tage. So also the landed gentry, and chase the wild beasts
of the forest towards the same, &c. But no other person
should claim such benefit of hunting in the pourallees,
beides the proper owner of the soil thereof, who is left at
liberty to suffer the pourallees to remain forest till, as fome,
in effect, have thought most expedient, because thereby en-
titled to the benefit of the common within the forest, which
otherwise they were excluded from. Hence, if the bears
chance to wander out of the forest into the pourallees, the
king hath a property in them, whilst every man, but
the owner of the ground wherein they are, who hath a spe-
cial property in them, ratione foli; yet so as he may only
take them by hunting, or chasing with his greyhounds or
dogs, without any foresetlling or foresetting them in their
course again towards the forest.

Before what hitherto has been said of the difference be-
tween forest and purlieu, or pourallees, there is this farther
diversity, that all the woods and lands within the regard
of the forest are absolutely within the bondage or charge of
the forest, as well in respect to the owners thereof, as of
any other person; for no one may cut down his own woods,
or improve his own lands, within the regard of the forest,
without licence from the king or his chief justice in eyre of
the forest. Neither shall any person hunt, chase, or molest
the wild beasts of the forest in his ground, within the regard
of the forest, without licence or warrant from the king, or
his chief justice of the forest to so do.

But those, whole grounds are within the purlieus, are
not subject to these restrictions. Yet are not the woods
and lands in the purlieus absolutely freed from the bondage
of the forest, in respect of the wild beasts having their
haunts therein, when they happen to stray out of the forest;
but as they were once absolutely forest, so they are still con-
ditionally so.

PURLIEU-Man, or Purlieu-man, or Pouralle-man, is one
who has land within the purlieu; and is allowed or qualified
to hunt or course within the same, though under certain
restrictions.

By Stat. 13 Ric. II. he who may lawfully hunt in any
pourallees, ought to have woods or lands of freehold within
the purlieu, to the yearly value of 40L. By Stat. Jac. 1,
he ought to have lands of inheritance of the yearly value
of 10l. or lands of freehold of the yearly value of 30l. or
have
have goods worth 200l. or be the son of a knight or baron, or
perfon of a higher degree, or fon and heir apparent of an
esquire. But, by a later act, Car. II. no man may keep
greyhounds within the pouralle, or elsewhere, within
England or Wales, unless he have a free warren, or be
lord of a manor, or such a freewarre, as is afeid, in his
own right, or in right of his wife, or within lands, tenements, or
heritaments of the clear yearly value of 40l. over and
above all charges and reprifes of such effate of inheritance;
or of lands, tenements, or hereditaments, in his own right,
or in right of his wife, for term of life or lives, of the yearly
value of 80l. over and above all charges and reprifes, or that
is worth in goods in chattels 400l.

The pouralle, or purhane, then, is fayd to be for him that
is fo qualified: others, not qualified, and therefore not pur-
hane-men, yet having land in the pouralle, may, if they
find any wild beafts of the forest in their own ground
within the pouralle, chafe them thereout with little dogs;
but not with greyhounds, or other dogs.
Nor is the purhane-men left at large to hunt at his own
determination; but he is tied down to several rules: as,
1. That he always begins his chase in his own ground;
and, that, though he finds such wild beafts in his own
pouralle, and in respect thereof, hath a property in them,
ratione fatis, against all perfon, but the king; yet such
his property is only on this condition, that he can flay them
with his dogs in chase, without foareftalling them, before
they can recover the fell. If they be within the liit
of the forest, before the dogs flain them, they are the
king's, or other owner of the fell.
2. But if the pourhane-man firft make his chase in his
own freehold, he may pursue the fame through every man's
ground within the pouralle, and his dogs falen on a wild
beast, before he can get within the bounds of the forest,
and the beast draws the dogs into the forest, and is there slain by
them; here the pourhane-man fhall not enter into the forest,
nor take the beast so killed, because his course was irregular
from the beginning, as he could claim no property in the
beast, ratione fatis.
3. A pourhane-man may hunt in his own pouralle with
no more company than his own servants; neither may he
appoint, licence, or warrant any other perfon, except his
servants, to hunt by his commandment in his pouralle.
4. Every pourhane-man is forbidden, by the laws of the
forest, to hunt in his own grounds within the pouralle every
day, or oftener than three days in any one week, Sunday
excepted.
5. Nor is any man to disturb, or make a course after any
deer found in his pouralle, within forty days after the king
hath made a general hunting in the forest adjoining there-
unto; because then the wild beafts of the forest come not
into the pouralle of their own accord, but as they are
forced into the same by the hunters, with clamours, and
blowing of horns, fo that they fly thither for refuge.
6. No man shall hunt within seven miles of the borders of
the forest, or in his own pouralle, within forty days next
before the king hath issued out his proclamation, declaring
his royal will and pleasure to make a general hunting in that
forest.

Inasmuch as the pouralle were once, and in some fenfe
still are forest, it was necessary to have officers to attend,
and take on them the charge of the preservation of the
game that may happen to wander out of the forest into the
pouralle; since otherwise the laws of the pouralle could
not be executed, but the forest itself would soon be destroyed
by the pouralle-men.

For this reason, rangers were first appointed, who,
though not officers in the forest, yet appertain thereto; for
all officers in the forest have charge of the vert and venison
of the forest; but a ranger hath no charge of the vert, but
only of venison coming out of the forest, into the pouralle,
his place of charge; from whence his office is to conduct
the same back again into the forest.

This officer is appointed by the king, or his chief justice
in eyre, and is made by patent, with a fee commonly of
twenty, thirty, or forty pounds, or more, by the year,
payable out of the exchequer, as also certain fees, deer, and
fallow, to be taken annually, at proper feasons, out
of the forest.
The substance of his oath is, to rechase, and with his
hounds drive back, the wild beafts of the forest, as often as
they range out of the same into his pouralle; to prevent all
unlawful hunting and hounding of wild beafts of venery and
chase, as well within the pouralle, as within the forest;
and to prevent thefe and other offences, at the next court
of attachments or swainmote, which shall first happen.

Rangers, it is to be observed, belong only to such pou-
ralles as were once the woods and lands of the subject, and
were afterwards diffafised again, and so became pour-
alle. Hence, as there are some forests in England, which
never had any enlargement by new affeerations, and there-
fore have no pouralle at this day, there can be no rangers
belonging to them. Manwood's Forest Laws, part 2. c. 70.

PURNALL, in Geography, a town of Hindooftan; 15
miles W.S.W. of Allahabad.

PURNERENT, a town of North Holland, on a brook
of the fame name, governed by a council, bailiff, and burgo-
masters. The town had a voice in the assembly of the flates;
10 miles N. of Amsterdam. N. lat. 52° 33'. E. long. 4°
46'.—Also, a small island near the coast of Java, on which
lies an hospital for the diseased poor of Batavia.—Also, a
small island in a large bay on the N. coast of New Guinea.
S. lat. 2° 16'. E. long. 135° 12'.

PURNA. See PANNAH.

PURNACH, a circur of Bengal, bounded on the N.
by Murung, on the E. by Dinagepour, on the S. by Raj-
mal, and on the W. by Bahar; about 80 miles long from
N.E. to S.W., and 70 from N.W. to S.E. The capital of
the fame name is fituated on a river which runs into the
Ganges; 200 miles N. of Calcutta. N. lat. 25° 48'. E.
long. 87° 46'.

PURNITZ, a town of Moravis, in the circle of Iglau;
7 miles S.E. of Iglau.

PURPARTY (Fr. pour part, i.e. pro parte) is that
part or share of an estate, first held in common by parcers,
which is by partition allotted to any of them. To make
purparty is to divide and fever the lands that fall to par-
cers, which till partition they held jointly, and pro indivi-
duo. Old Nat. Br. 11.

PURPLE, PURPURA, a red colour, bordering on
violet; now dyed chiefly with cochenille.

Purple was much esteemed among the ancients; espe-
cially the Tyrian purple, which underwent more dyes than
the red, and which was almost peculiar to the emperors and
kings. Yet this purple did not exceed that now in use.
The chief reasons why the ancient purple dye has been dif-
figured are, that the latter is both cheaper and finer.

The ancient purple was tinged or given with the blood
or juice of a precious turbinated tellinaceous sea-fish, called
by the Greeks περπυρα, and by the Latins purpura; of
which we have descriptions in several authors, and shells in
most of the cabinets of the curious. See PURPLE-FISH.
The method of obtaining the colour, Mr. Cole (see Purpl. Fitch) describes thus:

The shell, which is very hard, being broken, (with the mouth of the fish downwards, so as not to crush the body,) and the broken pieces being picked off, there appears a white vein lying transversely in a little furrow or cleft next the head of the fish.

In this vein is the purple matter lodged; some of which, being laid on linen, appears at first of a light green colour; and, if exposed to the sun, changes into a deep green, and in a few minutes, into a sea-green, and, in a few more, into a blue; whence it soon becomes of a purple-red, and, in an hour more, of a deep purple red.

And here the sun’s action terminates; but by washing in scalding water and soap, and drying it, the colour ripens to a mottled bright and beautiful crimson, which will bear washing admirably without the addition of any dyptic. While the cloth marked with this colour lies in the sun, it will yield a very strong and fresh smell, as if garlic and asa förada were mixed together.

The juice which gives this beautiful purple colour is, says M. du Hamel, while it remains in the body of the animal, and while that is in health, wholly white; but no sooner is it exposed to the sun, than it begins to change colour, and in less than five minutes goes through the several changes of pale green, yellowish, and a beautiful emerald green; after this it becomes of a deeper and duller green, then blueish, reddish, and finally a deep and very beautiful purple. Sometimes the juice is found naturally green in the animal: this is probably from the creature’s being in a diseased state. But when it is naturally thus, it immediately becomes red, and afterwards purple, on being exposed to the sun; its several preceding changes seeming to have been made already in the body of the animal.

If a piece of linen is rubbed over with this juice, and part of it exposed to the sun, part not, that only will turn red which is so exposed, the other remaining green without any alteration; and it is observed, that the stronger the sun’s influence, the quicker the change appears, and probably the colour is in proportion also the more beautiful and lively. And it is very remarkable, that if a needle, or any other opaque body, be laid upon the linen which is yet green, and is to become red on being exposed to the sun; after such an exposure, the whole shall be changed red or purple, excepting only that small spot which is covered by the needle, which will still remain green.

A plate of glass, though it be three inches thick, will not prevent the colour from changing purple by being laid over it; but the thinnest piece of metal will keep it wholly green. The one being opaque, and the other pellucid, are evidently the only reasons for this difference.

If the coloured linen be successively covered by three pieces of paper, the one blacked with ink, the other in its natural state, and the third rubbed over with oil, it will change colour on being exposed to the sun in different degrees; and that exactly in proportion to the degree of transparency in each of the papers; most of all in that which was covered with the oiled paper; something less in that covered by the paper in its natural state; and least of all in that which was covered with the blacked paper, as that is least transparent.

The common heat of a fire, or that of a red-hot iron, produces no change at all in the colour when green. The vapour of burning sulphur produces a little; but the green, which had not changed to purple by these experiments, immediately changed to it on being exposed to the rays of the sun.

These experiments were all made in the months of January and February, by M. du Hamel, in Provence; and the sun having power to change the colour so speedily there in these cold months, probably in a warmer climate or season the air would have been sufficient for the purpose, without the open sun; since it seems, from experiment, that both the solar rays, and the light alone in a cloudy day, can act upon this colour. The light and heat of the sun both act on this colour: light is always sufficient to produce the effect, but the heat may easily be too great or too little; and to do the whole in perfection, it must be at a certain middle degree.

This beautiful purple, if it can ever be brought into use in dyeing, will have one very great advantage from its viscosity. The pieces of cloth that had been flayed by it retained their colour, in spite of several boilings in different liquors, which M. du Hamel made them pass through; and the colour, on examination, was found not to be superficial, but penetrated the whole body of the stuff, which was tinged by it. There are many inconveniences which must naturally attend the use of this substance as a dye, but they may, perhaps, all be got over by care and application. It is very certain, that it is of too vicid a nature easily to penetrate many substances; but it is also certain, that this might be obviated by dissolving it in some proper liquor. It appears very plainly, that the ancients had a method of thus dissolving their purple; but we neither know what was their purple, nor what was its dissolvent; nor, which would be of much more importance to us at present, what is the proper dissolvent for our own. Mem. Acad. Scienc. Par. 1756.

M. Reaumur has also discovered another very different kind of purple. This is produced in oval grains about a quarter of an inch long, full of white liquor bordering on yellow, which cover certain stones or sands, about which the buccina of Poitou usually assemble.

By the experiments M. Reaumur has made, it appears that these grains are neither the eggs of the buccinum, nor the seeds of any sea-plants, nor any rising plants, but the eggs of some other unknown fish.

These grains, being bruised on a white linen, at first only tinge it yellow, and that insensibly; but in three or four minutes they give it a very beautiful purple red, provided the linen be exposed to the open air; for the air of a room, even though the windows be open, will not do. This colour fades, however, a little by repeated washings.

M. Reaumur concludes, from some experiments he made, that the effect of the air on the liquor does not consist in its taking away any particles of it, nor in giving it any new ones, but only in its agitating it, and changing the arrangement of the parts that compose it. He adds, that the liquor of the buccinum, and that of the grains, seem to be nearly of the same nature: except that the latter is more watery, and only saline; whereas the other is hot, and pungent.

P. Labat gives us the description of another purple dye, produced by a tree growing in the Antilles. The juice of this tree, when cut running, is of a blood-red, and communicates the same colour to clothes; though, like the former, it lasts much in often washing.

Purple, Dyeing. See Dyeing.

Purple Gold. See Gold Precipitate, &c.

Purple, in Medicine, an epithet applied to every disease, in which eruptions of purple spots, or petechias, appear, and these being usually the accompaniments of fevers of every kind in their worst and most dangerous forms, to purple fever.
fever was nearly synonymous with putrid, or malignant fever. See Petechiae, and Purpura.

Purple Apple, in Botany. See Annona.

Purple Fish, Purpura, in Natural History, the name of a genus of shell-fish, the characters of which are these: it is an univalve shell, jagged and befit from head to tail with spines, tubercles, umbos, or spicules. The mouth is small and roundish; the tail is short, and usually the base runs out into a long beak. See Dyeing.

It has been usual with most authors to confound together the genera of the murex and purpura, and to use the words as synonymous: but though there is some external resemblance between many of the shells of the two genera, yet they are easily distinguished by this, that the mouth of the purpura is less long, and is less dentated and slanled than that of the murex. The body and the head of the shells of this genus are not so elevated as those of the murex kind, and are not covered with points or buttons at the mouth. If a shell is therefore found to have a small, smooth, and round mouth, and a body covered with undulated leaves, as it were, like those of favor or endive, and sometimes with long points, and its tail, whether long or short, be hollowed and somewhat bent, this may be called a purpura, and not a murex. Linnaeus makes the purpura a species of the murex.

The ancients distinguished three kinds of purpura; one which had a long and crooked tail, made hollow like a tube or pipe; a second which had either no tail at all, or at the most a very short one; and a third which had no spiral head, or, as we should express it, no clavicle.

On examining the whole family of the purpuræ, we may distinguish four remarkable specific differences among them. The first of these comprehends those purpræ which have the body of the shell garnished with a fort of undulated foliation in clouded ridges, and have a short and crooked tail. The second comprehends those which have the body of the shell covered with acute points, and have a long tail. The third comprehends those which have as long a tail as the former, but have a smooth body, or at the utmost have only a few flat protuberances and wrinkles on it. And the fourth takes in those which are small, and have an elevated clavicle, a short crooked tail, and the body of which is covered either with slender spines or hairs.

This species of fish, as well as the murex, served among the ancients to dye the fine purple colour they were so fond of, and some of the buccina (e.g. the lapillus of Linnaeus) have been of late found to have the same juice. The purpura and murex are both fished up in great plenty in the gulf of Tarentum; but the small quantity of the coloured juice which each fish contains, and the necessity of using it before the animal dies, makes it impossible to bring it to any regular article of traffic. The ancients used this colour only on cotton and woolen stuffs; whereas our cochineal, which was unknown to the ancients, strikes equally well on silks and stuffs. These shells are also found in various parts of the Mediterranean.

In the seas of the Spanish West Indies about Nicoya, is found a shell-fish, which perfectly resembles the ancient purpura, and, in all probability, is the same fish. This fish, Cage tells us, usually lives seven years; it hides itself a little before the dog days, and continues to disappear for three hundred days running.

They are gathered plentifully in the spring, and, by rubbing one against another, they yield a kind of salvia or thick hair, resembling soft wax; but the purple dye is in the throat of the fish, and the fleshy part is lodged in a little white vein; the rest of the body is of no use. He adds, that the chief

riches of Nicoya consist in this fish. Cloth of Segovia, dyed with it, is sold for twenty crowns the ell; and none but the greatest Spanish lords use it.

There are also found upon the coasts of the South-sea, near the equator, in the neighbourhood of the St. Helena, in the province of Guayaquil, certain sea-fish, as Don Antonio de Ulloa calls them, picking at the bones, and covered by the sea at high water, about the size of small nuts, which contain a liquor or juice that has the true colour of purple. The colour is very bright, and so durable, that washing rather increases than diminishes its luster, nor does it fade or decay by use and wearing. Woven stuffs are not dyed with it, but only cotton threads. As soon as a sufficient quantity of the liquor is squeezed from the fish, the cotton thread is drawn through it, and it takes and retains the tincture without any farther trouble; but the purple colour is not discovered till the thread is dry, the juice being of a milky colour at first, but it soon changes into green, and at last settles in a purple.

Besides the Indian purple fihes, we have others much nearer home. In the Philosoph. Transact. abr. vol. ii. p. 823, we have an account of purple fish discovered in 1684, by Mr. W. Cole, on the coasts of Somersetshire, South Wales, &c. where it is found in great abundance. The modern purple fish, M. Reaumur observes, is a kind of buccina, a name given by the ancients to all fishes whose shell bears any resemblance to a hunting-horn; and it appears from Pliny, that part of the ancient purple was taken from this kind of shell-fish: so that this may be esteemed a recovery of what had been suppos'd entirely lost. See Dyeing.

The fish, he observes, is good; and adds, that there are several kinds of it differing in size and shell, and also in the colour of the tingling liquor. There are some found on the coasts of Poictou.

The Caribbee islands have likewise their purple fish. This is called tozan, being of the size of the end of the finger, and resembling our periwinkles; its shell is of a brownish azure, its flesh white, its intestines of a very bright red, the colour of which appears through the body; and it is this that dyes the froth, which it calls forth when taken, and which is at first of a violet hue, bordering on blue.

To oblige them to yield the greater quantity of froth, they lay them on a plate, and shake and beat them against one another, upon which the plate is immediately covered with the froth, which is received on a linen cloth, and becomes purple in proportion as it dries.

P. Labat observes, that if this be the real Tyrian purple, the secret of preparing and fixing it is lost; this colour being found to dwindle and dissipate, in proportion as the linen dyed with it is washed.

The purpura lives on other fish. It usually hides itself at a small depth in the sand, sometimes even in fresh-water rivers, and as it lies hid, it thrills up a pointed tongue, which wounds and kills any thing that comes over it. We frequently find sea-shells with round holes bored through them, as regularly as if made with a boring instrument: these are generally allowed to be made by the tongue of the purpura, in order to its feeding on the fish within.

The purpura has two horns like that of a snail; and Fabius Columna says, that they have eyes in these, not placed at the ends, as in the snail, but in the middle of each horn.

The purpura is a shell-fish very well known, and has been known also in almost all times to afford a purple liquor; but as there has been no method discovered of bringing this li-
the gentlest pressure on the skin, such as is applied in feeling the pulse, will produce a purple blotch, like that which follows a fever blow.

When the disease is full more severe, in addition to these effusions of blood under the cuticle, considerable discharges of blood take place from those parts which are defended by a very delicate cuticle; whence these hemorrhages originate particularly from the internal passages and organs, and are occasionally very profuse, and occasionally destroying life. Most frequently, however, the bleeding is slow, and in small quantity, sometimes almost a constant oozying, and sometimes returning at intervals. These hemorrhages take place from the gums, nostrils, throat, the inside of the cheeks, the tongue, and lips; sometimes from the lining membrane of the eye-lids, the urethra, and the external ear; and often from the internal cavities, the lungs, stomach, bowels, kidney, uterus, and bladder. There is great variety, however, in the periods of the disease at which the hemorrhages commence and cease, and as to the proportion which they bear to the cutaneous effusion.

This singular disease occasionally appears suddenly, in the midst of good health, attacking during the night. It is always accompanied by great debility and depression of spirits; and often by pains in the chest, loins, or abdomen, by irregularity of bowels, or by cough; and the pulse is sometimes slightly quickened and very feeble, as in a moderate hectic. But in some cases these functions are not perceptibly disturbed. The duration of the disease is usually uncertain: in some instances it has terminated in a few days, while in others it has continued not only many months, but years. When it terminates fatally, it is commonly in consequence of a copious hemorrhage, either suddenly from some important organ, or more slowly from several parts at the same time.

The causes of this disease are not clearly ascertained, nor its pathology well understood. It occurs at every period of life, and in both sexes; but most frequently in women, and in boys before the age of puberty, particularly in those who are of a delicate habit, who live in cloze and crowded situations, and on poor diet, or are employed in sedentary occupations, and subject to grief, anxiety, fatigue, and want of sleep. It has likewise attacked those who are left in a state of debility by previous acute and chronic diseases, as after small-pox or small-pox-like diseases, or in a puerperal state, or after a violent suppuration from mercury. On the other hand, however, the disease appears occasionally in its most severe and fatal form, where none of those circumstances had previously existed: for instance, in young persons living in the country, and suffering no privation of any of the comforts of life, and previously enjoying good health. This fact tends greatly to obscure the pathology of the disease: for it renders the operation of these alleged causes extremely questionable, and it seems to establish an essential difference between purpura and scurvy, in the origin and nature of the morbid actions which constitute the disease. In scurvy (by which we mean the scorbutus, or true scurvy, formerly prevalent among seamen in long voyages, and among people in besieged towns, and other situations, when living upon putrid, salted, dried, or otherwise indigestible food, yielding imperfect nutriment,) the restoration of the proper nourishment, with the use of fresh vegetables and acids, invariably removes the symptoms, and they never commence where such diet can be obtained: while, in many cases of purpura, this diet has been taken abundantly, without the slightest alleviation of the complaint, and the disease has come on, where there had been no deficiency. "On the other hand, the rapidity of the..."
the attack, the acuteness of the pains in the internal cavities, the actual inflammatory symptoms that sometimes supervene, the occasional removal of the disease by spontaneous hemorrhage, the frequent relief derived from artificial discharges of blood, (see two cases of purpura by Dr. Parry, Edin. Med. and Surg. Journ. for Jan. 1829), and from purging, all tend to excite a suspicion that some local visceral congestion or obstruction is the cause of the symptoms in different instances." (Bateman's Practical Synopsis, of Cutan. Dif. p. 110.) Several facts in proof of these observations are stated in the work just quoted; but a sufficient number has not yet been collected to afford any general inference respecting the nature of the disease.

The cure of purpura is, therefore, not established upon any clear principle, and there has been considerable difference of opinion upon the subject. Dr. Willan has given a very imperfect view of this point. All that he says relative to the cure of the work's form of purpura, is comprised in these few lines. "In the treatment of this disease, we should recommend moderate exercise in the open air, a generous diet, and the free use of wine, Peruvian bark, vitriolic acid, &c. Without air, exercise, and an easy state of mind, the effect of medicines is very uncertain."

(On Cutan. Difeaes, p. 461.) Of this, indeed, he has given an ample proof in the next sentence, where he tells us that a patient "took for two or three months Peruvian bark in considerable quantities, the vitriolic and marine acid, and wine, without much advantage." In truth, the cure of purpura is, we believe, not to be effected by these means. In the lighter degrees of the disease, occurring in children who are ill fed and nursed, and excluded from the air and from all exercise, these toxes may seem to do good, when combined with air and exercise. "But," as Dr. Bateman observes, "when it occurs in adults, especially in those already enjoying the benefits of exercise in the air of the country, and who have suffered no privation in respect to diet; or when it appears in persons previously stout, or even plethora, when it is accompanied with a white and loaded tongue, a quick and somewhat sharp, though small, pulse, occasional chills and heats, and other symptoms of feverishness, however moderate;—symptoms which may be presumed to indicate the existence of some local congestion;—then the administration of tonic medicines, particularly of wine, cinchona, and other warm tonics, will be found efficacious, if not decidedly injurious. In febrile cases, free and repeated purgations of the bowels, by medicines containing some portion of the muriate of mercury, will be found most beneficial. The continuance or repetition of these evacuations must, of course, be regulated by their effects on the symptoms of the complaint, or on the general constitution; and by the appearance of the excretions from the intestines. If the pains are severe and fixed, and if the marks of febrile irritation are considerable, and the spontaneous hemorrhage not profuse, local or general blood-letting may doubtfully be employed with great benefit, especially in robust adults." Præct. Synopsis, before quoted, p. 114.

The importance of free purgeation in purpura has been clearly stated in a short but valuable communication from Dr. Harty, of Dublin, published in the Edinburgh Medical and Surgical Journal, for April, 1813: in more than a dozen cases treated in this manner by Dr. Harty, the hemorrhages ceased, and the purple spots disappeared, after a few doses of calomel and jalap had been taken. In the two cases related in the same useful journal by Dr. Parry, of Bath, before alluded to, and which were speedily cured by two bleedings from the arm, the blood drawn exhibited a tenacious contracted coagulum, covered with a thick coat of lymph, as in diseases of an inflammatory nature. The patients were a lady and an officer, the latter of whom was accustomed to free living; in both cases some degree of feverishness accompanied the purpura.

There is one variety of the disease, which Dr. Willan distinguished as a third species, by the title of purpura urticans, because the eruption commences in the form of rounded and reddish elevations of the cuticle, resembling the wheels of nettle-raft; but they are not accompanied by the same sensations, tingling and itching, which belong to the nettle-raft. These little tumours gradually dilate; but within one or two days they subside to the level of the surrounding cuticle, and at the same time their hue becomes darker and at length livid, or purple. As these spots are not permanent, but appear in succession in different places, they are commonly seen of different hues; the freshest and elevated ones being of a brighter red, while the level spots exhibit different degrees of lividity, and become brown as they disappear. They are most common on the legs, where they are frequently mixed with petechiae; but they sometimes appear on other parts of the body.

The duration of the purpura urticans is various, from three to five weeks, in the course of which time the hands and ankles are affected with edematous swellings: there is also a diathetic degree of languor and debility, and a loss of appetite, but seldom hemorrhage. It generally appears in summer and autumn, affecting those who are exposed to fatigue, and live upon poor diet, and delicate young women of indolent and luxurious habits. The same precepts, as to treatment, are applicable to this as to the other varieties of purpura.

When purple spots occur as symptomatic of bad fevers, they require no peculiar treatment. They are much less frequent concomitants of fevers than they were formerly; a circumstance which is probably to be ascribed partly to the more liberal use of purgatives at present in all febrile diseases, and partly to the more free admixture of fresh air, to the superior cleanliness, &c. now observed in these matters. The appearance of these spots has been occasionally noticed by various authors in agues, remittent fevers, palies, dropsy, and atrophy. Dr. Willan observes, that in the last stage of pulmonary consumption they sometimes occur as the immediate forerunners of death. (See Parry.) For histories and cases of purpura, see Duncan's Med. Cursier, vol. iii. and the Med. Cursier and Observ. p. 90. Annals of Medicine, vol. ii. Memoirs of the Med. Society of London, vol. iii. art. 20; and vol. iv. art. 17. Medical Tracts and Obs. vol. ii. Willan's Reports on the Diseases of London.

Purpurati, in our Ancient Historians, denote the sons of emperors and kings.

Purpure, Pourpre, or Purple, in Heraldry, according to fome, is one of the five colours of armories, mixed or compounded of gule and azure, bordering on violet; and, according to others, of a little black and much red colour. It is, by the heralds, supposed a symbol of temperance, liberality, dignity, authority, faith, and piety. Most authors in heraldry, as Favyne, Geliot, Monet, and Meneufier, do not allow purple for a colour, in regard it is not simple, but composed of a mixture of other colours. They rather esteem it a kind of intermediate tinture, sometimes metal, and sometimes colour; hence the Spaniards call it una misión; so that one cannot lay it on metal and colour without falsifying the arms.

Add, that many take the purple, as it is accounted, on many ancient bearings, by which fome of the moderns would evince
evince the regularity and legitimacy of this colour in armery, to be no other than silver tarnished.

Sperman, however, in his Apologia, allows purple the preference before all other colours, as having been an enigma of royalty for many ages; yet even he allows it to have been excluded, by the ancient heralds, as only an imperfect colour.

It is represented in engraving, by diagonal lines drawn from the finisher chief to the dexter base point. In the coats of noblemen it is called amethyst; and in those of princes, Mercury.

PURPURINA, a name used by Caneparius, and some other authors, for the aurum mosiacum, or aurum musium of the Persians, the present preparation of which differs from that of that author only in the proportions of the ingredients.

PURPURISSUS, in the Ancient Writers, both Greek and Roman, the name of a compound colour or focus of a fine purplish red, used to paint women's cheeks.

It seems by the composition to have been somewhat like our rose pink, as it is called by the colourmen. It was made of the creta argentaria, or fine white kind of chalk, disloved in a strong purple tincture of some of the roots of wood which dyed red; and when the coarser part was subdued to the bottom of the vessel, the liquor, while yet thick, was poured off into another vessel; and what subduced from this, which was as fine as flour, was of a beautiful pale purple, and was the purpurius favored for use.

Purrel, anno 35 Eliz. cap. 10, a lift ordained to be made at the ends of kerseys, to prevent deceit in diminishing their length.

Purrongur, in Geography, a town of Hindoostan, in the circuit of Burdwan; 20 miles S.E. of Burdwan.

Purrównah, a town of Hindoostan, in Oude; 28 miles E. of Goorapour. N. lat. 26° 57'. E. long. 84° 17'.

Purruch, a small circur of Bengal, about 16 miles in circumference; N. of Mauludah. Allo, a town of Bengal, and chief town of the said circur; 26 miles E.S.E. of Burdwan. N. lat. 25° 4'. E. long. 88° 25'.

Purshah, a town of Hindoostan, in Bahar; 18 miles N.W. of Chuprah.

Pursaummah, a town of Hindoostan, in Bahar; 35 miles E. of Durbungah.

Purse, a manner of accounting; or, as some call it, a species of money of account, much used in the Levant, particularly at Constantinople, where it is 500 apers; three apers being equal to a para, and forty paras equal to a piaitre, called by the Turks grouch, and by the English dollar. By the regulations of 1580, the purse of 500 piaitres was to weigh 2812.5 Turkish drams. A single piaitre weighed 52 drams, or 277 English grains; and the other pieces in proportion. Their standart of fineness was reduced at the same time to 50 carats (or hundredth parts) of fine silver, and 50 of alloy; which gave the value of the piaitre at 1934. shilling, and the other finenes in proportion. But since that period the Turkish coins have undergone a deterioration, so that a piaitre of the late coinage being weighed and assayed by the king's aljay master of the Mint, appeared to be in weight 8 dwt. 6 gr. In finenes, 5 oz. 6 dwt. worse than the English standard. This gives its fineness 47 carats 2 grains Turkish, and its value, in shilling, 13d. Kelly's Un. Cambill.

This money of account is called purse, because all the grand signior's treasure in the feraglio is kept in leather bags of this value.

In this, however, there is some difference; for the purse in Egypt is 25,000 medins, or 75,000 apers; and in other parts of Turkey it is only 20,000.

This method of accounting the Turks derive from the Greeks, and they from the Romans; the emperors of which brought it to Constantinople, as appears from a letter of Constantine to Cicilian, bishop of Carthage, quoted by Eusebius "Sct. Nichor. See Fossi."

Purse-Net is a Rural Economy, a net used for taking both hares and rabbits at certain times; and three or four of them are sufficient to lay over their holes: they are to be fastened, by tying strings to flocks thrust into the earth, otherwise when the rabbits bolt out, they will run away and get out of the nets; but when the nets are fixed, and all things are in order, there must be one or two persons to lie close, to see what game comes home; while, in the mean time, you beat the bushes, to force them homewards. But another way to take rabbits with these nets is, at their coming out of their paracres: and they should be secreted in this manner. First hunt them up and down, to force them all in, then put in a ferret, with a bell about her neck, which gives the rabbit notice of her coming, who, in endeavouring to avoid the ferret, runs into the net.

Purse, an officer aboard a man of war, appointed by the lords of the admiralty, who receives her victuals from the victualler; and is to take care that it be in good condition, and well laid up and flowed. He is also to see that they are carefully distributed to the officers and crew, according to the instructions which he has received from the commissioners of the navy for that purpose. To him also belongs the distribution of slops, &c.

He is also to keep a list of the men and boys belonging to the ship, and to set down, exactly, the day of each man's admittance into pay; that the paymaster or treasurer of the navy may issue out his disbursements, and pay off the men according to the muster-book.

Purpiveness, or Purvisness, among Farriers, thickness of wind, a name common to all those diseases in horses which arise from obstructions in the passages of the lungs.

Purpiveness, sometimes also called broken wind, may proceed from an ulcer, or some inward wasting of the lungs, in which the small vesicles are worn or abraded by the phlegm or acrimony of the common discharges.

The like disorder may also arise from a stagnation, hindering the air from penetrating so as to lift up the lungs in the act of respiration; or from some tough and mucilaginous matter separated in the branches of the wind-pipe.

The usual occasions are cold, surfeits, and other diseases not thoroughly carried off. Purvise disorders may also arise from unwholesome food, bad air, and hard riding when a horse is full. The signs are commonly a heaving and beating of the flanks; a wheezing and rattling. Sometimes the kernels about the throat will swell, and there will be a grunndulous running at the nose, which is the utmost stage of the disease, and usually reputed dangerous.

Pursur, in Geography, a town of Hindoostan, in Oude; 13 miles N. of Mahomdy.

Purver, Anthony, in Biography, was born at Up-
Hurborn, in Hampshire, about the beginning of the 18th century. His education was extremely limited, but he exhibited a striking proof of his capacity for learning while he was very young; for, being prevented by illness from attending school almost six weeks, he applied, by himself, during that time, with such diligence and success to the study of arithmetic, that upon his return to school he was able to explain the precedents of evolution to his master, whose attainments had not carried him so far. At this time of life he exhibited great powers of memory, by committing to it twelve of the longest chapters in the Bible in as many hours. He was put apprentice to a shoemaker, who was also a dealer in sheep, and employed Anthony a good deal in looking after his flock. This was not by any means an irksome business, as it afforded him an opportunity for reading the Scriptures, to which he was particularly attached. As he advanced in years, he found that his favourite book contained doctrines that were very differently interpreted by different persons, and he was resolved to study the Old and New Testament in their original languages. Having renounced the occupation for which he was originally intended when he was about twenty years of age, he commenced teaching in a school, but afterwards removed to London, for the sake of more easily acquiring the means of prosecuting his studies. Here he probably refided in 1727, when he published his work, entitled "The Youths Delight." While at London he became a Quaker, and officiated among the friends in the character of a minister. He returned to Hurborn, and refumed his school in 1727, and probably continued it for some time, during which he began to translate the books of the Old Testament, from the original Hebrew. While thus employed, he felt it his duty to become a missionary, and travelled through several counties of the kingdom, till he came to Stambrook, near Bristol, towards the latter part of the year 1738. Here he refided at the house of a maltster, whose son he instructed in classical learning, while he devoted his leisure to his favourite employment of translating the Scriptures. In 1746 he made an attempt to publish his translation of the Old Testament in numbers; but for want of encouragement he did not proceed beyond two or three numbers. When he had completed the translation of the whole Bible, he could find no bookseller who would embark in the publication. Thus was the labour of thirty years likely to be lost, till Dr. Fothergill made him a present of 1000l. for the copy, and took upon himself the expense of printing the work. Under his auspices, it made its appearance in the year 1764, with the title of "A new and literal Translation of all the Books of the Old and New Testament, with Notes critical and explanatory," in 2 vols. folio. It was the author's intention to have published a second edition, with various corrections and alterations, but he did not live to accomplish the design. He died in 1777, about the age of 75. Purver was described by Dr. Fothergill as "a man of great simplicity of manners, regular conduct, and a modest reserve: he is readily attentive to truth, hates falsehood, and has an unconquerable aversion to vice; and to crown the portrait, he is not only greatly benevolent to mankind, but has a lively sense of the divine attributes, and a profound reverence of, and submission to, the Supreme Being." PURITY. See POURVANCE.

PURVIEW. See PURVIEW.

PUS, from the French, pourrue, a gift, grant, provision, &c. a term frequently used, by Sir Edward Coke, for the body of an act of parliament, or that part which begins with Be it enacted, etc. as contradistinguished from the preamble.

The statute of 3 Hen. VII. stands upon a preamble and a purview. 12 Rep.

PURULENT, PURULENTUS, in Medicine, something mixed with, or partaking of, pus or matter.

Phthisical people frequently spit a purulent matter. In a dysentery, the stools are purulent: when there is an ulcer in the reins or bladder, the urine is purulent.

PURUSH, in Mythology. See PARISH.

Puruz, in Geography, a river of La Plata, which rises about S. lat. 17° 20', taking the name of "Rio Beni," and afterwards called "Amaru-Mayu," or "The Serpent," from S. lat. 12° its course is not ascertained till it comes to S. lat. 6°, after which it assumes the name of Puruz, and runs into the river of the Amazons, or Maranon, S. lat. 3° 44'. W. long. 45° 6'. Its whole course is northernly about 800 miles.

Purwar, a town of Hindoostan, in Lahore; 14 miles S. of Sialkot.

Purysburg, a handsome town of South Carolina, in Beaufort district, which district contains 25,887 inhabitants, on the E. side of Savannah river, 37 miles from the ocean, and 20 from Savannah. It derives its name from a Swiss, John Peter Purv, who settled a colony of his countrymen here about the year 1735, with a view to the culture of silk. The mulberry-trees are still standing, and some attention is paid to the raising of silk. The town contains between 40 and 50 dwelling-houses, and an episcopal church; 64 miles W.S.W. of Charleston. N. lat. 32° 24'. W. long. 81° 12'.

Pus, from mater, matter, the fluid contained in abscesses, and discharged from ulcerated surfaces, and sometimes from membranous surfaces which are merely inflamed, and quite free from ulceration, as is illustrated in cases of gonorrhea, empyema, etc. Pus is formed by a peculiar process, which is termed suppuration, of which we shall have occasion to speak in a future volume of this work.

In the present place, we shall content ourselves with inferring a few observations on the qualities and uses of pus, chiefly taken from the writings of Mr. Hunter.

True pus has certain properties, which, when taken singly, may belong to other secretions, but which, conjointly, form the peculiar character of this fluid, viz., globules swimming in a fluid, which is coagulable by a solution of sal ammoniac, which no other animal secretion is, and, at the same time, a confluence of inflammation.

The colour and the confidence of pus are the two qualities which first attract the notice of every, the most superficial, observer. The colour arises from the largest portion of this fluid being composed of very small round bodies, very much like those little globules which, swimming in a fluid, make cream. The fluid in which the globules of pus swim, we might at first suppose to be the serum of the blood, for it coagulates with heat, like the latter fluid. Pus is also probably mixed with a small quantity of coagulating lymph; as it partly coagulates after it is secreted.

The fluid part of pus, however, is known to have properties which ferum has not. There being a similarity between pus and milk, experiments have been made to ascertain whether the fluid of pus could be coagulated with the gallic juice of animals; but no coagulation could be effected in this manner: a solution of sal ammoniac made the fluid part of pus coagulate; but not any other secretion, or
PUS.

or natural fluid; and hence it was concluded, that whenever globules were found swimming in a fluid, coagulable by sal ammoniac, the matter was to be considered as pus.

The proportion which the white globules bear to the other parts of pus, depends on the health of the parts producing the discharge. When the globules are very abundant, the matter is thicker and whiter, and is called healthy pus; the meaning of which is, that the fluids, which produced it, are in good health; for these appearances in the matter are no more than the result of certain salutary processes going on in the fluids, the effect of which processes is to produce the disposition, on which both suppuration and granulation depend.

Pus is specifically heavier than water, and is probably about as heavy as blood.

Besides the above properties, pus has a sweetish mawkish taste, very different from that of most other secretions, and the same taste takes place, whether it is pus from a fore, or an irritated inflamed surface.

Pus has a smell in some degree peculiar to itself; but this differs in different cases. Some diseased, it is said, may be known by the smell, as, for instance, a gonorrhea.

Pus sinks in water; mucus floats. Pus communicates to water an uniformly troubled white colour; mucus gives the appearance of stringy portions floating in it. Mucus is said to be more readily disolved by sulphuric acid than pus is. It has also been asserted, that if water be added to such solutions, the pus is precipitated to the bottom of the vessel; while the mucus, instead of being completely precipitated, forms swimming flakes. A solution of caustic alkali dissolves both pus and mucus; but when water is added, the pus is said to become separated, but not the mucus.

Though solutions in chemical menstrua and precipitations have been thought a test of the distinction between these two fluids; yet the method has been thought absurd and unphilosophical. It has been conceived, that all animal substances whatever, when in solution, either in acids or alkalis, would be in the same state, and therefore, that the precipitation would be the same in all. Calcareous earth, when dissolved in muriatic acid, is in that acid in the same state, whether it has been dissolved from chalk, limestone, marble, or calcareous spar, and precipitations from all are the same. Hence experiments were made on organic animal matter, such as muscles, tendon, cartilage, liver, and brain; and on inorganic, such as pus and the white of an egg. All these substances were dissolved in sulphuric acid, and precipitated with the vegetable alkali. Each precipitation was examined with such magnifiers as plainly showed the forms of the precipitates, all which appeared to be flaky substances. The precipitate by the volatile alkali had exactly the same appearance. The same appearances were seen when the above kinds of animal matter were dissolved in the vegetable caustic alkali, and precipitated with the muriatic acid. A flaky substance, void of any regular form, composed each precipitate.

Pus does not irritate the particular surface which secretes it, though it may be irritating to any other. Hence no suppuring surface, of any specific kind, can be kept up by its own matter. If this had not been the case, no fore of a specific quality, or producing matter of an irritating kind, could ever have been healed. This is similar to every other secretion of stimulating fluids, as the bile, tears, &c., which fluids do not stimulate their own glands or ducts, but are capable of stimulating any other part of the body.

Whenever a real diseafed attacks either the suppuring surface, or the constitution, the production of true pus ceases, and the fluid becomes changed in some measure, in proportion to these morbid alterations. In general it becomes thinner and more transparent, and it partakes more of the nature of the blood, as is the case in most other secretions under similar circumstnaces. Særitis is the term usually applied by surgeons to pus in this degenerated state. This unhealthy sort of matter has more of the serum, and frequently more of the coagulating lymph in it, and less of the combination, which renders it coagulable by a solution of sal ammoniac. It has also a greater proportion of the extraneous parts of the blood, which are soluble in water, such as fats; and it has a greater tendency than true pus to become putrid. Such unhealthy matter may even be irritating to the surface which produces it.

The discharge, when of an irritating sort, is more stimulating to the adjoining parts with which it comes in contact, than to its own secreting surface. In this manner it frequently produces excoriation of the skin and ulceration. Thus the tears excoriates the skin of the cheek, in consequence of the quantity of fats which they contain. From this effect, matter has been called corrosive, a quality which it has not; the only property which it possesses being that of irritating the parts which it touches, so as to cause their absorption.

When the vessels thus lose the power of producing good pus, they also lose more or less the power of forming granulations. This may depend on some deviation from the due structure and action which such vessels should possess, in order to be qualified for the performance of these operations.

Pus, from several circumstances, would appear in general to have a greater tendency to putrefaction than the natural juices have; but, perhaps, this is not the case with pure pus, which, when first discharged from an abcesse, is commonly perfectly sweet. There are, however, some exceptions to this, but these depend on circumstances entirely foreign to the nature of pus itself. Thus, if the abcesse had any communication with the air, while the matter was confined in it; or if the collection has been so near the colon, or rectum, as to have been infected by the feces, then we cannot wonder that the matter should become putrid. When blood is blended with pus; when flous are mixed with it; when the parts forming the seat of the abcesse are in a gangrenous state from an erysipelas affection; the matter has a greater tendency to putrify than the pure pus discharged from sound abcesse, or healing sores. Pure matter, though easily rendered susceptible of change by extraneous additions, is in its own nature tolerably uniform and immutable. It appears so unchangeable, that we find it retained in abcesse for weeks, without having undergone any alteration. These qualities, however, only belong to perfect pus.

In the preceding paragraph it is stated, that matter remains very often unchanged in abcesse for weeks. This expression of Hunter's is not strictly correct; for it is well known, that the surfaces of the cavities of abcesse are always absorbing, as well as secreting ones; consequently there must be a continual mutation going on in the contained matter.

When there are diseased bones, or other extraneous bodies, exciting irritation, sometimes even to so great a degree as to make the vessels bleed, and often wounding the vessels of the part, the matter is always found to be very offensive. This state of the discharge is one mark of a diseased bone.

The
The discharge of an unhealthy sore blackens silver probes, and preparations of lead. This effect is imputed by Dr. Crawford to the sulphurated hydrogen gas generated in the matter. Phil. Trans. vol. lxxv. for the year 1790.

P. 291, &c.

Use of Pus.—By some it is supposed to carry off humours from the constitution. Suppuration is sometimes regarded as a constitutional disease, changed into a local one, which constitutional malady is discharged, or thrown out of the body, either in the form of pus, or together with this fluid. Critical abscesses have been thought to be cases of this sort. Suppuration has also been imagined to carry off local complaints from other parts of the body, on the old principle of derivation or revulsion. For this reason, fores or illies are made in found parts before allowing other sores to be dried up. Suppuration is sometimes excited with a view of making parts, such as indurated swellings, dissolve into pus; but we have endeavoured to shew that no dissolution of the solids is concerned in the production of pus.

A secretion of pus is looked upon as a general prevention of many, or of all, the cauæ of disease. Hence illies are made to keep off both universal as well as local diseases. However, the use of pus is perhaps unknown; for it is formed most perfectly from healthy sores, and in healthy constitutions; and large discharges from parts not very essential to life, produce very little change in the constitution, and as little upon being healed up, whatever some may suppose to the contrary.

This is certainly the case with many old ulcers, the suppuration from which seems to have little or no effect in impairing the health. Nor is there any real reason to be afraid of healing such ulcers, when possible, lest a worse disease should follow from the stopping of the discharge, to which the system is supposed to be habituated so much, that the continuance of such discharge is essential to health.

Every one knows, that when there is no interference of art, that is, when the surface of a sore is left uncovered, the thin part of the matter evaporates, and the thick part dries and forms a scab. Nature, therefore, seems to have designed, that one use of pus should be to make a cover or protection for ulcerated surfaces. Among the secondary uses of suppuration may be mentioned, opening a communication between a disease and the external surface of the body; forming a passage for the exit of extraneous bodies, &c.

PUS, in Geography, a town of Hindoostan, in Bahar; 32 miles E. of Hajjypour.

PUSBACH, a town of Germany, in the principality of Kulmbach; 12 miles S. of Kulmbach.

PUSCHENGA, a river of Russia, which rises in lake Urus, in the government of Archangel, and runs into the Pigna near Kevrol.

PUSCHIAVO, a town of Switzerland, in the Grisons, from which is derived the name of one of the jurisdictions ceded by the duke of Milan, in the year 1456. The greater number of the inhabitants confines of Roman Catholics. The town lies three miles N. of a lake of the same name, abounding in fish, and distant 14 miles S.W. of Bormio, and is situated 17 miles W.S.W. of the fame town, and 20 miles E. of Chiavenna.

PUSCHIMA, a town of Russia, in the government of Novgorod; 40 miles N.E. of Biebozerk.

PUSHAN, in Mythology, a name for Surya, a personification of the sun, among the Hindoos, and a name also of their god Siva.

PUSHENG, in Geography. See Kooshinje.

PUSHERS, a name given to Canary birds when new flown. See Brancher, and Canary bird.

PUSHING, in Geography, a considerable town of Persia, in the province of Khorasan, a little to the N. of Isfarrat, built on the banks of the Horroid, and celebrated for the beauty of the cypris trees which grow in its vicinity.

PUSHPADANVA, in Mythology, one of the names of the Hindoo deity Kama, the cupid of their mythology. It means with a flowery bow; his bow, which is made of a sugar cane, having its string composed of flowers and bees. See KAMA.

PUSHPAKA, the name of a flowery car, in which the Hindoo Plutus, named Kuvera, is conveyed. See KuVERA.

PUSILLATUM, a word used by some medical writers to express a coarse powder, or any medicinal substance, beat into small pieces for infusion, or the like purposes.

PUSTING, in Geography, a town of Hungary, on the Waag; eight miles N.N.W. of Leopoldstadt.

PUSTOMERZ, a town of Moravia, in the circle of Brunn; 16 miles N.E. of Brunn.

PUSTOZIRSK, a town of Russia, in the government of Archangel, near the Petchora. N. lat. 67° 15'. E. long. 51° 14'.

PUSTULE, PUSTULA, in Medicine, a small elevation of the cuticle, upon an inflated bafe, containing pus. Pustules originate from an inflammation of the skin, and the consequent partial effusion of purulent matter under the cuticle, by which the latter is elevated into small circumscribed tumours. Pustules are of various sizes, sometimes very minute, and sometimes extending to half an inch in diameter; and they terminate either in small ulcerations, or more commonly in scabby crusts. Dr. Willan constituted an order of cutaneous diseases under the head of pustules, including five genera, impetigo, perrigo, ecchyma, varioila, and scabies; but he never completed this part of his work, a brief compendium of which has been drawn up by Dr. Bateman. (See his Practical Synopsis of Cutaneous Diseases, 1813.) See also IMPETIGO, PERRIGO, SMALLPOX, and RITCH.

By many writers the use of the word pustule is very general, including not only purulent elevations of the skin, but vesicles and even pimples; and it must be admitted that the belief of authority has evinced even a more extensive acceptance of the word, including even wheels, “quæ ex urticâ vel fudore nascuntur.” (Cellus, lib. v. cap. 28.) But not only the etymology (qualis pus vularis), but accuracy of language would lead us to limit the term to pustules eruptions, as in the above definition, and as some correct writers have done. See Prof. Arnemann, Comment. de Aphantis. Linnaeus. Gen. Morbor. clav. xi. ord. 4, &c.

PUSTIVOLA, in Geography, a river of Asiatic Turkey, which runs into the sea of Marmora; 16 miles W. of Artaki, in the province of Natolia.

PUȘU, in Botany, the name of a famous plant growing in China, and greatly esteemed there. This and the ginseng these people a long time kept to themselves; but at length it was discovered, that the one was esteemed a certain prolonger of life, and the other a preservative against all diseases.

They, in their manner of speaking, say, that the puși gives immortality. We have not been so happy to obtain any of this famous plant for the trial, but the ginseng having been brought over, and found not to possess those great virtues they ascribe to it, and the people in China, who are possessed of the puși, dying, as well as those who have it not, we find, that the virtues of both are so greatly exaggerated.
exaggerated by the eastern dialect, that there is not much to be expected from them.

PUSULA, in Geography, a town of Sweden, in the province of Nyland: 37 miles N.N.W. of Helsingors.

PUT, in the Manege, called in French manege, is used for the breaking or managing of a horse: thus,

To put a horse to corsets, or caprioles, is to teach him those parts of the manege.

To put a horse upon his haunches, called in French affair, is to make him bend them handomely in galloping in the manege, or upon a flop. See HANChES.

To put a horse to the walk, trot, or gallop, is to make him walk, trot, or gallop.

To put a horse under the button, see BUTTON.

PUTAGE, Putagium, in our old La zo Books, denotes whoredom or fornication on the part of a woman.

The word is formed from the French putte, where: putagium, q. d. putam agere. "Quod autem generaliter follet dies, putagium hereditatem non admisce: ilium intelligatur off de putagio matris: quia illius hares legitimus est, quem nuptae demorantur." Glanv. lib. vii. cap. 12.

PUTALIA, in Geography. See PUTILL.

PUTALLOM, a town on the coast of Ceylon, near Calpenteen, remarkable for its salt-pans. This place, before the arrival of Europeans on the island, supplied the natives with salt; and on account of its convenient situation, was pitched upon by the Dutch for the manufacture of the salt with which they supplied the king of Candy's dominions, according to the articles of their treaty with him. The salt-pans are formed by an arm of the sea which overflows part of the country between Putallom and Calpenteen. A very large quantity of salt was manufactured here by the Dutch; they looked upon it as of the highest importance to their interests in the island, and the most formidable weapon which it was in their power to employ against the native king, as it was impossible for him to procure any but through their means. Since the British have obtained possession of the island, this manufacture has been almost entirely neglected. It is capable, however, of being rendered very profitable, as it is the only one of this kind on this side of the island, and the most conveniently situated for supplying the king of Candy's dominions. The Dutch enacted very severe laws to prevent individuals from manufacturing or trading in this article; the government taking upon itself the management of the works, and the care of supplying both its own subjects and the Candians. In order to keep a constant check on the latter, the Dutch were careful not to allow them too great a quantity at once; and whatever remained at Putallom, after supplying the demands of each year, they destroyed, that it might not be seized upon by forprife.

PUTANGES, a town of France, in the department of the Orne, and chief place of a canton, in the district of Argentan; nine miles N.W. of Argentan. The place contains 502, and the canton 11,934 inhabitants, on a territory of 212 square kilometres, in 31 communes.

PUTANISMO, Putanism, an Italian term, naturalized by some English writers, signifying whoredom, or the life or condition of a courtesan.

The word we borrow immediately from the French, putanisme; and they from the Italian putana, whore; of puta, girl.

PUTAO, in Geography, a town on the S. coast of the island of Lucon. S. lat. 13° 6'. E. long. 123° 28'.

PUTATIVE, Suppositive, something reputed to be what it really is not.

The word is seldom used but in the phrase putative father.

Thus we say, Joseph was the putative father of J esus Christ.

PUTAVERI, in Biography, a native of Otaheite, brought into France by the circumnavigator Bougainville: of whom a gentleman, who had refrided a considerable time in Italy, and was an excellent judge of music, affured us that the effects of French music, when fairly tried upon him immediately on his arrival, were not those of rapture, but ridicule. He danced to it, indeed, as we would to a marked measure beat on a drum or a table; for as soon as he returned from the great opera, whither he was carried, he mimicked what he had heard and seen in the most natural and ridiculous manner possible; giving the company a specimen of the French opera, which was the most admirable parody imaginable of French singing, or rather of the screams and howlings at the Académie Royale de la Musique in the time of Louis XV. Our friend wished to try the effects of Italian music upon this demi-favage native of Otaheite; but there was no opportunity, for how could it be properly executed at Paris? However, according to the late lord marshal, the experiment had been fairly made on another occasion.

A young Greek lady being brought from her own country to Paris, some years since, was, soon after her arrival in that city, carried to the opera by some French ladies, supposing, as she had never heard cultivated music, that she would be in raptures at it; but, contrary to those expectations, she declared that the singing only reminded her of the hideous howlings of the Calmuc Tartars, and as to the machinery, which it was thought would afford her great amusement, she proclaimed her dislike of many parts of it, and was particularly shocked by what she called the impious and wicked imitation of God's thunder. Soon after this experiment the went to Venice, where another trial was made on her unprejudiced ears, at an Italian opera, in which the famous Gi zziello sung, at whole performance she was quite disdoloved in pleasue, and was ever after passionately fond of Italian music.

PUTAWATAMES, or Pouototaries, in Geography, Indians who inhabit between St. Joseph's and Detroit in North America, and can furnish about 500 warriors. There are two tribes of this name, the one of the river St. Joseph, and the other of Huron. At the treaty of Green ville, Anguill 3d, 1795, they ceded lands to the United States, who paid them a sum of money, and engaged to give them goods to the value of 1000 dollars per annum, for ever.

PUTBUS, a town and fort of the island of Rugen; five miles S. of Bergen.

PUTCABARY, a town of Hindoostan, in Bengal; 145 miles S.E. of Moorheadabad.

PUTEA, in Ancient Geography, a town of Africa propria, S. of A dremutum, between Campan and Caraga, according to Ptolemy. Alba, a town of Syria, in the Palmyrene, between Orico and Ahada. Ptol.

PUTEAL, among the Romans, a small kind of edifice raised in the place where a thunder bolt had fallen. See BIDENTAL.

PUTELKAW, in Geography, a town of Prussia, in the province of Ermland; six miles S.W. of Flauen burg.

PUTEMAHRY, a town of Hindoostan, in Bengal; 16 miles N. of Kifhanagur.

PUTEOLANUS Fulvis. See POZZOLANA.

PUTHLOSE, or PUTLOS, in Geography, a town of the duchy of Holstein; four miles N.W. of Oldenburg.

PUTI, or Potti, a town of the principality of Guriel, at
at the mouth of the Rione, on the Black sea; 80 miles W.S.W. of Cotatis. N. lat. 42°. E. long. 41° 28'.

PUTICULI, among the Romans, ditches or holes in the earth, a little without the Equiline gate, in which the poorer fort of people were buried.

PUTIGNANO, in Geography, a town of Naples, in the province of Bari; 33 miles S.E. of Bari.

PUTIVLI, a town of Russia, in the government of Kuril, on the Sem; 72 miles W.S.W. of Kuril. N. lat. 51° 20'. E. long. 34° 14'.

PUTLACH, a town of Bavaria, in the bishopric of Bamberg; five miles E. of Gollweinstein.

PUTLITZ, or Putlitz, a town of Brandenburg, in the Mark of Pregnitz; 10 miles N. of Perleberg. N. lat. 53° 16'. E. long. 12° 5'.

PUTLEGS, or Putlocks, in Building, short pieces of timber, about seven feet long, used in building scaffolds. They lie at right angles to the wall, with one of their ends bearing upon it, and the other upon the ledges or poles which stand parallel to the side of the wall of the building.

PUTNA, in Geography, a town of Moldavia; 32 miles W. of Suceava.—Also, a river of Moldavia, which runs into the Mileau, at Focană.

PUTNAM, a county of America, in the southern district of Georgia, containing 6800 free persons, and 3220 slaves. Its chief town is Eatonton.

PUTNEY, a town of America, in Windham county, and state of Vermont, containing 1667 inhabitants.

PUTNEY, a village and parish in the west half hundred of Brixton, and county of Surrey, England, is situated on the south bank of the river Thames, at the distance of four miles from Hyde Park corner, London. The parish contains 1630 acres, of which the greater proportion is an open common or heath. In the time of the civil wars it was the scene of some very interesting transfigurations. The parliamentary army lay at Putney, for a considerable time, in the year 1647; and here the general officers, after long debates in the church, completed their propositions for the future government of the kingdom, and sent them to the king at Hampton Court. Here also were born two celebrated statesmen, Nicholas Wilt, bishop of Ely, and Thomas Cromwell, earl of Effex, the protector of Wolsey, and the successor to his power and misfortunes. In this parish are many agreeable villas; in one of which the late illustrious William Pitt breathed his last. The church was originally built as a chapel of ease to Wimbledon, not long after the conquest; but was, in a great measure, re-erected in the reign of Henry VII. It is a small edifice, with a low tower at the eastern extremity of the south aisle, built by bishop Wilt, is, however, its chief ornament. Monuments and inscriptions are numerous, but few of them deserve notice. Over the Thames, in this parish, is a wooden bridge, constructed in the year 1729, at the expense of 23,975l. and yielding a revenue, by tolls, to the proprietors of about 3000l. per annum. A fishery here was possessed by the lord of the manor, previous to the conquest; and is now rented for a considerable sum. All horsemen and porpuses are claimed by the lord mayor of London, but the fishermen receive 5s. for each of the former, and a guinea for each of the latter, when delivered to the water bailiff. On the common stands an obelisk, erected, in 1756, in memory of Hartley's invention for extinguishing buildings against fire.

PUTNOK, a town of Hungary; 36 miles W.N.W. of Tokay.

PUTORIUS, in Zoology, the Pole-cat, a species of Mustela; which see. See also Pole-cat.

Putorius Serpens, a name given by some to that species of serpent called by others drymum.

PUTREFACTION, or Putrification, in Chemistry, is a species of fermentation (which see); being the last stage of the fermentative processes, and connoting not merely in the decomposition and transposition of the particles of putrefying substanstances, whether animal or vegetable, by which new combinations are produced, but also in the extraction and expulsion of some of the constituent parts of the substanstances.

This decomposition or derangement of the constituent parts of vegetable substanstances is usually called fermentation, and that of animal bodies, is denominated putrefaction. The agents that produce both kinds of decomposition, and the circumstances that attend them are, in various respects, very similar, and the chief difference of the products that are obtained from both depends upon the diversity of their constituent parts. The process of putrefaction, and its effect in dissolving the combination of the constituent parts of bodies, are sufficiently obvious to feme; but the rationale of the process, and the mode in which gaseous and volatile compounds are separated from bodies that are disorganized and afterwards form new combinations, are still involved in considerable obscurity; and different writers have disagreed in their explication of them. Several facts, however, are universally acknowledged; and of these we shall give a brief account in the sequel of this article, together with a detail of some of those principles and theories that have been adopted for explaining them. Becher long ago observed, in his "Phys. Subt. l. i. §. 5," that air is the principal agent of decomposition, but that water and heat very much facilitate its action. Thus he says, "Fermentation ergo definitur quod sit corporis denfioris rarefacio, particularumque aerarum interpoftio; ex quo concluditur debere in aere fieri nec nimum frigidum, nec rarefacio impediatum; nec nimum calido, ne partes raribiles expellantur."

An animal substanstance may be preferred from putrefaction by depriving it of the contact of the air; and this process may be accelerated or retarded by varying or modifying the purity of the same fluid. When we observe putrefaction occurring without the access of atmospheric air, the effect is produced by the water which impregnates the animal substanstance, becomes decomposed, and affords the element and the agent of putrefaction. Hence it appears, that moisture is an indispensible requisite to facilitate putrefaction. A moderate degree of heat is also a condition favourable to animal decomposition.

Dr. Hales, it is well known, ascribed the cohesion and solidity of bodies to the air, which exils in them in a fixed state, and forms, as he expresses it, the cement or bond of union between their several constituent particles. To this purpose he observes, that air abounds much more in solid than in liquid bodies; and that solid bodies being generally denser than water, the attraction of the air of those solid bodies in a fixed state, and its repulsion when in a liquid state, are greater than the attraction and repulsion of the lighter weight particles in a fixed and in an elastic state; and hence the particles of air are fitter to be the principal bond of union in solid bodies, than the particles of water. This opinion was afterwards adopted by baron de Haller, who maintains, that air is the vinculum elementorum primarium, or the true cement which binds together the earthy particles
PUTREFACTION.

particles of bodies. Mr. Macbride, as we have elsewhere shewn, has taken occasion, by a variety of experiments, to illustrate and establish this opinion; and in support of it he alleges, that the preservation of firmness and soundness in bodies depends on restraining the escape of that principle, since known by the name of fixed air, and which he supposes to be the immediate cause of cohesion: for the moment it flies off and refumes its effulgence, the other constituent particles, viz. the earthy, the saline, the oily or inflammable, and the aqueous, being thereby put in motion, immediately begin to exert their several peculiar attractive and repulsive powers, and run into new combinations, which first change, and at length altogether destroy the texture of the substance they formerly composed; provided that this substance contained in itself a sufficient quantity of water to allow of the interline motion, by giving the proper degree of fluidity; for without fluidity there can be no interline motion; and without interline motion there can be no change of combination: because we see that fish and vegetable bodies are as suddenly deprived of their water, or, generally, contain very little, are almost as durable and unchangeable in their texture as minerals. Hence Acosta observes, that in Peru, and others have observed the fame in Egypt, where it very rarely rains, every thing will continue a long time uncorrupted; unless we should rather ascribe this effect to the abundance of nitrous falt in the air of those places, which is known to refit putrefaction. Indeed all putrefactions, both of animal and vegetable bodies, are affirmed by the learned Boerhaave to be performed by means of water alone. Take, says he, a pound of fresh flesh, and keep it in a heat like that of our body, and, in a few days the putrefaction will be completed; but if you first drain out, or exhale, all the watery part from the fame in some chemical vessel, though the fat and oil remain, the flesh will harden like a stone, and may be kept for ages without putrefaction. Though when thus hardened, water poured on it, or even the common dew, will soon fet it a putrefying. Thus Villaris and Cazalet of Bourdeaux, as Chapital informs us, dried meat by means of fives, which was preferred for several years without contracting any bad flavour.

By such means, bread, flesh, or the like foods, may be preferred for many ages; provided regard be had to the place. Hence it is that in dry countries, as Egypt, dead carcases never putrefy, but dry and harden uncorrupted: as we see also in the mummies found buried under the sand.

The sands and light porous earths preferve human bodies by exhausting their juices and drying the solid parts. Hence it is, that thare carasses have been discovered in Arabia, confelling of men and camels, preferred in the sands under which the impetuous winds have buried them. In the library of Trinity college, Cambridge, a human body may be seen in a perfect state, which was found under the sand in the island of Teneriffe. Hence putrefacions putrefy much more slowly when exposed to a drying wind, than in a sheltered place.

Nevertheles, too much humidity impedes putrefaction. To this purpose Becher observes: "Nimia quoque humiditas a putrefacione impedit, prout nimius calor; nam corpora in aqua potius gradatim confummi quam putrefecerit, fi nova fumer affluens sit, experientia docet: unde longo tempore integra interdum submersa profuerat a putrefacione immuniam vidimus; adeo ut nobis aliquid speculatio occurreret, tractando tali modo cadavera anatomico subducti, quod duxit a factore et putrefacione immunia forest." Accordingly it is necessary, that in order to a body's putrefying by moisture, that the water should impregnate but not inundate it. It is also necessary, that it should remain in the texture of the animal body, without being renewed; for thus the lymph is diffused, and the mot putrefiable substance is presented to the air with the greatest extent of surface; and the water itself is decomposed, and by this means affords the putrefactive principle.

Even human blood, which, naturally, is so prone to putrefaction, if you deprive it of its watery part, may be kept for fifty years. Goat's blood, we actually find kept fo long in the shops, without corrupting; though, if you diffuse it in water, and expose it to a gentle warmth, it will putrefy immediately. Blood is said to be the most putrefactive substance, as is known; and this property is ascribed partly to its fluidity and partly to the large quantity of fibrin and uncondensed albumen, which it contains, and especially to the former. See Blood.

We shall here add, that animal substances seem to be (ceteris paribus) more putrefact in proportion to the number of constituent parts which they contain. The substances either absolutely or nearly imputrefiable are bone and condensed albumen, the latter being such as exsils in cuticle, nail, hair, &c. which long remain unaltered in the midle of putrefying substances. Animal oil also putrefies with great difficulty, and hence the people that live in the most northern parts of America, the Equinoxians and others, preferve fish and meat to a certain degree from putrefaction by immersion in fish-oil.

In putrefaction there is a great intestine motion, which, when carried to an extreme, and when the putrefying substance is much comprized, is accompanied with heat and smoke, and sometimes flame. However, M. Beaumé affirms, that putrefaction is not attended with any sensible heat: when, indeed, it proceeds slowly, and the quantity of putrefying matter is but small, the heat, if any, is very little. That putrefactive substances emit light, is an unquestionable fect; and on this principle philosophers account for the luminousness of the fea, the ignis fatuus, &c. To this purpose M. Ant. Martin (Swed. Abbad. vol. xxiii. p. 255, cited by Dr. Priestley, in his History of Light, &c. p. 576;) observes, that human bodies have sometimes emitted light about the time they begin to putrefy; and that the walls and roof of a place in which dead bodies had often been exposed, had a kind of dew or clammines upon them, which was sometimes luminous. And he imagines, that the lights which are said to be seen in burning grounds may be owing to this cause. It has been observed, that heat extinguishes the light of putrefact substances; Mr. Canton, attending to this circumstance in some experiments for ascertaining the cause of the luminousnes of the sea, remarks, that though the greatest summerheat is well known to promote putrefactions, yet twenty degrees more than that of the human body would hinder it; for putting a small piece of luminous fish into a thin glass ball, he found that water of the heat of one hundred and eighteen degrees would extinguish its light in less than half a minute; but that on taking it out of the water, it would begin to recover its light in about ten seconds: but it was never afterwards so bright as before. See Light.

It has been observed, that a temperature from about forty degrees to the highest natural heat is favourable to the putrefaction of animal matter, whereas a freezing temperature is known to stop putrefaction, as it is the custom in cold countries to bring victuals frozen to market, and in this state they are kept for any length of time without any other preparation; and besides, bodies of men or of other animals remain unaltered under ice for many weeks. We
might allege many other circumstances of a similar nature. On the other hand, a scorching heat also prevents putrefaction; probably by expelling the moisture which is essential to the process, because by an inferior degree of heat putrefaction is promoted. The influence of temperature on animal putrefaction is thus stated by Becher: "Aer calidus et humidos maxime et putrefactionem facit—corpora frigida et secus difficiliter, imo aliqua proprus non putreunt; quae ab imperitis proinde pro fanitis habita fuerit; ita a aer frigido et secus, imprimis calidus et secus, a putrefactione quoque praeferunt; quod in Hispania videmus, et locis alibi calida, frigida. calidis aer cum retineatur, ubi corpora non poterunt et refolviis; nam cadavera in oriente in arena, imo apud nos arte in fornas, eccari, et sic ad fines mundi utque a putredine praeferant, certum est: intemperatrum foetis quae frigus a putredine praeferant unde corpora Stockholme tota hyeme in patibulo suprema fine putredine animadvertimus." From the facts already stated, we may deduce the most effectual means of preventing, and increasing putrefaction, and also of modifying it at pleasure. A body may be preserved from putrefaction by depriving it of the contact of atmospheric air; for this purpose nothing more is required than to place the body in a vacuum, or to envelope it in a covering, which may defend it from the immediate action of air; or also to envelope it in an atmosphere of some gaseous substance, which does not contain vital air. Putrefaction may also be favoured by keeping bodies at a suitable temperature. A degree of heat from between sixty-five and ninety degrees diminishes the adhesion of the parts, and favours the action of the air; but if the heat be greater, says Chaptal, it volatilizes the aqueous principle, dries the solids, and retards the putrefaction. Hence it is inferred, that for the decomposition of an animal substance, it is necessary that it should have the contact of atmospheric air, and that the purer the air is, the more speedily will the putrefaction: that it be exposed to a moderate degree of heat: and that its texture be impregnated with humidity.

The most sudden and remarkable changes produced upon a body by putrefaction, are upon its colour, smell, and taste. Flesh beginning to putrefy, is well known to exhale very soon after a penetrating fetid smell, its colour becomes paler, then inclining to blue, and afterwards livid and black, and its taste nauseous. Transparent liquor, as urine and broth, during putrefaction, becomes also turbid: as the putrefaction advances, the smell becomes more and more fetid, and it also acquires great pungency, which is caused by a large quantity of volatile alkalies, diffused from those substances that are completely putrefied. Solid bodies, whilst they are putrefying, will become soft, lose the cohesion of their parts, and are lastly reduced to a very disagreeable putrid pulp, mafs: the fluids become turbid, and the effluvia are loathsome and thickening, and after a time a putrid gas is diffused in a slow but sensible effervescence. A foul and brown serum then sweats out from the pulp mafs, and about this time the effluvia is very feebly ammonic, which is indicated by its effects on the eyes and throat, and by forming a white vapour with muriatic acid gas. For some time a large part of the putrid sub stance is evaporated, and carried off in the putrid gas and diffused in the atmosphere, after which the extreme factor sublimes; and finally the products of putrefaction cease, and leaves a kind of fat fetid earthy matter. All the gases certainly known to be produced by putrefaction, are carbonic acid, carbonated hydrogen, sulphuretted and phosphuretted hydrogen, and ammonia; but either these, or some of these, must be considerably changed by the solution of the animal matter; or some compound not yet examined, must be produced in that state of putrefaction, when the gas evoluted occasions such dreadful effects upon those that have the misfortune to fall in the way of it, even when diluted considerably with common air. This is said to be the case when the abdomen of a large animal is first burst, after some days or perhaps weeks of putrefaction; the gas from which causes instant fainting, and sometimes death, and even when the person exposed to it receives the first shock, it leaves excessive debility and other alarming symptoms for a considerable time. The most deleterious gas that is known, is perhaps, carbonated hydrogen, but the effects of this, as obtained by chemical means, are far short of those above-mentioned, when equally diluted. The generation of ammonia has been satisfactorily accounted for, since the discovery of the constituent parts of the volatile alkalies, by the new combination formed between the azote of the animal matter, and the hydrogen, of which latter there are many fources, and particularly that of the decomposition of water. As ammonia is always produced during putrefaction, it seems rational to suppose that one important purpose of the moiture necessary to the process, is to afford, by its decomposition, the hydrogen of the volatile alkalies. The nitrous acid is also an undoubted product of putrefaction; but further experiments and facts are necessary for explaining the reason, why in some cases the azote tends to unite with oxygen to form this acid, and in others with hydrogen to form ammonia. For an account of the peculiar changes which animal flesh undergoes, by which it is converted into a fermentablelike substance, instead of passing through the usual process of putrid decomposition, we refer to the article Aminciren.

Sir John Pringle has observed, that, as all the humours of all animal bodies become thinner by putrefaction, so the solid or fibrous parts are thereby relaxed, and rendered more tender: and hence the extraordinary bulk of the heart, liver, and spleen, incident to persons labouring under putrid diseases, may be accounted for. It is remarkable, that in defecpions of persons who die of the plague, the heart is almost always found of an uncommon magnitude; and as to the scurvy, the liver and spleen are sometimes enlarged to such a degree, that the tumour may be seen outwardly.

From matters completely putrefied may be obtained by distillation volatile alkalies, some liquid and some solid; a pungent fetid oil, which at first is thin, and afterwards becomes more thick; and a residuum of coal, not easily reducible to ashes. Some writers on this subject have apprehended, that putrid substances are not to be regarded as alkalines. Sir John Pringle, finding from the experiments which he made in the year 1759, that fyrup of violets was not changed into a green colour by the ferum of putrid blood; that this ferum did not make any effervescence, when spirit of vitriol was poured upon it; that water, in which corrupted flesh had been for some time infused, neither effervesced nor changed the colour of the fyrup; and that alkaline salts, both fixed and volatile, powerfully oppose putrefaction; was led to adopt this opinion. But when he became acquainted with the experiments made by M. J. Bapt. Gaber of Turin (Aucta Taurinens. vol. i. p. 78, &c.) he was convinced with the liberality of a true philosopher, the first opportunity of acknowledging his mistake. M. Gaber, having poured a drop or two of aqua fortis upon bile, taken out of the gall-bladder of a person who had died of an infe rvere jaudice without a fever, and whose body had lain about twenty-four hours in a cold place in winter, found, that the mixture immediately effervesced, became feebly warm, and that several air-bubbles rose to the surface. He also exposed the remainder of this bile in three open glasses

G 2
to the thirty-fifth, twenty-fifth, and tenth degrees of heat, indicated by Reaumur's thermometer, and at the end of twenty-four hours mixed them with acids; and he found, that the bile which had been placed in a degree of heat answerine to thirty-five, was most dilated, and gave very slight indications of effervescence; that which had stood in twenty-five was also dilated, and the acid produced a more sensible effervescence, but still very slight; and the bile which had been exposed only to the temperaturn of the air, varying from seven to ten, preferred its tenacity, and fermented as much as that in his first experiment. Having mixed some blood, taken out of a vein of the dead body at the same time, and which appeared to be of the yellowish-red, with spirit of nitre, the mixture effervesced, but in a much less degree than the bile: this mixture, being left to digest for some hours, a yellow serum separated from the blood, and covered its whole surface; and the blood, being subjected to the same heat as the bile, and for the same time, appeared more disposed to effervescence than the bile, though this disposition afterwards gradually diminished. From these experiments the ingenious writer infers, that in diseased bodies the humours may become fo alkaline as to effervesc with acids: that a very slight degree of putrefaction and putrefaction, which is not sufficient to produce alkali out of the body, will produce it in the body; that alkali formed in the body, and contained in the bile, is extremely volatile, since the heat of twenty-five degrees made a great part of it evaporate; and that the same alkali contained in the blood, being a little more entangled with other elements, is consequently less volatile, since the same degree of heat continued for the same time, dissipated but a very inconsiderable part of it: and, therefore, that the different phenomena taken notice of by those who have prosecuted experiments of this kind, some of whom affirm that they have been undoubted proofs of the presence of an alkali, and others that they have scarcely discovered any such indications at all, are the effects of different degrees of heat, the likeness of the substance exposed to the heat, or the different volatility of the alkali arising from its cohesion with other principles. Having made similar experiments upon healthy bile, blood, and serum, and submitted them to the action of mineral acids, he found the bile most disposed to effervescence; that human bile was more disposed to effervescence than the bile of an ox; that corrupt blood ferments with acids still flow; and that serum ferments slower than blood. He also observed, that putrefactive humour not only effervesced with mineral acids, but with very weak distilled vinegar; and that those humours that have been exposed to artificial heat, become fixed and effervescence lost, and soon arrive at the flat stage of fermentation; in which case the fermentation ceases, though the heat is continued; and the smell, which till then is intolerably fixed, becomes herbaceous, and is not disagreeable. The father, he says, manifeseth itself sooner and lasts longer than the alkali.

M. Gaber further observes, in relation to the experiments of Sir John Pringle, that at the degree of heat to which he exposed putrefactive substances, and which was equal to the hundredth degree of Fahrenheit, corresponding nearly to the thirtieth degree of Reaumur, animal humours very soon become putrid; but that they as soon lose the alakefence which they derive from putrefaction, if this degree of heat is continued: so that as the corrupting humours manifest their alakefcent quality only for a very short time, it might easily happen that no sign of alakefence appeared in his experiment, if it was not made in the critical moment, i.e., if he examined the putrefactive humours a little before the alkali was formed, or a little after it had evaporated. And he, therefore, apprehends, that if Sir John Pringle's experiments were made with a degree of heat just equal to his own, the result, ceteris paribus, must have been the same.

From other experiments this writer infers, that blood received from the arm, agitated and left to putrefy, does not putrefy so soon, nor so soon manifest signs of alakefence, as the red part separated from the serum, because the serum putrefies more slowly than any other animal humour; and that the alkali, which evaporates with a degree of heat from twenty-five to twenty-eight of Reaumur, being collected in a receiver, will effervescence, and that the residuum is a mass extremely fixed, wholly diftilted of alkali, and, consequently, that no effervescence is to be expected by pouring acids upon it. Having kept some blood in a glass vessel close stopped, he found that it retained its alakefence a long time, though exposed to a degree of heat equal to twenty-five; but upon unstopriing the vessel, it flew off with great violence, in an extremely fixed vapour. These explosions he attributes to the expansion of the air, in consequence of the putrefaction; and hence he deduces the reason, why the humours that are contained in the veins of a human body become alakefcent while they are yet scarcely fixed, although when drawn from the body, and kept in open vessels, they become fixed, before they give signs of alakefence. As soon as they begin to form alkali in the vessels, the alkali is retained; but as it exahles from vessels exposed to the air, a greater quantity must be formed than exahles before it can become sensible. Having collected the distilled liquor of blood in such a state of putrefaction as to effervescence with acids, and exposed it to the action of various acids, a violent effervescence ensued; and when poured upon syrup of violets, it produced as fine a green as sprits of hartshorn; and this tinture, having been changed into a red by the effusion of a few drops of aqua fortis, became again blue, upon pouring into it some more of the distilled liquor: whence he concludes, that putrefactive humours form a true alkali, which exahles with a very slight heat. From other experiments he infers, that the alkali of putrefactive substances is not the productive cause of their factor, because the latter remains when the former is departed. But as both appear in the same degree of heat, when long continued, it appears, he says, that this factor is produced by the effluvia of parts extremely volatile, but different from volatile alkali, which, though sooner produced, are more slowly dissipated. Alakefcence, however, may be sometimes connected with a flight factor; and, on the contrary, extreme factor may subsist without alakefcence. And this fact confirms the observation of Sir John Pringle, who found a difference between the fixed and alakefcent particles; since the exhalations of fresh urine are not pernicious, though they contain more alkali than any substance in a state of putrefaction, the odour of which is pungent in the highest degree; and, therefore, putrefactive effluvia are of a different nature from alakefcent salts. M. Gaber further adds, by way of inference from this fact, that a volatile alkali is not a necessary product of putrefaction, and that the degree of alakefence is not equal to that of putrefaction. Dr. Croll, professor of chemistry at Brunswick, has objected to this doctrine, as not conformable to the phenomena (Phil. Trans. vol. lxi. part i. art. 29.) for he supposes, that as all smell depends on a saline matter joined with phlogiston, and the saline matter producing the putrid fæces was very probably not an acid, it must be a volatile alkali, which, involved in phlogistic matter, might fly off before the alkali was developed. From some experiments made with a view of ascertaining this fact, he infers that the volatile alkali is present as long as, at least, as the putrid smell continues, and that this volatile alkali is the basis of it; because, as this was
PUTREFACiON.

distilled over in his experiments, the residue, being still in intelline motion, required only the herbaceous smell. The
reason why the volatile alkali has been distinctly observed at a certain period of putrefaction, and not in the other, he
apprehends to be this: the volatile alkali has, it seems, a tendency to difentangle itself, by intelline motion, of all
such matter as it is involved with; but if it is not combined with fuch matter as retains it till it has gone through all
its evolutions, it is, being itself volatile, carried off by the
still more volatile phlogistic matter with which it is commonly
joined. For this reason, he supposes the putrefying matter
flows in its beginning no signs of volatile alkali, because its
smell depends only on those particles which have been on
the surface, without any strong cohesion with the subfance.
In the further progres of putrefaction, the matter involving
the alkali, or fumming it, is intermixed, and in connection with
the folid particles of the subfance, and is by these means
reftained till the alkali is come to its purer state. Towards
the end of putrefaction, the cohesion of the particles being
almost entirely taken off, the volatile alkali is carried off before
it can go through all its fates.

Dr. Macbride made several experiments with putrid blood
and putrid bile, which aften the fact, that as soon as an
animal subfance begins to putrefy, it begins to difcover an
alkaline quality; and this volatile matter, now produced in
it, may be feparated by fiffillation in a very gentle warmth;
but he observes, that the volatile alkali obtained from putrid
subfances is not exactly similar to that obtained by
violent heat from animal subfances not putrid. It difters
remarkably in the flavour, which is naufeous and disagreeable,
is not fo pungent, and is much weaker than the common
volatile alkali; and this latter is capable of difpoifling the
putrid alkali, and of driving it off from any body to which
it has been united. But to return from this digrefion. As
to the caufe and procefs of putrefaction, it has been generally
believed, that the contact of atmosfherical air is neceffary
for this purpofe, and that bodies become putrid, because air
communicates fomewhat to them: accordingly it has been
alleged, that bodies buried deep under the earth, or in
water, out of the reach of any air, have remained entire for
ages; which, when exposed to the open air, have soon
rotted and mouldered away. It is aliowell known, that
bodies are preferved from putrefaction by covering them with
wax, fuc, &c.; and Mr. Boyle relates, that he has preferved
lemons, oranges, and other fruits, from putrefaction, during
feveral years, by including them in an exhausted receiver.
Experiments of the fame kind have been lately made by
M. Eller of Berlin, which show that subfances, even of the
most putrefent nature (fuch as blood) may be kept
found in vacuo for many years. But Dr. Macbride has
urged a variety of facts and confiderations to prove, that
putrefaction ensues in confequence of the loss of fome
principle, which cemented the confluent particles of bodies,
and that, when this is difeigned from them, they separate,
and are difinte. This principle he difcovered to be air,
which, in putrefaction and fermentation, is extricated and
thrown off, from a fixed and non-elastic flate, into one that
is volatile and elastic; but which immediately, upon meeting
with a proper recipient, returns again to its former nature.
Thus he found, that caufeful alkali and quicklime may be
rendered mild by afsorbing this air, extricated from putrefy-
ing and fermenting subfances; that without the eftinction of
this air no putrefaction can happen; and that even by ab-
sorption of it, putrefied subfances may be corrected and
rendered fweet. To the fame purpofe Dr. Alexander has
endeavoured to prove, that putrid matter will preferve other
subfances from putrefaction; which is not improbable,
caufe, being already faturated with the putrid effluvium,
they cannot readily take any more. Dr. Macbride, having
expofed putrid matter to the vapours arising from ferment-
ating mixtures, or from alkaline subfances effervescing with
acids, found that the putrid quality was destroyed; and
hence he confiders the fixed air as powerfully antifeptic.
And it appears alfo from the experiments of Dr. Priestley,
that fixed air corrects and renders wholefome air tainted with
repiration or putrefaction. Hence he infers, that lime-kilns,
which difcharge great quantities of this air, may be wholefome
in the neighbourhood of populous towns, the atmoferph of
which mult abound with putrid effluvia. Sir William Lee, in
a hot feafon, contrived, by impregnating water with fixed air,
in the manner defcribed under Pyromont Water, and waffling
meat with it two or three times a-day, not only to preferv et
it as perfectly fweet and good to the extent of ten days, as
at the firft killing, but alfo to recover fome meat that had
begun to change. And it is farther well known, that fixed
air, or carbonic acid, has been lately introduced into the materia
medica, and administered with fuccefs in a variety of putrid
cafes. Dr. Macbride has alfo proved, that putrefaction is
accelerated by taking off the prefure of the atmoferph;
and from fome experiments he was led to conclude, that it will
take place sooner in vacuo than in the open air; but making
a more complete vacuum by means of two brafs hemifpheres
joined together, he found that the observation of Mr. Boyle
and others was agreeable to fect. It appeared alfo, by in-
cluding flefh in condenfed air, that increasing the prefure
of the surrounded air, retarded putrefaction; and hence he
deduces, what he deems to be a demonstrative proof, that
bodies do not putrefy, because the air adds fomething to
them; for if they did, then a piece of flefh which lay in
condenfed air ought to have putrefied the sooner, becaufe it
had the greater quantity of air applied to its surface. But
the reafon why, according to his fystem, condenfed air pre-
vents putrefaction is, that the prefure of every fide muft force
the confluent particles clofter together, thus increase their
cohesion, and prevent the intelline motion; and without
intelline motion there can be no change of combination.
However, it is observed by Sir John Pringle, that the putre-
facition of meat and other subfances, advances quicker in a
confined than free air; for as the most putrid parts are alfo
the moft fugitive, they infcinually sifh from a corruptible
subfance, and difpefe with the wind; but in a stagnation
of air they remain about the body, and in the nature of a
ferment excite its corruption.

It has been long obferved, that putrefaction generates air.
Hence, though flefh, as well as blood, be specificly heav-
ier than water, yet dead bodies are found to float, after
lying some time at the bottom, from air generated in the
bowels by putrefaction. And since it has been found by
experiments, that the blood and other animal subfances
begin to emit air before they are fo far corrupted, as they
frequently are in putrid difeafes, it is probable that feveral
of the symptoms in deep furfets may be owing to the action
of the confined air. As dead bodies become putrid from
the loss of their fixed air, according to Dr. Macbride's
theory, he fuggetts, that the immediate caufe of putrefa-
cion in living bodies may be the detachment of too large a pro-
port of their fixed air. This principle is supported by an
enumeration of the symptoms that occur in the furvy,
and other highly putrid difeafes, which shew that the air
is actually detached from the blood in fuch cafes; as well
as from an examination of the principal and prevailing cafes
of fuch disorders. And since the air tainted with animal or
vegetable putrefaction is the fame with air rendered noxious
by animal respiration; since both equally extinguiih flame,
are equally noxious to animals, are equally and in the same way offensive to the smell, equally precipitate lime in lime water, and are restored by the same means, Dr. Priestley suggests; that one ufe of the lungs is to carry off the putrid effluvia, without which, perhaps, a living body might putrefy as foon as a dead one. See Blood and Respiration.

We fhall here observe, that putrefying and fermenting fubftances have been found, by the experiments of Mr. Cavendish, Dr. Priestley, &c. to yield not only fixed but inflammable air. From an experiment of Dr. Priestley, intended to determine the proportion of each of the kinds of air in the different fages of the putrefactive procefs, it appears that a piece of mutton weighing four penny-weights fix grains, yielded in all two measures of air, of which 3 was fixed, and the rest inflammable; and that all the inflammable part was exhausted a considerable time before the fixed air. The fame ingenious writer has observed, that the diminution of common air, by means of putrefaction, amounts to a complete fourth part of the whole, notwithstanding the production of fome permanent air from the putrefying fubftance, and has, in all refpects, the appearance of being produced solely by the precipitation of fixed air. It must occur to every reader, in any way acquainted with this fubjeft, if the philogical theory be admitted, (which indeed is now generally discarded,) that if inflammable air be the fame with phlogiferon, as Dr. Priestley feemed to have difcovered, many of the phenomena of putrefation, depending on this principle, fuch as the smell, colour, light, &c. will probably from hence admit of an easy explication.

We fhall here fubjoin fome observations with refpect to the decomposition of animal bodies that are interred in burying-grounds. In this situation, the decomposition is four times as foon as when the putrefying animal is expofed to the air. It is not perfectly ended, according to Mr. Petit, till three years after the body has been interred, at the depth of four feet; and it is flower in proportion as the body is buried at a greater depth. These facts agree with the principles which we have already eftablifhed for bodies buried in the earth, and subject to laws of decomposition very different from thofe which take place in bodies expofed to the air. In this cafe, the decomposition is fupported by the waters which filter through the earth, and diffolue and carry with them the animal juices. It is also favoured by the earth, which absorbs the juices with more or lefs facility. Meflrs. Lemery, Geoffroy, and Hunaud, have proved that argillaceous earths exert a very frow action upon bodies; but when the earths are porous and light, the bodies then dry very fpedifly. The feveral principles of bodies abforbed by the earth, or carried by the vapours, are difperfed through a great space, imbibed by the roots of vegetables, and gradually decomposed. This is what paffes in burying-grounds in the open air; but it is very far from being applicable to the fepulchres which are made in churches and covered places. Here is neither water nor vegetation; and consequently no caufe which can carry away, difsolve, or change the nature of the animal fluids: and we cannot but applaud the wisdom of government, which has prohibited the burying in churches; a practice which was once a fubjeft of horror and inflammation.

The accidents which have happened at the opening of graves and vaults are but too numerous, to render any apology neceffary for our fpreading a few words refpecting the method of preventing them.

The decomposition of a body in the bowels of the earth can never be dangerous, provided it be buried at a fufficient depth, and that the grave be not opened before its entire and complete decomposition. The depth of the grave ought to be fuch that the external air cannot penetrate it; that the juices, with which the earth is impregnated, may be conveyed to its surface; and that the exhalations, vapours, or gases, which are developed or formed by decomposition, should not be capable of forcing the earthy covering which detains them. The nature of the earth in which the grave is dug, influences all its effeets. If the ftratum which covers the body be argillaceous, the depth of the grave may be lefs, as this earth difficulty affords a paffage to gas and vapour; but in general it is admitted to be neceffary that bodies should be buried at the depth of five feet, to prevent all these unhappy accidents. It is likewife neceffary to attend to the circumftances, that a grave ought not to be opened before the complete decomposition of the body. This decomposition, according to Mr. Petit, is not perfect until the expiration of three years, in graves of four feet depth; or four years, when they are fix feet deep. This term affords many varieties, according to the nature of the earth, and the confitution of the subjects buried in it; but we may consider it as a medium. The pernicious custom, which allows a fingle grave to families more or lefs numerous, ought therefore to be fuppressed; for in this cafe, the fame grave may be opened before the time prefcribed. There are abfufes which ought to occupy the attention of government; and it is time that the vanity of individuals should be facrificed to the public safety. It is likewife neceffary to prohibit burying in vaults, and even in coffins. In the firft cafe, the principles of the bodies are fpread into the air, and infect it; in the fegond, their decomposition is flower and lefs perfect.

If thefe precautions be neglected; if the dead bodies be heaped together in too confined a place; if the earth be not proper to absorb the juices, and decompose them; if the grave be opened before the entire decomposition of the body;—unhappy accidents will no doubt be produced; and these accidents are but too common in great towns, where every wife precaution is neglected. An intance of this happened, when the ground of the church of St. Benoit at Paris was dug up a few years ago: a nauseous vapour was emitted, and several of the neighbours were affected by it. The earth which was taken out of this grave was unfavourable, vifcid, and emitted an infectious smell. Meflrs. Maret and Navier have left us feveral fimilar obfervations. Chaptal's Elem. of Chem. vol. iii.

Putrefation is one of the inflruments in nature by which many great changes are brought about. In the procefs of vegetable putrefation, if we throw together any of the tender, green, and succulent parts of recent vegetables, whether acid or alkaline, in a large heap, in the warm open air, and prefs them down with an additional weight, if their own be inconfiderable; the middle part of the heap will, in a little time, spontaneously conceive a small degree of heat, and pasa fucceffively through the other degrees, till it arrive at a state of obfubition, and be perfectly putrefied.

In the space of three days, from the firft putting them together, they will yield a heat, perceivable by the hand, equal to that of a human body in a healthy state; by the fifth, the heat will be too great for the hand to bear without pain; and, laftly, by the firft, seventh, or eighth day, the juices will generally appear ready to boil; and sometimes the matter will even flame, and burn away. By this spontaneous operation, the vegetable acquires an abominably putrid, fcorcoraceous, or cadaverous, tale and odour; and turns entirely into one foft, fimilar, pulpy mass, or craffamentum, greatly refembning feticl human excrements in the fcent, and putrefied flesh in the table.
PUTREFACTION.

If now this putrid matter, thus obtained, be directly, whilst it remains in its putrid state, committed to a glass retort, and distilled with proper degrees of fire, there will come over, 1. A water impregnated with an urinous spirit, perfectly like that obtainable from animal subjects, and separable by a fresh distillation, made in a tall flask, into elementary water, and a large quantity of pure, white, volatile, dry, alkaline salt, not to be distinguished from animal fats. 2. A volatile, alkaline, oily salt, that reverts into globes. 3. An exceedingly volatile and thick putrid oil, both which are entirely like those of animals. And, lastly, the remainder, being calcined in an open fire, affords not the least particle of fixed salt; just as if the subject had really been of the animal, and not of the vegetable kingdom.

This process is truly universal, and holds equally in all kinds of vegetables, though ever so different in their nature and virtue.

Experiments have been made in the coldest and moist succulent, or watery, plants; such as purline, forrel, &c. as well as with the hottest and most climatious, such as the fpruges, &c. and it was always found to succeed; but that the foamer, as the vegetable employed contained the greater quantity of oil; though with the same phenomena.

It will likewise succeed with dry vegetables, provided they be moistened with water before they are thrown into heaps; and thus we sometimes see, that flacks of hay will spontaneously take fire, and burn away; especially if the hay was not well dried in the making.

The conditions necessary for the putrefaction of vegetables are similar to those required in the putrefaction of animal substances. It is necessary that the organization be impregnated with water; the contact of air is necessary, as is also a certain degree of heat; and for the due effect of this kind of decomposition, the vegetables should be heaped together, and their juices be abundant. In these circumstances, the phenomena of decomposition are as follow: the colour of the vegetable is changed; the green leaves become yellow, the texture becomes lax, and the parts less coherent; the colour of the vegetable itself changes to black or brown; the mafs rifes, and perceptibly swells up; the heat becomes more intense, and is perceived on approaching the heap; and the fumes which arise have already a smell, which sometimes is not disagreeable; at the lame time bubbles arise, and break at the surface of the liquid, when the vegetables are reduced to a magma. This gas is a mixture of nitrogen, hydren, and carbonic acid. At this epoch, likewise, an ammoniacal gas is emitted, which is formed in these circumstances: and, in proportion as these appearances diminish, the strong and offensive odour is succeeded by another which is fainter and milder, and the mafs becomes dry. The internal part still exhibits the vegetable structure, when the flem is solid, and the fibrous matter has been the predominating principle; and it then constitutes manure or soil. Hence it arises that the herbaceous plants of a loose texture, and abounding in juices, are not capable of forming manure by their decomposition, but are reduced into a brown mass of little confluence, in which neither fibre nor texture are observed; and this is what, for the most part, forms vegetable mould.

Vegetable mould usually constitutes the first covering or stratum of our globe; and in such cases wherein it is discovered at a depth in the earth, there is no doubt but it has been buried by some revolution.

When a vegetable is converted into earth by this tumultuous fermentation, it still retains the remains of the vegetable, mixed and confounded with the other solid earths and metallic products; and by distillation it affords oil, nitrogen gas, and often hydrogen. It may, therefore, be considered as an intermediate substance between crude and organic bodies, which participates of the inertia of the one, and the activity of the other; and which in this state is still subject to an insensible fermentation, that changes its nature still more, and deprives it of all its organic contents. These remains of vegetables, still contained in vegetable earth, serve as food for other plants that may grow in it. The insensible progress of fermentation, and the fucction of vegetables, impoverish the vegetable earth, deprive it of all its organic matter, and there remain only the earths and metallic residue which form the stiff poor soils, and occludes when the ferruginous principle is very abundant.

As this muddy earth is a mixture of all the primitive earths, and of the metals which are the product of vegetation, as well as the oils, the fats, and other products we meet with in it; we may consider it as the residuum of vegetable decomposition, as the deposit of mineral agents, and by which nature repairs the continual losses the mineral kingdom undergoes. In this mixture of all the general principles, the materials of all compounds exist; and these materials are so much the more disposed to enter into combinations, as they are in a more divided and distinguished state. It is in these earths that we find diamonds, quartz-crystals, fprars, gyptum, &c. It is in this matrix that the bog ores, or ochreous ores of iron, are formed; and it appears that nature has reserved the impoverished residue of vegetables for the reproduction or reparation of the earthly and metallic substances of the globe, while the organic remains are made to serve as nourishment for the growth of other succeeding vegetables.

Some have taken occasion to apply the process of putrefaction to that of digestion, or the change which the aliment suffers in the human body. (See Digestion.) For the change our vegetable foods undergo in the body, being such as brings them to be of the same nature, and to afford the same principles, with the change induced by putrefaction, is a presumption, that digestion is nothing else. Besides, as we know that neither animal nor vegetable substances can become aliment, without undergoing some degree of putrefaction, many distempers must proceed from a deficiency of this action; the crises of fevers seems to depend upon it; and even animal heat, according to Dr. Stevenfion, does the same.

Now, that the concoction of the humours is nothing else but putrefaction, seems probable from hence, that whenever they are in that state, they are always more fluid, and fitter to pass through the smaller vessels, where they stagnated before. Again, the offensiveness of the sweats, or other excretions consequent on a crisis, is likewise a sure sign of a high degree of corruption. The time of resolution or putrefaction depends on the degree of heat, the habit of the patient, and on the part obstructed. Resolution is the putrefaction of the impacted humour only, but fupputation implies a corruption of the vessels also. This manner of speaking, indeed, has been disputed, from the prejudice that nothing was putrid but what was offensively so; whereas, in fact, every fibre becoming more tender, and humour thinner, may be considered as putrid in some degree, whether the change tends to the better health, or to the destruction of the person, or whether it becomes grateful or offensive to the senses.

Mr. Boyle has used the words fermentation and putrefaction of the blood promiscuously, in his Treatise on the Human Blood. Stahl and other celebrated chemists likewise use the term putrid ferment; which see.
PUTREFACTION.

It is, therefore, justly observed by Lord Bacon (Nat. Hist. cent. iv.) that an enquiry into the means of preventing or delaying putrefaction is of excellent use in phylec. Sir John Pringle has made many curious experiments with a view of determining the power of certain substances to promote or to prevent putrefaction, together with remarks on this subject, which are published in the Phil. Trans. vol. xlv. p. 480. 525. 550, and by way of appendix to his Observations on the Diseases of the Army. From the experiments of this learned and judicious physician, it appears, that fats of every kind, whether acid, alkaline, or neutral, fixed or volatile, as well as the astringent and gummy-refinous part of vegetables, all of them resist and most of them correct putrefaction; and he purified this branch of enquiry so far as to enable him to form a table shewing the comparative antiseptic power of the several substances, that of sea-felt being the standard. See this table under the article Antiseptic.

Of all re fins substances, he found that camphor resisted putrefaction most powerfully; its antiseptic power being three hundred times greater than that of sea-felt. Decoctions of wheat, barley, and other farinaceous grains, checked putrefaction, by becoming four. He also made experiments to discover the effects of mixing vegetable with animal matters.

Two drams of raw beef, as much bread, and an ounce of water, being heat to the confidence of paper and exposed to 90° of heat, according to Fahrenheit's thermometer, began to ferment in a few hours, and continued in a fermentation two days. When it began to ferment and swell, the putrefaction had begun; and in a few hours afterwards the smell was offensive. Next day the putrid smell ceased, and an acid taste and smell succeeded. Fresh alimentary vegetables, as spinach, asparagus, scurvy-grass, produced similar effects as bread on flesh, but in a weaker degree. From several other experiments, he found that animal substances excite the fermentation of vegetable substances; and that the latter substances correct the putrefaction of the former.

By adding saliva to a similar mixture of flesh, bread, and water, the fermentation was retarded, moderated, but rendered of twice the usual duration, and the acid produced at last was weaker than when no saliva was used.

By adding an oily substance to the common mixture of flesh, bread, and water, the fermentation was retarded, moderated, but rendered of twice the usual duration, and the acid produced at last was weaker than when no saliva was used.

Sugar was found to resist putrefaction at first, as other fats do, and also to check the putrefaction after it had begun by its own fermentative quality, like bread and other fermentative vegetables.

Lime-water made some small resistance to putrefaction.

Port-wine, small beer, infusions of bitter vegetables, of bark, and the juice of antiscorbutic plants, retarded the fermentation of mixtures of flesh and bread. But an untrained decoction of bark considerably increased that fermentation.

Lime-water neither retarded nor hallowed the fermentation of such a mixture; but when the fermentation ceased, the liquor was neither putrid nor acid, but smell agreeably.

Flesh pounded in a mortar was found to ferment more slowly than that which had not been bruised.

The tough inflammatory crust of blood was found to be more putrecessant, next to which the cafflamentum, or red congealed mass, and lastly the serum.

Charcoal is a powerful antiseptic; hence all sorts of glass vessels and other utensils may be purified from long retained smells of every kind, in the cafflament or most perfect manner, by rinsing them out well with charcoal powder, after the grosser impurities have been fowerd off with sand and potash. Rubbing the teeth and washing out the mouth with fine charcoal powder will render the teeth beautifully white, and the breath perfectly sweet, when an offensive breath has been owing to a fcorbatic disposition of the gums. (Cree's Journal, vol. ii.) Meat also, which is a little tainted with putridity, may at once be made sweet by charcoal, and it has been said, that common raw spirits agitated with charcoal will be deprived of their bad flavour, but they are apt to refine their old flavour, if kept in the dark only a few weeks.

The experiments of the author of the "Essai pour servir à l'Histoire de la Putrefaction," shew that metallic salts, reinosus powders, extracts of bark and opium, are very powerfully antiseptic, and that salts with earthy bases are less antiseptic than any other salts.

The same ingenious physician made some experiments towards the sweetening of corrupted flesh by means of mild substances. For this purpose he put a piece of putrid flesh into an infusion of chamomile flowers, which was renewed twice or thrice in as many days, and its sweetness and firm texture were recovered. Several pieces of putrid flesh were also sweetened by repeated infusions of a strong decoction of the bark; and he conflatly observed, that not only the corrupted smell was removed, but a firmness restored to the fibres. The corrupt yolk of an egg, diluted with water, was sweetened by mixing it with a strong infusion of chamomile flowers. He found also that decoctions of wormwood, of the bark, and infusions of chamomile flowers, and of snake-root, preferred yolks of eggs for a longer time than water, even with the addition of a considerable quantity of sea-felt; and that they were preferred better by salt of hartshorn than by four times the weight of sea salt. Ox-gall was kept for some time from putrefaction by small quantities of lea of tartar, spirit of hartshorn, crude ful ammonia, and the saline mixture; and still longer by a decoction of wormwood, infusion of chamomile flowers and of snake-root, and by solutions of myrrh, camphor, and salt of amber. The serum of human blood was preferred by a decoction of the bark, and an infusion of snake-root, as effectually as flesh. See Antiseptic.

For an account of Sir John Pringle's experiments and observations with respect to those subjects that haffen or promote putrefaction, see Septics.

Dr. Macbride's experiments confirm many of those above related, especially those which shew that the fermentation of vegetable substances is accelerated by a mixture of animal or putrescent matter, that the putrefaction of the latter is corrected by the fermentative quality of the former; and that the putrefaction and fermentation of mixtures of animal and vegetable substances were accelerated by additions of absorbent earths and of Peruvian bark. He also found, that although unburnt calcareous earths were septicks, quick-lime and lime-water prevented putrefaction, but that they did not destroy or dilute the texture of flesh.

From his experiments we learn also, that acids, even when strongly lowered, have a strong degree of power to resist putrefaction, and also to correct it; but that they destroy the texture of the substance whose soundness they were supposed to restore; that salts in general, by a property which is common to them all as salts, have the same power,
power, but that they exceed the acids in their efficacy for correcting putrefaction; that fermenting and effervescence mixtures are the most powerful of all known antiseptics; and, in general, that whatsoever hath a power to restrain the escape of the fixed air, or hinder the intellefire motion, must of course prevent putrefaction; and that fixed air, when transferred from a sound body to one that is putrid, appears to revolve to that body the principle which has been destroyed or lost.

Dr. Macbride objects against the adminiftration of acids in putrid difeases, for the following reafons; because, if they came unchanged to the aborbent vessels, they would not admit of them, and if they did, they would be dangerous, and they are quite changed before they leave the prime air. Dr. Crell (Phil. Trans. vol. ixi. part. i. p. 340.) has replied to this reafoning, and proposed experiments to prove, that acids, though changed in the alimentary canal to so fart as to effervece with alkalis, may, notwithstanding, check putrefaction, and, therefore, that their ufe is of great confequence, and ought not to be omitted in putrid difeases.

With regard to the exhibition of alkalis, Dr. Macbride obferves, that the point is not yet satisfactorily fettled. There can be no doubt of their power to refifit and correct putrefaction in dead bodies; but whether, upon the preufumption of this virtue, they can be given with propriety as antifeptics, he adds, is not fo clear. Dr. Crell affirms, that they can never be used in living bodies as antifeptics; for, laying aside their-flimming quality, which muff prevent their ufe in moff of the putrid difeases, they would, he apprehends, increafte the morbid matter, by being intimately mixed by circulation with phlogifitic matter, which they find abundantly in fuch bodiyes. Altrifying, says Dr. Macbride, prevent putrefaction very powerfully, but they have not the least degree of efficacy in correcting it; and as antifeptics, they can be of importance only in thofe cafes where, from extreme relaxation and resolution of the fluids, the difloved fluids are fuffered to tranfufe, and either form spots of different hues, or run of by actual hemorrhage; and he apprehends, that acfids act in thofe cafes where they have been administered withfficels, merely as altrifying. The antifeptic virtue of the gummy-refinous vegetables, judging of their effect by that of the bark, appears to depend on their fermenting in the body, and partaking with fixed air in the courfe of their fermentation, and throwing a great quantity of it into the blood; and attending to the things that prevent putrefaction in living bodies, we fhall find that the dependence is on the quantity of air. Thus, vegetable food prevents the putrefactive diathesis; and to the frequent ufe of fresh vegetables and fugar, in the diet of the European nations, it is owing that putrid difeases or plagues are now no uncommon. And what proves almost to a demonstration the antifeptic power of the fermentable fubftances, is the cure of the lea-fcurry.

Dr. Crell digs agreements with the opinion of Dr. Macbride, that putrid difeases may be cured with fermentable fubftances only; nor is he convinced that putrefaction depends only on the loss of fixed air. Thus, he apprehends, is an effect rather than the caufe of putrefaction. We fhall here only add, that Dr. Macbride recommends, in the putrid yellow fever of the Weft Indies, to give the patient repeated doses of the alkaline farts, in fresh lime-juice, or the like, and to let it be swallowed during the effervence; and to order the patient's drink to be somewhat of the highly fermentable kind; such as the juice of the green fugar-cane, diluted and acidulated with fome of the recent four juices. The natives on the coaft of Africa give in fvers of this kind, with gooduccels, a drink prepared by macerating in water a fruit of the plum kind, that grows there in great plenty. He adds, that by throwing in fuch a quantity of antifeptic vapour as would be furnished from this kind of materials, the putrefactive acrimony, which at first seems chiefly to affect the bilary fystem, might be corrected and faturated. See on the subje6t of this article Dr. Macbride's Essays, 1776, pages 335, 336.

**Putrefaction.** in *Physiology*, the spontaneous changes which animal substances undergo, when deprived of life. See Death.

**Putrefaction**, in *Agriculture*. It is by means of putrefaction, as flated under its appropriate article, that various substances and bodies are decomposed, reduced, and brought into the state proper for being applied to lands for the support of crops; but this is more fully explained, in speaking of the nature of the different materials that are capable of being made ufe of in ameliorating land for the growth of crops. See Manure.

**Putrefaction of Water.** It is said to be the peculiar quality of the Thames water, that it will flink and yet be wholesome; and after this will recover itself again. Many sailors have been obliged to drink it flinking, to that they held their noses while they poured it down their throats, yet no ficknefs ensued from it. It generates a fpirit alfo in this flinking flate, which will take fire at the approa6h of a lighted candle, as if spirit of wine were touched by the fame.

It appears from the article *Putrefaction*, that though a volatile alkali may be obtained from putrid fubftances by difflation, fuch fubftances muff not be suffered to remain too long before they are diffilted, unlefs they are kept in clofe vessels; because the volatile alkali, which is the offspring of putrefaction, is difsipated as falt as it is generated, inomuch that, at length, nothing is left behind but an infipid water, or a solid matter, being an earth fimilar to common mould. It is in this way, fays Dr. Macbride, that flinking water, after fome time, becomes fweet: the volatile alkali, generated by the putrefaction of the animal and vegetable fubftances at first contained in the water, being, after a while, entirely difsipated, leaves the remainder without any difagreeable fmal.

Putrid water is immediately deprived of its offensive fmal by charcoal. If putrid water be agitated with a small quantity of magnesia, it will lose its bad taste and fmal in a few minutes. See Crell's Journal, and Prouf, Journal de Physique.

A method of preferving water free from putrefaction was fome years fince proposed by Dr. Alton. It confifted in adding a quantity of lime to every caflk of water; and as lime is known to have a strong antifeptic property, water, as long as it retains the impregnation of lime, never putrefies. In order to free the water, at the time of using it, from the lime, Dr. Alton proposes the precipitation of the latter by throwing a quantity of magnesia alba, on this principle, that as lime-stone is rendered foluble in water by the deprivation of its fixed air, and has a greater affinity with that air than magnesia has, the particles of quicklime difflated in the water would attract the air from the magnesia, and thereby becoming no longer soluble, would fall to the bottom, and leave the water tasteless and fit for economical ufe. See Lime-water and Magnesia.

The expence, however, attending this procefs prevented the execution of the propofal. Mr. Henry has not long ago suggefted a cheap and eafily practicable method of precipitating the lime, and thus of reftoring the water to its original taste. The following is a short fketch of the author's procels. To
preferre the water from putrefaction, two pounds of good quicklime are directed to be added to each cask of water of a hundred and twenty gallons. To free the water afterwards from the lime with which it has been impregnated, it is to be drawn off into a strong cask, containing about sixty gallons, with an aperture at one end large enough to admit a vellum, which is to be let down into it by means of string, and which contains a proper quantity of effervescence materials, that is, of marble or chalk, and vitriolic acid. Eight ounces of mild calcareous earth, and fix ounces of strong vitriolic acid, will be sufficient for sixty gallons of lime-water. The mouth of this last vellum is to be flopped with a tubulated stopper, through which the fixed air, let loose from the marble, paffes up through the body of the water. The lime is thus rendered insipid, and is soon precipitated in the form of an impalpable powder of chalk; the water being thus reflored to the same state of purity as when it was first shipped on board; or, as Mr. Henry believes, to a state of still greater purity; several hard waters having, in consequence of this process, been rendered as soft as rain water, and freed from different impregnation. For farther particulars, and the description and drawing of an apparatus for this operation, see Henry's Account of a Method of preserving Water at Sea, &c. p. 10, &c. 1781.

PUTRESCENT MATTERS, in Agriculture, such subflances as are in a state of putridity. Various materials of this kind are capable of being made use of by the farmer. It has been lately suggested by Dr. Hunter, of York, in a paper in the third volume of the Farmer's Magazine, that different materials of this nature may form a substitute for the folding of sheep.

The trouble and expense of keeping a flock of sheep for the purpose of folding, may probably be avoided by forming large ponds, so constructed as to receive and hold water. Into these ponds let drains from the stables, cow-houses, ox-halls, pigeon and wash-houses be directed; and, in order to enrich the water, let all kinds of vegetable and animal subflances be thrown in, particularly the contents of the necessaries and slaughter-house. It is presumed, that this putrid water, when put upon the land by means of water-carts, will prove as beneficial as a flock of sheep kept for the express purpose of folding; and where no sheep are kept for that purpose, such will prove an excellent manure for meadow land. A pond of sixty feet diameter, by six feet deep, which will contain upwards of 7000000 gallons of water and putrefective bodies, may be equal in its effects to a considerable fold of sheep. The putreficiency of the water may be greatly increased, by occasionally supplying the ponds with the refuse of fish, and sea-weed, where they can be conveniently procured; and in all places within a reasonable distance of sea-parts, where ships are employed in the Greenland fisheries, the farmer will find a seasonable supply of putrefactive matter by the purchase of the whale blubber, after the oil has been taken from it. Such is the strength of the last named subflance, that it is well worth the farmer's while to be at the expense of carrying it in casks to a considerable distance, for the purpose of giving vigour to his compost dunghills. The ancients were fru♥ulously nice in the formation of their dunghills; and it is a reproach to the present race of farmers, that to material a branch of their business should, at this day, be in imperfectly known or attended to. And in many large cities, and especially Edinburgh, it would be a great improvement, if a well-constructed resevoir was made to receive the excrementitious matter, the slough being occasionally replenished with earth and small rubbish. In this manner, many thousands of loads of rich manure might be saved from the sea, to which place the excrementitious matters are upon their passage.

PUTRID, PUTRIDES, something rotten, or putrefied. See Putrefaction.

Thus we say, putrid flesh; a putrid humour; putrid limbs, i.e. mortified ones, are to be cut off.

PUTRID DISSECT. See Putrid Fever, &c.

PUTRID FERMENT. See Ferment.

PUTRID FEVER, &c. in Medicine, an epithet originating in the chemical school of physis, in which the true operations and phenomena of life were mistaken for the fermentations and decompositions of the laboratory. This mistake was probably the refult of the offensive smell, and actual putrefactive odour of some of the discharges from the living body, in the last stages of severe fevers; but farther observation has demonstrated that, however the excrescences may undergo the processes of putrefaction after they are thrown out of the living body, no degree of putrefaction can exist for a moment in the circulating blood, without occasioning infant death.

The symptoms which were formerly ascribed to putrefaction, but which are now believed to originate from a great deficiency of the vital or nervous power derived from the brain and nervous system, are such as occur in typhus gravior, the hospital and gaol fever, and in the worst cases of dysentery, and small-pox; among which are a black tongue and mouth, extreme proliteration of strength, fetid evacuations from the stomach, bowels, and bladder, haemorrhages, petechiae, and purple blotches, &c. See Fever, and Typhus.

PUTRID Ulcer. See Ulcer.

PUTRINE, in Geography, a town of Prussia, in Oberland; six miles W. of Paffenhein.

PUTT, in Rural Economy, a provincial word, applied commonly in some districts to the mole-hill. Alto, sometimes to animals which put or thrust with their horns.

PUTT, or Pine, in Geography, a town of Anterior Pomerania; eight miles S.W. of Stralland.

PUTTAN-SUMNAUT, a town of Hindoostan, in Guzerat; near which was a famous pagoda, much venerated and frequented by devotees from all parts of the country. In the year 1602 this town and temple were taken by Mahommed, king of Ghizani, and plundered of their great wealth. In the temple was found a statue, in which, on being broken, was found a vast quantity of precious stones. The Hindoos believed that the souls of deceased persons came to this place to be transferred to other bodies; 80 miles S. of No~magur. N. lat. 21° 1'. E. long. 69° 40'.

PUTTEN, VANDER, HENRY, in Biography, was born at Vandloo in 1574; after studying at the universities of the Low Countries, he visited Italy; and for a considerable time was professor of rhetoric at Milan, where he took the degree of doctor of laws. He was nominated historiographer to his Catholic majesty, and received the honour of citizenship at Rome. In 1656 he was invited to the chair of Lipius, who had been his tutor. He was also made a counsellor to the archduke Albert, and entrusted with the government of the citadel of Louvain. When a truce was negociating between the Dutch and the king of Spain, in 1633, he published a work, entitled "Statuta Beli et Pacis," in which he shewed how important a peace would be to the Spanish Netherlands. This work gave great offence, and the author had nearly experienced the usual fate of those who counsel pacific measures, at a time when passion, prejudice, and interest, urge the continuance of war. He died at Louvain in 1646, age 72. Besides his "Statuta," mentioned above, he published "Historia Infurbia;" "Orchelira
"Orchestra Burgundica;" "Theatrum Historicum Imperatorum:" "Comus, feu de Luxu;" "De usu Bibliothecarum," with a catalogue of the Ambrosian library; besides several tracts relative to classical antiquities, printed among the collections of Graevius and Gronovius. Moreri.

Bayle.

PUTTEN, in Geography, a small island of Holland, in the Meufe, E. of Voorn.

PUTTERAHEN, a town of Hindooftan, in the cirear of Gohud; 27 miles E.E. of Gohud.

PUTTOCKS, or Putock-Srounds, otherwise called futlock or foot-book srounds, in a Ship, are small srounds which go from the srounds of the main-mast, fore-mast, and mizen-mast, to the top-mast srounds; and if there be any top-gallant mast, there are puttocks to go from the top-mast srounds into these. These puttocks are at the bottom fixed to a flaff, or to some rope which is fixed to a plate of iron, or to a dead-man's eye, to which the laniards of the foremast srounds come. See Srounds.

PUTTY sometimes denotes a white powder of lead and tin calcined together, in the proportion of two parts of lead to one of tin; used in polishing, and giving the last gloss to works of iron, steel, Rone, and glas. This is also the basis of white enamels, and glazings for earthen-ware.

PUTTY is also used to denote epidium.

PUTTY, in its popular sense, denotes a kind of paste, compounded of whiting, with or without a little white lead, and linseed oil, beaten together to the consistence of a tough dough; used by glaziers for softening the surfaces of glasses in sround-windows, &c. and by painters, to float up the crevices and clefts in timber and wainscot, to prevent the wet from getting in, and ruining the work.

PUTTIRAM, in Geography, a town of Hindooftan, in Bengal; 18 miles E.S.E. of Dioneapour.

PUTUAY, a small island on the coast of Bengal. N. lat. 22° 41'. E. long. 89° 28'.

PUTUMAYO, a river of South America, which rises about 80 miles S. of Popayan, pursues an eastern course, inclining to the south, about 300 miles, and after being joined by a branch of the Caquet, takes the name of Ica, and running S.E. about 200 miles, joins the river of the Amazons in S. lat. 3° 30'. W. long. 50° 40'.—Also, a town of South America, in the government of Popayan, on a river of the same name; 50 miles E. of Paifu.

PUTURA, a crom claimed by the keepers of forests, and sometimes by bailiffs of hundreds, to take man's meat, horfe's meat, and dog's meat, of the tenants and inhabitants, gratis, within the perambulation of the forest, hundred, &c.

"Johannes claunum unam putaram in prioratu de Pegovfham, qui eft quaedam cella abbatis de Eyevham, pro fe & miniftris, equis, & gbaronibus libus, per unum diem & duas noctes, de tribus femina, in tres femina, vic. de viciafulibus, ut & elenchis & potulentis, ad coltas prioratus predicati indebito." Placit. apud Pratton. 17 Edw. III.

This crom, within the liberty of Knaurebarg, was long since turned into the payment of four-pence, pro putra.

The land subject to this service is called terra puturata. The learned Sonner has erred in his exposition of this word.

PUTYAJURY, in Geography, a town of Bengal; 30 miles S.S.W. of Silhet.

PUTZIG. See PAUZK.

PUSIGLIO, a town of the duchy of Parma; nine miles N.E. of Parma.

PUWAKHAGA, in Botany, the name by which some authors call the faufel-tree, of whose fruit the exprefted juice called terra Japonica, or Japan earth, is made.

PUXUANAIRIO, in Geography, a town of Mexico, in the province of Mechoacan; 25 miles N.W. of Mechoacan.

PUY, Peter du, in Biography, the third fon of Claude du Puy, a magistrate in the parliament of Paris, was born in that city in 1582, and was educated with great care under his father. While a youth, he made extraordinary proficiency in literature, and full further improved himself by a journey to Holland, whither he accompanied the French ambassador. After his return he laboured with great industry incerte, in ascertaining the rights of the crown of France over some of the neighbouring districts, and for that purpose indefatigably in his examination of ancient charters, and thereby acquired a profound knowledge of French history. The reward of this, and other labours of the same fort, were the places of king's counsellor, and keeper of the royal library, in both of which he was distinguished by his patriotism and love of letters. His works were numerous and valuable. In almost all of them he aims at reproducing the ecclesiastical authority, and the claims of the see of Rome; hence they were not well received at the papal court. They are, however, said to contain a rich treasure of facts relative to all the matters on which he treats. He died at Paris in 1651, at the age of 69, and his life was written by his intimate friend Nicholas Rigault. Some of his writings are as follows: "Preuves des Libertés de l'Eglise Gallicane," "Histoire Veritable de la Condemnation de l'Ordre des Templiers," "Traité de la Loi Salique," "Du Concordat de Bologne entre le Pape Léon X., et le Roi François I;" "Apologie de l'Histoire de M. le Prince de Thou." He had a brother, James, prior of St. Sauveur, who became keeper of the king's library after the death of Peter, whom he assisted in all his works, of the greater part of which he was the publifer. He died in 1656, leaving behind him a high character for learning and probity. Another brother, Christophe du Puy, was prothonotary to the cardinal de Joyeuse, and by his reminiscences he prevented the congregation of the Index from putting the first of De Thou's history in the list of heretical books. He was king's almoner, and, while attached to cardinal du Perron, he made a collection entitled "Perroniana." He became a Carthusian, and died at Rome in 1554, proctor-general of his order.

PUY, Louis du, a man of letters, was born at Clarey, in Bugey, in 1709; he studied in the college of Lyons, and came to Paris in 1732. He was for a considerable time principal editor of the Journal des Scavous, and during thirty years enriched this collection with a great number of critical dfferences. He was well versed in the learned languages, and in the mathematics, and acquired an extensive knowledge of history and antiquities. The prince of Souhille entrusted him with the management of his library, and by his care it was rendered one of the most valuable in the metropolis. In 1753 he was nominated secretary to the Academy of Inscriptions, in which situation he pronounced the eulogies of twelve of his associates, and edited from the 36th to the 41st vols. of its memoirs. He died in 1795. He was author of "Observations on infinitely small Quantities, and the metaphysical Principles of Geometry," inserted in the Journal des Scavous for 1759; "A Translation of four Tragedies of Sophocles," 1762; "A Translation of the Greek Fragments of Anthemius on mechanical Paradoxes, with Notes," from memoirs on the Roman coin, the silver denier of Charlemagne, and other antiquarian and literary subjects. Du Puy was highly eflenced for strict probity,
PUY

fincerity, and an obliging disposition, which displayed itself in useful advice and information to those who consulted him on literary topics.

PUY, Mademoiselle du, a celebrated performer on the harp, who had acquired a considerable fortune by the exercise of her talents in different parts of Europe. She died at Paris in 1777, and made a will that seem'd dictated by infamy. Among other articles, the ordered that no blind, lame, or deformed person should attend her funeral. She ordered that her house should be let to none but nobility. She left a large piece of ground to be formed into a public garden, upon condition that no flunted trees should be allowed a place in it. And lastly, she bequeathed an annuity for the maintenance of cats, of which she was fond, and for a perfon to take care of them. But the annuity depended wholly on the life of the cats. The harp upon which she had acquired her possessions, was left to a blind harper in the Hopital des Quinze Vingts, who played tolerably well on many different instruments. Great pains were taken to fet this will aside, but without effect. It was declared valid by law, and obliged to be executed. Laborde.

PUY, Le, in Geography, a town of France, and principal place of a district, in the department of the Upper Loire, and capital of the department, situated on a small river near the Loire; before the revolution, the fee of a bishop; a place of considerable trade, especially in lace; 38 miles S.W. of Lyons. The place contains 15,915 inhabitants, in two cantons, the one containing 13,106, and the other 1,810, on an extent of 185 kilometres, in 16 communes.

N. lat. 45° 21'. E. long. 3° 57'.

PUY-Laurent, a town of France, in the department of the Tarn, and chief place of a canton, in the district of Lavaur; 12 miles S.E. of Lavaur. This place contains 6548, and the canton 9817 inhabitants, on a territory of 125 kilometres, in 9 communes.

PUY-d'Evêque, a town of France, in the department of the Lot, and chief place of a canton, in the district of Cahors; 14 miles W. of Cahors. The place contains 2082, and the canton 12,127 inhabitants, on a territory of 285 kilometres, in 11 communes.

PUY-Mirab, a town of France, in the department of the Lot and Garonne, and chief place of a canton, in the district of Agen. The place contains 1265, and the canton 8072 inhabitants, on a territory of 125 kilometres, in 11 communes.

PUY-de-Bellard, a town of France, in the department of La Vendée; 18 miles N.W. of Fontenay-le-Comte.

PUY-Caillou, a town of France, in the department of the Gers; nine miles N.E. of Auch.

PUY-de-Dôme, a mountain of France, near Clermont en Ferrand, 810 toises in height.

PUY-de-Dôme is also the name of one of the nine departments of the central region of France, so called from the mountain that is situated in it; it is bounded on the N. by the department of the Allier, on the E. by that of the Rhône and Loire, on the S. by the departments of the Cantal and Upper Loire, and on the W. by those of the Correze and Creuse; formerly Lower Auvergne, in N. lat. 45° 40', containing 8450 kilometres, or about 35 French leagues in length, and 22 in breadth, or 447 square leagues, and 508,444 inhabitants; divided into five districts, viz. Riom, including 126,640; Thiers, 61,530; Ambert, 75,535; Clermont, 158,440; and Issoire, 88,290 inhabitants; 50 cantons, and 438 communes. The circles, according to Haffenratz, are 8, the cantons 71, and the population 516,593. Its capital is Clermont. The general total of its contributions in the 11th year of the new French era, was estimated at 3,656,547 francs; and its expenses for administration, judiciary, and for public instruction, at 37,468 francs, 37 cents. The soil of this department, diversified with hills and plains, is remarkably fertile, producing abundantly grain, wine, fruits, hemp, and pastures. It has mines of silver and lead, mineral springs, &c.

PUY le Garde, a town of France, in the department of the Lot; 15 miles N.E. of Montauban.

PUY Guillaume, a town of France, in the department of the Puy de Dome; eight miles N.E. of Lezoux.

PUY Laurens, a town of France, in the department of the Aude; seven miles S.E. of Quillan.

PUY Martin, a town of France, in the department of the Upper Garonne; 17 miles N. of St. Gaudens.

PUY Midian, a town of France, in the department of the Lot and Garonne; six miles E. of Marmande.

PUY Molleron, a town of France, in the department of the Lower Alps; 15 miles S. of Digne.

PUY Notre Dame, or Puy en Velay, a town of France, in the department of the Aveyron and Loire; 10 miles S.W. of Saumur.

PUY de la Pois, a town of France, in the department of the Puy de Dome; 18 miles E. of Clermont.

PUY la Reque, a town of France, in the department of the Lot; 17 miles N.E. of Montauban.

PUY St. Martin, a town of France, in the department of the Drôme; 11 miles N.E. of Montelimar.

PUY Val d'Or, a town of France, in the department of the Eastern Pyrenees; 10 miles N.W. of Montlouis.

PUYA, in Botany, the vulgar name, in Chili, of a plant, which is figured in Feuillee, v. 3. 59. t. 39, and adopted as a genus, after Molina, in Juffieu's Genera 447, under the above barbarous appellation, with the following character. "Calyx in fix deep segments; the three innermost largest, and vaulted. Stamens six, inserted into the lower part of the calyx; their filaments formed like a scale at the base, and bearing honey. Germen superior, triangular; (style and stigma unknown). Capsule of three cells, with numerous minute seeds, (doubtful whether furnished with down.)"

Feuillée's description is to the following effect. The roots are fibrous, throwing up several items, about nine feet high, as thick as a man's body at the bottom, where they are clothed with the scaly imbricated vestiges of old leaves, above which stand the numerous leaves of the present year. These are three or four feet long, and about two inches wide, refembling the foliage of the Pine-apple; their margins being fringed with very sharp hooked prickles, five lines long, and about an inch and a half asunder; the surface of the leaves is smooth, shining, of a fine bright green. The Indians make use of these prickles as fish-hooks. The part of the stem above the leaves is round, two inches or more in thickness; of a bluish-green externally; white and watery within, clothed with very thin, alternate, clasping leaves, or scales. The summit confines of a large pyramidal of flowering branches, or spikes, the lowermost a foot long; all clothed with similar scales, or bracteas, each of which is accompanied by a feathery axillary flower. Each flower is composed of six leaves, three large and three small, in a double row. The latter are three quarters of an inch long, (Feuillee 5 1/2, apparently by mistake, three inches,) and three lines and a half broad, covered with minute white down: the three larger are of a greenish-yellow, two inches and a half long, and nine lines broad, terminating like a Gothic arcade. The flowers roll up spirally as they fade. Six flaments spring from the bottom of each flower, surrounring a triangular pistil, which extends beyond them, and becomes a fruit.
PWL

a fruit of three cells, filled with an infinite number of seeds. Feuillet met with several specimens of this plant in the kingdom of Chili. He refers it to his genus of *Renelia*, the *Tillandsia* of Linnaeus. Jussieu justly suspected its being the same genus with *L'Heritier's Pitcairnia*, see that article; of which therefore the plant in question may be presumed to constitute an additional species to the four we have described; agreeing most with *P. brasiliensis* in habit, size and colour, but differing in having more spiny leaves, as well as a more compound inflorescence.

The reader will observe that Jussieu, according to the principles he has assumed, calls the whole integument of the flower a calyx, while we follow other writers in taking the three inner parts for petals; a measure justified, if we mistake not, by their habit, and mode of withering. The little differences respecting the scales or nectaries may easily be reconciled.

PUYCERDA, in Geography, a town of Spain, in Catalonia, and capital of the county of Cerdagne, surrounded with walls and battlements, and defended by a castle; 19 miles E.N.E. of Urgellus. N. lat. 42° 39'. E. long. 1° 49'.

PUYX or PUYX, a town of France, in the department of the Landes; nine miles S.W. of Aire.

PUYS, a term used for the poles with which the keels on the Tyne river are rowed along.

PUYSEGUR, James de Chastenet, Lord of, in Biography, lieutenant-general under Lewis XIII. and XIV., was born in 1600. He entered the army at the age of seventeen, and served, without intermission, during forty-three years. He was present at about thirty battles, and one hundred and twenty sieges, without ever having been sick or received a wound, but he had not the good fortune to rise in his profession, being more zealous for the king's service, than complaisant to the ministers. He drew up "Memoirs," comprising the period from 1617 to 1658, in which are contained various remarkable particulars relative to the campaigns in which he served, with useful military instructions. They were printed at Paris and Amsterdam in 1690, 2 vols. 12mo. under the inspection of Du Chevne, hitorigrapher of France, and they have the character of narrating with freedom and fidelity. He died at his country seat in 1682. Moreri.

Puysegur, James de Chatelet, Marquis de, was son of the preceding, born at Paris in 1655, and entered into the army under his father, and gradually rose to the post of commander-in-chief in the French-Netherlands, and finally, to the still more important one of a marshal of France in 1734. He died at Paris in the year 1743, at the age of 88. He was author of a work "On the Art-Military," published by his only son the marquis of Puysegur. Moreri.

PUZZALO, in Geography, a town of the island of Sicily, in the valley of Noto, near the S. coast of the island; 12 miles S.W. of Noto.

PUZZLING BAY, a bay in the fruistrates of Magellan, on the coast of Patagonia. N. lat. 53° 35'. W. long. 74° 28'.

PUZZOLANA. See Pozzolana, and Calcareous Cement.

PUZZUOLI, in Geography. See Pozzolana.

PwLHeLi, a borough, market, and sea-port town in the parish of Denio, county of Cambogia, cantref of Lleyn, now called the hundred of Glyflogion, county of Caernarvon, South Wales, is situated on the South side of the promontory of Lleyn, in St. George's Channel, at the distance of 27 miles S.S.W. from Caernarvon, and 241/4 miles W.N.W. from London. This town consists chiefly of aingle street, parallel to the shore. It was constituted a free borough by Edward the Black Prince, at the request of Nigel de Lohareyn, and had its privileges confirmed by king Edward III. The government is vested in a mayor, recorder, and two bailiffs, who have the powers of justices. The market days here are Wednesday and Saturday, weekly; and there are besides six annual fairs. This port has a considerable trade; and upwards of eighty ships, of different burthen, belong to it. Along the coast to Bardsea inland, an extensive and valuable herring fishery has been lately established. The harbour is good, and well sheltered from the winds; and the bay, to which the town gives name, affords excellent anchorage ground. PwLHeLi is one of the contributory boroughs with Caernarvon, in returning one member to parliament, and is likewise the seat of the petty sittings for the district of Lleyn, which extends about twenty-two miles in length, and from three to ten in breadth, projecting into the sea in a manner similar to the county of Cornwall. According to the parliamentary returns of 1811, the parish contains 312 houses, and 1383 inhabitants, of which number, above one-half are resident in the town of PwLHeLi.

At the distance of five miles from this town is Carn-Madryn, a strong fortress, which formerly belonged to the sons of Owen Gwynedd. The bottom, flat, and top are filled with cells, varying in size and shape, many of which are still nearly entire. Close to the sea-coast is an entrenched, called Dinah Dinlle, which constitutes an object of great attraction from the road to Caernarvon by Clynnog, a neat romantic village, boating one of the largest and handsomest churches in Wales. Near it is the valley called Nant-y-Gwthrewir, or the valley of Vortigern, where that prince is said to have concealed himself, to avoid the persecution of his subjects. It is bounded on two sides by rocky slopes, only productive of heath and flinted gravel, and on the third by a tremendous precipice. The only opening to this seclude spot is towards the sea, "a northern aspet, where chilling winds exert all their fury, and half freeze, during winter, its few inhabitants." Nichollson's Cambrian Traveller's Guide, 1813. Carlile's Topographical Dictionary of Wales, 1811, 4to.

PYANEPSIA, *Piano*, in Antiquity, a feast celebrated by the Athenians in the month Pyanepsis; which, according to the generality of the critics, corresponded to our September.

Plutarch refers the institution of this feast to Theorus; who, at his arrival from Crete, made a kind of sacrifice to Apollo of all the provisions remaining in his vellum; putting them all into a kettle, boiling them together, and eating them with his six companions; which custom was afterwards continued. The scholium of Aristophanes says, this was done to acquit himself of a vow he made to Apollo in a temple.

M. Baudelot writes the word *Panoepis*, and takes it to be a feast instituted in memory of Theorus's return after killing the Minotaur.

The Greeks vary as to the origin and signification of the word Pyanepsis, whence the feast is denominated. Harpocrates calls it *Panoepos*; he adds, that others call it *Panoepis*, because then the fruits all appear to the eye. Herodotus writes *Panoepis*; and derives it from *Panoepis*, *beau*, and *fagi*, *comps*, because in this feast the Athenians gathered their beans, and made a kind of broth of them.

PYANEPSION, 12 March, in the Athenian Chronology, a month of thirty days, in which the festival Pyanepsis was celebrated, and called by the Bactians Damatrius.

PYAPOUR, in Geography, a town of Hindooftan, in Bahar; 13 miles E. of Bahar.

PYEO.
PYBOLOWO, a town of Lithuania; 25 miles E. of Mink.

PYCnanTHEMum, a name contrived by Michaux, from πυκνός, denso, and αἷμα, a flower, to express the dense inflorescence.—Michaux Boreali-Amer. v. 2. 7. Ait. Hort. Kew. v. 3. 376. Puri. v. 2. 409. (Brachytylum; Michaux Boreali-Amer. v. 2. 5.)—Class and order, Didynamia Gymnofpermia. Nat. Ord. Verticillate, Linn. Labiatae, Jüf.  

Gen. Ch. Cal. Perianth of one leaf, inferior, tubular, frayed, erect, permanent, with five awl-shaped, acute, nearly equal teeth; the mouth naked. Cor. of one petal, ringent; tube cylindrical, the length of the calyx; upper lip nearly erect, oblong, slightly convex, rounded, scarcely notched; lower lip much the largest, widely spreading, channelled, three-lobed; the lateral lobes semi-elliptical; the middle one longest. Stam. Filaments four, awl-shaped, dilated, various in length; two of them shorter than the act; anthers with two parallel cells. Pel. Germen superior, four-cleft; style bristle-flapped, rather shorter than the corolla; stigma two, spreading, acute. Perc. none, except the permanent calyx. Seeds four, roundish.  

Eff. Ch. Calyx five-cleft. Middle segment of the lower lip of the corolla longer than the rest. Stamens diant. Anthers with parallel cells.  

Obs. This genus seems to differ from Satureja principally in the form of its corolla. The species, as far as we know, are all American.  

—Found in old fields and copses, from Virginia to Carolina; flowering from July to October. It was cultivated in Shepard's garden at Eltham before the year 1732, but has scarcely been attended to by recent amateurs. The root is perennial. Stem three feet high, erect, somewhat branched, leafy, bluntly quadrangular. Leaves about two inches long, on short stalks; their under side mottled hoary or downy. Flowers white, tinged with red, in dense ferralled hoary whorls, with a terminal head; their inner bracteas bristle-flapped. The whole herb is clothed with fine softly pubescent, the leaves marked with pellucid dots; their scent aromatic, partaking of the common, as well as sweet, Marjoram.  

2. P. arifatum. Brilfy Tufted Savory. Michaux v. 2. 8. t. 33. Puri. n. 2. Ait. n. 2. (Nepeta virgina; Linn. Sp. Pl. 870. Willd. Sp. Pl. v. 3. 56. Chinopodium amarum folio, flore albo; Pluk. Phys. t. 85. f. 2.)—Leaves ovato-lanceolate, somewhat hoary, slightly ferrated. Heads seffile. Bracteas and calyx awned.—Native of dry woods, on a limestone soil, from Maryland to Carolina, flowering in July and August. Miller appears to have cultivated this species in 1752. It is perennial, with altogether the herbage and aspect of Origanum. The leaves are not an inch long, nearly seffile, dotted, veiny, thick-edged, very minutely, and scarcely perceptibly, hoary. Flowers white, small, in numerous, dense, terminal, hoary, compound heads. Bracteas lanceolate, entire, with long, rigid, awn-like points.  

—Native of high mountains in Carolina, according to Michaux, the only person who appears to have gathered this plant. The stem, and part of the rest of the herb, are usually tinged with purple. We have seen neither specimen nor figure.  

—Found on the mountains of Virginia and Carolina, but as yet a stranger to our gardens. It flowers from June to August, and is perennial. The habit of the plant, and its coloured bracteas, resemble Monarda filiformis. The flowers are small, and pale red, according to Mr. Pursh, on whom we depend for the synonymy of Walter.  

—Found in rather dry and mountainous meadows of North America, from New England to Carolina, flowering in July and August. Miller had it in cultivation in the year 1739, and it is still preferred in curious gardens, being a tolerably hardy, somewhat shrubby, perennial, of a bushy corybose habit, about eighteen inches or two feet high. The whole plant smells strongly of Penny-royal. The stem is square, pale, downy chiefly at the angles; its upper branches rising all nearly to a level, and forming a corynbous of numerous, globose or hemispherical, downy heads, of small white flowers. The bracteas are numerous, all ovate; the outer ones large, the inner very downy. Such is the plant intended by Linneaus under the above synonym, and which is perhaps rather the P. lanceolatum of Pursh, than his linifolium. In the latter the flamines are longer than the corolla; in the former they are shorter; but this is evidently, as in Mints, a variable circumstance; and therefore the Pycanthemum and Brachylylum of Michaux, are certainly one and the fame genus. We are confident also that there is no specific difference between Pursh's and Willdenow's linifolium and lanceolatum.  

Sect. 2. Stemens within the tube. Brachylylum of Michaux.  

6. P. muticum. Pointed Tufted Savory. Puri. n. 7. (Brachylylum muticum; Michaux v. 2. 6. t. 32.)—Leaves ovate, pointed, smooth, somewhat ferrated, Heads terminal, fleshy, solitary. Bracteas lanceolate, acute, awn-leaved.—Gathered by Michaux in Upper Carolina. Mr. Pursh never found this species. The former writer is incorrect in his definition of the leaves, which are by no means ‘‘ lanceolate-oval,’’ nor are they ‘‘ dentate,’’ but truly ferrated, at least in his plate. The heads bear some resemblance to those of our fifth species, but are less globose.  

7. P. verticillatum. Whorled Tufted Savory. Puri. n. 8. (Brachylylum verticillatum; Michaux v. 2. 6. t. 31. Origanum clinopodioides; Walt. Carol. 165.)—Leaves ovate, pointed, entire. Flowers capitately and whorled, Bracteas lanceolate, pointed.—Native of mountains in North America, from Pennsylvania to Carolina, flowering in
PYC

in July and August. Purp. This, like the reef, is perennial. It nearly resembles the last, but differs in having entire leaves, and one or two dense axillary whorls of flowers, beyond the solitary terminal heads. The bracteas are also said to be more pointed.

PYCNI, πυκνός, in the Ancient Myth, was used for such founds or chords of a tetrachord as might enter the psalm, or στάρκαντα. These were the hypate, the parypate, and the lichani, of the several tetrachords. The hypate were called barypycan, ραυρπακάν; the parypate, melopycen, μελοπάκαν; and the lichani, oxyypcnc, ὀξυπακάν; because the first were the lowest notes; the second, the middle notes; and the third, the highest of the psalm. Such chords as could never enter the psalm were called apycnai, ἀπυκνάν, υπεκόκκασια, τρισπακάν, τριαπόκαισια.

Hence, in the Greek scale or diagram, containing eighteen chords, there were five barypycan, as many melepycen, and an equal number of oxyypycnai, together with three apycnai. The apycnai and barypycan were stabiles or fixed chords; but the melepycen and oxyypycnai were movables, or mobiles.

PYCNIATE, in Mineralogy, is the mineral called galinite by Klaproth, leucite by Davy, and chalcous beryl by Werner, who first called it as a sub-species of beryl. It is now arranged with the topaz, to which its constituent parts bear a nearer resemblance. It is remarkable for containing, like the topaz, a portion of fluoric acid. Pycnite is generally found crystallized in long, fixed prisms imbedded in granite rocks. Small four-sided prisms may be obtained by a careful mechanical division from the large crystals; the bases of these are rhombohedrons of angles of 120° and 60°. Bucholz considers this to be the primitive form of pycnite. The colour of this mineral is either various shades of white, passing on one side from greyish and yellowish-white to straw-yellow, or from reddish-white to a peach blossoms and crimson red. Some specimens are marked with spots of violet blue. The crystals are translucent. The crose fracture is imperfectly foliated, with the longitudinal imperfectly small conchoidal. It is harder than quartz, which it scratches, but is easily broken in a direction perpendicular to the axis of the crystals. Its specific gravity is 3.61.

By the analysis of Vanquelin, pycnite contains

Bucholz makes the proportion of fluoric acid 17 per cent. There is no less difference in the proportion of fluoric acid in different specimens of the topaz, as given by Klaproth and Vanquelin. See Topaz. B.

PYCNON, πυκνόν. See Spissum.

PYCNOTYLE, πυκνόταλην, formed from πυκνός, close, and ταλήν, columns, in the Ancient Architecture, a building where the columns stand very close to one another; one diameter and a half of the column being allowed for the intercolumniation.

The pycnotyle is the smallest of all the intercolumniations mentioned by Vitruvius. Some make it the same with the styyle; others distinguish the latter by its allowing half a module more in the Corinthian intercolumniation.

The pycnotyle, Mr. Evelyn observes, chiefly belonged to the Composite order, and was used before the most magnificent buildings; as, at present, in the peristyyle of St. Peter’s at Rome, confining of near three hundred columns; and which as yet remain of the ancients among the late discovered ruins of Palmyra.

PYCNOTONICS, INCASSANTS, or medicines of an aqueous nature, which have the faculty of cooling and condensing, or thickening, the humours.

The word, in its original Greek, πυκνότονος, signifies something that has the power of thickening.

Purpureus, the neuphar or water-lily; lolanum, &c. are ranked among pycnotics.

PYDNA, in Ancient Geography, a town of Macedonia, in Pieria, on the coast of the Thersian gulf, some miles N. of the river Alaemon. It was near this town that the Romans gained over Perseus the battle which terminated the kingdom of Macedon. Steph. Byz. calls it Cydana.—Alfo, a town of the Rhodians.—Alfo, a mountain on the island of Crete.—Alfo, a town of Asia, in Phrygia, in the vicinity of Mount Ida.

PYE, in English Antiquity. See Pica.

Pye, in Mechanics. See Crab.

Pye, in Ornithology. See Pice.

Pye, Sen. See Pica Marina.

Pye’s Islands, in Geography, a cluster of small islands in the North Pacific ocean, near the W. coast of North America. The southermost forms, in various appearances of it, a very conspicuous peak; its S. extremity is situated in N. lat. 59° 10'. E. long. 210° 21'.

PYGAIA, in the Materia Medica, a name by which some authors have called the ipecacuanha, or vomiting Indian root.

PYGARGA, in Zoology, a species of Antelope; which see.

PYGARGITES, in Natural History, a name given by Pliny and some others of the old writers to the eagle-stone, when it was variegated with white, in the manner of the tail of the eagle, called pygargus.

PYGARGUS, in Ornithology, a species of eagle, called also by some authors albicilla, and bicornudaria. Linnaeus has called this bird among the vultures, calling it the vultur albicilla, because its bill is rather slimmer than is usual in the eagle; but Mr. Pennant observes, that it can have no claim to be ranked with that genus, because the pygargus is wholly feathered; whereas the characteristic mark of the vulture is, that the head and neck are either quite bare, or only covered with down. It is a large and fierce bird, of the size of the common turkey; its beak is yellow, and covered with a yellow membrane at its base; it has large hazel-coloured eyes; its feet are yellow, and its claws extremely strong and sharp; the head is white, and there are no feathers, but some fine hairs between the eyes and nostrils; the upper part of the neck is of a reddish-brown, and the rump black; all the body besides this is of an obscure dull colour, and its wings are partly black, partly grey; its tail is long, and the upper half of it is white, and the rest black. It is from this white part that it has its name albicilla. The male is of a darker colour than the female. This bird inhabits Scotland and the Orkneys, and feeds on fish as well as on land animals.

Authors who have written on this subject seem not at all agreed to call the same bird by this name. The pygargus of Aldrovand seems different from this, and the pygargus prior of Bellonius seems no other than the male of that kind of hawk, called in English the hen-harrier.

Mr. Willoughby imagines his first pygargus, p. 61, to be only a variety of the white-tailed eagle, having the same charac-
characteristic mark, and differing only in the pale colour of the head.

Pygargus, Accipiter, a name by which many authors have called the fubbuteo, a bird of the hawk kind; the male of which is called in English the hen-harrier, and the female suppofed by fome to be the ring-tail. See Falco.

Pyrgela, in Ancient Geography, a town of Asia Minor, in Ionia, where was a temple of Venus Munychian, according to Strabo and Steph. Byz.

Pygmé, πυγμαχος, the length, or extent, between the elbow, and extremity of the hand; the fift being fhort; called also a cubit.

Pygmy, Πυγμαχος, πυγμαχος, formed of πυγμα, cubis, a dwarf, or perfon of exceeding small stature, not exceeding a cubit in height. See Dwarf.

The appellation is given among the ancients to a fabulous nation, said to have inhabited Thrace; who generated and brought forth young at five years of age, and were old at eight; famous for the bloody war they waged with the cranes.

Pygmy, Apes, in Zoology. See Simia Sylvanua.

Pythia, in Geography, a large lake of Sweden, in the province of Savolax, N.E. of Lake Saima, and communicating with it.—Allo, a river of Sweden, which runs into the Gulf of Bothnia, at Brabeftad.

Pyhajarvi, a town of Sweden, in the province of Nyland; 34 miles N.W. of Helsingfors.

Pyhajoki, a town of Sweden, in East Bothnia, near the sea-coast; 10 miles S.S.W. of Brabeftad.

Pyhamaa, a small island in the Gulf of Bothnia, on a peninsula of the coast of Finland. N. lat. 69° 59'. E. long. 21° 12'.

Pykehaus, a town of Bengal; 52 miles S.E. of Pauccolo.

Pyker, or Pykar, in our Writers, a small ship or herring boat.

Pyia, in Geography, a town of the duchy of Warsaw; 48 miles N. of Pofen.—Allo, a river of England, in Monmouthshire, which runs into the Olwy; 2 miles N.E. of Ulke.

Pylaes, in Biography. See Bathyllus, Hylas, Mime, and Pantomime.

Pyleς Persides, in Ancient Geography, a famous trait in Asia, between the Peridea and Sufiana, according to Diodorus Siculus. This trait is named Porta Periche by Strabo, and Pyle Susides by Arrian.

Pylos Sarmitae. Sarmitia is bounded on the S. by mount Caucasus, which separates it from the neighbouring countries. Ptolemy speaks of two traits or paffages in this famous mountain; one called Porte Caucaza, which affords entrance into Siberia; the other named Pyle Albanez, and gives entrance into Albania.

Pylea, a town of Macedonia, in Trachinia, situated at the foot of mount Oeta, according to Phiolaltus. This gave name to the Pylaic gulf, mentioned by Strabo.

Pylea, Πυλες, in Antiquity, a name given to the affembly of the Amphiétyons, as well when they met at Delphi as at Thermopylae. The concourfe of people at these affembles was fo great, that the term pylea came to be used for any very numerous affembly, or crowd of people. Mem. Acad. Infer. vol. iv. p. 287, 290.

Pylagorion, Πυλαγοριον, a name given to the Amphiétyons, because they affembled at Thermopylae, or Pyle.

Pylai, in Geography, a town of Pusilia; 18 miles S. of Konigberg.

Pylé, Θιμασ, in Biography, was born at Stodey, near Holt, in Norfolk, in the year 1674. He received his academical education at Caen college, Cambridge, where he took his degrees, and became an excellent scholar. When inducted to the church, he discharged all the duties attaching to his situation as curate with the most conscientious integrity. His great aim was to amend and improve his hearers, and his discourses and urgent manner gained him the attention for which he was anxious. In early life he took part in the Bangorian controversy, and acquired for himself so much to the satisfaction of bishop Hardly, that his lordship presented him with a prebend, and procured for him a rectoryship in the cathedral church of Salisbury, and likewise made his two sons prebendaries of Winchester. He died in his 84th year. He was greatly admired as a preacher, and no less so as a faithful friend, an agreeable companion, a man of the most liberal sentiments, and so free from all pride and conceit of his own abilities, that he was apt to pay a deference to the opinions of many persons much inferior to himself. Archibishop Herring speaks of him as a worthy man, but who had not at all times the proper government of his own temper. He was author of several works: as “A Paraphrase, with Notes, on the Acts of the Apollines, and Epiftles,” being a supplement to Dr. Clarke’s Paraphrase on the Four Gofpels: “The Scripture Preparative against Popyry; being a Paraphrase, with Notes, on the Revelation of St. John.” He published also, between the years 1715 and 1725, “A Paraphrase, with short and useful Notes, on the Books of the Old Testament.” In 1773, his friends published two vols. of pithymous fermons, to which, in 1783, a third was added. Though these fermons want the care and polish of finished compositions, they are reckoned interesting and highly useful family difcourfes.

Pyler-Rudebar, in Geography, a town of Peria, in the province of Ghilan; 32 miles S. of Rethid.

PYLING the Ground for Foundations. See Foundation, and Pallification.

Pyloric Artery and Vein, in Anatomy, are blood vefids belonging to the ftomach. See Stomach.

Pylorus, the circular ring by which the ftomach communicates with the small intestine. See Stomach.

Pylstart, in Geography, an island in the South Pacific ocean, about six miles in circumference, discovered by Tafman in 1643. It pretends to view two lofty hills, which feem separated from each other by a low valley; it is called by Maurelle “La Sola.” S. lat. 22° 22'. W. long. 175° 59'.

Pylus Meffenia, now Navarin, in Ancient Geography, was fittuated on the western coast of Meffenia, over-againft the island of Aifa.

Pylus (Zoncit), or Avanico Veia, a town of Meffenia, upon the sea-coafl, S.E. of Platamodes.

Pylus Elanus, a town of Triphyla, N.W. of Onus, upon the Ladon.

Pymatuning, in Geography, a town of America, in Mercer county, Pennsylvania; 23 miles W.S.W. of Fort Franklin. It contains 376 inhabitants.

Pynaker, Adam, in Biography, a landscape painter, was born at the village of Pynaker, near Delft, in 1621. Whether his real name was that by which he is known or not, is not now to be ascertained. By an earnest study of the art, first in his native land, and afterwards at Rome, he acquired very considerable skill and celebrity. He generally exhibits brilliant effects of sunshine, in subjects not always happily selected, but executed with great freshness, purity, and taste. In his pictures we frequently fee ruins of elegant and antique buildings, and figures well adapted to the scene.
PYR

In general his pictures are of a small size, and are rather scarce. He died in 1672, at the age of 52.

PYRANG, in Botany, a name by which some authors call the faufal, or areca-tree; a kind of palm, from the expressed juice of which the drug commonly, but improperly, called Japan-earth is made.

PYNY, in Geography, a town of Hindoostan, in Comorob.; 18 miles S. of Daraporum.

PYONY WATER. See Water.

PYRACANTHA, in Botany, a name given by some authors to the lyrium, or box-thorn.

PYRÆA, or PYRETHEA, among the Eastern Nations of Antiquity, were great inclosures uncovered, and dedicated to the sun, in which a perpetual fire was kept up in honour of this luminary, which was worshipped by most of them. See CHAMANIA.

PYRALIS, the firefly, a name given by authors to a supposed insect, which they say is produced in the violent fires of the galls and metal furnaces. Plin. lib. ii. c. xxxvi. See LAMPIRIS.

PYRAMID, pyramis, in Geometry, a solid standing on a square, triangular, or polygonal base, and terminating at top in a point; or a body whose base is a regular rectilinear figure, and whose sides are plain triangles; their several vertices meeting together in one point.

Euclid defines it a solid figure, consisting of several triangles whose bases are all in the same plane, and have one common vertex.

Wolthus defines it a solid, bounded by as many triangles, A D C, D C B, and A D B, terminating in one point D, as the base A B C has sides. Plate XI. Geometry, fig. 18.

The pyramid is said to be triangular, quadrangular, quinquangular, &c. according as the base is triangular, quadrangular, &c. The pyramid may be called a square, triangular, &c. cone; or the cone a round pyramid.

PYRAMID, Properties of the. 1. All pyramids and cones standing on the same base, and having the same altitude, are demonstrably to be equal.

2. A triangular pyramid is the third part of a prism, standing on the same base, and of the same altitude.

3. Hence, since every multangular may be divided into triangulars, every pyramid is the third part of a prism, standing on the same base, and of the same altitude.

4. If a pyramid be cut by a plane, a b e, parallel to its base, A B C, the former plane, or base, will be similar to the latter.

5. All pyramids, prisms, cylinders, &c. are in a ratio compounded of their bases and altitudes; the bases, therefore, being equal, they are in proportion to their altitudes; and the altitudes being equal, they are in proportion to their bases.

6. Similar pyramids, prisms, cylinders, cones, &c. are in a triplicate ratio of their homologous sides.

7. Equal pyramids, &c. reciprocate their bases and altitudes; i.e. the altitude of the one is to that of the other, as the base of this to the base of that.

8. A sphere is equal to a pyramid, whose base is equal to the surface, and its height to the radius of the sphere.

Pyramid, to measure the surface and solidity of a. Find the solidity of a prism that has the same base and height with the given pyramid. And divide this by three; the quotient will be the solidity of the pyramid. Or, multiply the base by the perpendicular height; and one-third of the product will be the content.

Suppose, v. gr. the solidity of the prism be found 67010328, the solidity of the pyramid will be thus found 22336776.

Vol. XXIX.
modern writers. Herodotus (lib. ii.) makes the base of it to be 820 Grecian feet long; Diodorus (lib. i.) 700; Strabo (lib. xvii.) less than 600; and Pliny (lib. xxxvi. c. 12.) 883. Among the moderns, Sanders found it to be 300 paces; Bellumius 324; Greaves 693 English feet; Le Bruyn 704 French feet, or 750 English feet; Proper Alpinus 750 French feet; Thevenot 682; Niebuhr 710; Chazelles 764.80 English feet. In order to reconcile these differences, Dr. Shaw observes, that none of the sides of this pyramid are exactly upon a level; so that it is difficult to find a true horizontal base; besides, it is impossible to say how much the drifts of sand, to which it is exposed, may have been accumulated above the foundation of it; and, therefore, all calculations depending upon the time and circumstances of the situation, when they were made, must be exceedingly precarious. The perpendicular altitude of it, according to Greaves, is 499 feet; but its oblique height is equal to the breadth of the base, or 693 feet. The whole area of the base contains 480,249 square feet, or 11,484 English acres. The height, according to Herodotus, is 800 French feet; according to Strabo 625; according to Diodorus Siculus 600 and a fraction; as stated by Le Bruyn 616; by Proper Alpinus 625; by Thevenot 520; by Niebuhr 440. The ascent to the top of the pyramid is by steps, the lowermost being near four feet high and three broad; the second of the same dimensions, but retiring inward from the first near three feet; and in the same manner the third is placed upon the second, and the rest in the same order to the top, which terminates in a small flat or square, and they are so disposed, that a line stretched from the bottom to the top would touch the angle of every step. These steps are called by Herodotus little altars; on account of their form; and their number has been variously assigned; Greaves states them at 227; Maillet at 208; Pococke at 212; Belon at 250; Thevenot at 208, and Chazelles at 498.222 English feet. For a description of the inside of this pyramid, we must refer to Greaves, Savary, &c. infra.

This pyramid, being that already described, is situated on a rocky hill, in the sandy desert of Libya, about a quarter of a mile from the plains of Egypt, above which the rock rises 100 feet or more, with a gentle and easy ascent. Upon this advantageous elevation, and solid bafs, the pyramid is erected: the height of the situation adding to the beauty of the work, and the solidity of the work affording it a stable support.

We may here observe, that the sides of this pyramid stand exactly facing the four quarters of the world, and consequently mark the true meridian of the place: which precise position could not have been well owing to chance, but was, probably, the effect of design and art; and this is said to be confirmed by the position of the tomb itself, which lies within it. We may hence infer that the Egyptians had made an early progress in astronomy.

The second pyramid stands at about a bow-shot from the first, towards the south of this. Herodotus says, after having measured both, that it falls short of the other in magnitude; that it has no subterraneous chambers, and that the Nile is not conveyed into it by a channel, as into the former, but that it is of an equal altitude. Diodorus informs us, that it resembles the first in its architecture, but is inferior to it in magnitude; each side of the base containing a stadium, or 600 Grecian feet in length, so that by his computation each side is less than the of the former in length by 100 feet. Pliny makes the difference to be greater by 46 feet. Thevenot lets it but 631 feet square. Strabo supposes these pyramids to be equal, and Greaves affurs us, that the bases of both are alike, and that the height is not inferior to that of the first. This pyramid has no entrance like the other, and is built of white stones, not near so large as those of the first: the sides do not rise with gradations, but are smooth and equal, and the whole fabric, except on the south side, is quite entire. On the N. and W. sides of this second pyramid are two very flatly and elaborate pieces of architecture, about 30 feet in depth, and about 1400 in length, cut out of the rock in a perpendicular direction and squared by a chisel; supposed to be designed for the lodging of the Egyptian priests.

The third pyramid stands at about the distance of a full length from the second, on an advantageous rising of the rock, so that at a distance it appears equal to the former, though it be much less and lower. Herodotus says that it is 300 feet on every side, and to the middle, built of Ethiopean marble. Diodorus gives the same dimensions of its base, and adds that the walls were raised fifteen stories with black stone, like Thebaic marble, and the rest finished with such materials as the other pyramids are built with; that this piece of work, though it be exceeded by the two former in magnitude, yet far excels them in respect to the structure, art, and magnificence of the marble; and that on the side towards the north, the name of Mycerinus, the founder, is engraved; but this inscription has been defaced by time. Pliny writes to the same effect, except that he makes this pyramid 363 feet between the angles.

Dr. Shaw apprehends, that neither of these pyramids was ever finished, supposing that the steps already mentioned should have been filled up with prismatical stones, so that each side of the pyramid might be smooth and level, like that of Celsius at Rome.

But from the description of Maillet and Savary, the first pyramid appears to have been covered with a coating of marble, and thus finished on the outside, but closed; and that it has been since forcibly opened, and the stones which flit the passagle and were of an enormous size have been removed. This passagle was composed of marble, and the stones which form its four sides are of the finest white and hardest marble. For other particulars we refer to Greaves, Maillet, and Savary.

The ancients inform us, that the stones of the pyramids were brought from the mountains of Arabia, and Herodotus (lib. ii. c. 124.) has described the manner in which they were conveyed; but Dr. Shaw imagines, that they were taken from the spot where they were employed; and he observes, that the greatest of them, especially, is not an entire heap of hewn stones, because that portion of it, which lies below the horizontal section of the entrance, may probably be no more than an incrustation of the natural rock on which it is founded. Dr. Bryant conjectures, that, like the sphynx, which stands directly in the front of the second pyramid, they were immense rocks which stood upon the brow of the mountain; that the Egyptians caved them over with large stones, and brought them by these means to a degree of symmetry and proportion. At the same time they filled up the unecessary interstices with rubbish and mortar, and made chambers and apartments, as the intervals in the rock allowed, being obliged to humour the indirect turns and openings in the original mals to execute what they proposed. This he infers from the narrowness and unnecessary sloping of the passages, which are often very close and steep, and also from the fewness of the rooms in a work of so immense a structure. That the pyramids were built upon a rock in the place where they now
PYRAMID.

Now stand, was suggested by Mr. Hooke. See Birch's Hist. Royal Society, vol. iv. p. 245.

It is very surprising that the pyramids, which have been reckoned among the wonders of the world, should not have preferred a more certain era, and tradition of the names of their founders. Play, reckons a number of authors who have wrote concerning them; and all, he informs us, disapprove in their accounts of those who built them. Some modern writers maintain, that they were erected by the Egyptians, under the tyranny of the Pharaohs, and allege to this purpose the testimony of Josephus, Antiq. lib. i. cap. 5.

According to the relations of Herodotus (lib. ii.), and Diodorus (lib. i.), the first pyramid was erected by Cheops, or Chemmis, a king of Egypt, who is said to have employed three hundred and sixty thousand men for twenty years in its structure. Cephen, brother and successor to the former king, is said to be the founder of the second pyramid; and the third is said to have been built by Mycerinus, the son of Chemmis, according to Diodorus, but according to Herodotus, of Cheops. However, Herodotus says, that some ascribed the left to Rhodope, a courtzan, and the other two to the shepherd Philanth. The learned Greaves places the three kings who erected these pyramids in the twentieth dynasty; Cheops having begun his reign in the year 3448 of the Julian period, 400 years before the first olympiad, and 1266 years before the Christian era. He reigned fifty years, says Herodotus, and built this pyramid, as Diodorus observes, 1000 years before his time, or in the 180th olympiad; whereas, he might have lived 1207. Cephen, the builder of the second, reigned fifty-fix years; and Mycerinus, the builder of the third, seven years.

Dr. Bryant gives a different account of the origin of these pyramids: he ascribes the structure of them to the Cuthites (see Dispersion of Mankind), or Arabian shepherds, who built Heliopolis, and who were the giants and Titans of the first ages. These sons of Chus, according to this writer, seem to have come into Egypt immediately after their dispersion from Babel.

Many have considered these ancient structures with contempt, as being vast piles without any great symmetry, and have thought the labour idle, and the expense unnecessary. Thus Pliny (lib. xxxvi. cap. 12.) calls them regum pecunio atrofa ac fluita olenation, &c. built for ostentation, to keep an idle people employed, and to prevent commotion and rebellion. Arriistle (Polit. lib. iii.) calls them the work of tyranny.

The general opinion with regard to their intention and use is, that they were sepulchres and monuments of the dead, particularly of kings. This is expressly affirmed by Diodorus (lib. i.), and Strabo (lib. xvii.), and the opinion is confirmed by the writings of the Arabsians. And the reason, says Greaves, of their erecting these magnificent structures is founded in the theology of the Egyptians, who, as Servius shews in his comment upon Virgil (Aeneid, lib. iii.), where he describes the funeral of Polydorus—Animamque sepulchro constrictus—believed, that as long as the body endured, so long the soul continued with it; and this was also the opinion of the Stoics. Upon this principle, that the bodies might neither be reduced to dust by putrefaction, nor converted into ashes by fire, they embalmed them, and laid them up in these lately repositories, where they might continue free from the injury of time and of men. The reason of their building their sepulchres in the form of pyramids, was either from a notion that this was the most permanent form of structure, or because they hereby intended to represent some of their gods: particularly, as Greaves conjectures, Osiris, or the sun with many rays; for, under this form, the statues of the gods were frequently exhibited, and the gods themselves worshipped.

Among the Egyptians, the pyramid is said to have been a symbol of human life; the beginning of which is represented by the bafe, and the end by the apex; on which account it is that they used to erect them on sepulchres.

Herodotus.

Some, however, have objected to this design of the Egyptian pyramids, and are of opinion that they were originally intended for some nobler purpose. If Cheops, or any other person, was the founder of the great pyramid, intended it only for his sepulchre, what occasion was there for such a narrow crooked entrance into it; for the wall, as it is called, at the end of the entrance; for the lower chamber, with a large nitch or hole in the external wall of it; for the long narrow cavities in the walls of the upper room; or, for the two anti-chambers and the lofty gallery, with benches on each side that introduce us into it?

As the whole of the Egyptian theology was clothed in mysterious emblems and figures, it seems reasonable to suppose, says this writer, that all these tumbling, apartments, and crypts in architecture were designed for some purpose of religion, and that the Deity, which was typified in the outward form of this pile, was to be worshipped within. The square chest of granite marble, which is placed in the upper chamber of the great pyramid, may be supposed to have been rather intended for some religious use than for the coffin of Cheops. It might have served for one of their sacred chests, in which either the images of their deities, or their sacred vestiments or utensils were kept, or it might have been a hypocon or cistern, such as contain the holy water used in their ceremonies. Its length favours the opinion of its having been designed for a coffin, but its height and breadth far exceed the dimensions that were adhered to on such occasions; the Egyptian stone coffins were made of a different form, and inscribed with hieroglyphics. Nor is this chest placed according to the manner in which the Egyptians deposit their dead; for their mummys always stand upright, whereas this chest lies flat upon the floor. If, therefore, this chest was not intended for a coffin, it is inferred that the pyramid itself could not have taken the name of a sepulchre from it.

Cheops, indeed, and others might have been buried within the precinct of this or any other of the pyramids, and this was no more than was practised in other temples, and therefore could not destroy the principal use and design for which they were erected. Upon the whole, Dr. Shaw concludes, from the outward figure of these piles, the structure and contrivance of the several apartments in the infide of the greatest, together with the ample provision that was made on each side of it for the reception, as may be supposed, of the priests, that the Egyptians intended the latter for one of the places, as all of them were to be the objects, at least, of their worship and devotion.

Dr. Bryant has lately maintained, with considerabfe force of argument, this opinion, that the pyramids were designed for high altars and temples, and were constructed in honour of the Deity. If the chief pyramid were designed for a place of burial, what occasion, says he, was there for a well, and for passageways of communication, which led to other buildings? The apartments near the pyramids he supposes to be designed for the reception of priests, and to be appendages not to a tomb, but to a temple of the Deity.  

12
The stone coffin, he apprehends, was a trough or reservoir for water, which, by means of the well, they drew from the Nile. The priests of Egypt delighted in obscurity, and they probably came by the subterraneous passageways of the building to the dark chambers within; where they performed their labors, and other nocturnal rites. Many, he adds, of the ancient temples in this country were caverns in the rock, enlarged by art, and cut out into numberless dreary apartments; for no nation upon the earth was so addicted to gloom and melancholy as the Egyptians. From the top of the pyramids they observed the heavens, and marked the constellations; and upon the fame eminence it is probable that they offered up vows and oblations. See on this article Greaves's Works, vol. i. p. 1, &c. Shaw's Travels, fol. p. 413, &c. Pococke's Description of the East, vol. i. p. 41, &c. Perry's View of the Levant, p. 413, &c. Bryant's Analysis of Ancient Mythology, vol. iii. p. 523, &c. Farmer's Worship of the Human Spirits, &c. p. 379, &c. Savary's Letters, vol. i.

The tomb of Portena, king of Etruria, at Clusium in Italy, is a ancient monument of square stone, each side of which is three hundred feet broad, and fifty feet high. Within the square base there is an inextricable labyrinth; upon this square there stand five pyramids, four in the angles and one in the middle, five feet-five feet broad at the bottom, and a hundred and fifty feet high, and terminating in a point at top they are covered with a bract circle, from which are suspended bells, which are put in motion by the wind, so as that their sound may be heard at a great distance. Upon this circle there are four other pyramids, each a hundred feet high, above which, upon one plane, there are five other pyramids. Such is the account which Pliny gives from Varro, lib. xxxvi. cap. 13.

PYRAMID, Scenery of. See Scenery.
PYRAMID, Optical. See Optical Pyramid.
PYRAMIDAL FOUNTAIN. See Fountain.
PYRAMIDAL MIRRORS. See Mirror.

Pyramidal Numbers are the sums of polygonal numbers, collected after the same manner as the polygonal numbers themselves are extracted from arithmetical progression. See Numbers.

These are particularly called first pyramids. The sums of first pyramids are called second pyramids. And the sums of those third pyramids, &c., are called, ad infinitum. Particularly, those arising from triangular numbers are called prime triangular pyramids; those arising from pentagonal numbers are called prime pentagonal pyramids, &c. The numbers 3, 4, 10, 20, 35, &c. formed by the addition of the triangular numbers 1, 1, 3, 6, &c. are usually called by the simple name of pyramids; and the general formula

\[ \text{for finding them is } n \times \frac{n^2 - 1}{2} \times \frac{n^2 - 2}{3} \text{; i.e. the fourth pyramid may be found by substituting } 4 \text{ for } n; \text{ the fifth, by substituting } 5 \text{ for } n, \text{ &c.} \]

PYRAMIDALIA Corpora, in Anatomy, two prominences in the medulla oblongata. See Brain, and Nervous System.

PYRAMIDALIS ABDOMINIS, one of the abdominal muscles. See Obliques.

PYRAMIDALIS NASI, a name given by some anatomists to that portion of muscular fibres which descends from the front occurs in the side of the nose. See Epi-

PYRAMIDOID, called also parabolic spindle, a solid figure, formed by the revolution of a semiparabola round one of its ordinates.

According to the method of indivisibles, this may be conceived to consist of an infinite series of circles, whose diameters are all parallel to the axis of the revolving parabola.

The parabolic spindle is equal to \( \frac{2}{\pi} \times \text{th of its circumference cylinder. See Spindle.} \)

PYRAMIDOID, Parabolic. See PARABOLIC PYRAMIDOIDS.

PYRAMIDS, in Geography, rocks in the Eif Indian sea, near the E. coast of the island of Myof. S. lat. 1° 55'. E. long. 130° 59'.

PYRAMUS, Gideon, in Ancient Geography, a river of Asia, rising in the country of Cataonia, where it begins to be navigable, and traversing mount Taurus through the rocks, it enters the plain of Cilicia, passes by the foot of the mountain of Azanbarus, and leaving it to the right, throws itself into Moppeute, and at length loses itself in the Mediterranean, at the point where was formerly situated the town of Megaris.

PYRAUM, in Geography, a town of Bavaria, and capital of a lordship united to Salzburg; 13 miles S.E. of Nuremberg.

PYRENEUM Promontorium, Cape de Creus, in Ancient Geography, a promontory of Hispania Citerior; which terminates the Pyrenees eastwards, and projects into the sea.

PYRENEUS Salutis, a name given by Cornelius Nepos and Livy to that part of the Pyrenean mountains which Hannibal traversed in his way to Italy, passing from Spain to Gaul.

PYRENE, a town of Gallia Celtae, near the place where the Danube rises, according to Herodotus.

PYRENE, in Natural History, the name of a stone found always in the shape of the stone of an olive. It is of the laps Judaeus kind, being no other than the petrified spine of some species of echinates.

PYRENEES, in Geography, a chain of mountains, celebrated since the time of Herodotus, forming the boundaries between France and Spain, and extending from the Mediterranean to the Atlantic, about 200 miles in length, and in its greatest breadth 100 miles. Its various branches are distinguished by different names, and may be considered as belonging either to France or Spain. The highest summits of these mountains, which are in the centre of the chain, have presented to the research of the naturalist not only calamitous appearances, but even shells. The highest elevation of the Pyrenees is Mont Perdu, for an account of which, we refer to that article. The Canigou was formerly reckoned the highest summit, though it does not exceed 8444 English feet. Other noted heights are Tucarcory, Marboré, the pic de Midi, 9300 feet high, the pic de los Reyes, 7620 feet high, the pic d'Offano, 11,100 feet in height, the pic d'Ari, the Niéu Vallée, the Vigne Marn, La Breche de Roland, &c. At a distance the Pyrenean chain appears like a shaggy ridge, presenting the segment of a circle fronting France, and defended at each extremity till it disappears in the ocean and Mediterranean. Thus, at St. Jean de Luz, only high hills appear, and in like manner on the east beyond the summit Canigou, the elevations gradually diminish. The highest summits are covered with perpetual snow. Blocks of granite are interfused with vertical bands, argillaceous and calcareous, the latter primitive or secondary, and supplying the marbles of Campan and Antin, of beautiful red spotted with white, though the general mountain mass be grey. To the S. and W. the Pyrenees present nothing but dreadful sterility, but on the N. and E. the defect is more gradual, and affords frequent woods and pastures. Besides the dreadful fall of rocks,
rocks, undermined by the waters, they are exposed to Lavanges, or the impetuous defile of vult mates of snow, called Avalanches in Switzerland, and have their glaciers and other terrific features of the Alps.

The opinion of Ramond, that the summit of mont Perdu (which last) must have been covered by the sea, is confirmed by Lapérouse, (Journ. des Mines, N° 46.) A singular feature of the Pyrénées consists of "boules," as they are called, or walls dipping in a circular form. Near the summit of mont Perdu is a considerable lake, more than 9000 feet above the level of the sea, which throws its waters to the E. into the Spanish valley of Béarnis; and which the travellers allege as a proof that mont Perdu really belongs to Spain, and that the Taccoaroy forms the boundary. Lapérouse suggests it as probable that the sole access to the summit of mont Perdu will be found on the side of Spain; there being three summits called by the Spanishards "Las Tres Sorellas," or the Three Sisters; the highest being to the N., and the lowest on the S., but separated by large glaciers. Hence he infers the existence of chains of mountains, in which bands of granite, porphyry, trap, hornblende, and potas-

flex, alternate vertically with primitive limestone, and are so intermingled as to prove a common origin. But in the Pyrénées these bands are surmounted by secondary limestone, replete with marine fossils, and containing even skeletons of animals, so that he concludes that the highest mountains of the chain must have yielded to the fury of the ocean, and that the secondary parts only now exist. Mr. Townsend (Spain, i. 89.) observes, that the limestone and schists feed the vegetation on the N. of the Pyrénées, while the S. is barren, and confined to granite; while, in fact, mountains are generally barren and precipitous on the S. and W., because the most violent rains and tempests come from these regions. Pinkerton's "Geog. vol. i."

The passages over these mountains from one country to another are five; the three principal of which are from St. Sebastian to St. Jean de Luz; from Pamplona to St. Jean de Luz; and from Jacqauera to Perpignan. These mountains afford quantities of timber for shipping, which are conveyed, by means of the Ebro and other streams to the sea, with abundance of pitch and tar. The Pyrénées give name to three of the French departments.

Pyrénées, Baixara, one of the nine departments of the southern region of France, in N. lat. 42° 46', formerly Rouffion, bounded on the N. by the departments of the Arriere and the Aude, on the E. by the Mediterranean, on the S. and W. by Spain; about 58 miles from E. to W., and from 18 to 25 from N. to S., or 28 Fr. leagues in length, and 15 in breadth, containing 73,373 square miles or 212 square leagues, and 175,764 inhabitants; it is divided into 3 districts, 17 cantons, and 249 communes. The three districts are Perpignan, including 31,961 inhabitants, Ceret, 24,759, and Frades, 48,693. According to Haffenfratz, the number of circles is 3, of cantons 25, and of inhabitants 1,14,175. The contributions in the 11th year of the French era amounted to 1,010,220 fr., and the expenses for administration, education, &c. to 181,961 fr. 85 cents. The capital is Perpignan. This department is fertile in corn, wine, oil, flax, hemp, fruits, and pastures. On the hills there is little wood, but variety of medicinal plants and herbs. There are several lofty mountains on the S. and W. boundaries, as Massane, Canigou, &c.

Pyrénées, Lower, a department of France, in the S.W., or Garonne region, composed of Bear, Navarre, Basque-Francais, with a part of Chalofia and of Landes, in N. lat. 43° 16', and bounded on the N. by the departments of the Landes and Gers, on the E. by the department of the Upper Pyrénées, on the S. by Spain, and on the W. by the sea; 70 miles in length, and from 15 to 45 in breadth, or 16 Fr. leagues in length and 10 in breadth. It contains 8072.3 square kilometres, or 388 square leagues, and 84,030 inhabitants. It is divided into 5 districts, 40 cantons, and 660 communes. The districts or circles are, Pau, including 90,486 inhabitants, Oloron, 69,484, Mauléon, 65,447, Bayonne, 69,486, and Orthez, 86,127. According to Haffenfratz, its circles are 6, its cantons 44, and the number of its inhabitants 138,539. Its capital is Pau. Its contributions in the 11th year of the French era amounted to 1,753,760 fr. and its expenses for administration, &c. to 205,170 fr. 66 cents. This department, bounded on one side by the Pyrénées, and on the other by the ocean, presents a great variety of soil and diversity of prospect. The mountains are crowned with woods; the hills are covered with vines; the valleys are rich and populous; the heaths are wild and uncultivated. The plains yield wheat, rye, barley, oats, millet, flax, fruits, and pastures. It has mines of silver, copper, iron, quarries of marble, granite, flint, and mineral springs.

Pyrénées, Upper, a department of France, in the Garonne region, formerly Bigorre, in N. lat. 43°, bounded on the N. by the department of the Gers, on the E. by that of the Upper Garonne, on the S. by Spain, and on the W. by the department of Lower Pyrénées; 20 Fr. leagues long and 16 broad, or 53 English miles in length, and from 25 to 38 in breadth; a small district towards the N. being scarcely more than seven miles in breadth. It contains 4937½ square kilometres, or about 235 square leagues, and 206,680 inhabitants. It is divided into 3 districts, 26 cantons, and 501 communes. Its districts or circles are Tarbes, including 87,005 inhabitants, Bagnères, 78,099, and Argelès, 41,376. According to Haffenfratz, its circles are 5, and cantons 30, and the number of its inhabitants 188,690. Its capital is Tarbes. Its contributions in the 11th year of the French era amounted to 893,637 fr. and its expenses for administration, &c. to 173,759 fr. 12 cents. The plains in this department yield little wheat, but abundant crops of rye, barley, and millet, excellent wine, flax, and pastures. The hills produce considerable forests, with mines of iron and lead, quarries of marble, flint, and mineral springs.

Pyrénoides Processus, in Anatomy, a process of the second vertebra of the neck; called also odontoides, and densiformis, or the tooth-like processes.

The word *pyrénicae* is formed of *pyrên* nucleus, *kerneil*, or *berry*, and *sides*, figure.

Pyrethrum, in Botany, an ancient Greek name, adopted by Haller, Gartner, and the writer of the present article, who are followed by Willdenow and Aiton, for the genus in question, on account of its resemblance to the *pyrénicae* of Dioscorides. The latter is, however, the *Antimias Pyrethrum* of modern writers, or Pellitory of Spain; owing its Greek appellation to the fiery or pungent flavour of the root; whence also it obtained the Latin name of *Santaria*, because it cauets so remarkable a flow of itspia. Our present *Pyrethrum* is made up of several Linnaean species of *Chrysanthemum* and *Matricaria*, with some new ones.—Haller Helvet. v. 1. 405. Sm. Fl. Brit. 500. Wild. Sp. Pl. v. 3. 2150. Ant. Hort. Kew. v. 5. 97. Pursh v. 2. 527. Gardn. t. 169.—Clafs and order, *Synge*

Gen. Ch. *Common Calyx* hemispherical, imbricated; the scales close-pressed, rather acute, membranous at the edges. *Cor.* compound, radiated. Florets of the disk perfect, numerous,
numerous, tubular, funnel-shaped, with five spreading segments; those of the radius more than 12, female, ligulate, elliptic-oblong, three-toothed. Stem in the perfect florets. Filaments five, capillary, very short; anthers united into a cylinder, hardly fo long as the corolla. *Pil.* German, in all the florets, oblong; style thread-shaped, longer than the stamens; stigma two, divaricated, abrupt. *Peric.* none, the calyx remaining unaltered. Seeds nearly alike in all the florets, oblong, quadrangular, each crowned with an erect, membranous, more or less lobed border. *Recept.* naked, dotted, convex.

Section 1. *Radius white; rarely reddish.*

1. *P. frutescens.* Shrubby Feverfew. Willd. n. 1. *Ait.* n. 1. (Chrysanthenum fruticosum; Linn. Sp. Pl. 1251.) Leucanthemum canariense, *fapore pyrethri*; Walth. Hort. 31. t. 24. Buphthalmum canariense leucanthemum; Pluk. Almag. 73. (Willd. t. 272. f. 6.) — Stem shrubby. Leaves feathery, pinnatifid, linear, toothed; three-leafed at the extremities. Native of the Canary Islands, from whence it was brought very early; flowering in the green-house most part of the year. The woody *stem* is much branched. The *flowers* are crowded about the ends of the branches, and in their feathery texture, as well as linear forked figure, resemb line those of a *Crepidum*, or *Artemisia*. The *flowers* are terminal, solitary, on long naked stalks, and resemb line a white daisy.

2. *P. simplicifolium.* Simple-leaved West Indian Feverfew. Willd. n. 2. (Matricaria?; *prostrata*; Swartz Ind. Occ. v. 3. 1366.) — Leaves obovate; toothed at the extremity. Stalks axillary, single-flowered. Branches prostrate. Gathered by Von Rohr in Curacoa and the neighboring islands. It has never been brought alive to Europe. *Stem* herbaceous, branched, decumbent, round, downy, especially the ends of the branches. *Leaves* alternate, nearly fleshy, wedge-shaped, obovate, or roundish, half an inch long, downy, ribbed, notched or serrated; mostly accompanied by two minute leaves at the base. Stalks opposite to the leaves, thickish, an inch long, erect, downy, each bearing a yellowish-white, nearly globose, *flower*, whose disk is entirely yellow. *Seeds* crowned with a quadrangular middle border. *Sauria.*

3. *P. ptarmicifolium.* Goose-tongue Feverfew. Willd. n. 3. *Ait.* n. 2. — Leaves linear, finely serrated. Flowers corymbose. — Native of mount Caucasus. Sir Joseph Banks sent it to Kew in 1803. Willdenow describes this as perennial, with the habit of *Achillea Ptarmica*, only the flowers are twice as large. The *stem* is branched, either erect or decumbent. *Leaves* an inch long, very finely and sharply serrated. *Corymbs* terminal, simple, the stalks fleshy. *Radiant flowers* ovate. *Crown* half the length of the seed.

4. *P. ferrutum.* Creeping-rooted Feverfew. Willd. n. 4. *Ait.* n. 3. Pursh n. 1. (Chrysanthenum ferrutum; Linn. Sp. Pl. 1251.) *Jacq.* Obs. f. 4. 8. 1. 90. *Bellis americana*, procereus, ferotina, ramosa, flore amplissimo; Pluk. Almag. 65. (Phys. t. 17. f. 2.) — Leaves lanceolate; the lower ones strongly serrated; the upper entire. Branches corymbose. — Supposed to be a native of North America; but Michaux has it not, and Pursh merely saw a specimen in Mr. Lambert's herbarium, probably, like that of *Linnaeus*, from a garden. The plant was cultivated by Miller, and is a hardy perennial, flowering in October or later. Its *stem* is herbaceous, two or three feet high, much branched, lefthy, furrowed and angular. *Leaves* alternate, feathery, two or three inches long, and half an inch wide, entire or sparingly serrated in the upper parts of the stem, but mostly furnished, in our specimen, with a sharp tooth on each side of the base, which we do not find mentioned by authors. The *flowers* are terminal, solitary, much like our common *Chrysanthenum Leucanthemum*, but rather smaller.

6. *P. Halleri.* Hallerian Feverfew. Willd. n. 6. *P. n. 97; Hall. Helvet. v. 1. 41. *Leucanthemum alpinum* tenuifolium; *Bail.* t. 458. f. 3.) — Stem leaves lanceolate, deeply toothed; radical ones pinnatifid, on long stalks. *Stem* single-flowered. — Native of the Swiss Alps, in flouy places. The *roots* are creeping, black, long and flender, with very long fibres. *Stem* solitary, simple, lefthy, ascending, three or four inches high. *Leaves* smooth; the lowermost short, wedge-shaped, deeply pinnatifid, on long stalks; the uppermost feathery, deeply and sharply toothed, an inch or more in length. *Flowers* solitary, fliarped, terminal, large; the calyx-ears bordered with black; the radiant florets broad and elliptical. The above figure of Barrellier seems to accord better with our *Swiss* specimens than fig. 5. cited by Haller and his coptists, except that the upper leaves in fig. 3. are too narrow.

7. *P. alpinum.* Alpine Feverfew. Willd. n. 7. *Ait.* n. 4. (Chrysanthenum alpinum; Linn. Sp. Pl. 1253.) *Leucanthemum alpinum*; *Cluf.* Hilf. v. 1. 335.) — Lower leaves wedge-shaped, pinnatifid; uppermost linear and entire. *Stem* single-flowered. — Native of the German, Swiss and Italian Alps. The creeping *roots* throw out many short tufted leafy *flowers*, each bearing one long simple *flower* stalk; downy in its upper part, and furnished below with one, two, or more alternate, simple, linear, entire floral leaves. The *reft* of the *foliage* is flaked, pinnatifid, somewhat peptinate; the segments elliptical, entire, smooth, rather fleshy; each *leaf*, with its flat *stalk*, an inch or more in length. The *flower* is large, much like the last.

8. *P. Balsamita.* Collarv-leaved Feverfew. Willd. n. 8. *Ait.* n. 5. (Chrysanthenum Balsamita; Linn. Sp. Pl. 1252.) *Jacq.* Obs. f. 4. 8. 1. 89. *Leucanthemum orientale*, foliis hortensis folio; *Tourn.* Cor. 37.) — Leaves ovate-oblong, serrated, auricled. Flowers corymbose. — Native of the Levant; rare in our gardens. Mr. Blackburne is said to have cultivated it in his celebrated collection at Orford about 35 years ago. The habit of this species is so much like Common Collarv, *Tanacetum Balsamita* of *Linnaeus*, that one cannot help suspecting they are mere varieties of each other. The preference of a *radius*, in the plant before us, is known, by the examples of *Bidens* and *Coreopsis*, to be no infallible distinction. There is indeed the membranous crown of the seed, as Willdenow remarks, which makes this a *Pyrethrum*, not a *Chrysanthenum*; but such belongs to *Tanacetum* and confirms our supposition, or rather our belief, that the present is but a radiated variety of the Collarv. The *radius* is about twice the length of the *crown*, white, not yellow, as *Linnaeus* seems to describe it.

and half long; their segments lanceolate, toothed at the outer margin, the lower ones deep, the upper gradually confluent into a large cut terminal lobe, and entire. Stalks single-flowered, leafy, alternate, five or six at the top of the stem, composing a corymb. 

**Flowers** the size of *Chrysanthemum Leucanthemum* Willd. 

10. *P. pinnatifidum*. Pinnatifid Feverfew. Willd. n. 10. — "Leaves downy, glaucous, nearly fesile, lyrate-pinnatifid, unequally toothed. Flowers corymbose." — Willdenow described this from living specimens, but did not know their native country. The *fem* is long, with two feet high, branched, frayed, finely downy. Leaves downy on both sides; pinnate at the base; pinnatifid in the middle; cut at the end; their length two or three inches; their segments lanceolate, unequally toothed. *Coriopsis* simple, at the tops of the stem and branches. *Flowers* almost like the common *P. Parthenium*. 

11. *P. macrophyllum*. Large-leaved Feverfew. Willd. n. 11. Ait. n. 6. (Chrysanthemum macrophyllum; Waldst. et Kitaib. Hung. v. t. 97. t. 94.) — Leaves hairy, nearly fesile, pinnatifid, toothed, obtuse. Coriopsis terminal, compound. — Native of the woods and mountains of Hungary. Sir J. Banks introduced it, in 1803, to the Kew garden, where it is a hardy perennial, flowering in July and August. This plant resembles *Actiloba macrophylla*, for which some botanists have mistaken it, but is much larger. We have seen no specimen. 

12. *P. rofeum*. Rose-coloured Feverfew. Ait. n. 7. Willd. Enum. 905. (Chrysanthemum coccineum; Willd. Sp. Pl. v. 3. 21. 11.) Sims in Curt. Mag. t. 1860. Daphniphyllum orientale, tanacetifolium adamiophyllum, magnum coccineum; Tom. Cor. 37. Buxb. Cent. 2. 25. 21. — Leaves smooth, fesile; leaflets once or twice pinnatifid, serrated, acute, spreading. Stem erect, fingle-flowered. Gathered by Tournesort in Iberia. It is found also on the mountains of Caucaias from whence that distinguished cultivator Mr. Loddiges received seeds of this elegant species in 1803. The plant proves perennial and hardy, flowering in August or September. The *fem* is 12 or 18 inches high, more or less leafy, bearing one large handsome *flower*, whose disk is yellow, and the radius of a rich rose colour, or crimson, on its upper side; sometimes varying to white. The *leaflets* are from two to four inches long, fesile, rigid, paler beneath, pinnate, variously serrated, cut or pinnatifid, all the points and serratures very acute. Tournesort gathered plenty of this plant, and his original specimens are dispersed through many collections. 

13. *P. corymbosum*. Mountain Feverfew. Willd. n. 12. Ait. n. 8. (Chrysanthemum corymbosum; Jacq. Altr. t. 379. Ch. corymbiferum; Linn. Sp. Pl. 1251. Tanacetum non odoratum; Ger. Em. 650.) — Leaves pinnate; leaflets lanceolate, pinnatifid, sharply serrated; the upper ones confluent. Flower-talks corymbose. — Native of mountainous woods in Siberia, and many parts of Germany. Gerarde appears, by the catalogue of his garden, to have cultivated it in 1596. The *fem* is perennial, wooly, with long fibres. *Stems* erect, two or three feet high. *Leaves* somewhat like Tanf, but without fesile or taike, except that after a while, according to Jacquin, they cause a heat or pungency in the mouth. The numerous large white *flowers*, each with a bright yellow disk, form an ample terminal *corymb*. 

14. *P. Parthenium*. Common Feverfew. Sm. Fl. Brit. n. 1. Engl. Bot. t. 1234. Willd. n. 13. Ait. n. 9. (Matricaria Parthenium; Linn. Sp. Pl. 1255. Woody Suppl. t. 249. Fl. Dan. t. 674. Matricaria; Ger. Em. 602.) — Leaves pinnate; leaflets oblong, obtuse, pinnatifid and cut. *Stems* branched. *Flowers* corymbose. Radius about twice the length of the calyx. Seed-crown toothed. — Native of cultivated or waste ground throughout Europe, springing up abundantly with us in neglected gardens or court-yards, flowering all summer long. The *root* appears to be rather biennial than perennial. The whole herb is bitter and aromatic, hoary or downy. *Stems* bulky. *Leaves* fleshy, flat and diadate. *Flowers* numerous, each about the size of a common daily, but with a large yellowish disk, and bright white radius. Sometimes the latter is wanting; and more frequently the flowers are double, the disk becoming white and ligulate, like the radius, but each *florin* of a smaller proportion. The *receptacle* is flat. 

15. *P. parthenifolium*. Narrow Hoary Feverfew. Willd. n. 14. — "Leaves pinnate; leaflets oblong, obtuse, pinnatifid, toothed. Stem wand-like. *Flowers* corymbose. Radius thrice the length of the calyx. Seed-crown entire." — Willdenow described this from a garden, without knowing whence it came. He says it is very like the last, but has a taller wand-like *stem*, narrower leaves, a disk but half as large, though the radius is larger, and an entire, not toothed, margin to the *fem*. A plant, now become a weed in Kew garden, and said to have been imported from China, answers precisely to this description in every point, except that its *fem* is scarcely less robust than in *P. Parthenium*. It is difficult to separate, and we are persuaded, though confessing, that it is what Willdenow meant. Its *leaves* are conspicuously hoary, with narrower divisions than those of the last, and the *flowers*, on account of their long and brilliant-white radius, are more striking. We have had no opportunity of investigating the crown of the flower. 

17. *P. sufcatum*. Dingy Feverfew. Willd. n. 16. Sm. Prodr. Fl. Græc. Subh. n. 2095. (Chrysanthemum sufcatum; Desfont. Atlant. v. 2. 253. t. 237.) — Leaves downy, pinnate; leaflets with a few deep linear-oblong segments. *Stems* branched from the base, diffusely. — Gathered by Desfontaines in uncultivated fields near Tunis. Sibthorp found it in Greece. The *root* appears to be perennial, bearing many widely-spread or prominent *flowers*, a fingle long, which are leafy, and slightly branched. The *leaves* are rather fucculent. *Flowers* terminal, solitary, large, with a blackish *calyx*, pale yellowish disk, becoming brown in decay, and broad white elliptical radiate florets. It blossoms in winter. 

18. *P. inodorum*. Corn Feverfew, or Scentless Mayweed. Sm. Fl. Brit. n. 2. Engl. Bot. t. 676. Willd. n. 17. Ait. n. 11. (Chrysanthemum inodorum; Linn. Sp. Pl. 1253. Fl. Dan. t. 696.) — Leaves pinnate, in many capillary segments. *Stems* branched, spreading. Seed-crown entire. — Found in fields and waste ground throughout most parts of Europe, especially where the soil is gravelly, flowering in autumn. *Root* tapering, annual. Herb alomost without any peculiar scent, by which it is readily known, in every state of growth, from *Ambrosia Cotula*. The *fem* is a foot or more in height, widely spreading, clothed with pale-green *leaflets*, entire, with leaflets are deeply and variously divided into linear, almost capillary, pointed segments. More simple segments are numerous.
Pyrethrum.

Numerously crowded about the bottom of each leaf, rendering it, in a manner, lyrate, and surrounding the stem or branch. Branches somewhat corymbose, each terminated by a rather large flower, with long white rays, and a prominent yellow disk. The late Mr. Crowe once found in Norfolk a partly double-flowered variety.

19. P. maritimum. Sea Feverfew. Sm. Fl. Brit. n. 3. Engl. Bot. t. 979. Willd. n. 18. Ait. n. 12. (Materiae maritinae ; Linn. Sp. Pl. 1256. Chamæcemum maritimum paniculatum, folsis brevissimis obtusis viribus; Dill. in Rari Syn. 186. t. 7. f. 1.)—Leaves doubly pinnate; segments linear, pointless, fleshy; convex above; keeled beneath. Stem diffuse. Seed-crown lobed.—Native of the sea-coast in the north of Europe. Found in several parts of Scotland, as well as on the south coast of England, and in Lancashire and Durham, flowering in July and August. The root is perennial. Stems numerous, profuse, spreading circularly to the extent of two or three feet. The leaves are more fleshy than in the foregoing, the disk of the flower broader, in proportion to the length of the rays; and the crown of the disk divided into three or four lobes. The whole herb is slightly aromatic, and of a darker more shining green than inodorum.

20. P. parviflorum. Small-flowered Feverfew. Willd. n. 19.—"Leaves doubly pinnate; leaflets linear-thread-shaped, in two or three deep divisions. Stem erect, branched. Seed-crown two-lobed."—Described by Willdenow from living specimens, but the native country of this species is unknown. It is said to be annual, greatly resembling P. inodorum, but having a taller and upright stem; a shorter radius; and a green two-lobed crown to the seed.

Section 2. Radius yellow.

21. P. multicaule. Many-flaked yellow Feverfew. Willd. n. 20. (Chrysanthenum multicaule; Desfont. Atlant. v. 2. 182. t. 236.)—Leaves simple, smooth, flatulate; the lower ones toothed. Stem erect, much branched from the bottom.—Native of sandy hills near Mafcar, in Barbary. Root fibrous, apparently annual. Stem branched from the base principally, buffy; the branches naked above, each bearing a solitary flower, about as big as a French Marygold, whole radiant flowers are yellow, and of a very broad elliptical form, about eight or nine or number.

22. P. trifurcatum. Three-forked Yellow Feverfew. Willd. n. 21. (Chrysanthenum trifurcatum; Desfont. Atlant. v. 2. 281. t. 235. f. 2.)—Leaves simple, smooth, linear, acute; the lowermost pinnate; the uppermost undivided. Stem acending, single-flowered.—Native of fields near Kerwan in Barbary, flowering in winter. The stem is simple, a foot high; leafy below; naked above; terminated by a very large flower, with numerous yellow radiant florets. Some leaves are partly bipinnate; others three- or four-lobed, the uppermost simple; all linear, wavy, acute, and of equal breadth.

23. P. Bozonti. Dwarf Pale-Yellow Feverfew. Willd. n. 22. (Chrysanthenum aragonense ; Affo Synop. n. 845. t. 9. f. 1. Wild. Bellis mea, chrysantheri cretici folio; Bocc. Muf. 136. t. 80.)—Leaves hoary, flaked, pinnate; leaflets linear-awl-shaped; upper ones linear, undivided, and entire. Stems single-flowered.—Native of Spain and Sicily. Willdenow describes it thus from dried specimens. "Stems many-headed, woody. Stems several, simple, a span high, single-flowered. Leaves hoary; the radical ones flaked, oblanceolate when arriving at maturity, and altogether wanting when the flowers open; lower rem-leaflets flaked, pinnate at the extremity, with three or four pair of very short linear-awl-shaped leaflets, and a membranous linear footstalk; the upper ones linear, sessile, and entire. Rays of the corolla pale yellow. It resembles Chrysanthemum pinnatum, but differs abundantly in the calyx not being membranous, and in having a crown to the seed."

We know nothing of Affo's plant. Willdenow cites an additional synonym, Barbequin's t. 1152. f. 11, which seems to have no affinity to the figure of Boccone, and much more resembles Cineraria minor, Cavan. Ic. t. 35. f. 3, under which indeed Willdenow likewise quotes it, Sp. Pl. v. 3. 286.

24. P. orientale. Oriental Yellow Feverfew. Willd. n. 23.—"Leaves doubly pinnate; leaflets linear. Stems ascending, single-flowered."—Native of Georgia. Stems six inches high, naked above. Lower leaves an inch long; the upper ones half as long, and only singly pinnate. Scales of the calyx withered at the edge. Flowers deep yellow, the size of Chrysanthemum segetum. Willd.

25. P. milkefuliatum. Milkfoil-leaved Yellow Feverfew. Willd. n. 24. Ait. n. 13. (P. n. 174; Gmel. Sib. v. 2. t. 207. f. 1. 2. Chrysanthenum milkefuliatum; Linn. Syn. Veg. ed. 13. 643. Antirhium milkefolia; Linn. Sp. Pl. 1269. Achillea folia foliis &c.; Mill. Ic. t. 9.)—Leaves doubly pinnatifid, linear, blunting. Stems corymbose. Rays half as long as the diameter of the disk.—Native of Siberia. A hardy perennial, flowering throughout the summer. The stem is twelve or eighteen inches high, leafy, branched and corymbose, bearing eight or more long-flaked yellow flowers, whose disk is about half an inch in diameter, and their radiant florets of a short roundish figure, hardly extending a quarter of an inch from the disk. Seed-crown toothed. Leaves doubly and interruptedly pinnatifid, with linear, blunting segments, each tipped with a minute point; their surfaces both downy, or somewhat silky. The leaves, as well as flowers and seeds, are very distinct from Chrysanthemum italicum, to which Linnaeus compares this species.

26. P. bipinnatum. Wing-leaved Yellow Feverfew. Willd. n. 25. Ait. n. 14. (P. n. 172; Gmel. Sib. v. 2. t. 35. f. 1. Chrysanthenum bipinnatum; Linn. Sp. Pl. 1255.)—Leaves doubly or triply pinnatifid; their segments dilated upwards, minutely pointed. Stem nearly simple. Rays wedge-shaped, not a quarter so long as the diameter of the disk.—Native of Siberia, flowering in June. Introduced at Kew by Mr. Buxton, in 1796. This differs from the last in having more compound leaves, whose ultimate segments are almost elliptical, and all their points distinctly awned. But the flowers especially differ in being fower, from one to three on each stem, and furnished with a disk near an inch wide, while the radiant marginal florets are short, broad, and wedge-shaped, with broad spreading teeth. The calyx, as well as all the herbage, is haggy with soft hairs.

27. P. indicum. East Indian Yellow Feverfew. Sims in Curt. Mag. t. 1521. Ait. n. 15.—Leaves pinnatifid; their segments dilated upwards, lobed. Stem branched. Flowers on long flasks, nearly globular. Radiant florets few, very short.—Sent by Dr. Roxburgh, from the East Indies, to A. B. Lambert, esq. It proves a hardy annual in our gardens, flowering most part of the summer. The stem is much branched, but the pinnatifid, though more simple and broader, leaves, betray an affinity to the two last species, which is confirmed by the short yellow radiant florets. These however are, according to Dr. Sims, mostly generally wanting. The flowers are solitary, on long swelling furrowed flasks, terminating each branch; their disk nearly an inch wide, and finally convex. The herbage appears to be smooth.
The distinguishing characters of the pyricubia are these; they are compound, inflammable metallic bodies, of a cubic figure, or resembling a die, being composed of six sides. Of this genus there are only two known species. Hill.

PYRIFORMIS, in Anatomy, a muscle of the thigh, flattened and triangular in its figure, situated at the back of the pelvis, and extending from the facrum to the great trochanter. The posterior surface is covered by the glutus magnus, and partly by the medius. The anterior is partly in the pelvis, partly on the outside of the cavity. Within the pelvis it corresponds to the rectum, the faciculium, and the hypogastric vessels; externally to the cavity it covers the glutaeus minimus, the os innominatum, and the ischial tuberosity. The upper edge corresponds to the faciculium, and the glutaeus artery; it then lies close to the glutaeus medius. The inferior edge corresponds to the lesser faciculium ligament, and then is parallel to the genus superior: it is at first separated from the latter muscle by the great faciculium nerve, and afterwards approaches to, and is united with it.

The basis of the pyriformis is attached to the side of the anterior surface of the facrum, in the intervals of the facet bone; to the lateral areas, to the anterior surface of the great facio-facicular ligament, and to the posterior and upper part of the os innominatum. The muscle proceeds from within outwards, and rather downwards, passing out of the pelvis at the great facio-facicular oramen, gradually diminishes, and terminates in a small tendon, fixed to the upper part of the internal surface of the great trochanter.

The attachment of this muscle to the great trochanter is by means of a tendon, the lower edge of which is connected to that of the superior geminus. This tendon expands into an aponeurosis, which, after extending on the front of the muscle, enters into its substance. The fleshy fibres arise from the parts mentioned above, and are fixed in all directions to the tendon. Sometimes a portion of the faciculium nerve passes through a slit in the muscle.

When the thigh is extended, the pyriformis will rotate it outwards; but when it is bent, it will act as an abductor. If the thigh is fixed, it will move the pelvis in an opposite direction.

PYRIPHELEGES, a word used by the old writers in medicine to express a person labouring under an extreme degree of a febrile heat.

PYRIPOLYGIUM, the name of a genus of fossil, the characters of which are these: they are compound, inflammable, metallic bodies, found in loose detached masses of a simple and uniform, not striated internal structure, and arc covered with an invidious coat or crust.

Of this genus of fossils there are three known species. Hill.

PYRUSCULUS, a word used by the ancients to express a sweeting tree.

PYRITOS, a word used by some authors to express a brick when heated, in order to be applied to the body wrapped up in a cloth by way of a dry fomentation.

PYRICAUSTUM, a word used by medical writers to express a burn or scald.

PYRUCOMIUM, in Natural History, the name of a genus of fossil bodies, usually comprehended, with many others of very different figure and structure, under the general name pyrites.

Vol. XXIX.
PYRITES.

Word πυρίτης, formed of πῦρ, fire, denotes fire-dust; a denomination given to this substance on account of its inflammability. For the mineralogical characters of copper pyrites, and iron pyrites, see Copper Ore, and Iron Ore.

Besides the two named there are auriferous pyrites, auriferous pyrites, and tin pyrites. Combinations of sulphur with the metals are called by chemists sulphurets; and the different kinds of pyrites are properly metallic sulphurets. Sulphur has a great affinity for iron, and in combination with this metal, under the form of pyrites, exists in extensive beds in primary mountains, or is disseminated through the secondary rocks and strata, in veins and marls, or variously crystallized: it occurs also in beds of coal and bituminous clay. Iron pyrites may be considered, after the earths, as one of the most abundant substances in the mineral kingdom, forming a constituent part of the globe, and by its decomposition giving rise to many important subterranean phenomena.

The proportions of iron and sulphur in the different sub-species of iron pyrites enumerated by mineralogists are,

52 to 54 Sulphur
48 to 56 Iron.

Magnetic pyrites differs from common pyrites: its constituent parts, according to Mr. Hatchett, are,

36.50 Sulphur
63.50 Iron.

By the application of heat common pyrites becomes susceptible of action by the magnet; the excess of sulphur being expelled. Iron pyrites is not worked as an ore of iron, but is principally valued for the green vitriol or sulphate of iron, which it affords when exposed to air and moisture. Sulphur may also be obtained from pyrites when heated with charcoal.

The decomposition of pyrites is effected spontaneously by the absorption of oxygen from water and the atmosphere, which converts the sulphur into sulphuric acid, and the iron into an oxyd. These substances unite during the process, and form the sulphate of iron, or green vitriol.

Some kinds of pyrites are rapidly decomposed, others require to have part of the sulphur expelled by heat. The pyrites, or pyritous substance intended to form vitriol, is collected in extensive heaps, spreading the surface as much as can be conveniently done. The ground on which these heaps are spread should be impervious to water, and inclined, in order that the saline matter which effloresces may be washed off, and conveyed into referrers to crystallize. As the decomposition proceeds the mafs becomes heated, and is occasionally moistened, particularly when the air is dry and warm. These beds continue productive for many years, and if the pyrites be pure, but little residue is left. An excess of sulphuric acid is formed during the process, on which account a quantity of old iron is added to the solution, to saturate it, and obtain the salt in a crystallized state. During the decomposition of pyrites much heat is evolved, and a considerable absorption of oxygen from the atmosphere takes place. The fact was first observed by Henckel, who affirmed, in his "Pyrologia," that air was necessary to the process of vitriolization, and that it enters into combination with pyrites and remains fixed in it: "non ut instrumentum transiens sed immansus." This may be considered as a happy anticipation of one of the most important doctrines of modern chemistry. Some geologists have supposed that subterranean fires, and the temperature of hot springs, are occasioned by the spontaneous decomposition of immense beds of pyrites in the interior of the earth, and an experiment made by Lemery gives some plausibility to this opinion. He found that a mixture of iron filings and sulphur, moistened with a small quantity of water, becomes hot in a few hours, the mafs swells, and the parts adhere together: it then breaks with a perceptible noise and cracking, and emits aqueous vapour, and a fetid odour like that of sulphurated hydrogen gas. If the mixture be made in a large quantity, it takes fire in twenty-four or thirty hours. As soon as the emission of aqueous vapour has ceased, the heat becomes greater and greater, is succeeded by inflammation, the smell is then much stronger, and appears to arise from the hydrogen produced by the decomposition of water. Beaumé, who observed this phenomenon from a mixture of one hundred pounds of iron filings, with an equal quantity of sulphur in powder, states that the flames rule to a foot in height, but did not continue longer than two or three minutes; the mafs, however, remained red-hot for forty hours. Lemery the elder gave to this experiment the name of the artificial volcano.

Dr. Watton, in his Chemical Essays, vol. i. p. 187, says that he has repeated this experiment more than once. When made in the open air the flame is of short duration, and the whole mafs after the extinction of the flame, continues at intervals to throw out sparks. A ladle full of the ignited mafs being dropped down from a considerable height, descended like a shower of red-hot ashes. The success of this experiment depends on a due proportion of water. Half a pound of flower of sulphur, with half a pound of clean iron filings, mixed with fourteen ounces of water, and worked into a pate, will acquire heat enough to make the mafs take fire.

Some dark-coloured carbonaceous and bituminous earths contain pyrites in minute grains, and decompose with great rapidity when exposed to moisture. In the month of August 1751, the cliffs near Charnouth, in Dorsetshire, containing a similar kind of pyritic earth, took fire in consequence of a heavy fall of rain after a hot dry season, and continued at intervals to emit flame for several years. Almost all kinds of pit-coal in England contain more or less pyrites: in some the quantity is very inconsiderable, in other kinds it abounds so much as to render them unfit for domestic purposes, and totally inapplicable for forges or iron works, on account of the sulphur which they emit when burned. This pyritic coal may be distinguished by its greater specific gravity, and the brass-like metallic appearance of the pyrites with which it is intermixed. Pyritic coal and coal flake, or bituminous clay, containing pyrites, frequently take fire spontaneously in coal mines, or when exposed in heaps out of the pits, and continue burning many years. Instances of this kind now exist in the north of England; and so intense is the heat produced by the ignition of these malleys, that the coal flake is sometimes fused. We have seen specimens from these heaps which have all the characters of cellular volcanic lava. In the vicinity of Leeds there is a large heap of coal flake which has been on fire near half a century; it is covered in parts with vegetation, and presents no appearance of ignition during the day; but if a dry flake be thrust into it the surface is changed in a few minutes. In some of the coal mines in Leicestershire, near Ashby de la Zouch, the stratum of indurated clay over the main bed of coal contains so much pyritic matter, and is so subject to spontaneous inflammation when it falls down and is intermixed with small coal and moisture, that the miners are obliged to close up the space with brick-clay where the coal has been worked, to prevent the access of air to the combustible matter. In this state, excluded from the air, the pyritic earth sometimes becomes ignited, as is evident by the heat communicated to the neighbouring parts of the mine; but the fire is prevented from spreading among the coal.
coal, by the precautionary measure of closing the cavities with clay.

The great heat evolved during the decomposition of pyrites, may proceed in part from the combination of oxygen with the sulphur and iron, and may be increased by the different capacity of the new compound for heat. Whenever chemical changes take place rapidly, they produce a change in the temperature of substances, as in the well-known infusions of lime and water, nitric acid and vegetable oils, &c.

The phenomena accompanying the mud volcanoes in various parts of the world, present many appearances which give probability to the opinion, that they proceed from the decomposition of pyritic flates. See Volcano.

The formation of alum is also effected naturally, in many situations, by the decomposition of pyrites, the sulphuric acid combining with the alumine of pyritic clay. This is not unfrequently the case in excavations of coal mines that have been long worked out.

At Hartlet, near Glasgow, in the excavations of an old coal mine that has been worked some centuries, there is a very extensive formation of alum, from the decomposition of the roof of the pit. It is a pyritic clay ten inches thick. In the old workings of the mine which are dry, the air circulates slowly, and the roof gradually decomposes and exfoliates, and falls upon the floor, in which situation the decomposition proceeds, and the substance assumes the appearance of a peculiar efflorescence. In time the whole space to the roof is filled; it is then removed. The mafs consists of earth richly impregnated with sulphate of alumine, sulphate of iron, and in fome infiuences with sulphate of magnesia. The coal in this mine, contrary to the usual practice, is worked to the dip, so that the old workings are always dry. To this circumstance may principally be attributed the great accumulation of alum in this mine. In many of the mines in En- gland a similar formation of alum would take place, but they contain too much water to permit the saline substances to remain. In general, alum rock or alum flake require to be exposed in heaps, and burned in the open air, to expel the sulphur, and combine it with the oxygen from the atmosphare. The sulphuric acid thus formed unites with a requisite portion of the clay during the process.

The gypsum, or the sulphate of lime which occurs in beds, among secondary flates of red sand-flone and beds of marl, probably may owe its present flate to masses of pyrites, which have exilted over common lime-flone, and been decomposed naturally. The sulphuric acid thus produced would unite with the lime, and form gypsum. The great quantity of the red oxvd of iron which is in the flone and marl that accompany this kind of gypsum, gives much probability to this opinion. The cryftals of gypsum or felinite found detached in beds of clay had probably a fimilar origin.

Sulphuret of iron may be formed by heating together iron filings and sulphur. From the experiments of Vauquelin it is proved that there are four sulphures of iron, according to the degree of heat and other circumstances under which the combination may be formed. The firit sulphuret consists of

\[
\begin{align*}
78 & \text{ Iron} \\
22 & \text{ Sulphur} \\
\end{align*}
\]

Artificial.

The second sulphuret, of

\[
\begin{align*}
64 & \text{ Iron} \\
36 & \text{ Sulphur} \\
\end{align*}
\]

Natural magnetic pyrites.

The third sulphuret, of

\[
\begin{align*}
54.16 & \text{ Iron} \\
45.84 & \text{ Sulphur} \\
\end{align*}
\]

Artificial.

The fourth sulphuret, of

\[
\begin{align*}
47 & \text{ Iron} \\
33 & \text{ Sulphur} \\
\end{align*}
\]

Natural common pyrites.

When the quantity of sulphur does not exceed 40 per cent., pyrites is soluble in muriatic acid, and may be rendered permanently magnetic. The specific gravity of common pyrites is from 4.6 to 4.83. Of magnetic pyrites 4.51.

Arefenic pyrites, called marasite, is distinguished from iron pyrites by its colour, which is a silver white, and by yielding a smell like garlic when rubbed or exposed to heat. See Arfesic Ores.

Auriferous pyrites, or iron pyrites, with a small alloy of gold; the richest specimens of this ore in Europe are found in Transylvania, containing from 0.02 to 0.03 of gld. These ores are distinguished from iron and copper pyrites by their colour, malleability, and specific gravity.

Tin pyrites. See Tin Ores.

The pyrites, in substance, are never used medicinially; nevertheless, in their products they are very important. From these common sulphur is extracted, in Sweden and Saxony; the native vitriols are produced in caverns of the earth, or on its surface; the greatest quantities of artificial vitriol are prepared; and the mineral waters, vitriolic, aluminoius, sulphureous, hot or cold, are supposed to receive their impregnation.

When the matter of the pyrites is mixed with the lead ores, the method of separating the metal by affaying is this: roast two centners of the ore, as in the usual method, and keep a stronger fire than when the ore is pure. The pyrites, especially when it is merely iron, hinders ore from easily growing clammy or turning into large lumps, or entirely melting. When the ore is sufficiently Walker, let it cool, beat it to powder, and repeat the roasting to a third fire, till when it is red-hot in the fire, there is no smell of sulphur; then mix the ore with fix centners of the black flux, and two of sandvler, and finish the work in the common way, only making the fire greater, and continuing it longer, toward the end of the operation. Cramer's Art of Affaying, p. 292. See Lead Ores.

Pyrites is applied by some authors to the marasite ores of all metals; the names of which are varied according to the metals they partake of.

Thus chalcopyrites is that of gold; argentites that of silver; siderites that of iron; chalcites that of copper; and molybdenites that of lead, &c.

PYRITICUM LIQUAMEN. See Liquamen Pyriticum. PYRITRICHIPHYLLUM, in Natural History, the name of a genus of foliils of the clads of the pyrites, the characters of which are thse: they are compound, inflammable, metallic bodies, found in loose malls not of any regularly angular figure, and of a fritellated texture, with foliaceous ends to the frize, appearing on the surface, or within the mals.

Of this genus there are only two known species: the having the foliaceous ends of the frize on the outer surface of the mals; and the other having a smooth external surface, and the foliaceous ends of the frize covering the sides of internal hollows.

The friz of these is found in many of the English and German mals; the other has been yet only found in the mals on Mendip hills in Somersetshire, but there in considerable plenty. Hill.

PYRITRICUM, the name of a genus of pyrites, the characters of which are these: they are compound, inflammable, metallic foliils, always found in detached mals of K 2
PYR

no regularly angular figure, and of a simply fruticated internal structure.

Of this genus of pyrite there are three known species. All the three species are found plentifully in different parts of the kingdom: the first in all sorts of strata, and often loose on the ground; the second principally in the chalk-pits of Kent and Sussex; and the last in Essex and Hampshire, and very frequently in the German mines. Hill.

PYRITZ, in Geography. See PURITZ.

PYRMONT, a town of Germany, and capital of the county so named; its citadel is fortified with a broad ditch, high ramparts, and subterranean passages and vaults; 12 miles S.W. of Hamala. N. lat. 51° 57’. E. long. 9° 17’.—Alto, a county and principality of Germany, bounded on the N. by the principality of Calenberg, on the E. by Wolfenbuttel and Calenberg, on the S. by Wolfenbuttel, and on the W. by the county of Lippe; about nine miles long, and three broad. The revenues are estimated at 90,000 rix-dollars, principally arising from the springs and falt-works.

PYRMONT Water, in Physiology and Medicine, a very brisk, spirituous chalybeate, abounding in fixed air, and which, when taken up from the fountain at Pyrmont, in Germany, whence its name, sparkles like the brisket Champagne wine. It has a pleasant, vinous taint, and somewhat fulphyreous smell. It is perfectly clear, and bears carriage better than the Spa water.

The history of these waters is accurately given by Hoffman in his observations on them, both in their natural state, and in mixture with other bodies.

He first observes, that they contain a volatile and subtilt principle, much more penetrating and strong, as well as in larger quantity, than any other mineral water; but that this is not to be expected in them any where but upon the spot, for those who transport them to other places are constrained to let a part of this fly off, to preserve the rest.

If either glas or earthen vessels be filled at the spring, and immediately corked and fastened down, the consequence is, that they will burst on the first motion, or heat of the weather. They are, therefore, forced to fill them only in part at first, and let them stand awhile for this subtilt spirit to exhale; and then awhile after the filling them up, to cork and fit them for carriage.

2. If they are drank upon the spot in a morning, on an empty stomach, they affect the nose with a pungent tingling, and disturb the head for many hours afterwards.

3. If they are taken at the spring, they purge but very little; but if taken in another place, after transportation, they purge considerably more, and render the stools black. It is observable also, that if they are left in an open vessel a few days, their virtue wholly exhausts, and they no longer purge nor render the stools black.

4. If tea-leaves, bawdiyne-flowers, or galls, are put into this water, they first change it to a blue, from that to a purple, and finally to a black. This is a ready proof that black is only a deep purple, and purple only a deep blue: a little spirit of vitriol added to this liquor destroys all the colour, and renders it limpid as before.

5. If any acid be mixed with Pyrmont water, there is raised an effervescence, and bubbles of air are carried up in great quantity; and this whether the stronger acids, such as spirit of vitriol, or aqua fortis, be used; or the weaker, as vinegar, lemon juice, or Rhumif wine.

6. If an alkaline liquor be added, whether it be volatile, as the spirit of ful ammoniac, or fixed, as the oil of tartar, there is no ebullition raised, but the liquor becomes turbid and milky. If spirit of vitriol be afterwards added to this, to saturate the additional alkali, the liquor becomes limpid again.

7. Cow’s milk mixed in equal quantity with Pyrmont water does not coagulate, but, on the contrary, becomes thinner than before, and is preserved from turning four f0 soon as it otherwise would in hot weather. This is a proof that there is no predominating acid in these waters.

8. If syrup of violets be added to Pyrmont water, it turns it to a beautiful green. This is a proof of the alkaline nature of these waters; and it is further proved, by adding spirit of vitriol, or any other acid, to this green liquor, which on that becomes limpid again.

9. Four pints of this water evaporated over a gentle fire, yield no more than two scruples of a dry residiuim. Oil of vitriol being poured on this, an acid effervescence arises, and with it an acid and pungent vapour, like that produced by mixing oil of vitriol and common salt. If spirit of vitriol be used instead of the oil, the effervescence is in a less degree, and the salt is in part changed to a bitter saline mass, the remainder separated from which proves to be a calcareous earth, no longer fermenting with the spirit of vitriol.

If a quantity of Pyrmont water be exposed twenty-four hours to the open air in a bason, it will at the end be found to have lost all its virtues, tainting wholly infipid, and being turbid, instead of the fine clearness it had before, and a yellow ochreous earth is precipitated to the bottom: after this the liquor will no longer shew any of those qualities, which were before its distinguihing characters; it will no longer ferment with acids, nor turn black with galls, nor green with syrup of violets.

It appears from the whole, that the Pyrmont waters possess a pure, extremely penetrating, and efficacious mineral spirit, and that in a very large proportion; and to this their virtues are principally to be attributed. This mineral spirit, while it remains engaged in a calcareous earth, imitates the properties of an alkaline substance; and when joined with a subtilt martial earth, it emulates the properties of vitriol, giving the foals a black colour, and turning a tincture of galls into ink: and while this remains in the water in these forms of an alkaline or vitriolic principle of so great subtilty, it cannot but give them very great virtues in strengthening the tone of the visera, opening obstructions, and stimulating in a proper manner the excretory ducts, so as to make them duly perform their office; but as soon as by the standing of the water, or by any other accident, this subtilt element is evaporated, all the virtues of the water must be gone with it.

The great quantity of this powerful spirit contained in the waters, makes them more fit for the robust and strong constitutions, when depraved by illness, than for the weak and tender ones; but even the tenderest people may take them, only observing to take but a small dose, or to dilute them with an equal quantity of common water immediately before the taking them.

Hoffmann also recommends the Pyrmont water mixed with equal quantities of milk, on his own experience, in feverbrite and gouty cafes. Hoffmann, Oper. tom. v. p. 143, foq.

We have already observed, under the articles Acide and Carbonic Acid, that Pyrmont water, and other mineral waters of a similar nature, owe their acidulous taste and peculiar virtues to the fixed Air (carbonic acid) which they contain; and to these articles the reader is referred for a brief histor
of this important discovery. We shall here add some farther remarks on the effects and medical uses of this water.

Persons who drink it at the well are affected with a kind of giddiness or intoxication, which is probably owing to the great quantity of carbonic acid with which the water abounds. The common operation of this water is by urine; but it is also a gentle fudoric, and if taken in large quantity, proves laxative. However, in order to this effect, it is usual to mix some salts with the first glasses. It is drank by glassfuls in the morning, to the quantity of from one to five or six pints, according to circumstances; those who drink it walking about between each glass. This water is recommended in cafes where the constitution is relaxed; in want of appetite and digestion; weaknesses of the stomach, and heartburn; the green sickness; female obstructions and barrenness; the scurvy; and cutaneous diseases; and in the gout, especially, as Hoffmann observes, when mixed with milk; in colics; bloody fluxes; disorders of the breast and lungs; in which case it is best taken lukewarm; in nervous, hysteric, and hystereomalacic disorders; in apoplexies and palsy; in the gravel and urinary obstructions; in foulness of the blood; and in obstructions of the finer vessels. It amends the lax tenure of the blood; exhilarates the spirits without inflaming, as vinous liquors are apt to do; and is reckoned among the best restoratives in decayed and broken constitutions. It is said to provoke the general virtues of the Spa water, and at the fountain it is more spirituous, as well as a stronger chalybeate. Elliot's Medicinal Virtues, &c. of Mineral Waters, 1781, p. 181.

Near the famous well at Pyrmont is a stone quarry under ground, from some parts in which a sulphureous steam comes out, which commonly rises to a small height. Animals held in this steam are soon suffocated, but recover, if quickly taken out. When a man stands in this steam, but with his head over it, it proves an excellent fudoric. Dr. Scipproposes to perform cures in several diseases with it. See Phil. Trans. No. 448, sect. 4, and Misc. Berolin. tom. v. part 2. sect. 4. See Grotta del Serpi.

Pyrmont Water, Imitation of. This medicinal water may be imitated very nicely by art in the following manner: take a quart of the purest and lightest water, add to it thirty drops of a strong solution of iron made in spirit of salt, a drachm of oil of tartar per diluent, and thirty drops of spirit of vitriol, or a little more or less, as is found necessary, not to let the alkali of the oil of tartar prevail too strongly, though it must prevail a little. Shake all briskly together, and on tasting it will be found extremely to resemble the true Pyrmont water.

The basis of which this is founded is the analysis and trial of the true Pyrmont water, by which it is found to contain a subtle aqueous fluid, a volatile iron, and a predominant alkali, all joined together into one brilky pungent spirituous water. The artificial Pyrmont thus made, if the proportions are carefully mind'd, will extremely resemble the natural, and will have the same effect as a medicine. Shaw's Lectures, p. 96.

But the best method of forming artificial Pyrmont water is by impregnating it with fixed air, or carbonic acid, for which we are indebted to Dr. Priestley. The first paper, we believe, which actually compounded an artificial spirituous or spirituous water, like that of Belzachu or Pyrmont, was M. Venel; though he was ignorant of the real nature of the ingredient to which it owed these qualities, and which he erroneously supposed to be common air. For this purpose he diffused in a pint of water two draughts of folile alkali, to which he added an equal quantity of marine acid: in the process he made use of a vessel with a narrow neck, and to prevent the escape of the air, he disposed the ingredients in such a manner, that they could not communicate with each other till after the bottle was corked. In this case the fixed air diffused from the alkaline salt, in a phial nearly full and closely corked, being confined, suffers a degree of compression that greatly promotes its combination with the water. See Mémories présentés par les Savans Etrangers, tom. ii. containing two Memoirs of M. Venel, read before the Royal Academy of Sciences in 1750; and Lawiolier's Élens, &c. by him, p. 34, &c. However, Dr. Priestley was undoubtedly the first who to far improved upon the discoveries made by himself and others in relation to the principle then denominated fixed air, as to contrive an easy method of impregnating water with it. The first idea of this kind occurred to him in 1757, when, having placed shallow vessels of water within the region of fixed air on the surface of the fermenting vessels of a brewery, and left them all night in that situation, he found that the water had acquired a very feemeable and pleasant impregnation. He proceeded to accelerate the impregnation by pouring the water from one vessel into another, while they were both held within the sphere of the fixed air. The method of effecting this by air diffused from chalk and other calcareous substances, did not occur to him till the year 1772, when he published his directions for this purpose, together with a drawing of the necessary apparatus, which he had before communicated to the Board of Admiralty. This apparatus, represented in Plate XV. Pneumatics, fig. 1, consists of a glass vessel, a, with a narrow neck, and fo formed, that it will stand upright, with its mouth downwards: this vessel, when filled with water, and covered with a slip of paper or thin pasteboard, prefixed close to it, to prevent the admittance of common air, is inverted in another vessel, b, with a little water in it, so that the slip of paper or pasteboard may be withdrawn, and the end of the pipe, c, introduced into it. This pipe is flexible and air-tight, and bell made of leather, sewed with a shoemaker's waxed thread. It is kept open at both ends by a piece of a quill, while one of them is introduced into the vessel of water, and the other into the bladder d; the opposite end of which is tied round a perforated cork, kept open by a quill, and the cork is made to fit a phial, e, two-thirds of which should be filled with chalk just covered with water. Dr. Priestley has since found it most convenient to use a glass tube; and to prefer the advantage which he had of agitating the vessel e, he makes use of two bladders, communicating by a perforated cork, to which they are both tied. He also observes, that the flexible pipe is not necessary; but indeed of this a bent tube of glass must be ready to be inserted into the hole made in the cork, when the bladder containing the fixed air is separated from the phial in which it was generated. The extremity of this tube being put under the vessel of water, and the bladder being compressed, the air will be conveyed into it, as in the other case. Instead of the bladder, a small phial may be inserted between the phial containing the chalk, &c. and the vessel of water for thus the chalk and water that may be thrown up into the tube communicating with this phial will lodge at the bottom of the other, while nothing but the air will get into the pipe communicating with the water. The apparatus being thus prepared, let the phial containing the chalk and water be detached from the bladder, and the pipe also from the vessel of water; pour a little oil of vitriol upon the chalk and water; and having carefully press'd all the common air out of the bladder, put the cork into the bottle presently after the effervescence has begun. Also press the bladder once more after a little of the newly-generated air has got into it, in order the more effectually to clear it of all the remains of the common air; and then introduce
PYRMONT WATER.

Introduce the end of the pipe into the mouth of the vessel of water, as in the drawing, and begin to agitate the chalk and water briskly. This will presently produce a considerable quantity of fixed air, which will distend the bladder; and this being pressed, the air will force its way through the pipe, and ascend into the vessel of water, the water at the same time descending, and coming into the basin.

When about one-half of the water is forced out, let the operator lay his hand upon the uppermost part of the vessel, and shake it as briskly as he can, not to throw the water out of the basin; and in a few minutes the water will absorb the air, and taking its place, will nearly fill the vessel as at the first. Then shake the phial containing the chalk and water again, and force more air into the vessel, till, upon the whole, about an equal bulk of air has been thrown into it. Also shake the water as before, till no more of the air can be imbibed. As soon as this is perceived to be the case, the water is ready for use; and if it be not used immediately, should be put into a bottle as soon as possible, well corked, and cemented. It will keep, however, very well, if the bottle be only well corked, and kept with the mouth downwards.

It may be proper to observe on this process, that the phial, \( \text{a} \), should always be placed considerably lower than the vessel \( \text{a} \); that the water to which the chalk is put should be changed after every operation; that with a vessel of water holding three pints, and a phial containing the chalk and water of ten ounces, a little more than a teacupful of oil of vitriol will produce air enough to impregnate such a quantity of water, that the whole processes does not take up more than a quarter of an hour, and the agitation not five minutes; and that in this method the water is easily made to imbibe an equal bulk of air; whereas Dr. Browarigg found that Pyrmont water at the spring-head did not contain so much as one-half. This apparatus has received considerable improvements, which we shall briefly recite; but in justice to the merit of the original inventor, his method deserves to be recorded; and besides, it requires less time, and is much less expensive than those that are now generally used.

The apparatus contrived by Mr. Nook, and improved by Mr. Parker, is represented in fig. 2. It is made of glass, and stands on a wooden vessel, \( \text{d} \), resembling a tea-board; the middle vessel \( \text{B} \) has a neck, which is inserted into the mouth of the vessel \( \text{A} \), to which it is ground-air-tight. This lower neck of the vessel \( \text{B} \) has a glass stopper \( \text{S} \), composed of two parts, both having holes sufficient to let a good quantity of air pass through them. Between these two parts is left a small space, containing a plano-convex lens, which acts like a valve, in letting the air pass from below upwardly, and hindering its return into the vessel \( \text{A} \). The upper vessel \( \text{C} \) terminates below in a tube \( \text{r} \), which, being crooked, hinders the immediate ascent to the bubbles of fixed air into that vessel, before they reach the surface of the water in the vessel \( \text{B} \). The vessel \( \text{C} \) is also ground-air-tight to the upper neck of the middle vessel \( \text{B} \), and has a stopper \( \text{p} \), fitted to its upper mouth, which has a hole through its middle. The upper vessel \( \text{B} \) holds just half as much as the middle one \( \text{B} \); and the end, \( \text{t} \), of the crooked tube goes no lower than the middle of the vessel \( \text{B} \).

For the use of this apparatus, fill the middle vessel \( \text{B} \) with spring or any other wholesome water, and join to it the vessel \( \text{C} \). Pour water into the vessel \( \text{A} \) (by the opening \( \text{m} \), or otherwise) so as to cover the rising part of its bottom: about three-fourths of a pint will be sufficient. Fill an ounce phial with oil of vitriol, and add it to the water, shaking the vessel so as to mix them well together. As heat is generated, it will be best to add the oil by a little at a time; otherwise the vessel may be broke. Put to this, through a wide glass or paper funnel, about an ounce of powdered raw chalk, or marble. White marble being first granulated, or pounded like coarse sand, is better for the purpose than pounded chalk, because it is harder; and, therefore, the action of the diluted acid upon it is slower, and lasts a considerable time. On this account the supply of fixed air from it is more regular than with the chalk; and besides, when no more air is produced, the water may be decanted from the vessel \( \text{A} \), and the white sediment washed off, and the remaining granulated marble may be employed again, by adding to it fresh water and a new quantity of oil of vitriol. The funnel in this process is made use of in order to prevent the powder from touching the inside of the vessel's mouth; for if it happens, it will stick so strongly to the neck of the vessel \( \text{B} \), as not to admit of their being separated without breaking. Place immediately the two vessels \( \text{B} \) and \( \text{C} \) (fastened to each other) into the mouth of the vessel \( \text{A} \), as in the figure, and all the fixed air which is diffengaged from the chalk or marble by the oil of vitriol, will pass up through the valve \( \text{S} \) into this vessel \( \text{B} \). When this fixed air comes to the top of the vessel \( \text{B} \), it will dislodge from thence as much water as is equal to its bulk; which water will be forced up through the crooked tube into the upper vessel \( \text{C} \).

Care must be taken not to shake the vessel \( \text{A} \) when the powdered chalk is put in; otherwise a great and sudden effervescence will enflue, which will perhaps expel part of the contents. In such case it may be necessary to open a little the flappor \( \text{p} \), in order to give vent, otherwise the vessel \( \text{A} \) may burst. It will be proper also to throw away the contents, and wash the vessel; for the matter will stick between the necks of the vessels, and cement them together. The operation must then be begun anew. But if the chalk be thrown in without shaking the machine, or if marble be used, the effervescence will not be violent. If the chalk be put into the vessel loosely wrapped in paper, this accident will be still better guarded against. When the effervescence goes on well, the vessel \( \text{C} \) will soon be filled with water, and the vessel \( \text{B} \) half filled with air; which will easily be known to the eye, by the air going up in large bubbles through the crooked tube \( \text{r} \).

When this is observed, take off the two vessels \( \text{B} \) and \( \text{C} \) together as they are, and shake them so that the water and air within them may be much agitated. A great part of the fixed air will be absorbed into the water; as will appear by the end of the crooked tube being considerably under the surface of the water in the vessel. The shaking them for two or three minutes will be sufficient for this purpose. These vessels must not be shook while joined to the under one \( \text{A} \), otherwise too great an effervescence will be occasioned in the litter; together with the ill consequences above-mentioned. After the water and air have been sufficiently agitated, loose the upper vessel \( \text{C} \), so that the remaining water may fall down into \( \text{B} \), and the unabsoved air pass out. Put these vessels together, and replace them into the mouth of \( \text{A} \), in order that \( \text{B} \) may be again half filled with fixed air. Shake the vessels \( \text{B} \) and \( \text{C} \), and let out the unabsoved air as before. By repeating the operation three or four times, the water will be sufficiently impregnated.

Whenever the effervescence nearly ceases in the vessel \( \text{A} \), it may be renewed by giving it a gentle shake, so that the powdered chalk or marble at the bottom may be mixed with the oil of vitriol and water above it; for then a greater quantity of fixed air will be disgorged. When the effervescence can be no longer renewed by shaking the vessel \( \text{A} \), other more chalk must be put in, or more...
PYRMONT WATER.

more oil of vitriol; or more water, if neither of these produce the desired effects.

The ingenious Mr. Magellan has still farther improved the contrivance of Dr. Nootch and Mr. Parker; he has two sets of the vessels B and C. While he is shaking the air and water contained in one of these sets, the other may be receiving fixed air from the vessel A. By this means twice the quantity of water may be impregnated in the same time. He has a wooden stand K (fig. 3.) to fix the vessels B, C, &c., when taken off from A, which is very convenient. He has a small tin trough for measuring the quantity of chalk or marble requisite for one operation, and a wide glass funnel for putting it through into the vessel A, to prevent its sticking to the sides, as mentioned before.

He has also contrived a stopple without a hole, to be used occasionally, instead of the perforated one p. It has a kind of baffle at the top, to hold an additional weight when necessary. (See fig. 4.) The stopple must be of a conical figure, and very loose; but so exactly and smoothly ground as to be air-tight merely by its pressure, which may be increased by additional weights put into its baffle. Its use is to compress the fixed air on the water, and thereby increase the impregnation; for by keeping the air on the water in this compressed state, the latter may be made to sparkle like Champaign. And if the vessels are strong, there will be no danger of their bursting in the operation.

If the vessels be suffered to stand six or eight hours, the water will be sufficiently impregnated even without agitation. But by employing the means above described, it may be done in as many minutes.

The water thus impregnated may be drawn out at the opening A. But if it is not wanted immediately, it will be better to let it remain in the machine, where it has no communication with the external air. Otherwise the fixed air flies off by degrees, and the water becomes vapid and flat; as also happens to other acidulous waters. But it may be kept a long time in bottles well stopped, especially if they are placed with their mouths downwards.

Mr. Blades of Ludgate-Hill has still farther improved this apparatus, by changing the stopple at k for a glass cock, which is more convenient. He has likewise altered the middle vessel B into a form more advantageous for the impregnation. See fig. 5.

For Dr. Hulme’s method of impregnating water with fixed air, we refer to his “Safe and easy Remedy for the Stone;” &c. 1778: observing, that he merely mixes the solution of fixed alkaline salt and water, containing as much vitriolic acid as he finds necessary, a priori, for neutralizing the alkali, and expelling from it all its fixed air.

Dr. Withering, of Birmingham, has lately contrived a new apparatus for impregnating water with fixed air, which, he says, is preferable to that in common use, because it can be made at less expense, and is more easily prepared; because the whole quantity of fixed air produced is converted to use, without any waste of the vitriolic acid; because it impregnates three times the quantity of water at one time, more completely and with less trouble; and the impregnated water will always retain its virtue, if the joints and cocks of the machine are made perfectly air-tight; for which purpose they should once a year be supplied with a full quantity of unaltered lard. This apparatus is exhibited in fig. 6, and consists of a glass vessel A, about ten inches high in the cylindrical part, and six inches and a half in diameter; another glass vessel B, about twelve inches high in the conical part, one inch and a half in the neck, and five inches in diameter at the bottom; a copper pipe C passing through the stopple of the vessel B, and tied fast in the flexible tube D, made of strong leather, air-tight, and kept hollow by means of a spiral wire passing through its whole length; a conical brass pipe E, with a stopple fastened to the tube D; another conical pipe F, with a stopple G, into which the end of the tube E is accurately ground, so as to be air-tight, and cutting off all communication with the atmosphere when the pipe E is removed; two large hog’s bladders H, H, each of which ought to hold two quarts; a stopple I, to prevent the water entering into the bladders, when the vessel A is agitated; a bladder K, tied to the crooked tube with the stopple L, which occasionally opens or shuts the communication with the vessel B; a glass funnel M, accurately fitted with the glass stopper N; an aperture O, fitted with a glass stopper or a silver cock, from which the impregnated water is to be drawn for use; and, lastly, the tube P opening into the vessel A. When this apparatus is used, let the vessel A be filled with pure water, and any other ingredients that are required, in a proper proportion; into the vessel B put as much marble or whiting, in small lumps, as will cover its bottom to the height of about two inches, and pour in water to the height represented by the dotted line; let the mouth of the vessel A be well fitted with a cork, and through a hole in the cork pass the tube P, putting upon the cork melted sealing-wax of the softest kind, or modelling-wax, so as to make the whole air-tight. The modelling-wax may be procured at the engravers, or it may be prepared by adding to half a pound of melted bees-wax, two ounces of tallow, and one ounce of Venice turpentine; to this mix add a sufficient quantity of red lead, or Spanish brown, to give it a colour, and let the mixture be fired till it is cold; let the mouth of the vessel B be stopped with a piece of mahogany, turned into a conical figure in a lathe, and of a size somewhat larger than the mouth of the glasses will admit; put this piece of wood into melted bees-wax, and heat the wax till the wood begins to grow black; when cool, turn it again till it fits the mouth of the vessel; the tubes C, L, and M, are fitted into holes bored through the wooden stopper, previous to its being immered in the wax; push these tubes through the holes, and press the stopper into the orifice of the vessel B, and cement the whole with sealing- or modelling-wax; shut the stopcocks I and L, having previously pressed the air out of the bladder K; open the stop-cocks G and E; then squeeze the air out of the bladders H, H, and afterwards press the conical pipe E into the pipe F; pour about a large spoonful of oil of vitriolic through the funnel M, and stop it with its stopper N. The fixable air let loose by the effervescence in the vessel B, rising through the tube C, paffes into the bladders H, H, and diffuses it. In this case open the stop-cock I, and from the aperture O draw out about a quart of water; and the space before occupied by the water will be filled with fixable air, which soon begins to be absorbed by the remaining water, and is still supplied from the bladders H, H, and from the effervescence mixture in the vessel B. When the bladders are considerably collapsed, more vitriolic acid must be added through the funnel M, so that they may be always kept pretty fully diffused. When an impregnation is speedily required, turn the stop-cocks at G and E, and open that at L; then separate the pipe E from the tube F, and agitate the vessel A; the fixable air will pass into the bladder K, and may be pressed into the two other bladders, when the parts of the apparatus are united. During the agitation, the stop-cock at I should be closed, and open only occasionally to supply out of the bladders H, H, the fixable air absorbed by the water. If a strong impregnation be required, this process should be carried on in a room, the heat of which does not exceed forty-eight degrees of Fahrenheit’s thermometer. Dr. Withering observes,
observes, that the impregnated water receives no taint from the bladders: and that if the vessel A with its impregnated water be separated from the vessel B, at the conical parting E F, it may be inclosed in a pyramidal mahogany case, out of the lower part of which the silver cock at O projects; and thus serve for an ornamental as well as a luxurious and fabulous addition to the side-board, particularly in the summer and autumnal feasts.

Mr. Henry has described a method of impregnating water in large quantities with fixed air, so as to give it the properties of mineral water, for the use of the sick on board of ships, and in hospitals. He has given the following account of his apparatus and proceeds for this purpose. Cut off the two extremities of a calf’s or pig’s bladder (Figs. 7.) and having previously moistened them, into one end insert the top of the tubular stopper e, round the neck of which it is to be closely fastened with strong thread. Into the upper end introduce the part g of the long bent tube h, and tie them round in the same manner. The pipe k must be passed through a hole formed by a hot iron hourer, in a large barrel adapted to the orifice i in the cask B B, holding about ten or twelve gallons, to which it must be cemented: and the length of the pipe from this point must be such as to reach within a few inches of the bottom of the cask B B, which is to be completely filled with fresh water, or such as has been recovered from lime. See Putrefaction of Water.

To a quantity of mild calcareous earth and water, placed in the air-vessel C, add a small portion of strong vitriolic acid, and by the time most of the common air may be supposed to be expelled by the fixed air arising from the mild calcareous earth, add a larger quantity of acid, and putting the tubulated stopper e in its place, the bladder f will become inflated. Puts it gently till its sides collapse: and then introducing the pipe k h, with its cork, into the orifice f of the cask B B, again press the air forward, as it diffuses the bladder into the water cask, where, bubbling up through the water, it will rise to the surface, and by its prelure, force the water to ascend into the funnel l, which is to be cemented into the head of the cask at l. In proportion as the water in the cask becomes impregnated with fixed air, that in the funnel will return into its place; but if, at any time, the latter should rise so high as to be in danger of overflowing, a quantity of air may be let out of the water cask, by means of the small plug m. And this is necessary to be done, occasionally, to discharge the residuum of the fixed air, which is not soluble in water.

If the operation be required to be performed more expeditiously, it may be quickened by agitating the water cask. To do this, the tubular stopper e must be withdrawn from the air-vessel, and supported, together with the bladder, by an attendant, while the cask B B is shaken. During this time another tubular stopper must be put into the air-vessel, and it may be immersed into a quantity of lime-water to prevent waste. When the agitation has been continued for some minutes, in proportion to the falling of the water in the funnel, replace the stopper attached to the bladder f in the air-vessel when taken out of the lime-water, and proceed as before, repeating the agitation occasionally.

During the process, additional quantities of vitriolic acid may be introduced into the air-vessel through the opening at d, which is to be, at all other times, carefully secured with its stopper.

By this process, fixed air may be imparted to wine, beer, and almost any liquor whatever. And when beer is become flat or dead, it will be revived by this means; but the delicate agreeable flavour, or acidulous taint communicated by the fixed air, and which is manifest in water, will hardly be perceived in wine, or other liquors, which have much taint of their own.

The artificial mineral waters thus made, are more pleasant to the taste than the natural Pyrmont or Seltzer waters; which, besides their fixed air, contain saline particles of a disagreeable taint, which are known to contribute little or nothing to their medicinal virtues, and may be found in some cafes, hurtful. They are likewise confusably stronger. According to Sir John Pringle, these waters may be made more nearly to resemble genuine Pyrmont water, by adding to each pint of them from eight to ten drops of tinctura martis cum spiritu fals. Or this may be done, by adding to the water in the middle vessel B (fig. 2.) in the proportion of about thirty grains of Epsom salt, ten grains of common salt, a scruple of magnesia alba, and a drachm of iron filings, or iron wire, clean and free from rust, to one gallon of spring water, and impregnating the whole with fixed air in the manner already described. Let them remain till the other ingredients, and as much of the iron as is necessary, are dissolved, which will be in two or three days; or the magnesia may be omitted, and then the operation will be finished in less than half that time. These waters may be rendered ferruginous or chalybeate very easily, by putting in the middle vessel two or more smaller phials, filled with cuttings of fine iron-binding wire, or with small iron nails; because the impregnated water will dissolve the iron so fast, as to become well saturated with it in a few hours, according to the experiments of Mr. Lane. But the method of rendering these artificial waters chalybeate, used by Dr. Hulme, is to add one grain of salt of steel to each pint (sixteen ounces) of water already impregnated with fixed air.

The discovery of an easy method of impregnating water with fixed air is of great importance; as it is now well known that such water is a very powerful antiseptic, and that it both refines and corrects putrefaction. It is, therefore, given with great success in putrid fevers, in the febricary, in dysenteries, in mortifications, and in other disorders arising from a putrid cause, or attended with putrefaction, a draught of it being taken now and then, or even by way of common drink. But the ingenious Mr. Bewley has invented a still better method of exhibiting fixed air as a medicine. He directs a scruple of alkaline salt to be dissolved in a sufficient quantity (a quarter of a pint, or less) of water, which is to be impregnated with as much fixed air as it can imbibe; this is to be drank for one dose. Mr. Bewley directs it to be prepared in larger quantities at a time, and calls it his mephitic julep. If immediately after it a spoonful of lemon juice, mixed with two or three spoonsful of water, and sweetened with sugar, be drank, the fixed air will be extracted in the stomach; and thus a much greater quantity of it may be given than the same quantity of water alone can be made to imbibe. Fixed air acts as a corrodant; and, therefore, may be given with success in weaknesses of the stomach, and in vomitings arising from that cause. It has also been given with success in fevers in the lungs, and in nephritic complaints. When the lungs are purulent, fixed air, mixed with the air drawn into the lungs, has repeatedly been found to perform a cure. The bark also may be given with advantage in water impregnated with fixed air, as they both coincide in the same intention. Fixed air may be applied by means of a syringe, funnel, or otherwise, to inflamed breasts, putrid ulcers, mortified parts, ulcerated throat, and has been found in such and similar cases to have very remarkable efficacy. It may also be given internally at the same time. In putrid dysenteries, and in putrid ulcers, fixed air may be given by way of clyster.

Ferment-
Fermenting cataplans are of service chiefly as they supply fixed air to the part. In cases of putridity, fixed air has been successfully applied to the surface of the body, exposed to streams of it. It is also found an excellent cooling as well as strengthening beverage in hot relaxing weather, and has the advantage of being pleasant to the taste. See on the subject of this article PrieiJley's Exp. and Obs. on Air, vol. ii. p. 263, &c. 298, &c. Phil. Trans. vol. 17v. part i. p. 59, &c. PYROBOLOGY, or the art of missile fires, is derived from the Greek πυρ, fire, and τόξον, to throw. See Pyrotechny.

PYROBOLUS, in Natural History, a name given by many authors to the flower more generally called pyrites; others have called it siderites, pyroxanthes, pyropolus, and othomana, and the Greeks mylais.

PYROCHROA, in Entomology. See Lampyris.

PYROCTOGONIUM, in Natural History, the name given by Dr. Hill to a genus of fossils usually comprehended by authors, with many other bodies of a different figure and structure, under the general name pyrites.

The character of the pyroctogonium are these: it is a compound, inflammable, metallic body, of a regular octahedral figure, or composed of eight planes.

There is only one known species of this genus, which is a very singular and elegant foil, being composed of eight triangular planes; these being the sides of two quadrilateral pyramids, with broad bases, which being joined base to base, constitute the pyroctogonium.

It is found very frequently in Cornwall, Devonshire, and moft other of our counties where there are mines. It is sometimes met with loose in the earth, sometimes lodged in the bodies of maratists, or in the fold fossils, and varies sometimes from its iron colour to a dusky yellow. It is sometimes also found with many speeimens connected into a mass; these are seldom uniform in size, and coherent in various directions, often greatly injuring one another's figure. Sometimes also, as in the case of the cryftals, they form a large mass, of which the outer surface only is concreted into or covered with regular figures, the whole inner part being a confued fulbstance.

Metals of this kind are not unfrequently found of a regular orbicular figure, and befet all over with regularly figured pyroctogonia of various sizes. Hill.

PYROMALITITE, in Mineralogy, a mineral discovered some years ago in the mine of Bjelke, in Vemeland, a province of Sweden, situated on the N. side of the lake Venner, which was observed to have the property of giving out the odour of muriatic acid when heated, and hence distinguished by the name of pyromalite. J. G. Gahn of Fahlin has given the following description of it. Its colour is commonly yellow-brown, paling into greenish: internally, it is light greenish-yellow. It occurs crystallized in regular fix-sided prisms, without any terminating pyramids. It is composed of plates lying on each other in a direction perpendicular to the axis of the prism; principal fracture, repidant; cross fracture, uneven and without lustre; opaque; semi-hard; scratched with fleec: the cryftals are often several inches long; specific gravity 3.081. Before the blowpipe it becomes dark reddish-brown, and emits the odour of muriatic acid. It then melts into a black flag, and at last a small bead is obtained, more or less attracted by the magnet. It dissolves readily, and in considerable quantity in glass of borax, and gives a colour indicating the presence of muriatic and iron:—in phosphate of ammonia and soda it dissolves with great difficulty. Its constituents are silica, lime, iron, muriate, and muriatic acid. In the mine of Bjelke it occurs mixed with iron ore, calcareous spar, and black crytallized malaolite. Pyromalite was lately analysed by Mr. Hifinger, who found its constituents to be as follows:

The escape of the acid by heat seems to indicate the presence of a portion of water amounting to about two-thirds of the lobs stated as contained in the analysis. Annals of Philosophy, No. 12.

PYROGENUS, formed of πυρ, fire, and γενειο, name, is a term sometimes used for rectified spirit of wine; thus called because made by fire, or rather because rendered of a fiery nature.

PYROET, PYROEUT, or rather Pirouette, in the Manager. See Pirouette.

Gen. Ch. Cal. Periand inferior, small, in five deep segments, permanent. Cor. Petals five, roundish, concave, spreading. Stam. Filaments ten, awl-shaped, shorter than the corolla; anthers drooping, large, with two horns at the base, each discharging the pollen by a terminal orifice. Pf. Germin superior, roundish, angular; stylo cylindrical, permanent, various in length and direction, sometimes scarcely any; stigma thickish, variously shaped. Peric. Capsule roundish, deprived, five-sided, of five cells, burling at the angles. Seeds numerous, chilly.

Eff. Ch. Calyx five in deep segments. Petals five. Capule superior, five cells, burling at the angles, and many seeds. Anthers with two pores.

Obf. In some species the ilaments and stylo are erect; in others inclined to one side or the other; in some the former spread every way. The form of the stigma is different in different species. In two American ones the stigma is nearly, or quite, fesse. On which mark Mr. Pursh's genus Chimaphila is founded, its name being nearly synonymous with Winter-green, the English appellation of Pyrola.

Section 1. Style elongated. Pyrola of Pursh.

part in mountainous situations, in the more northern parts of Europe, also in North America, flowering in July. We have gathered it on the plain of mount Cenis, and in moir parts of the sandy downs of Holland; opposite to which, on the Norfolk coast, this plant has likewise been found by the accurate Mr. Lily Wigg, growing among bushes, on Bradwell common, not far from Yarmouth: where we likewise have seen it. There is more difficulty in ascertaining an indubitable fixation of this species in the northern or mountainous parts of Britain, because the media having been so much confounded with it, nor have we any specimens from those countries. The roots are perennial, long, creeping, thread-shaped, scaly. Stems very short and simple, leafy, solitary at the end of each shoot of the root. Leaves four or five; on bordered smooth footstalks of various lengths (from one to two inches); roundish or elliptical, obtuse, an inch or inch and a half long, very obscurely crenate, smooth, shining, reticulated with numerous veins; paler beneath. Flower-stalk terminal, solitary, about a span long, angular, slightly twilled, smooth, bearing a few scattered lanceolate membranaceous bracteas, and terminating in a long, rather loose, cluster of four or eight or ten large, handome, white, drooping, but not quite pendulous, fragrant flowers, each having a similar bractea to the reed, at the base of the partial stalk, and fully equal to it in length. Segments of the calyx lanceolate, acute, full half the length of the petals, which, though usually rounded and blunt, have sometimes a pointed appearance. Stamens about the length of the calyx; all turned upward, and crowded together; their anthers deflexed, yellow, with orange horns. Germ short, five-lobed. Style twice as long as the stamens, slender and quite pendulous in its lower part, gradually swelling towards the extremity, which is recurved. Stigma dilated, annular, with five small central points. Capsule the size of a pea, deflexed, five-lobed, crowned with the permanent style and stigma.

2. P. chlorantha. Greenish-flowered Winter-green.—Swartz in Stockh. Trans. for 1816. 190. t. 5. (P. folio obtuso, flor ore viriduscuio; Rivin. Pentap. Irr. t. 136. f. 1.)—Stamens slightly ascending. Style twice as long, club-shaped, deflexed and recurved. Cluster many-flowered. Calyx shorter than the stamens. Native of Sweden, and probably, by the synonym of Rivinus, of Germany, flowering about the middle of July. Professor Swartz distinguishes it from the foregoing, by the smaller, often abrupt, leaves; floral almost indissoluto of bracteas below; petals of a whitish, or yellowish, green hue; and stamens less curved upwards. We gather also, from his figure and description, that the bracteas which accompany each flower are much shorter than the partial stalks, and that the calyx also is shorter, and more close-preted, than in P. rotundifolia.

In the posture and form of the style we find no difference. The common flower-stalk is remarkably spiral. Perhaps the P. folio rotundo of Rivinus, t. 137, may represent this species in fruit; as the posture of the permanent style agrees better with it than with the following.

3. P. media. Intermediate Winter-green. Swartz in Stockh. Trans. for 1814 (not 1794); 257. t. 71. f. 1. Engl. Bot. t. 1945. Winch Guide, v. 2. l. 13. (P. rotundifolia; Linn. t. 110.)—Stamens regularly infixed. Style twice as long, deflexed perpendicularly. Cluster of many pendulous flowers. Calyx shorter than the stamens. Native of bushy shady places in Sweden, and various parts of the north of England, flowering towards the end of June. We suspect also that this is the Oxeldrihice species, commonly mistaken for minor, and that it has often in Scotland, from whence we have specimens, been taken for rotundifolia. The leaves most agree with the last-named, but the flowers differ essentially in being smaller, more pendulous, and of a less pure white. The stamens are nearly twice the length of the calyx, all regularly and equally infixed, not at all turned upward. Style bent in a curve downward, its extremity furrowed, slightly thickened, vertical, not recurved. The floral is spiral, as in the leaf, with about two distinct bracteas in its lower part, the bracteas which accompany each blower being nearly as long as the partial stalks. Even Linneas may perhaps have confounded this with its true minor.

4. P. minor. Lesser Winter-green. Linn. Sp. Pl. 567. Wilds. n. 2. Ait. n. 2. Engl. Bot. t. 158. Fl. Dan. t. 55. Rivin. Pentap. Irr. t. 136. f. 1. (P. rofes; Engl. Bot. t. 2543.)—Stamens regularly infixed. Style the same length, straight, stigma lobed, pointed. Cluster of many drooping flowers. Stalk straight. Native of woods and thickets on the mountains of Europe; occurring in several parts of Scotland and the county of Durham, and flowering in July. This is smaller in general than any of the foregoing; the leaves more elliptical; floral straight, not spiral, with three principal angles and a smaller one, bearing a few broad bracteas near the base, but feebly any other, except the small awl-shaped ones at each partial stalk. The flowers are very numerous, but small, drooping or even pendulous, white with more or less of a pink tinge. Stamens regularly incurved. Pores of the anthers dilated, not tubular. Style of a much shorter proportion than any of those we have hitherto mentioned; the floral large, five-lobed, deflexed, and dequated of points, in the centre. We can no longer doubt that t. 158 and t. 2543 of English Botany represent one and the same species, which we poetics also from mount Cenis, Savoy, and Switzerland, as well as in the Linnean herbarium. P. media, having been confounded by botanists in general with this, has caused all our perplexity expressed in Engl. Bot. 2543. The plant which Mr. Lightfoot introduced at Bullrude, we judge from memory to have been media; see Engl. Bot. 158.

5. P. afarifolia. Afarabacca-leafed Winter-green. Michteas Boreal-Amer. v. 2. 251. Pursh n. 2. “Leaves kidney-shaped. Stalk with a few feathering, convoluted, distant scales. Flowers turned every way. Style declining.” Michteas.—Found by Michaux in Canada; by Pursh in beech woods on the mountains of Pennsylvania, flowering in July. The flowers are yellowish-green. If it were not for the “feathering scales,” we should suspect this might be the same as our chlorantha, n. 2, whose leaves are often, it seems, short and abrupt; but we have no specimens unanswerable to either.

6. P. dentata. Toothed Winter-green. Leaves elliptic-obovate, obtuse, toothed. Stalk straight, obscurely angular, nearly naked. Stamens ascending. Style deflexed, strongly recurved. Stigma with a cylindrical point. Gathered by Mr. Menzies, on the west coast of North America. This species is readily distinguished from all others, hitherto discovered, by its leaves, which are obovate, or somewhat elliptical, one and a half or two inches long, half or three quarters of an inch broad; their margins beget with very remarkable dilisciency, small, blunt teeth, usually near a quarter of an inch; their surface not reticulated, but furnished with one series of connected arching veins, on each side the midrib. Floral-stalks triangular, about as long as the leaves. Floral-stalks fix inches long, nearly naked, round, very slightly angular, bearing a long loose cluster of flowers, much resembling those of the first species in size and structure, as well as in the position of their stamens; but their floral is still more remarkably recurved, so as to form a semi-circle; and the point of the floral much more prominent, of a cylindrical shape, five-cleft at the summit.

7. P. ophylla. Leaffets Winter-green. Stem and floral feely,
fealy, without leaves. Anthers beaked. Style deflexed and recurved. Stigma with a cylindrical point.—Gathered on the west coast of North America, by Mr. Menzies, who affirms the plant is always quite deficite of leaves, instead of which the angular stem bears numerous lanceolate, membranous, pointed scales, about half an inch in length, a few similar but more remote ones being scattered along the flake, which is angular. The flowers are nearly as large as the leaf, but our dried specimen will not allow us to determine the purpore of the flowers. The anthers are long and narrow, with a small acute point at the contrary end to the pores. Style deflexed, its end somewhat recurved. Stigma with a long cylindrical point, like the leaf.

8. P. pita. Variegated Winter-green.—Leaves ovate, somewhat ferrature. Flowers dropping all one way. Pores of the anthers contracted, tubular. Style curved. Stigma abrupt, with five small points.—This also was found by Mr. Menzies on the west coast of North America. In some points it agrees with the two last, as well as with the rotundifolia and its allies; in others it resembles the following, but is a totally different species. The leaves are near an inch and half long, and almost as thick with bluish, more or less dilated, ferrature, rather flabby, marked with large branching veins, and variegated with white or yellowish blotches. Flowers nearly as long as the leaves. Flower-stalk six inches long, obliquely ascending, quadrangular, twisted, bearing two or three short, ovate, pointed scales. Flowers numerous, as big as those of the rotundifolia, all, as far as we can judge from the dried specimen, dropping toward one side. Calyx short, broad, and spreading. Stamen all, as far as can be discerned, alike dispersed round the germin; their anthers short, ovate, minutely pointed, the pores prominent in the form of two short narrow tubes, contracted at the orifice. Style curved, but we cannot tell in what direction. Stigma scarcely at all thicker than the style, abrupt, with an acute edge, and apparently five minute sharp central points.

9. P. secunda. Serrated Winter-green. Linn. Sp. Pl. 567. Willd. n. 3. Ait. n. 3. Pursh n. 4. Fl. Dan. t. 402. Engl. Bot. t. 517. (P. secunda tenerior; Chuf. Hift. v. 2. 117. Ger. Em. 408. P. folio macronato; Rivin. Pentap. Irr. t. 138. f. 2.)—Leaves ovate, acute, ferrature. Flowers drooping all one way. Pores of the anthers dilated. Style straight. Stigma dilated, five-lobed.—Native of morly alpine woods in various parts of Europe, from Lapland to Greece, as well as of sandy barren woods in North America, from Canada to New Jersey, flowering in July. It occurs in fir or birch woods, in several parts of the highlands of Scotland; as also near Moffat in the lowlands; and according to Ray in Yorkshire. The stem is long and trailing. Leaves scattered or covered, an inch or more in length, with numerous fine shallow ferratures, and abundance of reticulated veins. Flowers from three to six inches long, erect, straight; round below; angular above; with two or three green ovate scales. Clusters of many crowded greenish-white flowers, not half the size of the foregoing, nor so much expanded. Stamen regularly placed round the germin, at first curving, then straight. Anthers whitish, short, pointed; their pores somewhat oblique, but not tubular, soon becoming dilated and jagged. Style straight, twice the length of the flower. Stigma much dilated, annular, but thin-edged, terminating in a large five-lobed umbilicated summit.

10. P. uniflora. Single-flowered Winter-green. Linn. Sp. Pl. 568. Willd. n. 6. Ait. n. 6. Pursh n. 5. Fl. Dan. t. 8. Engl. Bot. t. 146. (P. quarta minim; Chuf. Hift. v. 2. 118. Ger. Em. 408. P. flore singulari; Rivin. Pentap. Irr. t. 139. f. 1.)—Stalk bearing a solitary flower. Pores of the anthers contracted, tubular. Stigma with five rays.—Native of alpine forests, among sandy rills, in various parts of Europe and North America. It was first discovered, in the British dominions, by Mr. James Hoggan, who gathered wild specimens, now before us, in the western islands of Harris and Bernera, in 1783. Mr. James Hoy, and Mr. Brodie of Brodie, have also gathered this most elegant and curious plant in fir woods of the county of Moray. It is, like the red, perennial and evergreen, flowering in July. The leaves vary greatly in size and acuteness, but are generally roundish, about an inch long, more or less strongly ferrature, and reticulated with many veins. Foot-stalk half as long. Flower-stalk solitary, simple, erect, three inches high, with one concave bract, and a large, terminal, white, or slightly reddish, flower, an inch in diameter, and smelling like lily of the valley. Stamen spreading equally, half the length of the corolla, three of them lying on one of the petals, one only on another, and two on each of the three remaining. Anthers short, ovate, pointed; their pores tubular, considerably elongated. Style erect, straight, equal to the length of the germin. Stigma large, of five thick, spreading, acute, red, lobes. The wild specimen delineated in English Botany, having travelled so far a distance, was in too imperfect a condition to allow of that figure being so good as usual.

Section 2. Stigma nearly fimbria. Chimaphila of Pursh.

11. P. umbrata. Umbellated Winter-green. Linn. Sp. Pl. 567. Willd. n. 4. Ait. n. 4. Curt. Mag. t. 778. (P. terris fruticosa; Chuf. Hift. v. 2. 117. Ger. Em. 408. P. folio arbuti; Rivin. Pentap. Irr. t. 139. f. 2.)—Chimaphila Corymbosa; Pursh n. 2.)—Leaves ovate-obovate, ferrature. Flowers somewhat umbellate. Stigma nearly fimbria. Stamens smooth.—Native of woods in the northern parts of Europe, Asia and America, but not found wild in Britain. Mr. Menzies gathered it on the west coast of North America, and Mr. Pursh found it frequent in dry woods, from Canada to Virginia. Linneas, Gmelin, Pollich, Roth, &c. give it in their Floras. Dr. Sims, who received this species in flower in June, from Mr. Lodgises, justly afferts it to be the most beautiful of all the genus. The stem is woody, a span high, somewhat branched, angular, and roughish. Leaves crowded together into something like whorls, falked, narrow-obovate, blunted, strongly ferrature; dark green and veiny above; paler beneath; about an inch and a half long. Foot-stalk terminal, solitary, three inches long, reddish, bearing about five, imperfectly umbellate, simple, partial stalks, each an inch long, spreading, rough with glandular pubescence, and sometimes furnished with a little lanceolate bract. Flowers smaller than that of P. uniflora, but larger than any other of the foregoing, drooping. Petiole obicular, concave, cream-coloured, crinum at the base. Stamen short, red, all regularly inflexed. Anthers short, purple, with white tubular pores, dilated and lobed at the orifice. Germin globose, green. Style thick and very short, but certainly preent. Stigma obicular, convex, with five flight notches. The American species are usually less umbellate, and more racemose, than the European.

12. P. maculate. Holly-leaved Winter-green. Linn. Sp. Pl. 567. Willd. n. 5. Ait. n. 5. Curt. Mag. t. 897. (P. mariana, arbuti folium angustifolius, &c.; Plak. Mant. 157. Phyt. t. 349. f. 4.)—Chimaphila maculate; Pursh n. 1.)—Leaves ovato-lanceolate, with tooth-like ferratures. Stalks two or three-flowered. Stigma nearly fimbria. Stamens woolly.—This is exclusively an American species. Mr. Pursh observed it in shady gravelly or sandy woods, from Canada to Carolina, and Mr. Menzies brought speci-
ments from the north-west coast. It is now and then met
with in our more curious gardens, requiring bog earth, with
shade and moisture, and flowering in June and July. Its
shrubby habit is like the last, but of more humble growth.

Leaves more pointed, with sharper tooth-like serratures;
their upper surface marked, along the rib and veins, with a
pale stripe. Partial flowers, usually two, rarely three,
drooping. Flowers the size of the leaf, but white. Stamens
densely fringed in their lower part. Anthers with tubular
jagged-mouthed pores. Style very short and thick. Stigma
hemispherical, nearly entire, green. Mr. Pursh says this
plant is in high esteem among the natives of North America
for its medicinal qualities, and is called Sip-blenn. He
witnessed a successful cure of severe hysterics by a decoction
of this Pyrola. — We can by no means allude to the
establishment of that able writer's genus Chimaphila, hinted
at by Michaux; there being surely no diversity of habit to
support it; nor any character, but a difference of length
in the style; which the other species of Pyrola shew to
afford admirable specific, but no generic, distinctions.

PYROLAMPIS, in Zoology. See Glow-worm, and
Lampyris.

PYROLINEOUS Acid, or Empyreumatic acid of
wood, in Chemistry, a species of empyreumatic Acetous
Acid (which see), procured by distilling in a glas or
earthen retort a quantity of shavings of any kind of wood,
such as box, guaumatic wood, or beechn; in which an
extremely strong-smelling dark-coloured empyreumatic acid
liquid is obtained, nearly one-third of the weight of the
wood. This acid is furer, and also much blacker and more
empyreumatic, than either the pyrometus or pyroantacmeous
acid, probably as requiring a stronger heat for its production.

The acid of wood is obtained in a large quantity near London,
from the preparation of charcoal for gunpowder, by distilling
wood in cast-iron cylinders. It stains the hands deeply, and
wood indelibly. This acid is procured in such a quantity as to
be an object of manufacture. At the belt it is only an in-
erior acetous acid, and the difficulty of purifying it will
prevent the profitable use of it in many of the arts to which
vinegar is applied. However, as the process for procuring
radical vinegar at the same time purifies this empyreumatic
acid, it may perhaps be used for this purpose. It may be
added, that much of the acid from the distilled charcoal for
gunpowder, near London, is employed by calico-printers
in forming the acetated iron, used as a mordant, as in this
case the colour and smell of the acid are not at all detri-
mental. Some time ago Vauquelin announced, as a new
discovery, that pyrolineous acid is identical the name as
the acetous; but this was known to Glauber near two years
ago. In the folio edition of his works, p. 188, may be
seen directions for its distillation, with a copper-plate of the
apparatus which he employed. He there calls it the vine-

PYROMACHUS, a name given by some to antimony,
when reduced to a flaky hardness; and by others to copper,
when fused with sulphur, and thus rendered less ductile.

PYROMANCY, or Pyromancy, a kind of divination,
performed by means of fire.

The ancients imagined they could foretell futurity by in-
specting fire and flame: to this end they considered its di-
rection, or which way it turned. Sometimes they added
other matter to the fire, e. g. a vessel full of urine, with its
neck bound about with wood, watching narrowly on which
side it would burst, and thence taking their augury.

Sometimes they threw pitch on it, and if it took fire im-
mediately, they esteemed it a good augury.

PYROMETER, formed of γε, fire, and μετρ, I mea-
sure, in Physics, the name of a machine contrived to mea-
sure the alteration of the dimensions of metals, and other
fold bodies, arising from heat.

These instruments have been constructed of various forms;
but as their object is to render the small expansions of
foilds apparent to the observer, they have confined of a ma-
hine adapted to this purpose, and of an apparatus fit for
heating the bodies under examination to a determined degree.

The most usual, and, indeed, the most eligible mode of
heating the bodies, is to place them in water, in which a
therometer is placed, and to heat the water by means of
lamps. The small expansions of the heated solids have been
rendered visible, first, by multiplying-wheels, or by levers,
or by fine screws, which render a small motion communicated
to one end of the mechanism productive of a great move-
ment at the other end; and, secondly, by magnifying the
small expansion through microscopes; which seems, upon
the whole, to be the method that is both most certain and
most manageable; for with wheels and pinions, and even
with levers or screws, there is always some equivocal mo-
tion, arising from the loose connection of teeth and pinions,
or from the leers and bending of other parts.

Mufchenbroek, who was the original inventor of this
machine, has given a table of the expansion of the different
metals, in the same degree of heat. Having prepared cy-
lindric rods of iron, steel, copper, brass, tin, and lead, he
exposed them first to a pyrometer with one flame in the
middle; then with two flames; and successively to one with
three, four, and five flames. But previous to this trial, he
took care to cool them equally, by exposing them some time
upon the flame alone, when it began to freeze, and Fahrenheit's
therometer was at thirty-two degrees. The effects
of which experiment are digested in the following table,
where the degrees of expansion are marked in parts equal
to the $\frac{3}{4}$-width part of an inch.

It
PYROMETER.

It is to be observed of tin, that it will easily melt when heated by two flames placed together. Lead commonly melts with three flames placed together, especially if they burn long.

From these experiments it appears, at first view, that iron is the least rarefied of any of these metals, whether it be heated by one or more flames; and therefore is most proper for making machines, or instruments, which we would have free from any alterations by heat or cold, as the rods of pendulums for clocks, &c. So likewise the measures of yards or feet should be made of iron, that their length may be as nearly as possible the same, summer and winter.

The expansion of lead and tin, by only one flame, is nearly the same; that is, almost double of the expansion of iron. It is likewise observable, that the flames, placed together, cause a greater rarefaction than when they have a sensible interval between them; iron, in the former case, being expanded 117 degrees, and only 109 in the latter; the reason of which difference is obvious. By comparing the expansion of the same metal, produced by one, two, three, or more flames, it appears, that two flames do not cause double the expansion of one; nor three flames three times that expansion, but always less; and these expansions differ so much the more from the ratio of the number of flames, as there are more flames acting at the same time.

It is also observable, that metals are not expanded equally at the time of their melting, but some more, some less. Thus, tin began to run, when rarefied 219 degrees; whereas brass was expanded 377 degrees, and yet was far from melting.

As to the construction of M. Muschenbroeck’s pyrometer, together with Defaglier’s alterations and improvements, the curious may consult Defagiler, Experim. Philos. vol. i. p. 421, &c. See also Muschenbroeck’s translation of the experiments of the Academy del Cimento, printed at Leyden in 1731. And for a pyrometer of a new construction, by which the dilatations of metals in boiling fluids may be examined and compared with Fahrenheit’s thermometer, see Muschenbrock, Intr. ad Philosop. Nat. 4to. 1762, vol. ii. p. 610.

But it has been observed, that M. Muschenbroeck’s pyrometer was liable to some objections; and a contrivance was made, with a view of removing thes, by Mr. Ellicott, who has given a description of his improved pyrometer in the Philosophical Transactions, vol. 443. This may also be seen in Dr. Martin’s Abridgment, vol. viii. p. 464.

This instrument is formed with a flat piece of brass A A, (Plate XXIII. Misellany, fig. 4.) which is fixed down to a thick piece of mahogany. Upon this plate are screwed three pieces of brass, two of which, B B, serve to support the flat iron bar G, called the standard bar. The upper part of the third piece of brass is a circle D, about three inches in diameter, divided into three hundred and sixty equal parts; or degrees: within this circle is a moveable plate d, divided likewise into three hundred and sixty parts, and a small slide index. The bar of metal E, upon which the experiment is to be made, is laid on the standard bar. F is a lever two inches and a half long, fastened to an axis, which turns in two pieces of brass, screwed to one of the supports B. To the end of this lever is fastened a chain, or flk-line, which, after being wound round a small cylinder, to which the index in the brass circle, D, is fastened, passes over a pulley, with a weight hung to the end of it. Upon the axis, to which the lever is fixed, is a piece, a quarter of an inch in diameter, to which a piece of watch-chain is fastened, the other end of which is hooked to a strong spring G, which bears against one end of the metal E.

H is a lever, exactly of the same form and dimensions with the other; but the chain fastened to the pulley on its axis is hooked to the standard bar. The line fastened to the end of this lever, after being wound round a cylinder, to which the moveable plate is fixed, passes over a small pulley, and has a weight hung to the end of it; or rather the same line, pulling under a pulley to which the weight is hung, has its other end fastened to the lever F; so that one weight serves for both levers. From this description it is plain, that whenever the bar E is lengthened, it gives liberty to the weight to draw the lever F upwards by its action to the spring G; and the index will, at the same time, by means of the silk line, be carried forward in the circle; and when the bar shortens, it will return back again: the same motion will be communicated to the standard bar. When the bar is lengthened the 20th part of an inch, the index will be carried once round the brass circle, which is divided into three hundred and sixty degrees; and, therefore, if the metal lengthens the 720th part of an inch, the index will move one degree. In order to make an experiment with this instrument, lay a bar of any kind of metal, as E, on the standard bar; then heat this bar to any degree of heat, with a lamp, and mark the degree of its expansion, as indicated by the moveable plate; observe also the degree of expansion of the metal E, by the heat communicated to it from the standard bar, as marked on the brass circle by the index; let the instrument stand, till the whole is thoroughly cold; then removing the bar E, lay any others successively in its place, and proceed exactly as before; and thus the degrees of expansion of different metals, by the same degree of heat, may be estimated.

By the help of this instrument Mr. Ellicott found, upon a medium, that the expansion of bars of different metals, as nearly of the same dimensions as possible, by the same degree of heat, were as follow:

Gold, Silver, Brass, Copper, Iron, Steel, Lead, 73 103 95 89 60 56 149

The great difference between the expansions of iron and brass, has been applied with good success to remedy the irregularities in pendulums arising from heat. Phil. Trans. vol. xlvii. p. 485. See Pendulum.

Mr. Graham used to measure the minute alterations, in length, of metal bars, by advancing the point of a micrometer-screw, till it feebly stopped against the end of the bar to be measured. This screw, being small and very lightly hung, was capable of agreement within the three or four thousandth part of an inch. On this general principle Mr. Smeaton contrived his pyrometer, in which the measures are determined by the contact of a piece of metal with the point of a micrometer-screw. A B C D (fig. 5.) represents the main bar or bars of this instrument; E F is the bar to be measured, lying in two notches, one fixed to the upright standard A B; the other to the principal lever H J; the end E of the bar E F bears against the point of G, a screw which is of use in examining the micrometer-screw; the other end of the bar F bears against a small spherically protuberant bit of hard metal, fixed at the same height as G, in the principal lever H J; K is an arbor fixed in the bars, which receives at each end the points of the screws, H, L, upon which the lever H J turns and serves as a fulcrum to it; O is a slender spring, to keep the lever in a bearing plane against the bar; and P is a check, to prevent the lever from falling forward, when the bar is taken out; N is the feeder, somewhat in the shape of a T, in, suspended, and moveable up and down upon the points of the screws, I, M,
PYROMETER.

I, M, which, as well as L, H, are so adjusted as to leave the motion free, but without shake; Q R is the handle of the feeler, moveable upon a loose joint at R; so that by laying hold of it at Q, the feeler is moved up and down, without being affected by the irregular pressure of the hand; the extremity, S, of the feeler is also furnished with a bit of protuberant hard metal, to render its contact with the point of the micrometer-screw more perfect; T is the micrometer-screw; V the divided index-plate; and W a knob for the handle; the micrometer-screw passes through two solid screwed holes at D and Y; the piece YZ is made a little springy, and endeavours to pull the screw backwards from the hole at D, and consequently keeps the micrometer-screw constantly bearing against its threads the same way, and thereby renders the motion thereof perfectly steady and gentle; X is the index, having divisions upon it, answering to the turns of the screw. This piece points out the divisions of the plate, as the face of the plate points out the divisions upon the index. When the instrument is used, lay hold of the knob at Q with one hand, and, moving the feeler up and down, with the other move forward the screw T, till its point comes in contact with the feeler; then will the plate and index, V and X, show the turns and parts. The basis of this instrument, as well as the other parts of it, is bras: one end of which is terminated of the same piece at right angles, to the height of three inches and a half; and the other end acts upon the middle of a lever of the second kind, whose fulcrum is in the basis; and, therefore, the motion of the extremity of the lever is double the difference between the expansion of the bar and the basis. Hence, having the length of the lever from its fulcrum to the point of suspension of the feeler, the distance between the fulcrum and the point of contact with the bar, the inches and parts that correspond to a certain number of threads of the micrometer, and the number of divisions in the circumference of the index-plate; the fraction of an inch expressed by one division of the plate may be deduced. Those measures are as follow: from the fulcrum of the lever to the feeler, 5.875 inches; from the fulcrum to the point of contact, 2.805 inches; length of seventy threads of the screw, 2.455 inches; and the divisions in the circumference of the index-plate, 100. Hence the value of one division will be the \( \frac{1}{100} \) of part of an inch: but if the screw be altered one-fourth of one of these divisions, when the contact between the screw and feeler is well adjusted, the difference of contact will be very perceptible to the slightest observer; and, consequently, \( \frac{1}{100} \) part of an inch is perceptible in this instrument. When the instrument is made use of, if it is immersed, together with the bar to be measured, in a cistern of water; which water, by means of lamps underneath, is made to receive any intended degree of heat not greater than that of boiling, and thereby communicates the same degree of heat to the instrument, the bar, and to a mercurial thermometer immersed therein, for the purpose of ascertaining that degree. See fig. 6, in which A B is the cistern, C the cover, which, when the instrument (fig. 5.) is raised upon blocks, goes on between the bar E F and the basis B C; D a handle to take off the cover, when hot; E the mercurial thermometer; F the cock, to let out the water; and G H a hollow piece of tin, which supports seven spirit lamps, which are raised higher or lower by the screws I and K, in order to give the water in the cistern a proper degree of heat. With this pyrometer Mr. Smaton performed several experiments, which are arranged in a table; and their result agrees very well, he observes, with the proportions of expansions of several metals given by Mr. Ellicott. The following table shews how much a foot in length of each metal grows longer, by an increase of heat corresponding to 180° of Fahrenheit’s thermometer, or to the difference between freezing and boiling water, expressed in such parts of which the unit is equal to the 10,000th part of an inch.

For a farther account of this instrument, with its use, see Phil. Trans. vol. xlvi. art. 79. p. 598, &c.

Mr. Ferguson has constructed and described a pyrometer, which makes the expansion of metals by heat visible to the 45,000th part of an inch. The upper surface of this machine is represented by fig. 7. Its frame, A B C D, is made of mahogany, on which is a circle divided into three hundred and sixty equal parts; and within that circle is another, divided into eight equal parts. If the short bar E be pushed one inch forward (or toward the centre of the circle) the index e will be turned 125 times round the circle of 360 parts or degrees. As 125 times 360 is 45,000, it is evident, that if the bar E be moved only the 45,000th part of an inch, the index will move one degree of the circle. But, as in this pyrometer the circle is nine inches in diameter, the motion of the index is visible to half a degree, which answers to the 90,000th part of an inch in the motion or pulling of the short bar E.

One end of a long bar of metal F is laid into a hollow place in a piece of iron G, which is fixed to the frame of the machine; and the other end of this bar is laid against the end of the short bar E, over the supposing cross-bar H I; and, as the end, f, of the long bar is placed close against the end of the short bar, it is plain that if F expands, it will pull E forward, and turn the index e.

The machine stands upon four short pillars, high enough from a table, to let a spirit lamp be put on the table under the bar F; and, when that is done, the heat of the flame of the lamp expands the bar, and turns the index.

There are bars of different metals, as silver, bras, and iron; all of the same length as the bar F, for trying experiments on the different expansion of different metals, by equal degrees of heat applied to them for equal lengths of time; which may be measured by a pendulum that twangs seconds. Thus.

Put on the bras bar F, and set the index to the 360th degree; then put the lighted lamp under the bar, and count the number of seconds in which the index goes round the plate, from 360 to 360 again; and then blow out the lamp, and take away the bar.

This done, put on an iron bar F where the bras one
The inside of this pyrometer is constructed as follows.

In fig. 8, A a is the short bar, which moves between rollers; and, on the side $a$, it has fifteen teeth in an inch, which take into the leaves of a pinion $B$ (twelve in number), on whose axis is the wheel $C$ of one hundred teeth, which take into the ten leaves of the pinion $D$, on whose axis is the wheel $E$ of one hundred teeth, which take into the ten leaves of the pinion $F$, on the top of whose axis is the index above-mentioned.

Now, as the wheels $C$ and $E$ have one hundred teeth each, and the pinions $D$ and $F$ have ten leaves each, it is plain, that if the wheel $C$ turns once round, the pinion $F$, and the index on its axis, will turn one hundred times round.

But, as the first pinion $B$ has only twelve leaves, and the bar $A a$ that turns it has fifteen teeth in an inch, which is twelve and a fourth part more; one inch motion of the bar will cause the last pinion $F$ to turn one hundred times round, and a fourth part of one hundred over and above, which is twenty-five. So that if $A a$ be pushed one inch, $F$ will be turned one hundred and twenty-five times round.

A silk thread $b$ is tied to the axis of the pinion $D$, and wound several times round it; and the other end of the thread is tied to a piece of slender watch spring $G$, which is fixed in the head $H$. So that as the bar $f$ expands, and pushes the bar $A a$ forward, the thread winds round the axle, and draws out the spring; and as the bar contracts, the spring pulls back the thread, and turns the work contrary way, which pushes back the short bar $A a$ against the long bar $f$. This spring always keeps the teeth of the wheels in contact with the leaves of the pinions, and so prevents any shake in the teeth.

In fig. 7, the eight divisions of the inner circle are so many thousandth parts of an inch in the expansion or contraction of the bars; which is just one thousandth part of an inch for each division moved over by the index. Ferguson's Lectures on Mechanics, Suppl. p. 7, &c. 410.

Another pyrometer was invented by M. De Luc, in consequence of a hint suggested to him by Mr. Ramlden. The blade of this instrument is a rectangular piece of deal board two feet and a half long, fifteen inches broad, and one inch and a half thick, and to this all the other parts are fixed. This is mounted in the manner of a table, with four deal legs, each a foot long, and an inch and a half square, well fitted near its four angles, and kept together at the other ends by four firm crofs-pieces. This small table is suspended by a hook to a fland; the board being in a vertical situation in the direction of its grain, and bearing its legs forward in such a manner as that the crofs-pieces which join them may form a frame, placed vertically facing the observer. This frame sustains a microscope, which is firmly fixed in another frame that moves in the former by means of grooves, but with a very considerable degree of tightness; the friction of which may be incresed by the preffure of four fcrews. The inner flicing frame, which is likewise of deal, keeps the tube of the microscope in a horizontal position, and in great part without the frame, infomuch that the end which carries the lens is but little within the space between the frame and the board. This microscope is constructed in such a manner as that the object observed may be an inch distant from the lens; and it has a wire which is situated in the focus of the glaffes, in which the objects appear reversed. At the top of the apparatus there is a piece of deal, an inch and a half thick, and two inches broad, laid in a horizontal direfion from the board to the top of the frame. To this piece the rods of different subtances, whose expansion by heat is to be measured, are fupped; one end of it flices into a focket, which is cut in the thickness of the board, and the other end, which rels upon the frame, meetts there with a fcrew, which makes the piece move backwards and forwards, to bring the objects to the focus of the microscope. There is a very strongly driven through a hole bored vertically through this piece; and in another vertical hole, made through the cork, the rods are fixed at the top; fo that they hang only, and their dilataion is not counteracted by any preffure. In order to heat the rods, a cylindrical bottle of thin glaffes, about twenty-one inches high, and four inches in diameter, is placed in the inside of the machine, upon a fland independent of the rest of the apparatus. In this bottle the rods are fupped at a little lefs than an inch distance from one of the fides, in order to have them near the microscope. Into this bottle is poured water of different degrees of heat, which must be flired about by moving upwards and downwards, at one of the fides of the bottle, a little piece of wood falted horizontally at the end of a flick: in this water is hung a thermometer, the ball of which reaches to the middle of the height of the rods. During these operations the water rises to the cork, which thus determines the length of the heated part; the bottle is covered to prevent the water from cooling too rapidly at the surface; and a thin cafe of brafs prevents the vapour from fixing upon the piece of deal to which the rods are fixed. This pyrometer is represented in fig. 9, in which $a a$ is the fland to which it is fupped; $b$ the hook from which it hangs; $c c$ the deal-board, which is the basis of the whole apparatus; $d, d, d, d$, four arms, to which is fixed the frame $e e e e$: the other frame which carries the microscope is $f f f f$: $g, g$, are two crofs-pieces, through which passes the tube of the microscope, and which support it near both ends; $h h$ is the microscope; $i i$ its micrometer; $k$ the cork, through which passes the glaffes rod $l l$, and by which it is kept fupped; $m m$ a rod of metal, or any other subtance lefs dilatable than glaffes; $n$ the point of union, obtained by means of two connected rings, in which both rods are falleden by fcrews: above there is another pair of rings, in one of which the metal rod is free, and which rod it supports; $o o$ the piece to the which the glaffes rod is fupped; $p p$ a square piece fixed to the frame by four fcrews, behind which is a box, in which, as well as in a groove cut in the blade in $q q$, the piece $p p$ slides; $r r$ a fcrew, which fasses through the square piece $g g$, whose use is to move backwards or forwards the piece $p p$, in order to bring the surface of the metal rod to the focus of the microscope; $s s, s s, s s$, four fcrews, with round metal plates behind their heads, which serve to prefect the frame of the microscope against the frame $e e e e$: the longitudinal openings, through which the fcrews pas, permit the free motion of the firft frame, when one strikes gently with a hammer to the bottom or the top of one of the fides. If the microscope is wanted higher or lower than the grooves permit, the fcrews may be re-
moved to other holes made on purpose in the side pieces of the frame: it is the cylindrical bottle, in which hung the rods in order to be heated at different degrees by water of various temperatures; \( y_u \), \( y_u \) are the supports of the bottle; \( x \) the thermometer suspended in the water; \( z \) a rod, to the lower end of which is fixed a small plate, to stir the water, by moving it up and down; \( z = \) a syphon, one branch of which is within, and the other without, the bottle, the latter being furnished with a cock, which serves to draw off the quantity of water that is necessary for changing the temperature in the bottle. For a farther account of this instrument, together with the principle of its construction and use, both in the comparative measure of the expansions by heat, and the measure of their absolute expansion, and the experiments made with it, we must refer to an elaborate essay of M. De Luc on Pyrometry, &c. in the Phil. Trans. vol. lxviii. part i. art. 20. p. 419—546.

All the contrivances above described must be considered as inferior to that constructed by Mr. Ramden, of which general Roy has given an accurate and minute account in the Phil. Trans. vol. xxx. p. 462. We shall here give such an account as our limits will allow of this instrument, says major-general Roy, that it seems not easy to improve it; and refer for a fuller account illustrated by appropriate drawings. This pyrometer, named the microscopes, because by means of two microscopes attached to it, the expansion is measured, consists of a strong deal frame, 5 feet long, nearly 28 inches broad, and about 42 inches in height. The metallic bar, whose expansion is to be measured, and which may be even five feet long, is placed in a copper trough little longer than five feet; and this is placed over 12 spirit lamps, the flames of which heat the water of that trough fully to the boiling point, and of course heat the bar which is plunged into it. Two other wooden troughs, also full of water, are placed parallel to, and at a little distance from, the copper one. Each of these contains a cast-iron prismatic bar. To the ends of one of these bars two microscopes are fastened in an horizontal situation, perpendicularly to the bars. One of these microscopes is furnished with a micrometer, or mechanism, to measure the magnified image of an object; the other microscope has a sable mark. The parts of the microscopes, as well as the proper marks for measurement, are separated and dipped, partly upon the ends of the cast-iron rods, and partly upon the ends of the rod under examination, that if any of them be lengthened or shortened, that alteration is clearly perceived through the microscopes, and may be measured by means of the micrometer. It follows, that if the temperature of the cast-iron prismatic bars be kept unaltered, whilst that of the bar under examination is increased, then the increase of length, which is measured by the micrometer, must be attributed to that bar only, and by these means the expansions of seven substances were ascertained. For further particulars relating to the construction and use of this instrument, we refer to the Transact. (ubi supra), and to the article Expansion in this Cyclopaedia. For an account of Wedgwood's pyrometer, see Thermometer. Also, for a description of Mr. Troughton's pyrometer, we are under the necessity of referring to the fame article.

PYROMUCOUS Acid, or Empyrumatic acid of sugar, or Syrupus acid, is different from the acid of sugar, or Oxalic Acid, (which see) and denotes that prunent acid vapour of sugar, or any saccharine matter strongly heated, which is familiar to every person who has ever entered a sugar baking-house. It is prepared by chemists in the following manner: Put into a very large glas retort any quantity of pulverized sugar of any kind, so as to fill only one third of it, as the matter very much swells in the process; adapt to it a large receiver, not closely luted, and heat it gradually on a sand-bath. A great quantity of gas arises when the sugar begins to be scorched, which is mostly carboxic acid mixed with an inflammable gas, probably the gaseous oxvd of carbon. In the receiver is condensed a weak acidulous liquor, coloured by an oily matter, and also apparently foamed by a portion of fuliginous matter volatilized during the distillation. The quantity of acid, obtainable in this process, varies according to the regulation of the fire, which should at least be pushed so as to make the retort red-hot, and to reduce the sugar to a perfect charcoal; but in general about 5ths of the weight of sugar may be obtained of the distilled acid. Gum mucilage, manna, honey, starch, and other mucous or mucin-faccharine substances, yield, by distillation, the same acid as sugar. Aikin, Dict. Min.

PYROMONIA, a term used by the chemical writers to express the art of regulating fire, so as to make it subserve to all their processes in a determinate degree. 

PYROPE, in Mineralogy, a precious stone, formerly called the Bohemian garnet. (See Garnet.) The colour is a dark blood red; when held between the eye and the light, the red colour inclines to a yellow. The pyrope is never found crystallized, but occurs in small round or angular fragments imbedded in serpentine rock, or scattered in the sands on the sea-shore, and in alluvial ground. It feriates quartz. The specific gravity is stated by Klaproth 3:718. On account of its lustre, transparency, colour, and hardness, it is much prized by jewellers. The small grains, when powdered, are applied to cut softer stones. According to Klaproth, the constituent parts of pyrope are:

B.

PYROPHAGI. See Fire-Eaters.

PYROPHANES, in Mineralogy, a variety of the semi-opal; so called because, being heated in a fagon, it becomes transparent, but returns to its opaque state when cold, as Mr. Landriani has discovered. M. Saffures, junior, renders common hydrphanes transparent, and of a topaz colour, when heated by digesting them in melted wax. It is said that some pyrophanes are found in Armenia, which are transparent while exposed to the sun, and opaque at night. See Gem.

PYROPHORUS, formed of \( \nu_{10} \), fire, and \( \iota, \rho \), bear, in Chemistry, the name generally given to that substance called some black phosphorus; a chemical preparation possessing the ignilur property of kindling (spontaneously when exposed to the air.

This substance was accidentally discovered by M. Homberg, who prepared it of alum and human faces. (See Phosphorus Exaltata.) See also M. Le Fevre's preparation, described under Phosphorus of Sulphur.

It was apprehended for a considerable time after the discovery, that human faces were essential to the operation, till the yeungest son of the great Lernery found, that honey, sugar, flour, and, indeed, any animal or vegetable matter, might be substitiuted instead of the human faces; and since that time, M. de Stigny has shown that most vitriolic faults may be substituted for the alum, having added to the al-
PYROPHORUS.

The spontaneous ignition of the aluminous pyrophorus, on its being exposed to the air, has been a subject of considerable discussion among chemists and philosophers; several of whom have adopted the hypothesis proposed by M. de Suvigny, in the Mémoires de Mathématique et de Physique, tom. iii. To explain this curious appearance, M. de Suvigny observes, that the vitriolic acid in the alumin, during the calcination in the phial, leaves its earthy basis, and unites with the phlogiston in the coal. By its union with this inflammable matter, a part of it is undoubtedly rendered volatile, and exhaled partly under the form of volatile vitriolic acid, and partly in that of a blue sulphurous flame; while another part of it combines with the phlogiston forming a real sulphur, or an earthly hepar sulphuris; in which the sulphur is protected from the fire by the earth with which it is combined, and the particles of which remain every where intermixed with those of the powder. Thus far (says Mr. Bewley, an excellent chemist and philosopher) M. de Suvigny is supported by the appearances, and by a just chemical analysis of the powder: but he proceeds farther, and supposes that, at the end of the process, a part of the vitriolic acid is left in a disengaged, or uncombined state, and highly concentrated. In this state it is well known that this acid attracts moisture, and at the same time generates a considerable degree of heat. When the pyrophorus, therefore, is exposed to the air, it again supposes that this disengaged and concentrated acid suddenly attracts the watery particles floating in the atmosphere, and by the heat thus generated, sets fire to the sulphur and other inflammable matter contained in the powder. This hypothesis he has endeavoured to establish by the following observations: that the pyrophorus, as he apprehends, can be made only with substances fit for producing sulphur, or with sulphur itself:—that no pyrophorus will be produced, if the mixture be calcined by too long or too violent a fire; because then the whole vitriolic acid can be combined into perfect sulphur, and consequently is engaged, and not in a proper state to attract the moisture of the air; or else if it does not combine into sulphur, being half disengaged from its basis, it is driven off by the violence or long continuance of the fire; and, consequently, after this complete calcination, no acid remains partly disengaged, as it ought to be, that it might unite with the water with sufficient activity:—that when the pyrophorus is very slowly moistened, as when it is kept in a bottle not well closed, it does not kindle, because sufficient heat is not produced by this slow and gradual attraction of water; it is also spoiled and rendered incapable of kindling, when exposed to the open air; because its acid becomes then satu-rated, or nearly saturated with moisture, and cannot, therefore, unite with that of the air with sufficient activity:—that a pyrophorus, thus spoiled by exposure to moisture, may be restored to its peculiar properties by making it again red-hot in a matrafs; hence by this calcination its partly

Vol. XXIX.
difegaged acid is again concentrated, and refines all its force of combining with water;—and, lately, that the inflammation of the pyrophorus is accelerated by placing it upon a paper a little wetted, or by breathing upon it; because the acid then attracts the moisture more hastily, and consequently with more heat.

M. de Suvigny extends the fame reasoning to the several other pyrophors which he discovered, similar to that of alum; particularly to those which are made by subbituting vitriolated tartar, Glauber's salt, and other vitriolic salts with metallic, earthy, or alkaline bases, in the room of alum. Mr. Bewly has examined this hypothesis with his usual acuteness and accuracy; and from numerous well-conducted experiments he is led to conclude, that pyrophors of all the above-mentioned kinds may be prepared, differing from them in no other particular, except that they contain no vitriolic acid, and which nevertheless kindle as readily, on being exposed to the air, as those which have been impregnated with that principle. In order to shew that the presence of vitriolic acid is not necessary to constitute the pyrophorus made with vitriolated tartar, he added to a quantity of this tartar more than an equal weight of powdered charcoal, and calcined the mixture a long time, in a red heat, in an open crucible; frequently stirring the powder, in order to expel from it as much of the vitriolic acid as possible; the calcination was also sometimes repeated with fresh charcoal; and yet on heating the dust, thus deprived of a considerable part of its acid, with charcoal, in a crucible or tobacco-pipe, in the manner which we shall here subjoin, he observed no diminution in its quality of producing a pyrophorus.

Mr. Bewly, in several of his experiments, made use of the bowl of a tobacco-pipe, in which he combined the materials, which he wished to examine in small quantities, and in an expeditious manner; pressing them down lightly, so as to fill half or three-fourths of the bowl, and filling the remainder of it with fine sand. This is kept in a red heat twenty minutes, or half an hour; or it may continue there two hours longer, if the operator pleases, without any injury to the pyrophorus. The pipe being taken out of the fire, the matter is knocked out of it as soon as it becomes cool, and generally, pretty soon afterwards, takes fire spontaneously. Thus he formed his pyrophorus with a mixture confounding of two parts of alum, previously calcined in a red heat; and of powdered charcoal and salt of tartar each one part.

In another experiment, having added successively various and increasing quantities of fixed alkalii to the salt heated as above, till the vitriolic acid contained in the mixture might be considered nearly as an evanescent quantity, a pyrophorus was still produced on calcining it with charcoal as before. He also mixed equal parts of salt of tartar, and vegetable or animal coal, or sometimes three parts of the former with two of the latter, and calcined them in the usual manner; and this composition, on being exposed to the air, generally kindled in half a minute or a minute; though, as it contained no sulphur, it did not burn with so much vivacity as the vitriolic pyrophori. This, which Mr. Bewly calls the alkaline pyrophorus, differs in no circumstance from M. de Suvigny's neutral pyrophori, except in its not containing that principle to which he ascribes their accession. However, let it might be suspected that the falt of tartar which he employed might accidentally contain vitriolated tartar, or vitriolic acid, he repeated the experiment with tartar calcined by himself, as well as with nitre fixed or alkaliised by deflagration with charcoal, and with iron filings; and in all these cases with the same result. By diversifying in a like manner M. de Suvigny's experiments on the metallic pyrophori, Mr. Bewly found that none of the three vitriols, heated with charcoal alone, in its usual method, could produce a pyrophorus. And thus he found that the addition of an alkaline salt to the composition, which was a part of M. de Suvigny's process, was essential to its success.

Treating in the usual manner equal parts of calcined green vitriol and charcoal, the powder which contained no sulphur nor hepar sulphuri, did not acquire any of the properties of a pyrophorus. The vitriolic acid seemed to have been entirely diffused; having no bafe to detain it, when diffused from the metallic earth. The charcoal and cals of iron, left in this process, were calcined again, together with some salt of tartar; and a pyrophorus was produced, which exhibited indications of its containing a scarcely perceptible portion of hepar sulphuri. Thirty grains of crocus martis affringsens were calcined with fifteen grains of charcoal, and the fame quantity of salt of tartar; and the mixture burnt spontaneously, though it contained no hepar sulphuri, or vitriolic acid. Having by these experiments evinced that metallic pyrophori may be prepared without vitriolic acid, Mr. Bewly proceeded to form an aluminous pyrophorus of the same kind. For this purpose, he procured the earth of alum by a long and violent calcination; and examining a part of it, he found, by the usual tests, that it neither contained any sulphur, hepar sulphuri, nor alum undecomposed. This he considered as perfectly pure, though he afterwards found that it contained a small quantity of vitriolated tartar; and yet it repeatedly furnished a pyrophorus as active as when alum itself is employed. From these and similar experiments he infers, that the several kinds of pyrophorii are not kindled by moisture attracted by the vitriolic acid, as M. de Suvigny has maintained; and his conclusion is farther confirmed by some experiments of Dr. Priestley, from which it appears, that they are kindled in dry, nitrous, and dephlogificated air.

M. Proust, cited by Mr. Bewly, describes a variety of new pyrophorii, which neither contain vitriolic acid, nor seem likely to owe their accession to the attraction of humidity from the air. These principally consist of a coaly matter finely divided by metallic or other earths; such are the sediment left in the filter in preparing Gould's extract, various combinations of tartar, or its acid, or the acetous acid with metals, calcined earth. Mr. Bewly, having evinced the insufficiency of M. de Suvigny's theory, and discovered that the pyrophorii are not kindled by moisture, attracted (merely) by the vitriolic acid, directed his attention to the nitrous acid, which Dr. Priestley has shown to be a constituent part of atmospheric air, as the probable agent in the production of this phenomenon. The strong affinity which this acid has with phlogiston, and the heat, and even flame, which it is known to produce with certain inflammable matters, manifested that it was equal to the effect; and having excluded the vitriolic acid from having any essential concern in this operation, he fuggeled, either that the pyrophorus is kindled by moisture attracted by some of the other ingredients which compose it; or that it has the power of decomposing atmospheric air, by suddenly attracting its nitrous acid, and thereby generating a heat sufficient to kindle the phlogistic matter contained in it. This idea appeared plausible, when he farther considered that Dr. Priestley produced the purest inflammable air with this fame acid and with other principles; and that this as well as common air is diminished, and probably in part decomposed, in a variety of phlogistic processes. This ingenious writer concludes, upon the whole, from the experiments he hath made, that the pyrophorus seems to owe its ignifemo
lar property to its being a combination of earth or alkali with phlogiston; the vitriolic acid, when present, only occasionally increasing or diminishing the effect, according to circumstances. In the process of calcination, the earth or alkaline principle is not merely mixed, but actually, though loofely, combined with the phlogistic principle of the coal; so that the pyrophorus, considering it in its molt simple state, is only a perfectly dry phlogisticated alkali or earth. On these data, the phenomena may be explained in the two following methods; with respect particularly to the influence of moisture and heat upon the pyrophorus. Supposing either the alkaline or earthy principles to have a greater affinity to water than to the phlogiston with which either of them is united, they may be exposed to a moist atmosphere, attract the humidity, and therefore set the phlogistic principle at liberty; which may, in its turn, attract and be ignited by the suppoaced aerial acid, it's strong affinity to which is well known:—or, if this hypthesis be rejected, the inflammable matter may be kindled, merely in consequence of the heat produced by the combination of the alkali, &c. with moisture. This reasoning, however, supposes the existence of phlogiston, which modern chemists have generally explodned.

The chemical changes that take place during the formation and decomposition of pyrophorus, as they are stated by Aikin, appear to be the following: 1. By being heated below redness in the open air, the ingredients enter into fusion, and thus mix accurately with each other; then the water of crystallization is driven off from the alum, and of the fugar or flour, little else than the charcoal escapes volatilization. 2. The red heat to which it is expsoed in the phial causes the sulphuric acid of the alun and charcoal of the fugar to react on each other, by which part of the charcoal is driven off in the form of carbonic acid, and part of the sulphuric acid escapes as sulphuric acid. The blue flame that characterizes the latter part of this process is probably caused by the volatilization and combustion of a portion of sulphur, more than is requisite to saturate the potash of the alun. Thus the pyrophorus, when prepared, consists of alumine, charcoal, and sulphuret of potash in intimate mixture. 3. When this powder is exposed to the air, a rapid decomposition of the air itself, and of the moisture which it contains, takes place, the oxygen of each being absorbed by the fugar, while a sufficient quantity of heat is diffegaged, to bring the charcoal and remainder of the sulphur to a state of actual inflammation. See on the subject of this article, Macquer's Chemical Dict. art. Pyrophorus; and Priestley's Obs. on Air, vol. iii. Appendix, p. 386, &c. vol. iv. Appendix, p. 479, &c. Aikin's Dictionary.

PYROPHYLACIA, a term used by Kircher and some others, to express those magazines of fire which are placed in the cavities of mountains and other hollows of the earth, and serve to supply the several volcanoes in the different parts of the world. See Volcano.

PYROPHYSALITE, in Mineralogy, is so called from τως, fire, and ψαλτης, a bubble, because this mineral emits bubbles when exposed to the flame of the blowpipe. It is found at Embo, near Falhun, in Sweden, imbedded in a granitic rock. The colour of pyrophysalite is white, inclining to green, and occasionally small spots of blue fluor spar are seen on its surface. It commonly occurs in oblong pieces, some of which approach to an irregular rhomboid. It differs from felspar, to which it has the most resemblance, in having but one determinate direction in which it can be split; its specific gravity is also greater, and it fusces more easily. The fragments scratch glass, but are less hard than quartz. The powder of the finest fragments emit a phosphorescent light when heated. Its specific gravity is 3.45, and the constituent parts, according to Hefinger and Bertzelius, are:

The substance lost during the process is suspected to be fluoric acid. Hairy clusses this mineral with the topaz. See Topaz.

PYROPÆCILOS, in the Natural History of the Ancients, the name by which they call the granite of Arabia, commonly known to this day under the name of the Oriental granite.

The name is derived from the Greek, πυρ, fire, or fire-coloured, and ἀκτίων, spotted; and the ancients having used the epithet fiery to yellow, as well as red, some have imagined the granite must be a yellow stone; but it is evident that red is the colour meant by it here.

PYROSCOPE, an instrument invented by professor Leflieu for measuring the intensity of fire. This is merely the differential Thermometer (which fee), with one of its balls covered with silver leaf, while the other is naked. The fire heats the naked ball, but not the silvered ball. Hence the liquid in the tube rises or falls, according to the intensity of the fire, and of course marks that intensity.

PYROSCOPIA, formed of πυρ, fire, and σκοπεω, I consider, among the Greeks, a kind of divination, being the same with pyromancy and ignigraphia.

PYROSIS, in Medicine, called in Scotland the water-broth; is a disorder of the stomach, which is characterized by a sudden and violent attack of pain in that organ, followed by a copious discharge of a colourless, insipid, and generally cold fluid, resembling saliva, from the oesophagus, mouth, and throat.

The first description of this disease was given by Linneus, as a common affection of the Laplanders, under the appropriate appellation of Cardialgia putatorium; whence Sauvages gave it the denomination of pyrosis Succina. (Nefol. Meth. clas vii. gen. 18.) Dr. Cullen adopted the generic term pyrosis, and deems it an idiopathic disease. It seems to occur, however, in conjunction with other forms of indigestion, and might have been arranged as one of the symptoms of dyspepsia.

The fits of pyrosis usually come on in the morning and forenoon, when the stomach is empty. The first symptom is a pain at the pit of the stomach, with a sense of contraction, as if the stomach were drawn towards the back: the pain is increased by raising the body into an erect posture, and therefore the patient bends himself forward. This pain is often extremely severe, with a sense of burning; and after continuing for some time, it brings on an eruption of a thin watery fluid in considerable quantity. This fluid has sometimes an acrid taste; but most commonly it is described as being absolutely insipid. It continues to be brought up for some time, and does not immediately give relief to the pain which preceded it; but at length it terminates the pain, and the fit ceases.

These paroxysms come on without any evident cause, nor is the origin of the disease always to be imputed to any particular form of diet. It seldom, if ever, attacks those people who use fresh animal food daily; but appears to be most common among those who live almost entirely upon tea, milk, potatoes, and farinaceous substances. It is much more common
common in women than in men; sometimes it attacks pregnant women, and often those who labour under leucorrhœa. It seldom occurs in any one before the age of puberty, or in those who are considerably advanced in life; when it has once taken place, it is very prone to recur occasionally for a long time afterwards. It is more common in Scotland than in this country, and chiefly affects the lower classes of the people.

While the same diet is continued, it is not always easy to cure the disease. The paroxysm is most effectually relieved by anodynes, especially opium; hyoscynamus, &c. answer a similar purpose; and with less certainty; other stimulants and antipatmals, as sulphur, ammonia, the tincture of guaiacum, &c. alleviate the fit. These remedies, however, do not materially contribute to prevent the recurrence of the paroxysms; and butters, aromatics, and the whole of the remedies against indigestion, have been often employed in vain. A combination of aromatic fixatives, with strong alkalis and narcotics, have appeared to the writer of this article to be on the whole the most effectual remedies. See Cullen, Fifth Lines, vol. iv. p. 1.

Pyrosis is also a word used to express an intense heat and readvts in the face, such as of those persons who travel in extremely hot weather, and the like.

Gen. Ch. Cal. Perianth superior, short, in four deep, acute, broad segments, deciduous. Cor. of one petal, somewhat bell-shaped; tube thrice as long as the calyx, gradually upwards; limb of the same length, in four acute, equal, spreading segments, throat downy. Stem. Filaments four, short, inserted into the tube of the corolla, alternate with the segments of the limb; anthers oblong, erect, pointed, shorter than the limb. Pet. Germen tuberous, inferior; style short, cylindrical; stigma capitulate. Peric. Berry small, dry, pear-shaped, with eight furrows, and eight cells, distinct of any crown. Seeds solitary in each cell.

Eff. Ch. Calyx four-toothed. Corolla bell-shaped, four-cleft, downy in the throat. Berry inferior, obovate, with eight furrows and eight seeds.

Obf. Jaffeu, by an error which seems typographical, attributes five segments to the corolla, which Willdenow copies. There are, however, but four, as the analogy of the other parts, in this case, necessarily requires.

1. P. falteae. Willow-leaved Straw-berry. Willd. n. 1. (Prunus hoesides; Lamarck Illust. v. 1. 289. t. 68. f. 2. (not f. 4.)—Gathered by Commerson, in the Isle of Bourbon; not, as Willdenow has it, the Mauritius. A shrub, with round, smooth, greyish, leafy branches. Leaves opposite, on short stalks, rather crowded, two or three inches long, elliptic-lanceolate, sharp-tipped, entire, coriaceous, smooth, with one rib, and several lateral incurved veins, occasionally accompanied by an axial gland-like tubercle, that seems accidental; paler beneath. Sepals between the fruit-stalks, and of the same length, awl-shaped, erect, dilated at the base, deciduous. Flowers—stalks axillary, solitary, somewhat umbellate, bearing one or more simple, single-flowered, partial stalks, with a pair of oblong tapering bracts at the base of the latter. Flowers hardly a quarter of an inch long, erect, apparently white. Fruit, according to Lamarck, near an inch in length, pear-shaped, umbilicate, with eight deep longitudinal furrows. When cut transversely, it throws the eight seeds, compressed, and radiating from the centre.

PYROTARTAREOUS ACID, or Empyreumatic acid of tartar, a species of empyreumatic acetic acid, very different from Tartaric acid; which see. To procure this acid, distil any quantity of cream of tartar in a glass or earthen retort, and as in the process for Pyrometric Acid; the retort being half full of the tartar, on raising the fire very slowly, the first produce is a limpid, acidulous, somewhat bitterish water, after which, as the heat increases, a moat prodigious volume of the inflammable gas is given out, together with a stronger acid, and more empyreumatic liquid, and at last a black oil, and some volatile alkali.

The whole quantity of liquid acid procured from tartar in this method, is generally not more than about a quarter of the weight of the tartar, and is not quite so brown, nor so highly empyreumatic as the pyrometarum. This acid, and also the pyrrogous and pyromucous acids, are capable of very considerable purification by easy methods, so that they lose their empyreuma, their peculiar taste and smell, in which confit their characteristic differences, till at last, when brought into the most concentrated state by some of the modes in which vinegar is dephtegmated, they exhibit the characters of acetic acid so unequivocally, that no doubt can be entertained of their identity. Simple rectification, or redistillation in a very gentle heat, and slopping the procents when the liquor at last comes over much coloured, will purify, to a very great degree, the pyromius and pyrrolicher acids: the latter, by this process, from being of a dark coffee colour, assumes the hue of very pale clear brandy. But on long exposure to light, it again becomes brown, for it retains its empyreumatic character more than any other. Charcoal, newly burnt and powdered, contributes very much to the purification of all these acids; they may be either gently distilled off, or even merely filtered through a stratum of it. But the most effectual method of purification is by uniting these acids with lime, or a fixed alkali, evaporating to dryness, and then expelling the acid by means of the sulphuric acid, in the same manner as the concentrated vinegar is prepared. The acid vapour that rises in this process has now lost its empyreuma almost entirely; has both the strength and the powerful odour of radical vinegar; when again united to potash, forms acetated potash, which may be obtained white by repeated crystallization, or by charcoal powder, and in short in perfect acetic acid. Aikin.

PYROTECHNY, derived from the Greek words πυρ, fire, and τεχνη, art, is a term applied to the art or science which teaches the management and application of fire in certain operations. Although this term has been used in a very extensive sense by some writers, and applied to the use and structure of fire-arms and artillery employed in the art of warfare, yet it is commonly confined, as it will be in this work, to those articles and instruments made use of for amusement, and for grand public occasions, as the celebration of victories, the demonstrations of public joy on account of peace, after long continued war, &c.

Of the origin of artificial fire-works there is nothing certain recorded. In Europe the invention of them is of recent date, and is given to the Italians. The use of fire-works in China was very general long before they were known in European countries; and from an account given of some recent exhibitions at Pekin, it should seem that they have attained to a degree of perfection not surpassed even by the artists of England, France, or Italy. "The fire-works, in some particulars," says Mr. Barrow in his Travels in China, "exceeded any thing of the kind I had ever seen. In grandeur, magnificence, and variety, they were, I own, inferior to the Chinese fire-works we had seen at Batavia, but infinitely superior in point of novelty, neatness, etc."
neatness, and ingenuity of contrivance. One piece of machinery I greatly admired; a shell five feet square was hoisted up by a pulley to the height of fifty or sixty feet from the ground; the bottom was so constructed as then suddenly to fall out, and make way for twenty or thirty rings of lanterns enclosed in a box to descend from it, unfolding themselves from one another by degrees, so as at last to form a collection of full 500, each having a light of a beautifully coloured flame burning brightly within it. This deviation and development of lanterns were several times repeated, and, at every time, exhibited a difference of colour and figure. On each side was a correspondance of smaller boxes, which opened in like manner as the others, and let down an immense net-work of fire, with divisions and compartments of various forms and dimensions, round and square, hexagons, octagons, &c. which were like the brightest burnished copper, and flashed like prismatic lightning with every impulse of the wind. The variety of colours with which the Chinese have the secret of clothing fire feems one of the chief merits of their pyrotechny. The whole concluded with a volcano, or general explosion and discharge of stones and flames, kiphus, crackers, rockets, and granadoes, which involved the gardens for above an hour in a cloud of intolerable smoke."

The apparatus used in making fire-works consists of solid wooden cylinders, called cartridge, for rolling the cases on; similar cylinders, either of wood or metal, for ramming down the composition; moulds for holding the cases while filling; a machine for contracting the cavity of the cases; another for grinding the materials; and a particular apparatus for boring some cases after they are filled.

Construction of the Cartridges for Rockets. — A rocket is a cartridge, or case made of stiff paper, which, being filled in part with gunpowder, saltpetre, and charcoal, rifes of itself into the air when fire is applied to it. There are several kinds and sizes of rockets, but the three following are the principal: viz. 1. Small ones, the calibre of which is not larger than that of a bullet of a pound weight. 2. Rockets, the calibre of which is equal to the size of a ball of from one to three pounds weight. 3. Large rockets, equal to a ball of from three pounds to a hundred weight.

To give the cartridges the same length and thickness, they are put into a hollow cylinder of metal, or strong wood. This mould is not to be confounded with another piece of wood, called the former or roll, to which is rolled the thick paper employed to make the cartridge. The rule for the size of the mould and roller is this: if the calibre of the mould be divided into eight equal parts, the diameter of the roller must be equal to the sum of those parts; of course the vacancy between the roller and the interior surface of the mould is equal to a fourth of the calibre of the mould, which will be exactly filled by the cartridge.

The size of the mould is measured by its calibre; but the length of the moulds for different rockets does not always bear the same proportion to the calibre, the length being diminished as the calibre is increased. In small rockets, the length of the mould ought to be six times the diameter of the calibre; but in the larger fixed rockets, it need not be more than between four and five times the calibre of the mould.

Large stiff paper of a peculiar kind is employed in making cartridges, and hence it has obtained the name of cartridge-paper. This paper is wrapped round the roller, and then cemented by means of common paste. When the cartridge is formed, the roller is drawn almost out, by turning it round, until it is distant from the edge of the cartridge the length of its diameter. A piece of cord is then made to pass twice round the cartridge at the extremity of the roller; and into the vacancy left in the cartridge another roller is introduced, so as to leave a space between the two. By means of the cord, the cartridge must be pinched till there remains only an aperture capable of admitting an instrument called a piercer; then the cord is removed, and its place is supplied by a piece of packthread.

Besides the roller, a rod is employed to load the cartridge, which must be somewhat smaller than the roller, that it may be easily introduced into the cartridge. This rod is pierced lengthwise to a sufficient depth to receive the piercer, which must enter into the mould, and unite with it exactly at the lower part. The piercer, which decreases in size, is introduced into the cartridge through the part where it has been choaked, and tapers to preserve a cavity within it.

After the cartridge is placed in the mould, the prepared composition is to be poured gradually in, and rammed down with great accuracy. When the cartridge is about half filled, separate, with a bodkin, half of the folds of the paper which remains, and having turned them back on the composition, press them down, and pierce three or four holes in the folded paper, by means of a piercer, which must be made to penetrate to the composition of the rocket. These holes serve to form a communication between the body of the rocket and the vacancy at the extremity of the carriage, as it is called, or that part which has been left empty. In small rockets this cavity is filled with granulated powder, and covered over, which serves to let them off; in those that are larger, the pot, containing flares, serpents, and running rockets, is adapted to it.

It now remains to affix the rocket to its rod, which is thus done. When it has been constructed, in the way just described, it is to be fastened to a rod of light smooth wood. Its length and weight must be proportioned to the size of the rocket; that is, it ought to be as long as to remain in equilibrium with it, when suspended on the finger, or other fulcrum, within an inch, or an inch and a half of the neck. Before it is fixed, place it with the neck downwards, and let it rest on two nails, in a direction perpendicular to the horizon; and to make it ascend to a greater height, adapt to its summit a pointed cap made of stiff paper, which will serve to facilitate its passage through the air. To these rockets may be added several other things, as a petard, which is a box of tin plate filled with fine gunpowder, placed on the summit. The petard is placed on the composition, at the end where it has been filled, and the remaining paper of the cartridge is folded down over it, to keep it firm. The petard produces its effect when the rocket is in the air, and the composition is consumed. A representation of a rocket completely fitted up is given in Plate Pyrotechny, fig. 2.

Stars, serpents, &c. may be added to them, which is done by adjusting to the head of the rocket an empty pot or cartridge, larger than the rocket, in order that it may contain the things intended to render the exhibition more beautiful. The following tables are necessary to those who would manufacture rockets for themselves. The first shews the size of the calibre of the mould for rockets of a pound weight and below; and the second points out the size required for the calibre of moulds of from 1lb. to 50lbs. It must be observed, that a pound rocket is that which is just capable of admitting a leaden bullet of a pound weight, and so of the rest.

Here it is evident that the mould of a rocket of twelve ounces in weight ought to be nineteen lines in diameter; one of five ounces will require a mould of thirteen lines in diameter. Hence we derive an easy method of finding the size when the weights are given; and if the diameter of the rocket be given, it will be equally easy to find the weight of the ball corresponding to that calibre. Thus, if the diameter be fifteen lines, it will, by the table, be seen that it corresponds to a ball of eight ounces.

</table>

By this second table, if the weight of the ball be given the size of the mould may be found: suppose it be 18 pounds, opposite to it is the number 262. Then we lay by the rule of proportion (as 15 : 262 : 14 : x) therefore the required calibre is 18 lines nearly, or four inches and four lines, or 4 1/2 inches. But if the calibre be given in lines, the weight of the ball may be found: suppose the given calibre be 36 lines, then as 19 1/2 : 100 :: 36 : x. The nearest number in the table to this is 181, which shows that the weight of the ball will be rather more than 6lbs., or, in other words, that a rocket, the diameter or calibre of which is 36 lines, is a rocket of a 6lb. ball.

The composition of the powder for rockets must be different, according to the different sizes, it being completely ascertained that what is proper for small rockets would be too strong for the larger ones.

For rockets of one or two ounces, the composition should be one pound of gunpowder, and two ounces of finely ground soft charcoal.

For rockets of somewhat larger size, the composition may be ten ounces of gunpowder, three and a half of saltpetre, and three ounces of charcoal.

If the rockets be of five or six ounces weight, then to two pounds five ounces of gunpowder, add eight ounces of saltpetre, two ounces of sulphur, fix ounces of charcoal, and two ounces of iron filings.

If the rockets be from ten to twelve ounces, you may add to fixteen ounces of gunpowder, four ounces of saltpetre, three and a half of sulphur, and one of charcoal.

For rockets of a pound weight: to one pound of gunpowder add an ounce of sulphur, and three ounces of charcoal.

For rockets of from four to seven pounds: to thirty-one pounds of saltpetre, add four pounds and a half of sulphur, and ten of charcoal; and for those that are still larger, we may add to eight pounds of saltpetre, one pound four ounces of sulphur, and two pounds twelve ounces of charcoal. In all cases the ingredients are to be pounded separately, and finely sifted before they are used. Gunpowder, thus reduced from the corns in which it is manufactured, is called mahl-powder.

Matches.—The matches to let off rockets are thus made. Take linen, hemp, or cotton thread, and double it eight or ten times, if intended for large rockets, or only four or five times, if to be employed for flares. When the match is thus made, dip it in pure water, and being soaked, it is to be squeezed as dry as possible. Mix some gunpowder with a little water, so as to reduce it to a kind of paste, and immerse the match in it, turning and twisting it till it has imbibed a sufficient quantity of gunpowder; then sprinkle it over with dry powder, and when it is dry, it is fit for use.

In answer to the inquiry what causes rockets to ascend in the air, we may observe, that it is nearly the same as that which produces a recoil in fire-arms. Thus, when powder is inflamed in the chamber of a musket or cannon, it exerts its power against the breach of the piece, and against the bullet or wadding. But, the resistance opposed by the bullet being much less than that opposed by the mass of the barrel or cannon, the bullet is forced out with great velocity. The cause of the ascent of a rocket is nearly the same. At the moment when the powder begins to inflame, its expansion produces a torrent of elastic fluid, which acts in every direction, that is, against the air which opposes its escape from the cartridge, and against the upper part of the rocket; but the resistance of the air is more considerable than the weight of the rocket; therefore the rocket ascends by the exerts of the one of these forces over the other. This, however, would not be the case unless the rockets were pierced to a certain depth.

Brilliant Fire and Chinese Fire.—As iron-filings, when thrown into the fire, enflame and emit a strong light, this gave rise to the idea of rendering the fire of rockets much more brilliant, than when gunpowder, or the substances of which it is compounded, are alone employed. But the Chinese have long been in possession of a method of rendering this fire much more brilliant and variegated in its colours. It consists in the use of a very simple ingredient, namely, cast iron reduced to a powder more or less fine: the Chinese give it a name that answers to iron-fond in our language. It is prepared from old iron pots pulverized, till the grains are not larger than radish seed. Theh, however, are passed through sieves of different degrees of fineness; those that pass through the cloest sieve, are called sand of the first order;
order; those which pass through the next sieve in size, sand of the second order, and so on. This sand, when it inflames, emits an exceedingly vivid light, forming almost instantaneous luminous flowers and stars of various apparent magnitudes. It should be observed that rockets, into the composition of which iron-filings and iron-fand enter, cannot be long preferred, owing to their readiness in attracting the moisture which the saltpetre gives out. The following tables exhibit the proportions of the different ingredients for rockets of this kind of from 12 to 33 lbs.

When these materials have been accurately weighed, the saltpetre and charcoal must be three times sifted through a hair sieve, in order to their being well mixed; the iron sand is then to be moistened with brandy to make the sulphur adhere, and then they are to be thoroughly incorporated.

The upper part of rockets is generally furnished with some composition, which takes fire when it has reached to its greatest height, emits a considerable blaze, or produces a loud report and whizzing noise. Of this kind are salpétres, maroons, stars, flowers of fire, &c. To make room for an artefact of this kind, the rocket is crowned with what is called a pot, which is larger than the rocket. (See fig. 3.) The following is the method of making this pot, and connecting it with the body of the rocket.

The mould for forming the pot, though of one piece, must consist of two cylindrical parts of different diameters. That on which the pot is rolled up must be three diameters of the rocket in length, and its diameter must be three fourths that of the rocket; the length of the other ought to be equal to two of these diameters, and its diameter to thirds that of the rocket. Having rolled the thick paper intended for making the pot, twice round the cylinder, a portion of it must be pinched in that part of the cylinder which has the least diameter: this part must be pared in such a manner, as to leave only what is necessary for making the pot fall to the top of the rocket, and the figure must be covered with paper.

To charge such a pot, attached to a rocket. Having pierced three or four holes in the double paper which covers the cavity of the rocket, pour over it a small quantity of the composition with which the rocket is filled, and by shaking it, make a part enter these holes; then arrange, in the pot, the composition with which it is to be charged, taking care not to introduce into it a quantity heavier than the body of the rocket. The whole must be secured by means of a few small balls of paper, to keep every thing in its place, and the pot must be covered with paper cemented to its edges: if a pointed summit be added to it, the rocket is fit for use.

**Serpents.**—These are small flying rockets, without rods, which, instead of rising in a perpendicular direction, mount obliquely, and descend in a zigzag form, without ascending to a great height. The composition of these is nearly the same as that of rockets, and the construction is as follows. The length, A C, (fig. 4.) of the cartridge is about four inches; it must be rolled on a stick somewhat larger than a goose-quill, and after being choked at one of its ends, it is filled beyond the middle, as to B, with the composition; then it is to be pinched so as to leave a small aperture. The remainder, B C, must be filled with grained powder, which will occasion a report when it bursts. Lastly, choke the cartridge entirely towards the extremity C; and at the other extremity, A, place a train of moist powder, to which, if fire be applied, it will be communicated to the composition in the part A B, and cause the whole to rise in the air. The serpent, as it falls, will make several turns in a zigzag direction, till the fire is communicated to the grained powder in the part B C; on which the serpent will burst with a loud report before it falls to the ground. The serpent cartridges are generally made of playing cards. These are rolled round a rod of iron or hard wood, and to confine the card a piece of strong paper is cemented over it. Larger serpents may be made by cementing two playing cards together, first moistened with water.

**Maroons.**—Small cubical boxes, filled with a composition proper for making them burst. To construct these, cut a piece of paletteboard according to the method taught in geometry to form the cube (see fig. 5.); join these squares at the edges, leaving one only to be cemented, and fill the cavity of the cube with grained powder; then cement strong paper in various directions over the body, and wrap round it two rows of packthread, dipped in strong glue; then make a hole in one of the corners, and introduce into it a match. If the maroons are to be luminous, that is, which are to give out a brilliant light before they burst, they must be covered with a paste, the composition of which will be noticed below under Stars, and then rolled in meal powder to serve as a match or communication.

Maroons differ from maroons only in form. The cartridges of the latter are round, and must be only four times their exterior diameter in length. They are choked at one end in the same manner as a rocket, and a pellet of paper is driven into the aperture which has been left, in order to fill it up. They are then charged with corn powder, above which is placed a ball of paper, gently pressed down to prevent the powder from being bruised; the second end of the maroon being now choked, the edges are to be pared on both sides, and the whole is covered with several turns of packthread, dipped in strong glue, and then left to dry.

**Stars.**—Small globes which emit a most brilliant light, so that, momentarily, they may be compared to the light of the stars in the heavens. These balls are not larger than a mullet-ball, and when put into rockets they must be wrapped up in tow, prepared for the purpose. The composition of these stars is as follows: To a pound of fine mealed gunpowder, add four pounds of saltpetre, and two pounds of sulphur. When these ingredients are thoroughly mixed, take a piece as large as a small nutmeg, and having wrapped
wrapped it in a linen rag, or paper, form it into a ball; then tie it closely round with packthread, and pierce a hole through the middle of it, large enough to receive a piece of prepared tow, which is to serve as a match. This, when lighted, will exhibit a most beautiful appearance; because the fire as it issuing from the two ends of the hole in the middle will extend to a great distance, and will make it seem very much larger than it actually is.

There are other compositions for flars; viz. with three ounces of faltpetre, mix one ounce of sulphur, and two drachms of mealed gunpowder; or with eight ounces of mealed powder, mix four ounces of sulphur, and the same quantity of faltpetre. When these materials have been well sifted, and sprinkled over with brandy, in which a small quantity of gum has been dissolved, the star is made in the following manner. Take a rocket mould eight or nine lines in diameter, and introduce into it a nipple, the piercer of which is of an uniform fize throughout, and equal in length to the height of the mould. Put into this mould a cartridge, and by means of a pierced rod load it with one of the preceding compositions; when loaded, take it from the mould, without removing the nipple, the piercer of which passes through the composition, and then cut the cartridge quite round into pieces of the thickness of three or four lines. The cartridge being thus cut, draw out the piercer gently, and the pieces which resemble the men employed for playing at drafts, pierced through the middle, will be flars, which must be filed on a match thread, that may be covered with tow. To give more brilliancy to flars of this kind, a cartridge thicker than that already described, and thinner than that of a flying rocket of the same fize, may be employed; but before it is cut in pieces, five or six holes must be pierced in the circumference of each piece to be cut. When the cartridge is cut, and the pieces have been filed, cement over the composition small bits of a card, each having a hole in the middle, so that these holes may correspond to the place where the composition is pierced.

Étoiles à Pot are made in the same way nearly as fuc-divions already described, only that it will not be necessary to cover them with packthread; it will be sufficient if they are pierced at one end, in order that flars may be fastened to them, constructed according to the first method, the composition of which is dry; for if the composition be in the form of paste, there will be no need to tie it. In this case, a little more of the paper must be left hollow at the end of the fucivion which has been pierced for the purpose of introducing the composition, and to place in the vacancy, towards the neck of the fucivion, some grained powder, which will communicate fire to the fucivion when the composition is consumed.

Shower of Fire.—To form this sort of fire-work, mould small paper cartridges on an iron-rod two lines and a half in diameter, and make them two inches and a half in length. They must not be cloaked, it being sufficient to twist the end of the cartridge, and having put the rod into it to beat it, in order to make it assume its proper form. When the cartridges are filled, which is done by immersing them in the composition, fold down the other end, and then apply a match. This will fill the surrounding air with an undulating fire. The following compositions are given as proper for flars of this kind.

Chinée Fire.—Mealed gunpowder one pound, sulphur two ounces, iron-fand of the firft order five ounces.

Ancient Fire.—Mealed gunpowder one pound, charcoal two ounces.

Brilliant Fire.—Mealed gunpowder one pound, iron-flings four ounces. The firft of these compositions is thought to be the most beautiful.

Sparks differ from flars only in their fize and duration, for they are made smaller than flars, and are confumed sooner. They are thus prepared. Having put into an earthen vessel an ounce of mealed gunpowder, two ounces of pulverized faltpetre, one ounce of liquid faltpetre, and four ounces of camphor reduced to powder, pour over this mixture some gum-water, or brandy in which gum has been dissolved, till the composition becomes of the confistence of thick fop. Then take fome lint which has been soaked in brandy, or in vinegar, or even in a folution of faltpetre, and being dried and unravelled, throw into the mixture such a quantity of it as is sufficient to absorb it entirely, taking care to flir it well. This composition may be formed into small balls about the fize of a pea, and being dried in the shade, and sprinkled with mealed powder, they will readily catch fire.

Sparks may be made by the following method: Take saw-dufl of fir, poplar, &c. and boil it in water in which faltpetre has been dissolved. When the water has boiled some time, it is to be poured off, that the saw-dufl may remain in the vessel. When nearly dry, it is to be spread out on a table, and sprinkled with sulphur sifted through a very fine sieve, to which may be added a little mealed powder.

Golden Rain.—Some flying rockets, which, as they fall, make small undulations in the air like frizzled hair, are called by the French writers fues cheveux, and by us bearded rockets; they finish with a kind of shower of fire, which is called golden rain, and they are constructed in the following manner. Fill the barrels of some goose-quills with the composition of flying rockets, and place upon the mouth of each a little moif gunpowder, both to keep in the composition, and to serve as a match. If a flying rocket be then loaded with these quills, they will produce at the end a beautiful shower of fire, which is denominated golden rain.

Coruntings, or Rockets that fly along a Rope.—A rocket may be made to run along an extended rope, by affixing to the rocket an empty cartridge, and introducing into it the rope which is to carry it along. Place the head of the rocket towards that fide to which you intend it to move; if it be then set fire to, it will run along the rope without flipping till the matter it contains is entirely exhausted. If the rocket is to move in a retrograde direction, fill one half of it with the composition, and cover it with a small round piece of wood, to serve as a partition between it, and that put into the other half; then make a hole below this partition, so as to correspond with a small canal filled with braided powder, and terminating at the other end of the rocket. By these means the fire, when it ceases in the first half of the rocket, will be communicated through the hole into the small canal, which will convey it to the other end, and this end being then kindled, the rocket will move backwards, and return to the place from whence it set out.

Two rockets of equal fize, bound together by strong packthread, and so arranged that the head of the one shall be opposite to the neck of the other, in order that when the fire has consumed the composition in the one, it may be communicated to that in the other, and oblige both of them to move in a retrograde direction, may likewise be adjusted to the rope by means of a piece of hollow reed. Rockets of this kind are generally employed for letting fire to various other pieces when large fire-works are exhibited; and to render
render them more striking, they are made in the form of different animals, such as serpents, dragons, &c.

To give a rocket a kind of rotatory motion around the rope along which it advances, it will be sufficient to tie to it another rocket, placed in a transversal direction. But if the aperture of the latter, instead of being at the bottom, ought to be in the side, near one of the ends. If both rockets be fired at the same time, the latter will make the other revolve around the rope, while it advances along it.

Rockets which burn in the Water.—In these there must be a considerable variation in the construction of the models, and also in the materials of which they are composed. The mould may be eight or nine inches in length, and an inch in diameter: the former, on which the cartridge is rolled up, may be nine lines in thickness. The composition should consist of three materials mixed together, viz. three ounces of mealed powder, one pound of saltpetre, and eight ounces of sulphur. If the rocket is to appear on the water with a beautiful tail, the composition must consist of eight ounces of gunpowder, one pound of saltpetre, eight ounces of pounded and finely fitted sulphur, and two ounces of charcoal. When the composition has been prepared according to these proportions, and the rocket has been filled in the manner above described, apply a faculton to the end of it, and having covered the rocket with wax, pitch, &c. attach to it a small rod of white willow, about two feet in length, that the rocket may conveniently float. If it be required that these rockets should plunge down, and again rise up, a certain quantity of mealed gunpowder, without any mixture, must be introduced into them, at certain distances.

A rocket which is fired in the water, and, after burning there half the time of its duration, mounts into the air with great velocity, may be thus constructed. Take a flying rocket, furnished with a rod, and by means of a little glue attach it to a water-rocket, but only at the middle, A (fig. 6.) in such a manner that the latter shall have its neck uppermost, and the other its neck downward. Adjut to their extremity, B, a small tube, to communicate the fire from the one to the other, and cover both with a coating of pitch, wax, &c. that they may not be damaged by the water. Then attach to the flying rocket, after it has been thus cemented to the aquatic one, a rod, as D, and from F suspend a piece of packthread, to support a musket bullet E, made falt to the rod by means of a needle or piece of iron wire. When these arrangements have been made, fire to the part C after the rocket is in the water; and when the composition is consumed to B, the fire will be communicated through the small tube to the other rocket; the latter will then rise and leave the other, which will not be able to follow it, on account of the weight adhering to it.

Globes and Fire-Balls are made in different forms, viz. spherical, spheroidal, or cylindrical. The spherical are made in the following manner. Construct a hollow wooden globe of any size at pleasure, and very round both within and without, so that its thickness, A C or B D, (fig. 7.) may be about the ninth part of its diameter A B, and having an aperture, L M or O N, equal to the thicknesses A C or B D, that is, to the ninth part of the diameter A B. It is through this aperture, that fire is communicated to the globe, when it has been filled with the proper composition, through the lower aperture I K. A petard of metal, loaded with good grained powder, is to be introduced also through the lower aperture, and to be placed horizontally. The aperture I K, which is nearly equal to the thickness, E F or G H, of the cylinder E F G H, is to be closed by means of a wooden tompon dipped in warm pitch; and melt over it such a quantity of lead that its weight may cause the globe to sink in water, till nothing remain above it but the part G H; which will be the cale if the weight of the lead, with that of the globe and the composition, be equal to the weight of an equal volume of water. If the globe be then placed in the water, the lead, by its gravity, will keep the aperture, I K, directly downwards, and the cylinder, E F G H, in a perpendicular direction, to which fire must have been previously applied. The composition with which the globe must be filled, is as follows: to a pound of corned powder, add thirty-two pounds of saltpetre, eight pounds of sulphur, one third of scraped ivory, and eight pounds of sawdust previously boiled in a solution of saltpetre, and dried in the open air.

Globes which leap or roll on the Ground.—Having constructed a wooden globe, A, (fig. 8.) with a cylinder C, similar to the one just described, and having loaded it with the same composition, introduce into it four or even more petards, loaded with good corned powder to their orifices, as is shewn at A B, which must be well fopped with paper or tow. If a globe, prepared in this manner, be fired by means of a match at C, it will leap about as it burns, on a smooth horizontal plane, according as the petards are set on fire. The petards may be affixed to the exterior surface of the globe, as is seen in the figure, which they will cause to roll and leap as they catch fire.

Aerial Globes, called Bombs.—These globes are called aerials, because they are thrown into the air from a mortar. Though they are of wood, and have a suitable thickness, yet they are liable to burst unless the charge be nicely proportioned to their strength. The usual quantity is an ounce of powder for a globe of four pounds weight; two ounces for one of eight, and so on. As the chamber of the mortar may be too large to contain the exact quantity of powder sufficient for the fire-ball, which ought to be placed immediately above the powder, in order that it may be expelled and set on fire at the same time, another mortar may be constructed of wood, or of palse-board with a wooden bottom, which may be put into the large iron mortar, to be loaded with a quantity of powder proportioned to the weight of the globe. This small mortar must be of light wood, or of paper pasted together, and rolled up in the form of a cylinder, but the bottom must be of wood. The chamber for the powder must be pierced obliquely, so that the aperture may correspond to the aperture of the metal mortar, then the fire applied to the latter may be communicated to the powder which is at the bottom of the chamber, immediately below the globe.

The globe must be filled with several pieces of reed or cane, or common reed equal in length to the interior height of the globe, and charged with a slow composition, made of three ounces of mealed gunpowder, an ounce of sulphur moistened with a small quantity of petroleum oil, and two ounces of charcoal; and in order that these reeds or canes may catch fire the sooner, and with more facility, they must be charged at the lower ends, which rest on the bottom of the globe, with pulverized gunpowder moistened with petroleum oil or brandy, and then dried. The bottom of the globe ought to be covered with gunpowder, partly mealed and partly corned, which, when set on fire, will communicate the fire to the lower part of the reed. In stead of reeds, the globe may be charged with running rockets, or paper petards, and a quantity of fiery flars or sparkes mixed with mealed powder, placed above these petards, which must be choked at unequal heights, that they may produce their effect at different times.

Jets of Fire are a sort of fixed rockets, the effect of which is to throw up into the air jets of fire similar to jets of water. N They
They serve also to represent cascades, for if a series of such rockets be placed horizontally on the same line, it may be easily seen that the fire which they emit will resemble a fleet of water. When arranged in a circular form, like the radii of a circle, they form what is called a fixed fun. To form jets of this kind, the cartridge for brilliant fires must, in thickness, be equal to a fourth part of the diameter, and for Chinese fire only a sixth part. The cartridge is loaded on a nipple, having a point equal in length to the same diameter, and in thickness to a fourth part of it; but as it generally happens that the mouth of the jet becomes larger than is necessary for the effect of the fire, the cartridge must be filled equal to a fourth part of the diameter with clay, which must be rammed down. This will make the jet ascend much higher. When the charge is completed with the proper composition, the cartridge must be closed with a tomption of wood, above which it must be chocked. Jets intended for representing fleets of fire ought not to be chocked. They must be placed in a horizontal position, or inclined a little downwards. The following are the principal compositions for jets of fire.

1. For Jets of half an Inch or less in Diameter.—Chinese fire: Saltpetre and mealed powder 1 lb. each; fulphur 8 ounces; charcoal 2 ounces. White fire: Saltpetre 1 lb.; mealed powder 8 ounces; fulphur 3 ounces; charcoal 2 ounces; iron-land of the first order 8 ounces.

2. For Jets of an Inch or less in Diameter.—Brilliant fire: Mealed powder 1 lb., iron-flings 5 ounces. White fire: Saltpetre and mealed powder 1 lb. each; fulphur 8 ounces; charcoal 2 ounces. Chinese fire: Saltpetre 16 ounces; fulphur 5 ounces; charcoal 5 ounces; iron-land of the third order 12 ounces.

3. For Jets of 15 or 18 Lines in Diameter.—Chinese fire: Saltpetre 16 ounces; fulphur 7 ounces; charcoal 5 ounces; of the several different kinds of iron-land mixed 12 ounces.

Fires of different Colours.—For white fire the gunpowder must be mixed with iron or rather fleel-flings; for red fire, iron-land of the first order must be employed in the same way. Camphor mixed with the usual composition is said to make the flame appear of a pale white colour. Rainplings of ivory give a clear flame of a silver colour.

Page for representing Animals, &c. in Fire.—Take sulphur reduced to a very fine powder, and having formed it into a paste with starch, cover it with the figure of the thing to be represented, having first coated it with clay to prevent it from being burnt. After the figure is covered with the paste, it must be sprinkled, while moist, with gunpowder; and when the whole is perfectly dry, arrange about it several small matches, that the fire may be speedily communicated to it on all sides. In this way all sorts of garlands, felloons, and other ornaments, may be imitated by fire of different colours.

Suns, fixed and moveable.—For fixed funs, let a round piece of wood be cut, into the circumference of which are to be screwed twelve or fifteen pieces in the form of radii, to which are to be attached jets of fire, of the composition described above; so that they may appear as radii tending to the same centre, the mouth of the jet being towards the circumference. Apply a match in such a manner that the fire communicated at the centre, may be conveyed at the same time to the mouth of each of the jets, by which means, each throwing out its fire, there will be produced the appearance of a radiating fun. If a gun be fired with the wheel in a position perpendicular to the horizon. The rockets or jets may be so arranged as to cros each other in an angular manner, in which case, instead of a fun, you will have a star, or a cros. Some of these funs are made also with several rows of jets, which are called glories. For revolving funs, provide a wooden wheel, and attach to the circumference fire-jets placed in the direction of the circumference; they must not be chocked at the bottom, and ought to be arranged in such a manner, that the mouth of the one shall be near the bottom of the other, so that when the fire of the one is ended, it may immediately proceed to another. When the fire is applied to one of these jets, the recoil of the rocket will make the wheel turn round, and if is too large and ponderous. For this reason, when these funs are of a considerable size, that is, when they consist of perhaps twenty rockets, fire must be communicated at the same time to the first, the sixth, eleventh, and sixteenth, from which it will proceed to the second, the seventh, the twelfth, the seventeenth, and so on. These four rockets will make the wheel turn round with great rapidity. If two similar funs be placed one behind the other, and are made to turn in a contrary direction, they will produce a fine effect of crosset-fire.

Making, loading, and firing Pota des Brins.—These are made of paste-board, and must be rolled pretty thick; usually made three or four inches in diameter, and four diameters long, and pinched with a neck at one end, like common cafes. A number of these are placed on a plank thus: having fixed on a plank two rows of wooden pegs, cut in the bottom of the plank a groove the whole length under each row of pegs; then, through the centre of each peg, bore a hole down to the groove at bottom, and on every peg fix and glue a pot, whose mouth must fit tight on the peg; through all the holes run a quick-match, one end of which must go into the pot, and the other into the groove, which must have a match laid in it from end to end, and covered with paper, so that, when lighted at one end, it may discharge the whole almost instantaneously; in all the pots put about one ounce of meal and corn powder; then in some put flars, and others rains, fikes, perfents, crackers, &c; when they are all loaded, paste paper over their mouths. Two or three hundred of these pots being fired together, make a very pretty show, by affording so great a variety of fires. Fig. 9 is a range of pots des brins, with the leader A, by which they are fired.

Caduceus Rockets, in rising, form two spiral lines, or double worm, by reason of being placed obliquely, one opposite the other; and their counterpoise is in their centre, which causes them to rise in a vertical direction. Rockets for this purpose must have their ends chocked close, without either head or bounce, for a weight at top would be a great obstruction to their mounting; though they have been known sometimes to be bounced, but then they did not rise so high as those that were not; nor do any caduceus rockets ascend so high as single, because of their comet-like motion, and likewise the resistence of air, which is much greater than two rockets of the same size would meet with, if fired singly. By fig. 10 we see the method of fixing these rockets; the sticks for this purpose must have all their sides equal, which sides should be equal to the breadth of a stick proper for a fly-rocket of the same weight as those we intend to use, and to taper downwards as usual, long enough to balance them, one length of a rocket, from the crofs stick, which must be placed from the large stick, fix diameters of one of the rockets, and its length seven diameters; so that each rocket, when tied on, may form with the large stick an angle of sixty degrees. In laying on the rockets, place their heads on the opposite sides of the crofs stick, and their ends on the opposite sides of the long stick; then carry a leader from the mouth of one into that of the other. When these rockets are to be fired, suspend them between two hooks or nails,
PYROTECHNY.

nails, then burn the leader through the middle, and both will take fire at the same time. Rockets of one pound are a good size for this use.

Illuminated Spiral Wheel.—First have a circular horizontal wheel, made two feet in diameter, with a hole quite through the nave; then take three thin pieces of deal, three feet long each, and three quarters of an inch broad each: one end of each of these pieces nail to the fell of the wheel, at an equal distance from one another, and the other end nail to a block with a hole in its bottom, which must be perpendicular with that in the block of the wheel, but not so large. The wheel being thus made, take a hoop planed down very thin and flat; then nail one end of it to the fell of the wheel, and wind it round the three sticks in a spiral line, from the wheel to the block at top: on the top of this block fix a cafe of Chinese fire; on the wheel you may place any number of cafes, which must incline downwards, and burn two at a time. If the wheel should consist of ten cafes, you may let the illuminations and Chinese fire begin with the second cafes. The spindle for this wheel must be a little longer than the cone, and made very smooth at top, on which the upper end of the wheel to rest. See fig. 11.

Fromant Wheels.—First take a nave, made nine inches long, and three in diameter; near the bottom of this nave fix eight spokes, with a hole in the end of each, large enough to receive a two or four-ounce cafe: each of these spokes may be fourteen inches long from the block. Near the top of this block fix eight more of the same spokes, exactly over the others, but not so long by two inches. As this wheel is to run horizontally, all the cafes in the spokes at top must play obliquely upwards, and all of them in the spokes at bottom obliquely downwards. This being done, take a small horizontal wheel, made with eight spokes, each five inches long from the block; on the top of this wheel place a cafe of brilliant fire: all the cafes on this wheel must play in an oblique direction downwards, and burn two at a time, and those on the large wheel four at a time; that is, two of those in the top set of spokes, and two of them in the bottom set of spokes. The four first cafes on the large wheel, and the two first on the small, must be fired at the same time, and the brilliant fire at top, at the beginning of the last cafes. The cafes of the wheels may be filled with a grey charge. When these wheels are completed, you must have a strong iron spindle, made four feet fixed inches long, and fixed perpendicular on the top of a stand: on this put the large wheel, whose nave must have a hole quite through, from the bottom to the top. This hole must be large enough to turn easy round the bottom of the spindle, at which place there must be a shoulder, to keep the wheel from touching the stand: at the top of the spindle put the small wheel, and join it to a large one with a leader, in order to fire them both together.

Illuminated Globes, with horizontal Wheels.—The hoops for these globes may be made of wood, tin, or iron wire, about two feet in diameter. For a single globe take two hoops, and tie them together, one within the other, at right angles; then have a horizontal wheel made, whose diameter must be a little wider than the globe, and its nave fixed inches long, on the top of which the globe is fixed, so as to stand three or four inches from the wheel: on this wheel you may put any number of cafes, filled with what charge you like; but let two of them burn at a time: they may be placed horizontally, or to incline downwards, just as you choose. Now, when the wheel is clothed, fix on the hoops as many illuminations as will stand within two inches and a half of each other: these you fasten on the hoops with small iron binding wire; and when they are all on, put on your pipes of communication, which must be so managed as to light them all with the second or third cafe on the wheel. The spindle on which the globe is to run must go through the block of the wheel, up to the inside of the top of the globe, where must be fixed a bit of brass or iron, with a hole in it, to receive the point of the spindle, on which the whole weight of the wheel is to bear, as in fig. 12, which represents a globe on its spindle. By this method may be made a crown, which is done by having the hoops bent in the form of a crown. Sometimes globes and crowns are ordered so as to stand still, and the wheel only to turn round; but when you would have the globe or crown to stand still, and the wheel to run by itself, the block of the wheel must not be so long, nor the spindle any longer, than to just raise the globe a little above the wheel, and the wheel cafes and illumination must begin together.

Dodecahedron, so called because it nearly represents a twelve-sided figure, and is made thus. First take a ball, turned out of some hard wood, fourteen inches in diameter: when done, divide its surface into fourteen equal parts, from which bore holes an inch and a half in diameter perpendicular to the centre, so that they may all meet in the middle: then let there be turned in the inside of each hole a female screw; and to all the holes, but one, must be made a round spoke, five feet long, with four inches of the screw at one end, to fit the holes; then in the screw end of all the spokes bore a hole, five inches up, which must be bored planting, so as to come out at one side, a little above the screw; from which cut a small groove along the spoke, within six inches of the other end, where you make another hole through to the other side of the spoke: in this end fix a spindle, on which put a small wheel, of three or four sides, each side fixed or seven inches long: these sides must have grooves cut in them, large enough to receive a two or four-ounce cafe: when these wheels are clothed, put them on the spindles, and at the end of each spindle put a nut, to keep the wheel from falling off: the wheels being thus fixed, carry a pipe from the mouth of the first cafe on each wheel, through the hole in the side of the spoke, and from thence along the groove, and through the other hole, so as to hang out at the screw end about an inch. The spokes being all prepared in this manner, you must have a paper, on which you intend to fire the work, with an iron screw in the top of it, to fit one of the holes in the ball: on this screw fix the ball; then in the top hole of the ball put a little meal powder, and some loose quick-match; then screw in all the spokes, and in one side of the ball bore a hole, in which put a leader, and secure it at the end; and your work will be ready to be fired. By this leader the powder and match in the centre are fired, which will light the match at the ends of the spokes all at once, whereby all the wheels will be lighted at once. There may be an addition to this piece, by fixing a small globe on each wheel, or one on the top wheel only. A grey charge will be proper for the wheel-cafes.

Tree of brilliant Fire, is represented by fig. 13, as it appears when burning. First, let A be upright piece of wood, four feet long, two inches broad, and one thick: at top of this piece, on the flat side, fix a hoop, fourteen inches in diameter; and round its edge and front place illuminations, and in the centre a five-pointed star; then at E, which is one foot and a half from the edge of the hoop, place two cafes of brilliant fire, one on each side: these cafes should be one foot long each: below these fix two more cafes of the same size, and at such a distance, that their mouths may almost meet them at top; then, close to the ends of these cafes, fix two more of the same cafes; they must stand parallel.
rallied to them at E. The cates being thus fixed, clothe them with leaders, so that they, with the illuminations and stars at top, may all take fire together.

Illuminated Trew-tree.—First have a tree made of wood, such as is shewn by fig. 14. The middle piece, or stem, on which the branches are fixed, must be eight feet six inches high: at the bottom of this piece draw a line, at right angles, two feet six inches long at each side; then from L., which is one foot six inches from the bottom, draw a line on each side to C and D; these lines will give the length of the two first branches. Then put on the two top branches parallel to them at bottom; let the length of each of these branches be one foot from the stem: from the ends of these two branches draw a line to C and D; then fix on five more branches at an equal distance from each other, and their length will be determined by the lines A C and E D. When the branches are fixed, place illuminating port-fires on the top of each, as many as you choose: behind the top of the stem fallen a gerbe, or white fountain, which must be fired at the beginning of the illuminations on the tree.

Illuminated Seven Stars.—Let fig. 15. be a smooth circular board, six feet diameter; out of the midst of it cut a circular piece twelve or fourteen inches diameter, and over the vacancy put white Perlian silk, on which paint a moon’s face; then let I, I, I, &c. be flares each four or five inches in diameter, cut out with five points, and covered with oiled silk: on the front of the large circular board draw a seven pointed star, as large as the circle will allow; then on the lines which form this star bore holes, wherein fix pointed flars. When this piece is to be fired, it must be fixd upon the front of a post, on a spindle, with a wheel of brilliant fire behind the face of the moon; so that while the wheel burns, the moon and flars will appear transparent, and when the wheel has burnt out, they will disappear, and the large star in front, which is formed of flars, will begin, being lighted by a pipe of communication from the last cafe of the vertical wheel, behind the moon: this pipe must be managed in the same manner as those in regulated pieces.

Pin Wheels.—First roll some paper pipes, about fourteen inches long each; these pipes must not be made thick of paper, two or three rounds of elephant paper being sufficient. When your pipes are thoroughly dried, you must have made a tin tube, twelve inches long, to fit easily into the pipes: at one end of this tube fix a small conical cup, which done is called a funnel; then bend one end of one of the pipes, and put the funnel in at the other, as far as it will reach, and fill the cup with composition; then draw out the funnel by a little at a time, shaking it up and down, and it will fill the pipe as it comes out. Having filled some pipes, and made some small blocks, about an inch in diameter, and half an inch thick; round one of these blocks wind and paste a pipe, and to the end of this pipe join another; which must be done by twisting the end of one pipe to a point, and putting it into the end of the other, with a little paste; in this manner join four or five pipes, winding them one upon the other, so as to form a spiral line. Having wound your pipes, paste two slips of paper across them, to hold them together; besides these slips of paper the pipes must be paled together.

There is another method of making these wheels, called the French, which is, by winding on the pipe without paste, and flocking them together with sealing wax, at every half-turn; so that, when they are fired, the end will fall loose every time the fire paves the wax; by which means the circle of fire will be considerably increased. The forners for these pipes are made from one-half to four-fourteenths of an inch diameter, and the composition for them as follows: meal powder eight ounces, salt petre two ounces, and sulphur one; among those ingredients may be mixed a little fillet-filings, or the dust of cast-iron; this composition should be very dry, and not made too fine, or it will stick in the funnel. These wheels may be fired on a large pin, and held in the hand with safety.

Placing Fire-works to be exhibited, with the Order of Firing. Nothing adds more to the appearance of fire-works, than the placing them properly; though the manner of placing them chiefly depends on the judgment of the maker. We shall give such rules here, as have been generally observed; for example, whether your works are to be fired on a building, or on flands. If they are a double set, place one wheel of a fort on each side of the building: and next to each of them, towards the centre, place a fixed piece, then wheels, and so on, leaving a sufficient distance between them, for the fire to play from one without burning the other. Having fixed some of your works thus in front, place the rest behind them, in the centre of their intervals; the largest piece, which is generally a regulated or transparent piece, must be placed in the centre of the building, and behind it a fun, which must always stand above all the other works: a little before the building, or flands, place your large gerbes; and at the back of the works, fix your maroon batteries, pots des aigrettes, pots des brins, pots des fau- cions, air-baloons, and flights of rockets: the rockets may be fixed behind, or any where else, so as not to be in the way of the works.

Single collections are fired on flands, which flands are made in the same manner as healdole flands, only the top part must be long or short occasionally: these flands may be fixed up very soon without much trouble. Having given sufficient instructions for placing of fire-works, we shall proceed with the manner of firing them.

Order of Firing.

1. Two signal rockets.
2. Six sky rockets.
3. Two honorary rockets.
4. Four caduceus.
5. Two vertical wheels illuminated.
6. Two spiral wheels illuminated.
7. Transparent flars.
8. A line rocket of five changes.
11. Air-balloons illuminated.
13. Regulating pieces of four mutations each.
15. Three large gerbes.
16. A flight of rockets.
17. Two balloon wheels.
18. Cascades of brilliant fire.
19. Twelve sky-rockets.
20. Two illuminated yew-trees.
22. Four tourbillons.
23. Two fruilloni wheels.
24. Illuminated globes with horizontal wheels.
25. One pot des faucions.
26. Two plural wheels.
27. Maroon battery.
28. Two chandlers illuminated.
29. Range of pots des brins.
30. Twelve sky-rockets.
31. Two yew-trees of fire.
32. Neil
32. Neat of serpents.
33. Two double cones illuminated.
34. Regulating piece of seven mutations, viz.
   1. Vertical wheel illuminated.
   2. Golden glory.
   3. Octagon vertical wheel.
   4. Porcupine's quills.
   5. Cross fires.
   7. Six vertical wheels.
35. Brilliant fun.
36. Large flight of rockets.

When water-works are to be exhibited, divide them into several sets, and fire one set after every fifth or sixth change of hand and air-works. Observe this rule in firing a double set of works; always to begin with sky-rockets, then two moveable pieces, then two fixed pieces, and so on; ending with a large flight of rockets, or a maroon battery; if a single collection, fire a fixed piece after every wheel or two, and now and then some air and water-works. Jones's Fireworks, liv. 1776.

PYROTECHNICAL SPONGE. See SPONGE.

PYROTICS, πυροτικ ος, formed from πυρ, fire, in Medicine, caustics, or remedies, either actually or potentially hot; and which, accordingly, will burn the flesh, and raise an eschar.

PYROUET. See PIROUETTE.

PYROXENE, in Mineralogy. See Augite and Lava.

According to Hauy, the mineral called augite by Werner is the black or greenish-black variety of pyroxene found in volcanic countries and in basalt. The primitive form of the crystals of pyroxene is an oblique rhombohedral prism.

The greenish-transparent pyroxene, with the forms of the crystals distinctly marked, from the department of the Po, is the alabite of Bouvoisin. Journal des Mines, N° 115.

The greenish-grey, or whitish-grey variety, the primitive crystals of which are indistinct, from the same department, were called by Bouvoisin maffite. Both these varieties have been called by some mineralogists dioptide.

The greenish-grey and obscure green periclostahedral variety of pyroxene, is the folialte of Werner, called also malacolithe by Haüy. The mineral called coccipite, discovered by Dandridge at the iron mines of Sudermannland and Nierke, in Sweden, and Arendahl in Norway, is also brought under the species pyroxene by Haüy. Tableau Comparatif.

By reducing many varieties of minerals under one species, Hauy may be considered as having rendered an additional service to mineralogy, already too much loaded with pedantic or unmeaning terms; but the term pyroxene itself may be justly objected to, as being founded not on any distinct character, but on the hypothetical assumption that these crystals are foreign to the igneous products in which they are imbedded, an assumption for which there does not appear sufficient proof. The constituent parts of pyroxene, its specific gravity and hardness, to nearly agree with those of basaltic hornblende, that these substances ought perhaps to be classed as varieties of the same species, without regarding the small difference of their crystalline forms. See Hornblende.

PYROXENE en Roches, or Rock Pyroxene. In the Journal des Mines, Nov. 1812, a description is given of entire rocks composed of pyroxene, discovered by J. Charpentier in the Pyrenees. The fusibility is homogenous, of a texture commonly granularly lamellar, which in some pieces becomes floaty. Its most common colour is green of various shades, from the olive-green to an emerald green, sometimes cloudy but often clear. From a greenish-grey it passes to a reddish-brown and ochre yellow. It is amorphous. The

lullure is iplephant. Its fracture is lamellar, and has a two-fold cleavage equally perfect, crossing at an angle of about 92°. In other directions the fracture is either imperfectly lamellar or euhedral. It scratches glass, and gives some spark with steel. It melts with great difficulty by the blowpipe, but with borax it easily forms a green glass.

M. Vogel has analysed this mineral, and discovered chrome in the green specimen. From the detailed description of this rock, it appears nearly allied to schistose, fiper, and ferpernite. It is frequently intimately combined with tale, in which it is not easy to distinguish it from ferpernite. Rock pyroxene is found in beds in the primitive limestone, that forms vast mountains superincumbent on granite, extending from the valley of Vicedello, in the department of Arriege, to St. Beat, in the valley of Garonne. The masses of rock pyroxene are of extraordinary size, extending in length 5000 toises. Its thickness is difficult to determine, but is supposed to exceed 300 toises. Charpentier is disposed to class rock pyroxene as an intermediate rock between hornblende and ferpernite, and subordinately to primitive limestone. It neither contains foreign beds nor mineral salts; and is less liable to decomposition when pure, than almost any other rock. When intermixed with tale it decomposes rapidly.

PYRRHA, in Ancient Geography, a town of the island of Lesbos, between the promontory Sigrium and the town of Erethus, according to Ptolemy. The town took its name from a strait between Asia Minor and the island of Lesbos, and gave it to a river in the same island.—Allo, a town of Macedonia, in Magnesia. Pliny.—Allo, a town of Asia Minor, in Lybia. Pliny.—Allo, a town of Asia Minor, in Ionia, situated at the entrance of the northern part of the Latnic gulf, E. N. E. of the town of Miletus, and S. S. E. of that of Myus. Strabo places it at 100 stadia from Heraclea.—Allo, a promontory of Thessaly, upon the coast of the Phthiothide. Strabo says, that before this promontory were two isles; one called Pyrrha, and the other Deucalon.—Allo, a town of Greece, in the Phocide. Pliny.—Allo, a town situated in the vicinity of the Palus-Maeotis; submerged according to the relation of Pliny.—Allo, a town of Asia Minor, in Caria.

PYRRHICHA, πυρριχετος, in Antiquity, a kind of exercise on horseback; or a feigned combat, for the exercise of the cavalry.

It was thus called from its inventor Pyrrhus, or Pyrrhus, in Cydoria, who first taught the Cretans to march in measure and cadence to battle, and to obverse the pace of the Pyrrhic foot. Others derive the name from Pyrrhus, son of Achilles, who instituted this exercise at the obsequies of his father. Arisotole says, that it was Achilles himself who invented it.

The Romans also called it ludus Trojanus, the Trojan game; and Aulus Gallius decursus. It is doubtless this exercise, that we see represented on medals, by two cavaliers in front, running with lances, and the word decursus in the exergum.

PYRRHICHIUS, πυρριχετος, in the Greek and Latin Poetry, a foot consisting of two syllables, both short; as demus.

Among the ancients this foot is also called periantus; by others hegemon.

PYRRHICUS, in Ancient Geography, a town of Lacoia, upon the stream of Scryaxis, S. of Hypus. Here were two temples, one of Diana Altraeia, and another of the Amazonian Apollo. The statues of these deities were of wood, and it is supposed they were placed here, by the Amazons themselves.

PYRRHO. See PYRRHIONIANs.
PYRHOCORAX, in Ornithology, a species of Corvus (which fee), the Alpine crow of Latham, and the Choucas des Alpes of Buffon. Also, the Monedula, Coracias of Aldrovand, &c., Cornish crows, red-legged crow of Pennant and Latham, and Corvus Gracula, which see.

PYRRHONIANS, Pyrrhoniens, or Pyrrhonists, a sect of ancient philosophers, so called from their founder Pyrrho, a Greek philosopher, born at Elea, in Peloponnesus, who in early life studied painting, but aspiring to philosophical pursuits he became a disciple of Anaxarchus, and accompanied him as far as India. In this journey he followed Alexander the Great; and hence we may know in what time he flourished. In India he converted with the Brachmans and Gymnosophists, imbibing from their doctrine whatever might seem favourable to his natural disposition towards doubting; a disposition which was cherished by his master, who had formerly been a disciple of a sceptical philosopher, Metrodorus of Chios. As he was involved in fresh uncertainty by every advance he made in the study of philosophy, he left the school of the Dogmatists, who professed to be poiffessed of certain knowledge, and established a new school, in which he taught, that every object of human inquiry is involved in uncertainty, so that it is impossible ever to arrive at the knowledge of truth.

The distinguishing character of this philosopher was, that he professed to doubt of every thing, maintaining that men only judge of truth and falsehood from appearances, which deceive. On this principle he kept himself in continual suspension of mind, never determining on any thing; to avoid the inconveniences of error and false judgments. He found in all things (says Bayle) reasons to affirm and to deny; and therefore he suspended his affections after he had well examined the arguments pro et con, and reduced all his conclusions to a non liquet, let the matter be farther enquired into. Hence it is (says he) that he fought truth as long as he lived, but he so contrived the matter, as never to grant that he had found it. Though he is not the inventor of that method of philosophizing, yet it goes by his name.

The art of disputing about every thing, without doing any thing else but suspending one’s judgment, is called Pyrrhonism, or Scepticism.

Some have said, that this philosopher acted upon his own principles, and carried his scepticism to an extreme so ridiculous, that his friends were obliged to accompany him wherever he went, that he might not be run over by carriages, or fall down precipices. These reports, however, are inconsistent with the respect that is paid to him by ancient writers, and with the general history of his life, and are charged, as calumnies, upon the Dogmatists, whom he opposed. A great part of his life was spent in solitude; and he always preferred a settled composure of countenance, undisturbed by fear, or joy, or grief. He endured bodily pain with great fortitude; and in the midst of dangers he manifested no signs of apprehension. As a disputant, he was celebrated for the subtility of his arguments, and the perspicacity of his language. So highly was Pyrrho esteemed by his countrymen, that they honored him with the office of chief priest, and from respect to him, passed a decree by which all philosophers were indulged with an exemption from public taxes. Of the poets, and particularly of Homer, he was a great admirer; and frequently repeated passages from his poems. He flourished about the 110th olympiad, and died about the 90th year of his age, probably in the 123d olympiad, B.C. 288. After his death, the Athenians honored his memory with a statue; and a monument, as Lucretius informs us, was erected to him in his own country. His scepticism may in a great measure be ascribed to his early acquaintance with the system of Democritus. Having learned from this philosopher to deny the real existence of all qualities in bodies, except those that are essential to primary atoms, and to refer every thing else to the perceptions of the mind produced by external objects, that is, to appearance and opinion, he concluded, that all knowledge depended upon the fallacious report of the senses, and consequently, that there can be no such thing as certainty. In this notion he was encouraged by the general spirit of the Eleatic school, in which he was educated, which was unfavourable to science. But his scepticism was more confirmed by the subtleties of the Dialectic school, in which he was instructed by Bryton, the son of Stilpo. Regarding mental tranquillity as the great end of all philosophy, and observing that nothing contributed so much to disturb it, as the dilemmas which agitated the schools of the Dogmatists, and also inferring from their endless disputes the uncertainty of the questions which they debated, he had recourse to the doctrine of universal uncertainty; and thus it happened in his cafe, as in that of many others, that controversy became the parent of scepticism.

Pyrrho had several disciples, but none who merit particular notice except Timon, the Phliasian, who lived to the age of 90 years, and flourished in the time of Ptolemy Philadelphus. The public succession of professors in the Pyrrhonian school terminated with Timon, and in Cicero’s time this school was extinct. The disciples of Timon chose to screen their scepticism under the authority of the Academy; and after some interval, the school itself was revived by Ptolemaeus, a Cyrenian, and continued at Alexandria by Enepodemus, a contemporary with Cicero: the latter wrote a treatise “On the Principles of the Pyrrhonian Philosophy,” the heads of which are preferred by Photius. From his time it was transmitted, through a series of preceptors little known, to Sextus Empiricus, who has given a summary of the sceptical doctrine; for an account of which, see Sceptics. As for Pyrrho and his followers, they rather endeavoured to demolish every other philosophical structure, than to erect one of their own. They affected nothing; but professed positions merely in the way of enunciation, without attempting to determine on which side, in any disputed question, the truth lay, or even presuming to affirm, that one proposition was more probable than another.

Thus, the Pyrrhonians, or Sceptics, are persons who, from the great number of things that are dark and obscure, and from the aversion they bear to popular credulity, maintain, that there is nothing certain in the world.

The truth is, Pyrrhonism has some foundation in nature: we do not judge of things from their real essences, but from their relations to ourselves. Most of our ideas we receive by means of our senses; but our senses are not given us to judge of the essences, but of the relations of things to themselves; i.e., how they may affect us as to do us good or harm.

Thus, o. e., our eyes do not give us the real magnitudes of objects, but their relative ones only.

The Academicians differed from the Pyrrhonians, in that they owned there were some things more like or more near akin to truth than others, which the Pyrrhonians peremptorily denied. On account of the similarity of the opinions of this sect and those of the Platonic school in the Middle and New Academy, it happened, that many of the real followers of Pyrrho chose to screen themselves from the reproach of universal scepticism, by calling themselves Academicians (which see); and hence the appellation of Pyrrhonists.
rhonists fell into disuse, whilst the doctrine of Pyrrho had many advocates. For the difference between them, see Sceptics.

Le Clerc observes, that the Pyrrhonians destroy itself; for if there be nothing certain, then must that dogma itself be precarious; and if no one thing be more probable, or liker to truth than another, why shall the principle of the Pyrrhonians be believed preferably to the opposite one? since itself is come at in the same way as our other knowledge. Brucker's Hist. of Philos. by Enfield, vol. i.

PYRRHUM, in Ancient Geography, a town of Pannonia, on the route from Petovio to Sicia, between Aquaviva and Dautona, according to the Istin. of Antonine.

PYRRHUS, in Biography, king of Epirus, one of the most distinguished warriors of the period in which he flourished, supposed to be descended from Pyrrhus, the son of Achilles, was the son of Eácides, who was expelled the kingdom by a revolt of his subjects. When Pyrrhus was only twelve years of age, he was placed on the throne of his ancestors by Glaucis, king of Illiria, who had protected him in his infancy. He reigned in peace till he was about seventeen years of age, when, being absent from his kingdom, his subjects feized his treasures, and conferred the crown upon his great uncle, Neoptolemus. Pyrrhus being possessed of no force to enable him to recover his authority, repaired to Demetrius Poliorcetes, the son of Antigonus, who had married his sister, and under that eminent commander he learned the art of war, in company with many officers and soldiers of Alexander the Great. At the battle of Ipsus, in the year B.C. 301, he greatly distinguished himself, and after his loss by Demetrius, he secured for him the Greek cities, with the care of which he had been entrusted. When a treaty of peace was concluded between Demetrius and Ptolemy Lagus, king of Egypt, Pyrrhus consented to be one of the hostages sent into that country for the performance of the conditions. In the Egyptian court he excited general admiration by his amiable and correct behaviour, and his dexterity in martial exercises; and he obtained from the king his daughter Antigone in marriage. The next step was to restore him to his throne, which was effected by an armament supplied by Ptolemy, with the aid of which he defeated Neoptolemus. That prince, however, being supported by his allies, Pyrrhus consented to allot him a share of his dominions; but such a partnership was not likely to be durable, and Neoptolemus, it was said, attempted to poison Pyrrhus, which gave the latter a pretence to order his death. He being settled on the throne of Epirus, began to execute those schemes of ambition, in which the remainder of his life was spent. A civil war raging between the two sons of Callander, in Macedonia, one of them, Alexandre, applied to Pyrrhus for assistance. He gladly took occasion of interfering in the affairs of that kingdom, and being put in possession of all its maritime towns, proceeded to conquer the reft for Alexander. A peace was made, by which Macedonia was divided between the two brothers, and Pyrrhus seems to have withdrawn his troops to his own country. Shortly after, Demetrius made himself master of the kingdom, and notwithstanding their former friendship, hostilities ensued between him and Pyrrhus, who harassed him by incursions into Thessaly. They mutually invaded each other's kingdoms; and in one instance, Pyrrhus gained so complete a victory over the principal general of his antagonist, and displayed so much courage, that he struck with admiration the Macedonians whom he had defeated, who deferted their own king, and chose Pyrrhus for their sovereign. This occurred in the year B.C. 287. He held this crown, however, a short time; for Lycaimachus, in the following year, entering the country with a powerful army, and remonstrating against the injustice of conferring the kingdom on a foreigner, in prejudice to him, a native and commander under Alexander the Great, the allegiance of the Macedonians seemed to Pyrrhus so little to be relied on, that he withdrew from the contest, and returned to Epirus. The Romans, engaged in a war with the Tarentines, looked for affility to Pyrrhus. This prince eagerly listened to the proposal, and communicated his determination to his prime minister Cynes, who, being more prudent than his master, endeavoured to dissuade him from it. The enterprise was, however, resolved on, and Cynes was sent with a body of troops to Tarentum, where he subverted the Roman influence, which was beginning to prevail, and obtained the command of the fleet for an Epirian officer. Pyrrhus followed, and having left his son Ptolemy regent of Epirus, landed in Italy, in the year 280 B.C., bringing with him an army of about 25,000 men, of whom 7000 were Macedonians, the veteran soldiers of Alexander the Great. He also brought a number of war elephants, which was the first time that these animals were seen in that character, in Italy. He was greatly endangered in his passage by a storm, which dispersed his fleet, and destroyed some of the ships that kept company with him. On his arrival at Tarentum, he began to correct the licentious manners of the inhabitants, and ensure them to military discipline. At length he marched out to meet the Roman consul Valerius Lavinius, who was waiting for him on the bank of the Siri, in Lucania. The engagement was extremely obstinate, and Pyrrhus, who exerted himself in a manner worthy of his high reputation, was in great personal danger. Victory, however, decided in his favour, and he took possession of the enemy's camp. In interring the dead he made no distinction between his own men and the soldiers of his antagonist, but bestowed due encomiums upon the bravery of his fallen foes. He followed up his victory, and had proceeded so far as to obtain a distant view of Rome. The advance of the other confiul obliged him to retire, and he finished his campaign by returning to Tarentum. Sensible that he had engaged in no easy task, he was delighted to receive an embassy from the Romans, which he imagined was to solicit peace, but it was only to negotiate an exchange of prisoners. In this embassy was included the virtuous Fabricius, whom he in vain attempted to gain to his interest by large offers. He then attempted to make a treaty, and sent his minister, Cynes, to Rome for that purpose, but was unsuccessful.

In the next campaign, two consuls with their armies marched against the king of Epirus; the battle was extremely bloody, and the victory so indecisive, that both parties claimed it: one of the consuls was killed, and Pyrrhus was severely wounded; and such was the loss of men, that to one who congratulated him as having been the conqueror, he frankly replied, "such another victory will ruin me." Both the consuls of the next year, one of whom was Fabricius, were employed to oppose Pyrrhus, who had received fresh reinforcements from Epirus. They advanced to the Tarentine territory, where, while they were seeking an opportunity to engage, an offer was made them by the physician of Pyrrhus, to take him off by poison. Detect-
ing the treachery, they informed the king of his danger, which so affected him, that he immediately liberated all his Roman prisoners without a ransom. He now sent Cynoas to Rome to renew the attempt at negotiation, but was again unsuccessful. During the state of perplexity which a refusal had thrown him into, he was invited by the Syracusans and others to lend his aid against the Carthaginians, who had established themselves in Sicily. He accordingly seized the pretext for changing the field of action, and embarked the whole army for that island, leaving only a strong garrison in Tarentum. On his arrival he was received with general acclamations, and all the public force of Syracuse was put into his hands. He was soon so completely successful, that the Carthaginians sent deputies to Pyrrhus to treat for peace, but he refused to listen to any other condition, than that of their entire evacuating the island. In confidence of success, he caused a fan to be proclaimed king of Sicily, and then made preparations to cross over into Africa, and carry the war into the Carthaginian territories. These projects were not agreeable to the Sicilians, who became alienated from him, and whom he treated not as friends, but as a conquered people. After this he quitted Sicily, and embarked for Italy; in his voyage he was encountered at sea by a Carthaginian fleet, which sunk a number of his vessels and dispersed the rest, so that he reached a port in Italy with no more than twelve sail. Six years did he confine in Italy and Sicily, inflicting and suffering all the evils of war, and finally exhausted in force, and with diminished reputation. His retreat was not subdued, and for the purpose of employing and paying his soldiers, in conjunction with a body of Gauls, he made an irruption into Macedonia, where Antigonus Gonatus then reigned. His forces were beyond his expectations, for he not only obtained the pillage of many cities, but defeated Antigonus in battle, and wrested from him almost the whole kingdom. He now marched with a powerful army into the Peloponnesus, at the request of Cimonnes, and appearing before Sparta, required the inhabitants to receive his friend as their king. Upon their determination to resist this mandate, he attacked the city, but was repulsed with the loss of many men: he now retired to Argos, where, through the treachery of Arcteas, a bloody conflict ensued, during which, a woman, who saw Pyrrhus just going to kill her son, hurled a tile from the top of the house, which brought the king to the ground. In this state a Macedonian dragged him to a porch, and was going to cut off his head, when Pyrrhus opened his eyes, and gave him to receive a look, that his trembling hand failed in its office, and it was not till after repeated strokes, that he could execute his purpose. Thus in the year 272 B.C. terminated the life and exploits of this great warrior, whose career of reftlesse enterprise died alone could Rop. His military skill was held in the highest estimation by the Romans, who were so well able to judge of it by experience. Hannibal considered Pyrrhus as second only to Alexander, as a great general. He is said to have been the frill who understood the art of encampments, and of properly drawing up an army, and some treatises which he wrote on these subjects are mentioned by the ancients. He was brave to the borders of rashness, and sometimes left the commander in the field. He had unbeholden ambition, and a disposition perpetually to engage in new enterprises, for which, as we have seen, he readily abandoned such as proved more difficult than he had expected. He was fond of glory, but was poffessed of generosity, which disposed him to acts of kindness, and to a grateful acknowledgment of obligations. All his foes were warlike, and he encouraged the dispo-

**PYR**

**PYR**

tion by the declaration, that he would leave the kingdom of Epirus to him, who had the sharpest sword.

**Pyrrhus Campus, or Pyrrhus Pedum**, in Ancient Geography, a canton of Africa, in Mauritian Tingitana, in the country of the Nechiheres, according to Ptolomy.

**Pyrrhus Campus**, a canton of Africa, in Interior Libya, between the country of the Leucathoibes and that of the Perorhi, according to Ptolomy.

**Pyrrhus Mona**, a mountain of India, on the sea-coast, on this side of the Ganges, according to the Periplus of Arrian.

**Pyrrstein**, in Geography, a town of Auferia, 10 miles N.W. of Lintz.

**Pyrephorus**, *Pyrephoae*, in the Athenian festival, Hephaestia, the same with Lamosadephorus.

**Pyrrularia**, in Botany, so called, as it seems, because the fruit resembles a little pear, Michaux Boreali. v. 2. 231; has received a new appellation from Palladino in his v. 4. 1114. *Hamiltonia*, which Mr. Purh adopts, in his Flora, 178. This genus, referred by Michaux and Palladino to Dioecia Pendentaria, is placed by Purh in Pendentaria Monogynae, though he allows it to be dioecious. It is said to be allied to *Nysa*. See that article.

1. *Hamiltonia obisfera* of Purh, *Pyrrularia puber* of Michaux, is the only known species, a native of shady woods, on the mountains of Peru, in Virginia, near the sweet springs, and in Carolina, flowering in May and June. This is a *frit*, from four to six feet high, very downy, with alternate, oblong, pointed, entire leaves. *Stipulas* none. *Flowers* very small, greenish-yellow, in terminal clusters. *Fruit* known in North America by the name of Oil-nut. The root is said to be made by Michaux to have an unpleasing smell.

PYRUS.

Peric. Apple roundish, umbilicated, fleshy, with from two to five membranous, more or less rigid, cells. Seeds two, rarely more, in each cell, oblong, obtuse, pointed at the base, convex on one side, flat on the other.

Ef. Ch. Calyx five-cleft. Petals five. Apple inferior, from two to five cells. Seeds two in each cell.

Our remarks under the article *Messilus* apply equally to the present genus, as to the propriety of referring to it the whole Linnean genus of Sorbus, and some species of *Crataegus* and *Messilus*; disregarding the difference in the number of their styles, which is evidently uncertain and variable, and distinguishing *Messilus* by its berry, *Pyrus* by its apple. Even this distinction proves, in some instances, obscure enough. We shall, for convenience, follow Willdenow in the order of the species, introducing our additional ones according to their affinities.

2. *P. melanocarpa*. Black Bilberry Apple. Willd. Enum. 525. Purfb n. 2. (P. arbutifolia 8; Willd. Sp. Pl. n. 1. and Ait. n. 1. Mespilus arbutifolia; Schmidt Arb. 86. Purfb.)—Leaves oblong-oblong, pointed, serrated; smooth beneath; their mid-rib glandular above. Flowers coriaceous. Calyx smooth.—Found in the bogs of Canada, and on the high mountains of Pennsylvania, Virginia, and Carolina, flowering in May and June. The *fruit* is large and black, resembling in taste the berries of *Vaccinium myrtillus*.

4. *P. ovalis*. Oval Berry Apple. Willd. n. 3. Pursh n. 4. (Mespilus Amelanchier? Walt. Carol. 148. *Crataegus picata*; Lamarck Dict. v. 1. 84.)—Leaves roundish-elliptical, acute, serrated, smooth. Flowers racemose. Petals obovate. Germin and segments of the calyx downy.—Native of swamps, from New Jersey to Carolina, flowering in April and May. A small *frut*; the *fruit* black, eatable. Purfb. Lamarck, who first distinguished this species, says it is twice or thrice as tall as the following, at least in the French gardens, with rounder *leaves* and smaller *flowers*, while the *fruit* is larger, being as big as a floe. The narrow coloured deciduous *branch* more, which occur in both species, are in the present longer than each partial *flower-flake*, which is not the case with *P. Amelanchier*.

256. Willd. n. 4. Ait. n. 3. (Mespilus Amelanchier; Linn. Sp. Pl. 685. Jacq. Aufr. t. 300. Mill. l. t. 178. f. 1. Vaccinia alba; Ger. Em. 1416.)—Leaves roundish-elliptical, acute, serrated; downy beneath. *Flowers* raceme. Petals lanceolate. Germin somewhat downy. Segments of the calyx smooth.—Native of rocky mountainous situations in Germany, Switzerland, France, and the isle of Crete; common in shrubberies, ever since Gerard's time, blooming in May. From three to six feet high, or more when cultivated, making an elegant appearance with its copious drooping clusters of snowy *flowers*, whose *flakes* are very woolly. *Fruit* blueish-black, sweet, the size of a currant.

6. *P. criplicata*. Cretan Berry Apple. Willd. n. 5. Prodr. Fl. Grec. n. 1157. (Chamaecerasius Idaea; Alpin. Exot. 4.)—Leaves roundish, emarginate, with a small point, serrated; woolly beneath. Flowers racemose. Petals lanceolate. Germin and segments of the calyx woolly.—Found on the mountains of Crete. This differs from the last, of which it is juilply supposed of being a mere variety, in having rounder *leaves*, whose pubescence underneath is more permanent; as well as in having more woollyflakes than the *flowers*.

8. *P. communis*. Common Pear-tree. Linn. Sp. Pl. 686. Wildd. n. 6. Ait. n. 4. Sm. Fl. Brit. n. 1. Engl. Bot. t. 1758.—Leaves ovate, serrated, finally smooth. *Flower-flakes* coriaceous. Fruit elongated at the base.—Native of various parts of Europe, but even more general as a cultivated plant, the varieties of whose fruit are many of them highly valuable for the table. The truly wild, or iron, pear is not eatable. It blooms in April or May. The *tree* is tall and handsome; the wood light, fine-grained, and tolerably hard, making neat furniture. The branches, at first erect, subsequently become curved downwards, and pendulous. The serratures of the *leaves* commonly disappear by culture, as do the strong *thorns* found on the wild tree. When young, the *leaves* are downy beneath, and fringed with white. *Flowers* white, with pale *red anthers*; their inflorescence coriaceous, not umbellate as in the apple. *Fruit* obovate, more or less elongated at the base.

9. *P. polleuaria*. Woolly-leaved Pear-tree. Linn. Mant. 2. 244. Willd. n. 7. Ait. n. 5. (P. pollivillera; Bauh. Hist. v. 1. 59. Munch. Hauft. v. 3. part 2. 333.)—Leaves ovate, strongly serrated; most downy beneath. *Flower-flakes* coriaceous, subdivided.—Native of Germany, according to baron Munchhausen. John Bauhn first met with it in the garden of baron Pollvill, in Alfatia. It was sent to Kew, in 1786, by the late Mr. Graffer. This differs from the common Pear-tree in having the *leaves* downy on both sides, but especially beneath; the *flowers* cream-coloured, much smaller and more numerous, even forty in each *coromb*, their partial *flakes* being branched and forked. The *fruit* is small, sometimes but an inch long, and falls early when ripe.

flowering early in May. The leaves are white and silky beneath; nearly smooth above. Flowers large, white, strongly scented, in a simple downy corymb. Fruit about

two inches in diameter, globose, rather depressed, purplish-green. When gathered in October, as utile as an unripe medlar; but after lying a few weeks, it first acquires a sweet scent, which is but temporary, and at length towards December, these pears become soft, like medlars, and very
good eating.

11. P. malus. Common Apple, or Crab, tree. Linn. Sp. Pl. 686. Willd. n. 9. Ait. n. 6. Sm. Fl. Brit. n. 2. Engl. Bot. t. 179. Fl. Dan. t. 1101. Mill. Ill. fl. t. 44. (Malus sylvestris; Ger. Em. 1561.)—Leaves elliptic-oblong, pointed, serrated, smooth. Umbels simple, sefulle. Styles smooth.—Native of woods and hedges throughout Europe, and till more valuable, for its innumerable and useful varieties, as a cultivated plant, than even the Pear, n. 8. The Crab itself, or Wild Apple, though always too utile to be eaten raw, is subject to some varieties that are worthy of notice for kitchen use. This species produces its elegant pink-coloured blossoms in May. The branches are more horizontal than those of P. communis, as well as more twilled and disordered. The younger leaves are downy beneath. Fruit roundish, cohe-
cave, or umbilicated, at the base.

12. P. pumila. Dioecious Pear-tree. Willd. n. 10. Phytogr. f. 1. 8. Moench. Weidett. 87. t. 8. Wildl. (Malus non florens, fructiferum tamen; Bauh. Pin. 433.)—Leaves oval, pointed, serrated. Flowers axillary, dioecious. Petals linear, the length of the calyx.—The native country of this singular plant is unknown. Professor Willdenow, from whom we have dined specimens, supposes it to be possibly a variety of the preceding species. The flowers are small, forming in appearance short downy umbels, at the ends of the branches, but each separate stalk is accompanied by a leaf. Petals yellowish-green, not exceeding the calyx. Styles five, smooth. We have seen the female plant only.

Wildl. n. 11. Curt. Mag. t. 267. Schnee. IC. t. 15.—

Leaves oval-oblong, serrated, smooth. Umbels simple, sessile, nearly smooth, without bracteae. Styles woody at the base. Native of China, from whence Dr. Fothergill is said to have imported it in 1786. The tree proves tolerably hardy in our gardens, flowering early in May. The leaves are furnished with copious shallow ferratures, and have downy footstalks and ribs. The umbels are nearly, if not quite, smooth, and consist of eight or ten large and handsome rose-coloured flowers, for which alone this plant is cultivated, the fruit, which is yellow, an inch in length, and usually elongated a little at the base, being sparingly produced, and of no value. We can discover no braeacteae, and if we are not mistaken, the want of them affords the surest mark of distinction between this species and the two following.

Ait. n. 8. (P. Malus 2; Ait. ed. 1. v. 2. 1757. Cra-
tegus ocellati folio, floribus magnis; Mill. IC. t. 269.)—Leaves ovate, pointed, with shallow ferratures. Umbels simple, sessile, downy. Bracteae linear, toothed, deciduous. Styles woody at the base.—Native of Siberia, according to Miller, who says the seeds were sent from Dauria to Petersburgh, and who had it, bearing flowers and fruit, at Chelsea, before the year 1758. This tree is now common in gardens, the fruit, which resembles a white-heart cherry in size and colour, but which is liable, in both respects, to vary, being esteemed for preserving, as well as for tarts; nor is it, when mellowed by fruit, unpleasant to eat raw.

The leaves are rather more downy than the latt, but their ribs are smooth. Flowers copious, with a light sweet scent, their colour much paler and their size smaller than P. spec-
tabilis. Flower-stalks very downy. Braidate smooth, mem-
branous, very narrow, above half an inch long.

15. P. baccata. Small-fruited Crab-tree. Linn. Mant. 75; excluding the reference to Miller. Willd. n. 13. Ait. n. 9. Pall. Roff. v. 1. p. 23. t. 10. Giseke lc. fals. t. 12. (Crategus cerea folia, floribus magnis; Amm. Ruth. 155 t. 31.)—Leaves ovato-lanceolate, pointed, sharply serrated, smooth. Umbels simple, smooth, sessile. Bracteae linear, slightly toothed, deciduous. Styles naked. Fruit smaller than the petals.—Found in low situations, about the banks of rivers, in Siberia, flowering the end of May. We received specimens from the garden of the late Right Hon. Charles Greville, at Paddington, in flower April 21, 1803. This differs from the last, with which some botanists have confounded it, in having broader, more acutely serrated, smoother leaves; smooth flower-stalks and styles; and a small red fruit, not bigger than a common haw. The calyx in both is deciduous, leaving a scarred hollow on the top of the fruit.

flalks corymbose. Styles woody in the lower part. Native of woods in North America, from Pennsylvania to Carolina, flowering in May. It has long been cultivated in England, for the sake of the beauty and violet-like fragrance of its bluish-coloured blossoms, as well as for its fruit, which is as big as a small golden-pippin, extremely acid, but excellent for preserving with sugar. The leaves are distinguished by their breadth, and by being slightly lobed, like some of the leaves deeply cut leaves of the Hawthorn, but thrice as large.

Pursh n. 8. (P. coronaria; Wangerh. Amer. 61. t. 21. f. 47.)—Leaves lanceolate-oblong, thinning, with tooth-like notches; contracted and entire at the base. Flowers-corymbose. Found in the low woods of Carolina, flowering in May. It resembles the foregoing species, but the fruit is very small, Pursh. This is said in Hort. Kew. to have been cultivated in 1750, by Mr. Chipperton Gray. We have never examined it, nor have we any account of the flowers being downy or otherwise.

Wildl. n. 16. Ait. n. 12. Curt. Mag. t. 692. (Malus Japonica; Andr. Repof. t. 462. Buke; Kamps. Amo. 844.)—Leaves elliptic-oblong, sharply serrated, very smooth. Stipules lanceate, deeply toothed. Flower-stalks somewhat aggregate. Calyx abrupt. Seeds numerous in each cell.—Gathered by Thunberg, on mount Fakona in Japan, where it flowers from February to April. It proves quite hardy in our gardens, into which Sir Joseph Banks introduced it in 1796, flowering at the same season, and also frequently again in autumn. When the spring is severe, the beautiful deep scarlet blossoms require the shelter of a glass frame. The fruit is somewhat thorny. Leaves deep green; the fruit that come out are short and abrupt. Stip-

ulolates on the young branches, half an inch or an inch broad. Fruit globular, we have not seen it ripe. Seeds very num-

erous in each cell, one above another, so that we cannot but feel some scruples as to the genus of this species.

Woddy.
PYRUS.

Woodv. Med. Bot. t. 79. (Malus cotonea; Ger. Em. 1452. Matth. Valgr. v. 1. 217.)—Leaves roundish-elliptical, entire; downy beneath. Flowers solitary, raked. Calyx serrated, reflexed.—Native of the rocky banks of the Danube. Naturalized in the hedges of Germany. Dr. Sibthorp found it wild in the northern parts of Greece, in which country it retains the ancient name *vomius*. This was among the first exotic fruits cultivated in England, where it blooms in May or June, and ripens fruit in autumn. The tree is rather spreading than tall. *Leaves* roundish, various in size; smooth and light green above; white with soft down beneath. *Flower-flats* and calyx more or less woolly. *Petal*, large, flesh-coloured. *Fruit* large, yellow, with a yellow and alligator, but with a peculiar and very powerful fragrance. Cookery renders it mild, and to moft perons highly grateful. There are three or four angual *seeds* in each cell, ranged horizontally, not, as in the last, vertically. The Quince is supposed to be the golden apple of the Hesperides, so famous in ancient fable.

20. P. falsifolia. Willow-leaved Crab-tree. Linn. Suppl. 255. Wildl. n. 18. Ait. n. 14. Pallas Roff. v. 1. p. 20. t. 9.—Leaves linear-lanceolate, hoary, nearly entire; downy beneath. Flowers solitary, almoft fiffie. —Native of Siberia, America, and mountain Hamaus. Sent to Kew, by Pallas, in 1780. It is a hardy tree, flowering early in spring, and known by its hoary, narrow, willow-like leaves. The *flowers* are terminal, solitary, and nearly fiffie; not axillary. *Fruit* pear-shaped, an inch long, brown, not at all liable till mellowed by fruit, like medlar; and even then not very good.

22. P. Aria. White Beam-tree, or White Wild Pine-tree. Ehrh. Beitr. falc. 4. 20. Arb. 84. Sm. Fl. Brit. n. 7. Engl. Bot. t. 1858. Wildl. n. 15. (Crataegus Aria; Linn. Sp. Pl. 681. Fl. Dan. n. 301. t. 302. Aria Theophratti; Ger. Em. 1327.)—Leaves elliptical, cut, and serrated; white and downy beneath, with crowded parallel veins. *Corymbs* compoud, woolly. Styles two or more.—Native of limefone rocks, or chalky hills, in most parts of Europe; not rare in the mountainous countries of England, flowering in May, ripening fruit in September. A hardy small tree, much cultivated in home plantations. The young branches, like the *flats*, *seeds*, and backs of the *leaves*, are very white, with mealy or cottony down. The *leaves* vary from deep green to obovate figure, to a more correct oval, and are pretty regularly cut, as well as serrated, but not finnated or lobed; their veins, or side-ribs, numerous, straight and parallel; their upper side smooth. *Corymbs* subdivided, many-flowered, cottony. *Petal* white, the fize of the fiole of the Hawthorn. *Styles* two, often three, rarely four. *Fruit* nearly glofular, scarlet, dotted, mealy and acid; its cells coriaceous rather than hory, equal in number to the *styles*, with two *seeds* in each.

23. P. intermedia. Swedish White Beam-tree. Ehrh. Beitr. falc. 4. 20. Arb. 94. Wildl. n. 20. Arb. 268. Ait. n. 16. (Sorbus alpina, folis finmollis; Fl. Dan. n. 302. t. 301. fig. in flower only. S. hybrida; Hudfl. 216.)—Leaves elliptical, lobed, cut and serrated; white and downy beneath, with rather diffent veins. *Corymbs* compoud, woolly. Styles two or more.—Native of Sweden. Found by Mr. Waring, on the walls of castle Dinast yBran, North Wales. *Hybrid*. Specimens from the original plant prove the fame as those of Ehrhart, and differ from the common *P. Aria*, only in having the *leaves* so far cut, as to be, in some degree, pinnatifid, owing to which the tranverse veins are rather more diffent from each other. We can scarcely admit it to be more than a variety, as *Linnaeus* made it in Sp. Pl. 681. It is his Lapiad plant, Fl. Lapp. n. 199.

24. P. pinnatifida. Baftard Mountain Ash. Ehrh. Beitr. falc. 6. 92. Exficc. 145. Sm. Engl. Bot. t. 2331. (P. hybrida; Sm. Fl. Brit. n. 6, excluding the synonym of Hudfon and Withering. Sorbus hybrida; Linn. Sp. Pl. 684. Linn. Fl. falc. t. 6. Wildl. Sp. Pl. v. 2. 1008. Ait. Hort. Kew. v. 3. 204. Fl. Dan. n. 302. t. 301. fig. in fruit.)—Leaves oblong, deeply pinnatifid, or half pinnate; downy beneath. *Corymbs* compoud, woolly. Styles about three.—Native of Sweden. Gathered wild, by the late Mr. J. Mackay, in rocky places on Cains na Callich, and other mountains, at the north end of the isle of Arran. It is frequent in plantations, flowering in May, and propagated by seed. This was thought by Linnaeus to be a mule, between *Aria*, and *aucuparia* hereafter mentioned. It nearly accords with the former, but the *leaves* are more oblong and acute; very deep pinnatifid, or even pinnate, in their lower part. The *flowers* and *fruit* almost agree with those of *aucuparia*. The *styles* are usually three or four.

25. P. aucuparia. Mountain Ash; Quicken, or Roan Tree. Ehrh. Beitr. falc. 6. 94. Gaernt. v. 2. 45. t. 87. Sm. Fl. Brit. n. 5. (Sorbus aucuparia; Linn. Sp. Pl. 683. Wildl. Sp. Pl. v. 2. 1008. Ait. Hort. Kew. v. 3. 204. Fl. Dan. t. 1034. Mill. Illutr. t. 43. Engl. Bot. t. 337. S. sylvestris; Ger. Em. 1473. Matth. Valgr. v. 1. 238.)—Leaves pinnate; leaflets equal, serrated, smooth. *Corymbs* compoud, somewhat paniced. Styles about three.—Native of mountainous places, in the colder parts of Europe; abundant in Scotland, Derbyshire, &c. flowering in May, and very common in domestic plantations. An elegant and very hardy tree, of flow growth, the wood being hard and tough. *Leaves* all diminifely pinnate, of many pair of opposite, oblong, smooth, serrated leaflets, more or less entire towards the base, with an odd one; the young ones downy beneath. *Flowers* very numerous, white, the fize of the three half, but rather more paniced. *Fruit* scarlet, acid and bitter, yet eatable when prepared with sugar. According to Lightfoot, this tree is found generally about the Druidical circles in North Britain, and is still believed, by the superstitious Highlanders, to be powerfuly efficacious against witchcraft.

O 2 found
PYRUS.

found it in Greece, as well as on mounts Hæmus and Ainos, and in woods near Constantinople. Ray speaks of it as wild in the mountainous parts of Cornwall and Staffordshire. It is now rarely cultivated, being, though a handsome tree, yet of slow growth, and inferior in the value of its fruit to the Medlar. A solitary individual of this species now and then occurs, about ancient manions and very old orchards. It blossoms in May. The leaves are larger, and the flowers twice the dimensions of the leaf, being the size of hawthorn-blossoms, rather paniced than corylmbofe. Fruit like a small pear, reddish, above an inch long, with five cells, unwarble to the five 

**fyles**; its cells with two valves, like those of a Common Pear; and though only one 

**seed** is perfect in each cell, Gartfer observed two in an early stage. This fruit, if tailed before it is mellow, occasions a molt intolerable forenses at the back of the palate, lasting many hours. When ripe it is soft, brown, and agreeably acid. The name **Service** is evidently a corruption of **Sortalns**.

28. *P. hybrida*. Mule Service Pear-tree. Willd. Moench. Weiflent. 90. t. 6. Willd..—Leaves elliptical, serrated, downy beneath; simple or pinnate, the terminal one largelf. Flowers corylmbofe. Calyx hairy. This fruit is afforded by Professor Wildeuow, from whom we have specimens, to be a mule production, from the first species, *P. arbutifolia*, impregnated by the 29th, *aucuparia*. It retains indeed as great a resemblance to both parents as it possibly could to what are so fimilar to each other. The simple leaves are two inches or more in length, obtuse, strongly serrated; the lateral leaves, of the compound one, half, or one-third, as large, unequal at the base. **Stipulæ** ovate, toothed, recurved. **Flowers** not much unlike the leaf, but their **cymes** somewhat smaller, with hairy, rather than downy, stalk. It is curious that the rib of each leaf, on its upper side, retains some portion of the brown glands characteristic of *P. arbutifolia*. **Stipulæ** lanceolate, a little hairy, deciduous.

29. *P. anthyllidifolia*. Kidney-vetch-leaved Service-tree. —Leaves pinnate, entire; febulous beneath. Corylmbs axillary and terminal, of few flowers.—Gathered in the Sandwich islands, by Mr. Menzies, to whom we are obliged for specimens, under the name of *Sorbus*, to which, since aboflhed, Linnaean genus there can be no doubt that this tree belongs, though we have not seen the fruit. The leaves are all uniformly pinnate, two or three inches long, of eight or nine pair, besides an odd one, of equal, oblong or obvate, obtuse, minutely pointed, entire leaves, half an inch at least in length; smooth and shining above; paler and febulous beneath. **Stipulæ** lanceolate, a little hairy, deciduous. **Flower**-folks axillary and terminal, nearly the length of the leaves, downy, corylmbofe, though each bears but three or four flowers, which are about the size of *P. aucuparia*. **Bractæs** awl-shaped. **Calyx** woolly. **Stylos**, as far as we can see, three, hairy at the base. The leaves of this very pretty and remarkable species strikingly convey the idea, at first sight, of some kind of *Anthyllis*, especially *A. Barbericosa*.

**PYRUS**, in *Gardening*, contains plants of the fruit-tree kind, of which the species cultivated are the common pear-tree (*P. communis*); the common apple-tree (*P. malus*); the Chinese apple-tree (*P. spectabilis*); the Siberian crab-tree (*P. prunifolia*); the sweet-scented crab-tree (*P. coronaria*); and the quince-tree (*P. cyprium*). With respect to the frift, it is observed that "the wild pear, the mother of all the orchard and garden varieties, is thorny. The frilled are fetaeous, white (or reddish), deciduous; the peduncles alternate; and the calyx clothed with a ferruginous wool.

There are numerous varieties; but those of most importance for cultivation are,

The little mufk, which is often termed the supreme. The fruit, when ripe, is of a yellow colour; the juice somewhat mufky; and, when gathered before it be too ripe, it is a good fruit. It becomes ripe about the latter end of July, but continues good only a very short time.

The chio, or little baird mufk, which is pretty much like the other, but smaller. The skin, when ripe, has a few flecks of red on the fun side.

The green chifel, or Haftings, which is a middle-sized fruit, that always remains green, and is full of juice when ripe. It becomes ripe in the beginning of August.

The red mucadelle, which is a large early pear, of great beauty; the skin is of a beautiful yellow, striped with red, and the flesh has a rich flavour. It sometimes produces two crops in a year; the first about the end of July, and the second in September, or thereabouts.

The little mulcat, which is a small pear, having the skin very thin, and of a yellowish colour, when ripe. This fruit has a rich mufky flavour, but does not keep long. It becomes ripe about the beginning of August.

The lady's thigh, which is here commonly called jargonelle, is of a ruffet-green colour from the fun, but towards it inclining to an iron colour; the flesh is breaking, and has a rich mufky flavour. It becomes ripe about the middle of August.

The Windlor, which has a smooth skin, and when ripe is of a yellowish-green colour; the flesh is very soft, and, if permitted to hang but two or three days after it is ripe, grows mealy, and is good for nothing. It becomes ripe about the latter end of August.

The jargonelle, which is commonly called cuife madame. According to Mr. Forfthy, it is certainly the true French jargonelle, and the pear that commonly goes by that name here is the real cuife madame, or lady's thigh; it being very probable that the names have been changed, in coming to this country. This pear is somewhat like the Windlor; the skin is smooth, and of a pale green colour. It is a plentiful bearer; but the flesh is apt to be mealy, if it stands to be ripe, which is about the middle of August. It bears well on coldars.

The orange mufk, which is of a yellow colour, spotted with black; the flesh is mufky, but very apt to be dry. It ripens about the latter end of August.

The great bouquet, or bagpipe of Anjou, which has a smooth skin of a pale green colour; the flesh is soft, and full
full of juice of a rich flavour. It ripens about the middle of August.

The little blanquet, which is much less than the former, of a pale colour, and the flesh tender, and full of a rich musky juice. It ripens about the latter end of August.

The long-stalked blanquet has a very smooth skin, white, and a little coloured towards the fun, and is full of a rich fuggy juice. It becomes ripe at the latter end of August.

The skinless or early ruffleet, which is of a reddish colour, the skin extremely thin, and the flesh melting and full of a rich fuggy juice. It ripens in the latter end of August.

The musk drone, which has a skin of a yellow colour when ripe, and a rich musky taste; but is apt to grow mealy, if left too long on the tree. It ripens about the beginning of September.

The red orange, which is of a greenish colour, but the side next the fun changes to a purple colour, when ripe; the flesh is melting, and the juice fuggy, with a little perfume. It ripens in the beginning of August.

The calloette, or green muceat, is a small greenish pear, with some specks in the skin. It is full of a rich perfumed juice, and ripens in the latter end of September.

The great onion, brown admired, or king of summer, which is of a brownish colour next the fun, and becomes ripe in the beginning of September.

The musc orange, in which the skin is green, and the flesh melting. It ripens in the beginning of September.

The averat, or August muceat, which has a smooth skin of a whitish yellow colour; the juice is richly sugared and perfumed, and it is esteemed one of the best summer pears yet known. It is a great bearer, and becomes ripe in the beginning of September.

The rofe, or thorny rofe, which is shaped like the great onion pear, but much larger, of a yellowish-green colour, but a little inclining to red next the fun. The flesh is breaking, and the juice musky. It becomes ripe in the beginning of September.

The poire du puchet, which has the flesh soft and tender, and the juice fuggy. It ripens in the beginning of September.

The perfumed pear, which is of a deep red colour, spotted with brown; the flesh melting, but dry, and has a perfumed flavour. It ripens in the beginning of September.

The salviati, which is red and yellow next the fun, but whitish on the other side; the flesh is tender, and the juice fuggy and perfumed. It ripens about the middle of September.

The rose water, which has the skin rough, and of a brown colour, the juice very sweet, tallowing like rose-water. It ripens in the latter end of September.

The ruffleet, in which the flesh is soft and tender, and the juice agreeably perfumed. It ripens in the latter end of September.

The great mouthwater, which has the flesh melting and full of juice. It ripens about the latter end of September.

The prince's pear, which has a highly-flavoured juice, and is a great bearer, ripening about the latter end of September.

The summer bergamot, which is sometimes called Hamden's bergamot. The flesh is melting, and the juice highly perfumed. It ripens about the latter end of September.

The autumn bergamot, which is smaller than the former; the flesh is melting, and the juice highly perfumed. It is a great bearer, and ripens in the beginning of October.

The summer bonichretien, which is very full of juice, and is of a rich perfumed flavour. It ripens about the middle of September.

The beurre rouge, (the red butter pear,) which has the flesh very melting and full of a rich fuggy juice. It ripens in the beginning of October, and, when first gathered from the tree, is one of the very best sorts of pears.

The dean's pear, which has the flesh melting and full of juice, which is very cold. It is a great bearer, and ripens in the beginning of October.

The Swiss bergamot has a melting flesh, and is full of juice. It ripens in the beginning of October.

The long green, in which the flesh is melting and full of juice. It ripens in the latter end of October. It is, by some, reckoned the same with the mouthwater.

The white and grey monsieur John, which are the same; the difference of their colour proceeding from the different soils and situations wherein they grow, or the storks on which they are grafted. If this pear be rightly managed, there are not many sorts in the same season to be compared with it. The flesh is breaking, and full of a rich fuggy juice. It ripens in the latter end of October or beginning of November.

The flowered muceat, which is an excellent pear; the flesh is very tender, and of a delicate flavour. It ripens in November.

The vine pear, which is of a dark red colour; the flesh very melting, and full of a clammy juice. It comes into eating in November.

The routeline pear, which is of a deep red colour, with spots of grey; the flesh is very tender and delicate, and the juice very sweet, with an agreeable perfume. It ripens about the latter end of October, but does not keep.

The knife's pear, which has the flesh fine and tender, and the juice very much sugared. It ripens in the latter end of October.

The marquis pear, which, when it does not change yellow in ripening, is seldom good; but if it does, the flesh will be tender, delicate, and very full of juice, which is sugared. It comes into eating in November.

The Crafane pear, which has the flesh extremely tender and buttery, and full of a rich sugared juice. It is the very best pear of the season, and comes into eating about the latter end of December.

The Laflac, or Dauphiné pear, which has the flesh yellow, tender, and melting; the juice is sugared, and a little perfumed. It is in eating the beginning of December.

The martin fee (the dry martin), which is almost like the ruffleet in shape and colour; the flesh is breaking and fine; and the juice sugared, with a little perfume. It is in eating about the beginning of December.

The amadot, which is rather dry, but high-flavoured; it is in eating about the middle of December.

The little lard pear, which is extremely fine; the flesh melting; the juice much sugared, and has an agreeable musky flavour. It is in eating the latter end of December, and is esteemed one of the best fruits in that season.

The Louisfon (the good Lewis), which has the flesh extremely tender, and full of a very sweet juice. It is in eating about the middle of December.

The Colmar pear, which is very tender, and the juice greatly sugared. It is in eating about the beginning of January, and is esteemed an excellent fruit.

The Pefchafierie, which has the flesh melting and buttery; the
the juice is fragrant, with a little perfume. It is in eating about the first of January. It bears on standards.

The virgoulene pear, which is esteemed by some as one of the best fruits of the season; the flesh is melting, and full of a rich juice. It is in eating about the first of January. In dry and cold seasons it is very apt to crack, which greatly diminishes its value.

The ambrette, which is esteemed a very good pear; the flesh is quite melting, and full of sweet, very in yellow; its juice highly perfumed. It is in eating about the latter end of December.

The St. Germain pear, which is a fine fruit and keeps long; the flesh is melting, and very full of juice, which in a dry season, or if planted on a warm dry soil, is very sweet. It is in eating from December till February. Mr. Forsyth remarks, that it is an excellent bearer, when planted as a dwarf standard, and comes in succession after the same sort of pears on wall-trees are over.

The St. Auln, which is pretty full of juice, and which is often a little sharp; the flesh is tender but not buttery. It is in eating the latter end of December, and continues good two months or longer.

The Spanish bonchretien, which is a large fine pear; the flesh is breaking, and the juice sweet. It is in eating in January.

The wilding of Cafay, which is also called the small winter butter pear, is a small fruit; the flesh is melting, and the juice very rich; it is an excellent bearer on standards. It is in eating in January.

The martine, or the lord martine, which is a good fruit; the flesh is breaking and full of juice, which is very sweet and a little perfumed. It is in eating in January.

The winter russelet, which has the flesh buttery and melting, and generally full of a sweet juice. It is in eating in the latter end of January.

The franc real, or the golden end of winter, which is only esteemed for baking.

The brown beurré, which is of a reddish-brown colour on the side next the sun, and yellowish on the other side. The flesh is melting, and full of a rich juice. It ripens in October, and is esteemed an excellent pear.

The Holland bergamot, amoselle, or lord Cheney's, which is a very good pear; the flesh is half buttery and tender, and the juice is highly flavoured. It keeps from the end of January till April.

The German mufcat, which is an excellent pear; it is buttery and tender, and the juice is highly flavoured. It is in eating from February till April or May.

The pear of Naples, or Easter St. Germain, which is half-breaking; the juice is sweet, and a little vinous. It is in eating in March.

The winter bonchretien, which is very large; the flesh is tender and breaking, and is very full of a rich sugar'd juice. It is in eating from the end of March till June.

The lâ palatelle, which is tender and buttery, and the juice sweet. It is in eating in March.

The St. Martial, or the angelic pear, which has the flesh tender and buttery, and the juice very sweet. It is in eating in March.

The wilding of Chaumontelle, which is melting, the juice very rich, and a little perfumed. It is in eating in January.

The brown St. Germain, which is a very fine high-flavoured pear on dwarfs and standards, and comes in after the wall St. Germain. It continues in eating from December to the end of March.

The pear d'Auch, which was introduced by the late duke of Northumberland. It much resembles the Colmar, but is fuller towards the stalk. It is in eating from Christmas to April, and is, without exception, the best of all the winter pears.

The swan's egg, which is a middle-sized pear, in a shape like an egg; it is of a green colour, thinly covered with brown; the flesh is melting, and full of a pleasant muskty juice. It comes in eating in November. It is healthy, and bears well either as a standard or in any other way.

The bergamot de paque, which has also the following names: the terling, the amoselle, the Paddington, and the Tarquin. It is a fine handome fruit, green when gathered, and of a yellowish or straw-colour when ripe. It comes into eating about the month of April, continues till June, and makes a very handsome appearance at table.

The golden beurré, which is a very fine pear; it is of a beautiful scarlet colour next the fun, and of a gold colour on the other side. The flesh is melting, and the juice highly flavoured. It ripens in October. It succeeds best on an earth aspect, and a loamy soil. It is a plentiful bearer. Mr. Forsyth observes, that it was introduced from Burgundy by the late marshall Conway, and was first raised, in this country, at his seat of Park Place, near Henley-upon-Thames, now the seat of lord Malvern.

The Williams's feeding pear, which resembles a summer bonchretien, but is more juicy, is a great bearer, and ripens in September. Mr. Forsyth says that it will be a valuable acquisition to the market-gardeners, as it immediately succeeds the Windsor pear.

The citron de Carmes, which is a middle-sized pear, of a yellowish-green calk, full at the eye; of a round shape, but tapering a little towards the stalk, which is long. It becomes ripe in July.

And the true golden beurré, which in shape and size resembles the brown beurré; but is of a reddish-brown colour next the fun. It is a very fine pear, but does not keep long. It comes into eating in October.

Mr. Forsyth gives the following selection from Anderson's and Co.'s Catalogue of Edinburgh.

Of the Summer Kind.—The pear James, which is soon ripe, and soon rotten, has a little flavour, and is the earliest pear in Scotland.

The early carnock, which is indifferent, of a yellow colour, and bright-red towards the fun; making a beautiful standard tree.

The lemon, lady's lemon, or lady Lamont, which is indifferentely good, but principally valued for coming early, and being a good bearer in common.

The green pear of Pinkey, which is a small green pear, nearly round, of a sweetish taste or flavour.

The forrow cow, a Clydefdale pear, which is a large pear with a short stalk; flat towards the eye; the colour red and yellow; the flesh tender, and musky in its flavour.

The pear fance, a Clydefdale pear, which is a big-bellied beautiful pear; the tree large, a great bearer, and fit for an orchard; but the fruit is not very good.

The grey honey, which is a pretty good pear.

The green orange pear, or orange vert, which is a very good pear.

The brute bone, chaw good, or the pope's pear, which is only an indifferent fort.

The golden knap, supposed Scotch, which is a small summer pear, of tolerably good qualities.
The early achen, an indifferent fruit; greatly inferior to the winter pear of that name.

The hanging leaf, which is the name in Clydefdale, is good and beautiful; almost round; its colour red and yellow; a delicious sweetmeat is found in its stipe.

The Scots bergamot, which is a large good pear, of a yellow and red colour; its flesh tender and juicy.

The Longueville, which is very good, but a precarious bearer; supposed French, though not in their catalogues under that name.

The musked bonchriet, gratiole, cucumber, or Spinola's pear, which is a very good pear when grafted on a true stock; its pulp being somewhat between short and tender, with a great deal of perfumed juice, its colour red on one side, and white on the other.

And the furrat pear, which is a pretty large well-shaped pear, fit for the orchard or the field.

Of the Autumnal Kinds.—The keather, which is a Clydefdale pear, of middling size, and oblong shape, its juice agreeable.

The French carnock, which is tolerably good.

The elphin haft, or good-man pear, which is a long pear, flat towards the eye: its colour green and yellow; its flesh hard, dry, and sweet in the stipe.

The Drummond, or late Scotch carnock, which is very good, if eaten before it grows mealy; its colour a bright red and yellow.

The vicar, an oblong pear, with the colour yellow, red, and striped; tender, sweet, and musked, but dry in eating.

The royal orange bergamot, which differs from the orange bergamot in being yewyolent, and sometimes having a faint red on one side.

The green pear of Yair, which is sweet, juicy, and melting; of a moderate size; taking its name from Yair, on Tweed-side, where it was first discovered.

The roh hind, which is very indifferent.

The le beffier, the wilding of the forest of Ileri, in Bretagne, which is a yellowish pear, of middle size, but which is indifferent.

The unicorn pear, which is of a beautiful red and yellow colour; but rather auliere in the stipe or flavour.

Of the Winter Kinds.—The winter achen, which is a Scotch pear; among the best early winter pears, and equal to most of those of the French kind.

The brier bush, which is Scotch; a good pear, and will ripen in most seasons; it is a small pear, of a firm substance, and sweet stipe.

The Brompton park, which is a seedling sent by Jefferys of that name.

The round winter, which is a Clydefdale pear, a very excellent winter pear.

The poir portrait, or gate pear, which is proper for baking.

The la double fleur, or the double-flowering pear, which is a large flat beautiful pear, with a smooth skin, and blush colour on one side, and yellow on the other: it is the best to prefer, taking a beautiful red colour from the fire.

And to thefe: the following list is added:—The Ambrofia pear, the Ashton town, the autumn monk bonchriet, the bishop's thumb, the bloody pear, proper for baking, the brocas bergamot, the harland, proper for perry, the befier, fit for baking, the heurier du roi, the black pear, or Worcester, fit for baking, the Britannia, the burelleu, the Doyenne, or St. Michael, the caftillac, fit for baking, the Easter St. Germain, the Gafell's bergamot, the golden beurré, the grey beurré, the grey good-wife, the green furgar, the green bergamot, the Huntingdon pear, the huff-cap, proper for perry, the king's Catharine, the lammas, the London furgar, the muscat alsain, the muffl blanquet, the Oldfield, proper for perry, the orange bergamot, the pear piper, the furus pollveria, the red admirable, the rough cap, proper for perry, the Scotch bergamot, the seme-angled, the silver-striped, the Spanish red warden, befit for baking, the fwarz, proper for perry, the striped verte longue, and the white beurré.

And for small gardens, where there is room only for a few trees, the following are recommended as proper for furnishing a regular succession of fruit.

Summer Kinds.—The musked pear, the green chifell, the jargonelle, theummer bergamot, and the summer bonnechret.

Of the Autumn Kinds.—The orange bergamot, the autumn bergamot, the Gafell's bergamot, the brown beurré, the Doyenne, or St. Michael, and the Swan's egg.

Of the Winter Kinds.—The Craffane, the Chaumontelle, the St. Germain, the Colmar, the d'Auch, the Pechsalle, the winter bonnechret, and the bergamot de paque.

And the second fort, in its wild state, is the crab, or wilding, and is armed with thorns, as well as the wild pear. Miller mentions two varieties in the fruit of the crab, one white, the other purple towards the fun; but it is commonly yellowish-green with a tinge of red. And also a variety with variegated leaves.

There are a great many varieties of the apple, but the following are given by Mr. Forsyth as the most deserving of attention.

The Acklam's ruflet, which is a small Yorkshire apple, of a ruflet colour toward the fun, and yellow on the other side; it becomes ripe in January, and keeps till March.

The aromatic pippin, which is a very good apple, of a bright ruflet next the fun; and the stipe has a fine aromatic flavour. It ripens in October.

The Baxter's pearmain, which is a real Norfolk apple, of a handfome flize, and pale-green colour, full of small dark spots. It is a fine kitchen fruit, and will keep till April. It is also a good eating apple.

The beauty of Kent, which is a fine large apple, resembling a codling. It is streaked with a fine red towards the fun, and of a beautiful yellow, with some streaks of red on the other side. It is a very good apple, coming into eating in September, and keeping till the latter end of April.

The belia gristline, which is a new seedling raised at Norwich, of much beauty, and never failing to afford crops. It was first propagated by Mr. Lindley, who gave it this name. It is a handfome apple, resembling the burdoff, of a yellow colour, with red towards the fun, and an excellent table apple, keeping till March.

The Bell's pearmain, which is a real Norfolk apple, large and handsome; red toward the fun, and yellow on the other side. It is a fine kitchen fruit, and pretty good to eat raw, keeping till January.

The bell pool, which is a middle-sized apple, of a pale-green colour, streaked with red towards the fun. It is a good apple, in eating from January to April.

The black apple, which is a middle-sized fruit, of a dark mahogany colour next the fun, but fainter on the other side. It is of a pleasant sweet taste, keeping till the middle of April.

The Bland's summer pippin, which is a handfome apple, of a gold colour, and an agreeable flavour. It is a great bearer, ripe in September, and keeps till Christmas.

The Blatche's fine small table apple, which is about the fize
PYRUS.

size of a small golden pippin; red toward the fun, and green on the other side. It has a fugary taste, and comes into eating in January.

The boomery, which is a pretty large handsome apple, of a flat shape, and deep-red colour; and the flesh is streaked with red. It is not fit to eat raw, but will do well for cyder, or for the kitchen. It keeps till April.

The Bovey redstreak, which is a handsome apple, of a flatish shape, beautifully streaked with a bright red next the eye, which is small, and of a yellow colour about the footstalk. It keeps till the latter end of October.

The broad-eyed pippin, which is a fine large apple, with a very large eye; the colour is a greenish-yellow, with a little red toward the fun. It is a good apple, and keeps till May.

The brandy apple, which is about the size of a golden pippin, flat-shaped, and of a yellowish ruflet colour. It is of a pleasant flavour; comes into eating in January, and keeps till March.

The hardoff, or queen's apple, which is a beautiful fruit, red next the fun, and of a fine yellow on the other side. It is a very fine apple; in Mr. Forfey's opinion, next in perfection to the golden pippin, and about the same size. It is of a good flavour; ripening in January, and keeping till March.

The carнятие apple, which is a beautiful middle-sized fruit, finely striped with red. It is ripe in January, and keeps till May.

The Carbury pippin, which in size and shape resembles the French crab, and is of a deep green colour. It is a good baking apple, keeping till March.

The caraway rufflet, which is a handsome rufflet-coloured apple, about the size of a nonpareil.

The calville, red and white, which are good apples, and of a vinous taste. Some have a red and fome a white pulp, the white being reckoned of a most delicious taste. They are in eating in September, and the following month.

The cat's-head, which is a large oblong apple, of a greenish-yellow colour, with a little brownish-red next the fun; sometimes the colour inclines to a rufflet. It is a good baking apple, and is in eating from October to December.

The cockagee, which is a conical-shaped middle-sized apple, red on that side next the fun, and of a fine yellow colour on the other. If properly managed, the fruit keeps till February. It is a famous cyder apple, and also bakes well.

The codlin, which is generally the first apple that is brought to market. Its fruit is so well known that it needs no description. It is in eating from July to December; and is good either for baking or boiling.

The Cornish nonpareil, which is rather under the middle size, is a little flattened, and of a rufflet colour. It is a very good apple, and keeps till the middle of March.

The Cornish pearmain, which is of a middling size, and long shape; of a dull-green colour on one side, and rufflet on the other. It is a very good apple, and keeps till the latter end of April.

The Court-of-Wick pippin, which is described by Mr. Billinggley, in his "Survey of Somersetshire," as the favourite apple, both as a table and cyder-fruit, taking its name from the spot where it was first produced. It originated from the pip or fced of the golden pippin, and may be considered as a beautiful variety of that fruit. In shape, colour, and flavour, it has not its superior: the tree is large, handsome, and spreading, and a very luxuriant bearer. On the whole, it cannot be too strongly recommended. It is larger than the golden pippin, of a yellowish-green colour, and a little tinged with red next the fun. It comes into eating in January.

The Cockles pippin, which is a handsome oval-shaped apple, below the middle size, of a ruflet colour, mixed with yellow and red. It keeps till April.

The corpendu, or hanging body, which is a very large apple, and has a red callet on the side towards the fun; but is pale on the other side. It takes its name from always hanging downwards; and comes into eating in September.

The Dalmahoy pippin, which is about the size of a golden pippin, of a green colour, and a little streaked with red toward the fun. It has a tolerably good flavour, rather sharp; and is in eating from September to February.

The Dimock's red, which is under the middle size, of a fine red colour, intermixed with a little yellow on the side from the fun. It is ripe in January, and keeps till March.

The Dredge's seedling, which is a fine large apple, striped with red next the fun, and of a yellowish-green on the other side. This is an excellent kitchen apple, of a pleasant taste, and keeps till the latter end of January.

The Dredge's beauty, which is a beautiful apple, of a good size, and one of the finest yet known in point of general utility. It is of a fine bright yellow colour, spotted with red towards the fun; and has an excellent vinous flavour. It is good either for the table or baking, and keeps till March.

The Dredge's rufflet, which is a small apple, of a greenish-yellow rufflet colour, and of a pleasant flavour. It is ripe in November, and keeps till Midsummer.

The Dredge's white lily, which is a fine apple, of an exceeding high flavour, and keeps till March.

The Dredge's fair maid of Wiltshire, which is a fine middle-sized apple, of a yellowish-green colour, with some rufflet next the fun, of an excellent flavour. It is a great bearer, and is in eating from Christmas to Easter, being an excellent dessert apple.

The Dredge's queen Charlotte, which is a beautiful middle-sized apple, of a gold colour, with red towards the fun. It is of an excellent flavour, comes into eating about Christmas, and keeps till February.

The Dredge's fame, which is a good sized apple, red towards the fun, and streaked like the Ribston pippin on the other side. It is a most excellent apple, being in eating from Easter to Midsummer.

The dumpling apple, which is a handsome apple, and rather above the middle size, flat-shaped, and of a greenish-yellow colour, with some faint streaks of red. It keeps till March.

The Dutch queening, which is a large apple, somewhat resembling the cat's-head in shape. The colour is red next the fun, and green on the other side, with sometimes a little red. The fruit is fit only for the kitchen, and for making cyder. It is ripe in January, keeping till the end of March.

The Elton's yellow kernel, which is a handsome middle-sized apple, of a yellow colour. It is a good table apple, being in eating from January to March.

The English rennet, which is a handsome apple, beautifully streaked with red, but darkish towards the fun; of a tolerable flavour, but apt to grow mealy when kept too long. It keeps till the middle of May.

The embroidered apple, which is pretty large, and the stripes of red very broad, from which circumstance it takes its name. It is commonly used as a kitchen apple, becoming ripe in October.

The everlasting striped apple, which is below the middle size,
PYRUS.

fize, of a conical shape. The colour is a striped green towards the footstalk, and red towards the eye.

The famous, which is a pretty large apple, of a beautiful dark red, with a little yellow on the side from the fun. Its flesh is very white, and full of a rich sugary juice; coming into eating about the latter end of October. It was introduced from Canada by Mr. Barclay of Brompton.

The fenouillet, ou pomme d'anis, the fennel or anise apple, which is a middle-sized fruit, of a grey colour; the pulp is tender, and has a spicy taste, like aniseed. It becomes ripe in September and October.

The flower of Kent, which is a large handsome apple, of a yellow colour, and pretty good flavour. It keeps till the middle of April.

The fox-whelp, which is a small apple, streaked with red. It is ripe in January. It is a cyder apple.

The Franklin's golden pippin, which is a handsome middle-sized apple, of a conical shape and gold colour, beautifully marked with dark spots. The fruit has a fine aromatic flavour, and preserves the first place at the table; but it is a very fine bearer. It comes into eating about the middle of November.

The French crab, which is a large handsome apple, of a deep green colour, with a little red next the fun. It will keep all the year; is a good baking apple, and, if the summer be warm, pretty good for eating, and is a great bearer.

The French coxkin, which is a pretty large apple, of a conical shape, and green colour, with red towards the fun, coming into eating in January.

The Fearn's pippin, which is of the shape and size of a nongenerated. It is of a beautiful scarlet next the fun, and of a golden yellow on the other side. It makes a fine flow at table, and keeps till the latter end of February.

The French Spanish, which is a large apple, in form of a hexagonal prism with the angles a little rounded, and of a yellowish-green colour; it is pretty good, and keeps till the latter end of April.

The French or white rennet, which is a large fruit, of a yellowish-green colour, with some grey spots. It has a sugary juice, and is good either for eating or baking.

The Garguey pippin, which is a handsome conical-shaped apple, under the middle size, of a greenish-yellow colour, with a little red towards the fun. This is a pretty good apple, and keeps till May.

The gilliefower, which is a fine handsome apple, red towards the fun, and of a yellowish-green on the other side, having a fine flavour, and keeping till the latter end of March.

The golden rennet, which is a beautiful apple, a little flattered; of a fine red colour towards the fun, and yellow on the other side. It is a good eating apple, and keeps till February.

The golden pippin, which is a fine middle-sized apple, of a golden rennet colour, from which it takes its name. It is a good apple, and keeps long.

The golden pearmain, which is a fine apple, above the middle size, of a fine deep red towards the fun, with a little yellow on the other side; when much exposed to the fun it is sometimes red all over.

The golden Mundi, which is a fine handsome apple, beautifully streaked with red; of a good flavour, excellent for baking, and will keep till January. It is a good sauce apple.

The golden Glocester, which is a handsome middle-sized apple, of a flat shape, and gold colour, with red towards the fun. It is a good apple, and keeps till March.

The golden Knob, which is a handsome though rather small apple, of a fine gold colour, sometimes inclining to a russet. It has a pleasant flavour.

The golden pippin is well known; and the French own it to be of English origin. It is almost peculiar to this country; for there are few countries abroad where it succeeds well. It is yellow as gold; the juice is very sweet; the skin (especially where exposed to the fun) is often freckled with dark yellow spots. It is certainly the most ancient, as well as the most excellent, apple that we have. It ripens in October, and keeps through the winter. It has several sub-varieties.

The Godolphin apple, which is a very handsome large fine fruit, streaked with red on the side next the fun, and of a yellowish colour on the other side. It is in eating from the latter end of September to December.

The green dragon, which is a fine large apple, of an excellent flavour, and pale-green colour. It is rather too large for the table, and is therefore mostly used as a kitchen apple. It keeps till March.

The great or large russet, which is a middle-sized fruit, of a russet colour, with a little dark-red toward the fun. A pretty good apple, and keeps till April.

The Griddleton pippin, which is a large angular-shaped apple, of a greenish colour, with a little blush towards the fun. It is a baking apple, and keeps till March.

The Grumna's pippin, which is about the size and shape of a golden pippin; of a dingy-green colour next the fun, and of a dull yellow on the other side. It is ripe in January, and keeps till April.

The Hagloe crab, which is a yellow-coloured conical-shaped apple, below the middle size. It is ripe in January; but it is only fit for making cyder, or for baking.

The half-door, which is a fine large apple, of a flat shape, beautifully streaked with red toward the fun, and of a greenish-yellow on the other side. It is of a fine flavour, and is in eating from January till March.

The Hallingbury, which is a large flat-shaped apple, with large ridges from the base to the crown. It is of a beautiful red toward the fun, and of a yellowish colour on the other side and towards the eye.

The Hampshire nonsuch, which is a pretty large well-shaped apple, of a greenish-yellow colour, streaked with red. It keeps till the latter end of November.

The Harvey's russet, which is so called in Cornwall, is a large russet-coloured apple, with a little red toward the fun. It is a famous kitchen fruit, and tolerably good raw, with a mealy flavour.

The Holland pippin, which is a middle-sized apple of a flattish shape. Its colour is yellow, in some places inclining to green, with, sometimes, a little red toward the fun. It is a pretty good apple, keeping till the middle of April.

The hollow-eyed pippin, which is a middle-sized apple, of a yellow colour, beautifully spotted with red toward the fun; and the eye is pretty deep. It is a good sharp-flavoured apple, keeping till the middle of May.

The hollow-eyed rennet of Cornwall, which is a handsome flat-shaped apple, under the middle size, of a greenish-yellow colour, sometimes intermixed with russet. It is of an excellent flavour, and keeps till April.

The hedge apple, which is a new fruit, of middle size and handsome conical shape, red toward the fun, and of a straw colour on the other side. It is of a tolerably good flavour, and keeps till the latter end of April.

The hoghead apple, which is a small red fruit; the flesh is red, and the tallow amber. It is a cyder apple, becomes ripe in January, and keeps till March.
PYRUS.

The Hubbard's, or the ruflet pearmain, which is a real Norfolk apple; and, though not handsome, is one of the best table apples. It is of a dark ruflet colour, becomes ripe in January, and keeps till April.

The John apple, which is a middle-sized handfome fruit, of a greenish-yellow colour, with a little red toward the fun; the foottalk being very small. It is an excellent cyder and baking apple, from Devonshire; it is of an excellent flavour, and keeps till March.

The Isle of Wight pippin, which is a handfome middle-sized apple, of a greenish-yellow colour.

The juneting, or jenneting, which is a small yellowish apple, red on the side next the fun. It is a pretty fruit for early variety, and ripens about the latter end of June or beginning of the following month.

The kernel redbreak, which is of a greenish-yellow, with broad flecks of a dark-red all over it, and a yellow ground finely speckled with red next the fun.

The kernel pearmain, which is a small handfome apple, red toward the fun, and of a yellowish-green mixed with red on the other side. It is of a good flavour, keeping till the middle of May.

The Kentish pippin, which is a handfome sized apple, finely flecked with red. It is of a fine flavour, comes into eating about Christmas, and keeps till February.

The Kentish nonpareil, which is a handfome flat-shaped apple, of a light-ruflet colour, inclining to red toward the fun. It is of a good flavour, and keeps till May.

The king of the pippins, which is a middle-sized apple, of a fine gold colour, a little flecked with red toward the fun. It is ripe in January, and keeps till the latter end of March, when it becomes mealy.

The king apple, which is a middle-sized apple, of a conical shape; and its colour is that of a beautiful red intermixed with a little yellow on one side. This apple is of a pleasant fugitive taste, and keeps till the latter end of April.

The Kirke's feeding, which is a beautiful apple of a fine red colour towards the base, and yellow towards the eye. The foottalk is slender, and the eye large.

The Kirke's scarlet pearmain, which is a handfome middle-sized apple, of a beautiful red toward the fun, and a little yellow on the other side; becoming ripe in January.

The Kirke's scarlet admirable, which is a good apple for baking, and of a beautiful scarlet colour, is in eating about the month of January.

The Kentish full-basket, which is a species of codlin, of a large fize, and generally used for baking. It is in eating from August to October.

The Kirton or crack'd pippin, which is a middle-sized apple, of a greenish-yellow colour, with little dark spots. The coat is generally rough towards the foottalk. It is a good apple for the table, coming into eating in September.

The lady's finger, which is an excellent table apple, of a conical shape; red next the fun, and of a yellowish cast on the other side, having a sweet pefianflavour, and keeping till May.

The large flyre, which is a handfome cyder apple, of a yellow colour, with a little red next the fun. It becomes ripe in November.

The Lisbon pippin, which is a handfome middle-sized apple, of a flat shape, a fine red toward the fun, and a reddish-yellow on the other side. The flesh is firm, and has a sharp pefianflavour. It comes into eating in November.

The Loan's pearmain, which is a large oval-shaped apple, of a dull green colour intermixed with a brownish-red, deepest next the fun. It is a pretty good table apple, of a sharp taste, ripening in September, and keeping till May, but is apt to grow mealy.

The London pippin, or five-crowned pippin, which is a fine large apple, of a green colour, flecked with red toward the fun. It resembles the Ribblon pippin, but is larger. It has a pretty agreeable taste; and will come into eating about the latter end of November. It is good for the kitchen and table; and a most abundant bearer. It keeps till the middle of April.

The le calvingle d'automne, the autumn calvingle, which is a large fruit, of an oblong figure, and of a fine red colour toward the fun, having a vinous juice, and is much esteemed by the French.

The long laller, which is a middle-sized apple, of an angular shape, and fine yellow colour, with a beautiful red next the fun. It is of a tolerable flavour, and keeps till the middle of May, but is apt to become mealy.

The lemon pippin, which is a handfome oval-shaped apple, of a gold colour. It is of a fine flavour, and will keep till the beginning of March.

The long feam, which is a large angular-shaped baking apple of a pretty good flavour, with light green colour. It keeps till the latter end of January.

The lord Cheney's green, which is a middle-sized Yorkshire apple, resembling the Yorkshire greening. It is of a dark green colour, with a little of a chocolate colour next the fun. It is a baking apple, and keeps till the middle of May.

The lord Arundel's apple, which is large, of an angular shape; the colour is green, with a little dingy red toward the fun. It is from France, and good for sauce, keeping well.

The lord Camden's remnet, which is a good-sized feeding, of a yellow colour, with a little brownish-red next the fun. It is a good flavoured apple, and keeps till March.

The Lucas's pippin, which is a handfome, middle-sized, cylindical-shaped apple, of a beautiful orange colour. It is a pretty good fruit, and keeps till the latter end of April.

The maiden's blush, which is a small apple, of a dark mahogany colour next the fun, but paler on the other side, and sometimes of a greenish cast. The tale is soft, and of course this fruit is not fit for the table; but does very well for baking, or for cider. It keeps till the beginning of March.

The Mansfield tart, which is a large Nottingham apple, but most known in Yorkshire. It is handfome, of a green colour, having a little call of brownish-red, with dark spots next the fun, being a baking apple, and keeping till February.

The May gemnet, which is rather under the middle size, of a greenish-yellow colour, slightly flecked with red next the fun. It keeps till April.

The major Hemmings's apple, which is a handfome middle-sized fruit, of a light green colour, with a little brownish-red toward the fun. It is an excellent apple.

The margil, which is an excellent apple, about the size of a nonpareil. It is of a red colour, with some yellow on one side; continues in use from November to the latter end of March; and is often fold in the London markets for a nonpareil.

The Margaret apple, which is a fine and beautiful fruit, yellow, striped with red, of a delicate taste, sweet scent, and generally eaten off the tree. It is ripe in August.

The Minchall crabb, which is a handfome middle-sized Lancashire apple, of a yellow colour, with some brown spots.
It is common in the Manchester markets, and keeps till April. The monstrous rennet, which is a very large apple, turning red towards the fun, and of a dark green on the other side. It is generally preferred on account of its magnitude, as the flesh is apt to be mealy. It becomes ripe in October.

The mother rennet, which is rather under the middle size, of a greenish colour, with a little bluish towards the fun. The eye is large and deep, and the footstalk small.

The New-England pippen, which is a large angular-shaped apple, of a greenish colour, with a little brownish-red towards the fun. It has a pretty good flavour, and keeps till March.

The Newton pippen, which, according to Mr. Forfyth, is an American apple, but said to be originally from Devonshire. It is a fine large apple, of a greenish-yellow colour and red, with dark spots next the fun. When much exposed, it is of a beautiful red towards the fun, and of a gold colour on the other side. It has a fine flavour when not kept till it is too ripe, as then it becomes mealy. It is in eating from November to January.

The new red mul, which is a fine large apple, of a pale red towards the footstalk, and of a greenish colour towards the eye. It is a cider apple, and fit for baking.

The new red pippen, which is a beautiful middle-sized apple, of a darp red colour, with a mixture of yellow on the side from the fun. It keeps till March.

The nufuch, which is a good bearer, and very fit either for the table or kitchen; the cooks, however, complain that it makes but a very small proportion of sauce. It is ripe in September and October.

The nine-square, which, according to Forfyth, is a Gloucestershire apple. It is a large angular-shaped fruit, of a fine red towards the fun, and yellow on the other side, with a small mixture of red, keeping till April.

The Norfolk colman, which is a middle-sized apple, of a mahogany colour towards the fun, and a dark green on the other side. It keeps till August.

The Norfolk beethin, which is a good-sized apple, rather flattened, of a deep red colour towards the eye, but paler towards the footstalk.

The Norfolk paradise, which is a large apple, of a dark red colour towards the fun, and green on the other side. It is a nice baking apple, and of a tolerable flavour for eating. It keeps till the middle of May.

The Norfolk barber, which is a pretty large apple, of a dark red colour towards the footstalk, and green towards the eye. It is of a pleasant sharp flavour, being in eating from the latter end of January to the latter end of April.

The northern greening, which is a fine oblong apple, full at the footstalk, of a pale green colour, with a little red towards the fun. It is nearly of an equal size from the base to the crown, and has a fine flavour, being ripe in January.

The nonpareil, which is a fruit deferredly valued for the brilliantry of its tale. It is seldom ripe before Christmas, and, if well preserved, will keep till May. It is justly esteemed one of the best apples that have been yet known. The oak peg, or oaken pin, which is an oval-shaped middle-sized fruit, of a green colour striped with white. It is very full towards the footstalk, which is small, keeping till June.

The old English pearmain, which is an oval-shaped apple, of a middle size, and fine red colour, with a little yellow towards the eye. It is of a pleasant sweet flavour; and is in eating from January to March.

The old red mul, which is a fine large apple, somewhat resembling the new red mul, both in shape and colour, with the addition of dark red spots towards the footstalk.

The old red pippen, which is a middle-sized apple, red towards the fun, and of a greenish colour on the other side. It is a good apple, and keeps till March.

The orange pippen, which is about the size of a large golden pippen; of a beautiful gold colour, with a little pale red towards the fun. It is a handsome apple, of a good flavour, and makes a fine appearance at table, being in eating in October, and keeps till March, but gets flat in the table when too long kept.

The Orleans pippen, which is a small flat-shaped apple, of a dark red colour, resembling the Orleans plum.

The paradise pippen, which is a handsome middle-sized apple, of a reddish cast. It comes into eating in October, but will not keep. It grows mealy when too ripe.

The pashen, which is below the middle size, of a conical shape, and of a greenish-yellow, or light green colour. It is ripe in January.

The Pile's russet, which is a middle-sized longish-shaped apple, russet about the footstalk, yellow towards the middle, and of a brownish-red about the eye. It is a very firm fruit, of a sharp acid flavour, being much esteemed for baking. It ripens in October, and will keep till April.

The pigeonette, which is rather below the middle size, of a conical shape. It is of a pink colour, pretty dark towards the fun.

The Pearson's pippen, which is a nice apple, about the size of a large golden pippen, of a yellowish colour, and the form a little flat. In Devonshire, according to Mr. Forfyth, they put these pippens into the oven just after the bread is drawn, laying a weight over them to flatten them, in the same manner as they do the beets in Norfolk, and bring them to table as a sweetmeat. It is a very good dessert-apple, and keeps till March.

The pomme grise, which is a fine apple, from Canada, of a flatish form, and russet colour, streaked beautifully with red. It ripens late, and keeps till March. It is an excellent eating apple.

The pomme d'api, which is much valued for its colour, being a bright red. The tree is a good bearer, and the fruit is not subject to be shaken with high winds. The fruit should be suffered to hang on the tree till October or November, if the fruit do not set in. It comes into eating in February and March, and keeps long; but is more admired for its beauty than its flavour, or fineness of table.

The pomme violette, the violet apple, which is a pretty large fruit, of a pale green, striped with red towards the fun. It has a sugary juice, and a flavour of violets, from which it takes its name. It ripens in October, and continues in eating till February, or later.

The pommy, or king's apple, which ripens nearly as soon as the juneting, and though not so beautifully covered, is larger and much better raffled. It has a sub-variety, which is a winter apple.

The pound pippen, which is a large handsome apple, of a greenish colour, and is good for baking. It becomes ripe in January.

The poor man's profit, which is a dingy coloured oval-shaped apple, below the middle size. It is raised freely from cuttings; and keeps till January.

The queening, which is from Gloucestershire, is a large apple, of irregular shape, having large ridges from the base to the crown. It is of a dark red, but deepest towards the fun. It is a good cider apple, and bakes well, keeping till the latter end of November.
The queenie's kernel, which is a fine apple, above the middle size, of a deep red colour. Covered very thick with small whitish specks. It is a tolerably good apple, and keeps till the latter end of April.

The queenie's kernel, which is a small handsome apple, of a yellowish-green colour, sometimes inclining to red on the side next the sun. It is a fine-flavoured apple, very fit for the table, coming into eating in January, and keeping till May; but is apt to grow mealy when kept too long. Mr. Forthys says, "the tree never grows to the height of other apple-trees."

The quince-apple, which is a middle-sized fruit, of a yellow colour, with a little red towards the eye. It is of a pleasant sharp flavour, ripe in January, and keeps till April.

The Ramborn, which is a large fruit, of a fine red next the sun, and striped with a yellowish-green. It ripens about the middle of September.

The red pearmain, which is smaller than the pear mains in general. It is of a deep red, with a little yellow on one side. A pleasant sweet apple, and keeps till the middle of April.

The red-streak, which is a handsome middle-sized apple, beautifully streaked with red. It is a good cider apple, becoming ripe in January.

The red-streaked feldling from Longleat, which is from the Dorsetshire red-streak, is a beautiful apple, of a yellow colour, streaked with red, particularly next the sun. Forthys says, it is sold in the Bath and Bristol markets in the latter end of September, and beginning of October. It is a pretty good apple, but does not keep long.

The red bag, which is a beautiful large Herefordshire apple, of a longish shape, streaked all over with a dark red; and is in eating about the middle of October.

The red mutt, which resembles the old red mutt in shape; but is of a dark red colour towards the sun, and yellow on the other side. It is ripe about the middle of November.

The rennette grive, which is a middle-sized fruit, of a grey colour next the sun; it is a very good juicy apple, of a quick flavour, and ripens about the latter end of October.

The red sweet, which is a small round apple, red towards the sun, and of a greenish-yellow on the other side. It is a good bearer, according to Forthys, "and much esteemed among the country people of Cornwall, for making a kind of tart or pie, one of their dainties at Christmas." It is a pretty good table apple, and keeps till March.

The Ribston pippin, which is a fine apple, from Ribston Hall, near Knareborough, in Yorkshire. It is a little streaked with red towards the sun, and yellow on the other side, being one of the best apples for eating and baking, and continues in use from the end of October till April. It bears very well as a dwarf, and no garden should be without it.

The Robinson's pippin, which is about the size of a golden pippin, of a green colour, and partakes of the flavour both of a golden pippin, and a nonpareil. It keeps till May.

The royal George, which is a fine large apple, of a beautiful yellow on one side, and green on the other. It is a good apple, and keeps till June; but then grows mealy.

The royal nonpareil, which is a handsome apple, of a flatish shape, with a small footstalk and fine eye. It is about the size of a common nonpareil, of a green colour, with red towards the sun. It is ripe in January, and keeps till the latter end of March.

The royal pearmain, which is a fine large apple, beautifully streaked with red. It is ripe in January, and keeps till March, being a pretty good apple.

The royal ruffet, or leather-coat ruffet, which is a large fruit, and one of the best kitchen apples that we have. It is also a pleasant eating apple, and a great bearer, being in use from October to April.

The ruffet pippin, which is of a rough ruffet colour towards the sun, and of a green colour, sometimes inclining to yellow, on the other side. It is a good keeping apple, and fit either for baking or eating raw. It is ripe about the beginning of February, and keeps till March.

The summer pearmain, which is striped with red next the sun; the flesh is soft, but soon turns mealy; so that it is not much esteemed. It is in eating in August and September.

The silver pippin, which is a handsome middle-sized conical-shaped apple, of a fine yellow colour, with a faint blush towards the sun. The flesh is firm and very white, and of an excellent flavour. It keeps till the middle of May, or later.

The seek no farther, which is a handsome apple, rather above the middle size, of a pale green colour, a little streaked with red. It is of a pleasant though not very high flavour; and is in eating from January to May; but is apt to be mealy when kept longer than the beginning of April.

The Sykehouf, which is a handsome middle-sized apple, from Sykehoufe in Yorkshire, of an orange colour towards the sun, sometimes inclining to red, and yellow on the other side. This is a fine eating apple; ripe in January, and keeps till April.

The flone pippin, which is of a green colour, streaked with red towards the sun. It is of a sharp taste, and is in eating from January till the middle of May.

The Stoup codlin, which is a large handsome apple, of a pale-green colour, with a little red towards the sun. It is a baking apple, of a pleasant taste, and keeps till May.

The striped nonpareil ruffet, which is a handsome apple, of a greenish-ruffet colour, with a little brownish-red towards the sun. It is about the size of a large nonpareil, is ripe in January, and keeps till March.

The spice apple, which is a handsome middle-sized angular-shaped apple, of a yellow colour, and a pleasant flavour. It is ripe in January, and keeps till March.

The Skerry's kernel, which is a conical-shaped middle-sized apple, beautifully streaked with red, deep (or) towards the eye, and having a good deal of yellow towards the footstalk. It is ripe in January, and keeps till March.

The spice rennet, which is a handsome apple, below the middle size, red towards the sun, and yellow on the other side.

The Spanish pearmain, which is a middle-sized oblong apple of a carmine colour, and dark-red towards the sun. It is a pretty good apple, and keeps till the beginning of May.

The Spanish onion, which is a handsome round apple of a ruffet colour, with a dull red towards the sun. This apple, which is rather below the middle size, is very good for dessert, keeping till March.

The Sharp's ruffet, which is below the middle size, of a brownish-red colour towards the sun, and a pale-green on the other side. It is shaped like the fructum of a cone; is of a pretty good flavour; and keeps till May.

The Spencer's pippin, which is a middle-sized apple, of a yellowish colour, with many dark spots, being a baking apple, and keeping till the middle of May.

The Tunkerton, which is a conical-shaped yellow apple, with sometimes a little blush towards the sun. It is an excellent
PYRUS.

excellent sauce apple, and bakes well, being of an agreeable taste, but too large for the table. It will keep till February.

The transparent apple, which was introduced from St. Petersburg; but it is more curious than useful: a tree or two, therefore, will be sufficient for a garden. It ripens in September or October.

The Trevoird rennet, which is a small handsome russet-coloured apple, of an excellent flavour, and will keep till May.

The white corpendu, which is a middle-sized long-shaped apple, of a yellowish colour. It is a good eating apple, and ripens in January.

The ward apple, which is a beautiful flat-shaped apple, rather below the middle size, of a fine red towards the eye, and of a yellowish-green towards the footstalk. It is a sharp flavoured fruit, and keeps till June.

The Wheeler's ruffet, which is of middling size, the flesh firm, and of a quick acid flavour; it is an excellent kitchen fruit, and keeps long. It ripens in October.

The wine ruffet, which is a middle-sized conical-shaped apple, of a dark russet colour, and sharp flavour. It keeps till the latter end of April.

The Wheeler's extreme, which resembles the pomme grise, and is about the size of a nonpareil. It is a flat-shaped apple, beautifully clouded with red on a yellowish-russet ground; is of an excellent flavour, and keeps till April.

The white mulf, which is a middle-sized handome apple, of a greenish-yellow colour, with a little red towards the fun; the flavour is rather tart, but agreeable. It is ripe in January.

The Whitmore pippin, which is a good-sized handome apple, streaked with red towards the fun, and of a pale-yellow on the other side. It has firm flesh, of a tolerably good flavour, and is in eating from November to the latter end of April, or later.

The Wiltshire cat's-head, which is a large handsome apple, red towards the fun, and green on the other side. It is a very fine baking apple, and of a good flavour, being ripe in January.

The winter pearmain, or Herefordshire pearmain, which is of a fine red next the fun, and striped with red on the other side; the flesh is juicy, and flows well. It is fit for ufe in November, and, if properly managed, will keep till the latter end of March.

The winter pomroy, which is a pretty large conical-shaped apple, of a dark-green colour, a little streaked with red towards the fun. The coat is rather tough. It is a good baking apple, keeping till January.

The winter box apple, which is a middle-sized fruit, of a light green colour, and keeps till February.

The woodcock, which is a good-sized apple, of a dark red next the fun, and paler, with a little mixture of yellow, on the other side. It is ripe in January, and keeps till March, being a good cider apple.

The Wright's nonpareil, which is a Salopian apple, being a great bearer, of a good size, and a little flattened. It is a good kitchen apple, and keeps till June. The tree is smaller in size than most other apple-trees.

The Yorkshire greening, which is a good-sized flattened apple, of a dull-red colour, with a little green towards the eye. It keeps till August, or often later.

The sorts of apples advised for a small garden are the following: the juneting, the golden pippins, the nonufch, the Ribiton pippin, the nonpareils, the queen's apple, the Sykehoufe, the golden renant, the aromatic pippin, the grey Ledington, the scarlet pearmain, the lemon pippin, the pomme grise, the French crab, and different sorts of ruffetins and codlins, for baking.

But there are other varieties and sub-varieties that may be equally valuable with many of the above sorts.

Of the sixth sort there are the following sorts: the pear quince, with oblong-ovate leaves, and an oblong fruit lengthened at the base; the apple quince, with ovate leaves and a rounder fruit; the Portugal quince, with obovate leaves, and an oblong fruit, which is more juicy and less harsh than the others, and therefore the most valuable.

The quince is a very beautiful tree when in flower, as well as when the fruit is ripe in the autumn, and was cultivated in this country at an early period. According to Mr. Forfathy, the best sort for planting in the fruit-garden is the Portuguese, being the fittest for baking or stewing. It is of a fine purple colour when dried, and is much better for marmalade than any of the other sorts. The oblong kind, and the apple quince, are also planted in these situations, and other sorts are employed in the shrubberies for producing variety. The above sorts are like-wise valuable for mixing with apples in making pies, puddings, &c. as they add a quickness to the flavour when flat.

Method of Culture in the Pear Kind.—These trees are raised by grafting and budding upon any kinds of pear stocks; occasionally upon quince stocks; and sometimes upon white-thorn stocks; but the first sort are preferable for general use to have large trees, and the second for moderate growers.

The numerous varieties of these trees having been first accidentally obtained from seed, and as these seedlings rarely produce the same sorts again, the approved kinds are continued and increased only by grafting or budding upon stocks raised from the kernels of the kinds just mentioned. In order to refrain the growth of these trees, white-thorn stocks have also been used; but these are not so generally successful, and are almost in total diffuse in the nurseries: of course pear stocks are proper for general use, for principal large trees, both for walls, espaliers, and standards; and quince trees for smaller growths. For raising the stocks, the seeds or kernels of the different sorts should be sown in the latter end of autumn, as November, or December, or early in the spring, in beds of light earth, covering them near an inch deep; they come up in the spring; and in autumn, winter, or spring following, the strongest should be planted out in nursery-rows to remain for grafting and budding, for which, after having from one to two or three years' growth, they will be of proper size.

The operations of grafting and budding should be performed in the usual method; the former in the spring, and the latter in summer. (See Grafting and Budding.)

For this purpose the grafts and buds should be procured from such trees as produce the finest fruit of the respective sorts; those designed as dwarfs for walls, espaliers, or standard-dwarfs, being grafted or budded near the bottom; and in those for half or full standards, the stocks may either be previously trained up from three or four to seven or eight feet high to form a stem, then grafted near the top, or be grafted low-in the stock, like the dwarfs, and the first main shoot trained for a stem the above height: the grafted trees, both dwarfs and standards, should be pruned in their first year, but the budded ones not till the spring after; and when their heads are two years old from the grafting and budding, they may, if thought proper, be planted out for good, or remain longer in the nursery, as may be found convenient.

The dwarfs for walls, espaliers, &c. whether they remain longer in the nursery, or be transplanted to a year old into the garden, should have the first shoots from the graft or bud,
bloom, when a year old, headed down in March to five or six
eyes, to force out a proper supply of four, five, or more
lateral branches near the ground, to furnish the wall or
capital with borders quite from the bottom, these readily
producing others to cover the upper part.

Standards, supposing them to be grafted on high stocks,
may either be headed near the top of the stock, or permitted
to run up, as the case may require, so that if shortened it
will force out laterals near the head of the stem, and form
a more spreading full head; and if suffered to run up with
the first shoots entirely, they form higher and generally more up-
right heads in the end. Such standards, however, as are
grafted or budded low in the stock, as for dwarfs, must
have the first shoots trained upright at full length, fix or seven
feet high for a stem; if for full standards, they may either
be topped at fix feet height, to force out laterals near that
part to form a spreading head, or suffered to run and branch
in its own way to form a more erect and higher head.

The headed trees, both dwarfs and standards, on being
cut down in the spring, soon branch out from all the eyes
immediately below; when care should be taken during the
summer to trim off all shoots from the stem, suffering all
the top shoots to remain entire; when they will form hand-
Some beginning young heads by the end of summer, and in
autumn, winter, or spring following, may be finally planted
out into the garden, &c.

When from necessity they are retained longer in the nur-
ery, the whole should have proper pruning to reform ir-
regular growths, the proper trees being trained accordingly,
suffering the whole to branch away at full length, not
shortening any after the above general heading down, when
a year old, except it should form occasionally necessary,
either to reduce any casual irregularity, or to procure a
more full supply of lower branches; after which no further
shortening should be practised to the foot of trees;
for, after having obtained a proper set of regular branches
near the head of the stem, they readily furnish more in their
turn to increase the head on the upper part.

In regard to planting out the trees, they are moily of
proper growth for this purpose when from one to two to four
or five years old, from the graft or bud; but if larger trees
are required, those of six or eight years old may be safely
transplanted; younger trees, however, always succeed well,
even when only two or three years old.

In selecting pear-trees for planting, Mr. Forsyth advises
the choosing of the oldest trees that can be found instead of
the young ones, and such as have strong stems; to have
then carefully taken up, with as much of the roots as
possible, and carefully planted, after cutting in the roots a
little, spreading them as horizontally as can be done. Then
to fill up all round the roots with light dry mould; forcing
it in, about those which lie hollow, with a sharp-pointed
flick; filling the whole up to the top without treading the
mould, till the hole be filled with as much water as it
will contain, leaving it a day or two until the ground has
absorbed the water; then to throw on some fresh dry mould
and tread it as hard as possible, filling the hole up again
with mould to within an inch of the top, and giving it a
second watering, leaving the mould about three inches
higher than the border, to settle of itself, and to receive
the rain that falls, for at least a month. When the mould
has become quite dry, it may be trodden a second time;
then make a large bason all round the tree, and giving it
another watering, mulching the top over with some rotten
leaves or dung, continuing to water the trees once a week
in dry weather, and sprinkling the tops frequently with a
pot, or hand-engine, to keep the wood from shrivelling till
they have taken fresh root; and where the trees are planted
against a wall, the stems should stand sloping towards it; the
lower parts of them being fix inches from the bottom of the
wall, to give them room to grow, as when planted close to
the wall at bottom, the stems, in growing, will be confined
on the back, grow flat, and be very unsightly. If any
roots are in the way, to hinder it from being planted near
enough to the wall, they must be cut off; at the same time
taking care that the tree does not lean to either side, but
that, when viewed in front, it appear perfectly upright.
Sometimes standards and half-standards are seen planted a
foot or two from the wall, which gives them a very dif-
agreeable appearance; fix inches is, he thinks, quite suffi-
cient. Much care should be taken not to wound the stem
or root of the tree in planting.

When young trees have two stems, he advises always to
cut off one of them, leaving the stoutest and straightest,
planting that side outwards which has most buds on it.

It is added, that when the buds begin to break well, the
trees should be headed down to three or four eyes, to fill the
wall with fine wood, but never afterward, except the lead-
ing shoot to fill the wall, leaving the fore-highest shoots to
be pruned, as heretofore directed. He has had some trees
that had forty pears on them the second year, while some
of the same kind bore only eleven pears the fourteenth year
after planting, with the common method of prun"ing.
When such old trees as are recommended above cannot be pro-
cured, the stoutest and cleanest of the one-year's old grafting
should be provided. Where any of these trees become
stunted after a number of years, they should be headed down
as heretofore directed, which will bring them into fresh vigour
and fruitfulness. The proper season for planting them out
is any time in open weather from the end of October till
March, but the autumn or early winter are the most advan-
tageous periods. They succeed well in any common garden
soil, or good fertile orchard-ground, or field, that is not
very wet, or of a stiff or harden quality, but moderately
light and friable to the depth of one spade at least, and if
more the better. The ground should be prepared by proper
raking one or two spades deep, as the depth of good soil
will admit, wholly if for a full plantation, or only along
the place for each row of trees, in the place for each tree;
or only a hole for each tree at proper distances. The proper
distance for planting the dwarf fourts for walls or on cpa-
lizers, is for those on free flocks at not less than twenty feet, but if
twenty-five, or more, the better, especially if the walls be
rather low, &c. that there may be full scope to extend
their branches considerably in a horizontal direction, as they
will effectually fill that space, or even much more if it be
allowed them; but they are often planted much nearer to-
gether. It is however of importance to give the trees suf-
icient room, and the higher the walls the better, as is
evident by those trees growing against the ends of high
buildings, as they extend themselves very considerably
every way. Some plant cherry-trees or other moderate
fruit-trees in the intervals for a few years, till the
pears advance in growth and approach one another, when
they should be removed. They are to be planted in the
usual way, with their heads entire. See Planting.

However, for trees that are dwarfed by grafting or budding
uppon quince flocks, from fifteen to eighteen feet may be a
proper distance for planting, either for walls or cpa-
lizers. In respect to the distance at which pear-trees should
be planted against walls, it is observed by Mr. Forsyth that
when they are grafted on free flocks, such as colmers, pear
d'auche, crafanes, Pechafferies, virgouleufs, and winter
and summer bouchientos, it should at least be twelve yards
distant.
PYRUS.

distant from each other, supposing the walls to be from
twelve to sixteen feet high; but when they are only ten feet,
fifteen yards will be little enough for the purpose.

And where they are planted on south walls, vines, peaches,
nectarines, or apricots, may be planted between them, till
the trees extend so far as nearly to meet each other; then
they may be removed to any other situation in the garden
where they are wanted. And where the pears are planted
on west walls, the fame sort of trees may be planted between
them as on south walls; the fruit on a west aspect will come
into use to fecund that on the south. On an east wall dif-
ferent sorts of plums and cherries may be planted between
the pear-trees till they almost meet, then transplanted as
standards or wall trees.

It is advised that the borders for pear-trees in a large
garden should not be less than from ten to twenty feet wide,
with a foot-path about three feet from the wall, covered
over at top with coalashes or road-fand, to make a dry
walk for getting at the trees to cut and nail them, to gather
the fruit, &c. And that the depth of the mould for them
should never be less than three feet, laying the bell mould
at top, to encourage the roots to come as near the surface
as possible. If the bottom be clay, it will be very necessary,
once in every five or six years, to open the ground round
the roots of the trees, and cut off all the large ones that
are inclining to run into the clay; as, by this practice, the
trees will throw out fresh roots that will run near the sur-
face, provided the mould is good near the top of the borders.

And it is suggested that a crop of early peas, lettuces,
spinach, or any other small crops, may be grown on the
borders, during the winter and spring; but no late crops by
any means. If the ground can be spared, he would advise
have no summer crops, but keep the borders hoed, in
particular after rain; otherwise the ground, if a strong
loamy or clayey soil, will be apt to crack in dry weather;
but by frequent stirring between wet and dry this will in a
great measure be prevented, and the sun's rays admitted
into the mould, which will greatly heighten the flavour of
the fruit. When you can conveniently spare the borders
in winter, they should be ridged up to sweeten the mould,
which may be very well done if you sow early peas on the
sides of the ridges; which is by far the best way to preserve
the peas from the frost, and to prevent them from rotting,
which will sometimes happen, if the land be strong, before
they begin to vegetate; or, you may sow an early crop of
carrots or spinach on these borders.

With refer to the general management in the training
and pruning of these trees, if the young wall and espalier
trees thus planted are only one year old from the graft or
bud, having their first shoots of a year old entire, these
should in the spring be headed down to five or six inches, to
force out lower horizontal branches; but if they have been
previously headed, as advised above, and have thrown out
lateral true form a regular set of horizontal branches, con-
cfiting of fix or more near the bottom, they should not now be
shortened, but trained to the wall or espalier at full length
horizontally, preserving an equal number on each side five
or six inches and; they will readily emit a further supply
of horizontal shoots to cover the wall, &c. regularly up-
ward, and at the same time being shortened, they gra-
dually form themselves for bearing, as early shortening of
the branches of these trees retards their bearing a year at
least; if, however, there is a want of branches, some of
the middlesoft may be pruned short, and trained to the wall
or espalier. According as the trees shoot in summer, a
further supply of all the regular shoots in every part where
they occur, should be trained in at full length, unless it
shall seem necessary to prune some strong shoots to obtain a
greater supply of horizontal branches the same year, in
order to furnish the head as soon as possible; at this time,
however, displace all the fore-right and other irregular
branches of the year, continuing the supply of regular
shoots close to the wall, as they advance in length during
their summer's growth. And in the winter pruning, the supply
of shoots attained in summer should be well examined, fe-
ating all those that are well placed and properly situated
for training in, to increase the number of horizontal branches
on each side, which should be left wholly entire, and at the
same time retrenching any superfluous and ill-placed shoots
omitted in summer; then the whole supply of regular hori-
zontal branches in every part should be trained in straight
and close to the wall or espalier, equally on both sides of the
tree, every branch at the full length, at four, five, or six
inches apart. See WALL, ESPALIER-TREES, AND PRUNING.

But there is another method sometimes practised in training
these trees for walls and espaliers, which is, that after their
frist heading down, and having thrown out several laterals, to
select three of the strongest and most regularly placed, one
on each side and one in the middle, nailing the two sides
horizontally at full length, and the middle one upright:
the tree having produced a further supply of shoots in the fol-
lowing year, add two or four of them as side branches, arrang-
ing them on each side of the stem as the two former, train-
ing the middle shoot still in an upright direction; observing
that where it does not furnish horizontal slough enough, it may
be shortened fo as to make it throw out shoots at any requisite
height, continuing the middle one always upward for a stem,
and the side ones for bearers. In either of these methods of
training the trees, continue yearly increasing the number of
horizontal shoots, till the full space of walling or espalier is
regularly covered with bearers at equal distances, constantly
continuing them all at full length, as far as the scope of
walling, &c. will permit; as they naturally form fruit-spurs
at every eye, almost their whole length, and the fame branches
continue in a fruitful state a great length of time. When
the trees have once filled the wall or espalier with branches,
they need but very little further supply for many years,
and that only occasionally, according as any worn-out or decayed
branch occurs, and wants renewing with young wood. See
PRUNING.

And in the after-prunings in the summer, which should
e be begun in May, or early in June, rub off all the super-
fluous and unnecessary shoots of the year, and all fore-right
and other ill-placed shoots, retrenching them quite close,
being careful to leave the terminating shoot of every hori-
zontal or bearer entire; and referring here and there a well-
placed shoot, towards the lower parts in particular, and
where there are any apparent vacancies, to train up between
the mother branches, till winter pruning, when, if not wanted,
they must be retrenched.

But in the winter pruning, which may be performed any
time from the fall of the leaf until March, the branches
should be generally examined, to see if they are any where
too much crowded, or trained irregularly; and where any
such occur, they should be regulated as they may require;
and where there are any vacancies, some contiguous shoots,
referred in the summer dressing, should be laid in, and all
the other shoots not wanted must be cut clean out close to the
branches, being careful still to preserve the terminating shoot
of every branch entire, in all parts, as far as the allotted
space admits, like wise all the fruit-spurs in every part, fattening
in all the branches regularly at full length. In pruning
old trees at this season, where decayed and worn-out branches
occur, they should be cut out, and young wood trained in
its
its stead; likewise, where any branch, through age or any other defect, is become barren, it should be retrenched, and some eligible lower young branch, or shoot, be laid in its place.

Where any of the choicer sorts of these trees are become worn-out and barren, they should be renewed with young bearers, by heading the branches wholly down near the bottom in winter or spring, when they break out in the old wood, and in the following summer furnish a large supply of strong young shoots, which should be trained according to the rules already laid down, when they will soon form a fort of new tree, and bear good fruit. After each winter pruning, the trees which are again as it were and espaliers require a general nailing, &c. which should always be done with great regularity. See Wall-Trees, and Espalier-Trees.

The mode of training dwarf standard-trees of this sort is shown in speaking of trees of that kind. See Dwarf-Trees.

In respect to the culture of the borders where this sort of wall or espalier-trees are growing, it is commonly digging them once more every year, adding manure occasionally in common with the other parts of the garden; but if some good rotten dung be applied every other year, and the ground well dug or trenched every winter, it greatly promotes the size and perfection of the fruit. In regard to standard-trees of this kind, any of the forts bear plentifully in any open situation, though the fruit may not always be so large and fine as those of wall and espalier-trees: summer and autumn pears, however, ripen in great perfection on standard, as also most of the common winter pears. In planting them, trees of from two or three to four or five years old, having tolerable heads, are of a proper age and size for the purpose, and are preferable to older trees for any general plantation. They should be planted with all their heads entire, except retrenching any very irregular-placed branch, in the usual manner of tree-planting. See Planting.

In their future growth they should be suffered to branch naturally, so as to form large branchy heads, sufferring them all to remain entire. The general culture of this sort of trees, in respect to pruning, is very trifling, and only required occasionally, probably only once in several years; such as the retrenching any irregular growing branches, and thinning such branches are as very much crowded, cutting out all the decayed wood, and eradicating suckers from the roots and stumps. See Pruning.

When standard-trees are situated in a garden, in which the ground is necessarily dug over and trenched annually for the reception of the under-crop, and occasionally enriched with dung, they generally produce finer fruit than in orchards, or other places where the ground is not in similar culture.

Mr. Forsyth observes, that the method of pruning pear-trees is very different from that practised for apple-trees in general, in which the constant practice has been to leave great furs as big as a man's arm, standing out from the walls, from one foot to eighteen inches and upwards. The constant pruning invariably brings on the canker; and by the fur standing out so far from the wall, the blossoms and fruit are liable to be much injured by the fruit and blighting wind, and thus the sap will not have a free circulation all over the tree. The sap will always find its way first to the extremities of the shoots; and the furs will only receive it in a small proportion, as it returns from the ends of the branches; and the fruit standing at so great a distance from the wall is too much exposed to the weather, and, of course, is liable to be hard, spotted, and kerrinly.

The following method he has practised where the trees were all over cankered, and the fruit small, and not fit to be sent to the table. He cut the tops off as near as possible to where they were grafted, always observing to cut as close to a joint or bud as possible. The buds are hardly perceptible, but it can always be known where the joints, or forks, are, by the branches breaking out of the sides. He adds that finding the pear-trees in Kensington gardens in a very cankerly and unfruitful state in the years 1784 and 1785, he took out the old mould from the borders against the walls, and put in fresh loam in its stead; at the same time he pruned and nailed the trees in the common way, and left them in that state upwards of eighteen months, to see what effect the fresh mould would have on them; but to his great surprise he found that it had no effect. After this trial he began to consider if he should be content to recover their old trees. In this attempt he began with cutting down four old and decayed pear-trees of different kinds, near to the place where they had been grafted; this operation was performed on the 15th of May, 1786. Finding that they put forth fine shoots, he headed down four more on the 20th of June in the same year (for by this time the former had shoots of a foot long), which did equally well, and bore some fruit in the following year. One of the first four he headed down was a St. Germain, which produced nineteen fine large well-flavoured pears next year, and in the third bore more fruit than it did in its former state when it was four times the size. He left seven trees upon an east wall, treated according to the common method of pruning, which bore the following number of pears upon each tree. Epine d'hyver produced eighty-six pears, and the tree spread fifteen yards; a crafane produced one hundred pears, and the tree spread fourteen yards; another crafane produced thirteen pears, and the tree spread ten yards; a virgoule produced one hundred and fifty pears, and the tree spread nine yards; a colmar produced one hundred and fifty pears, and the tree spread nine yards; another colmar produced seventy-nine pears, and the tree spread ten yards; a l'echafferie produced sixty pears.

But seven trees headed down and pruned according to his own method, leaving the fore-right shoots in summer, bore as follows, in the fourth year after heading: a Louibonne bore four hundred and sixty-three pears, and the tree spread nine yards; another Louibonne bore three hundred and ninety-one pears, and spread eight yards; a colmar bore two hundred and thirteen pears, and spread six yards; a brown burre bore five hundred and three pears; another brown burre bore five hundred and fifty pears; a crafane bore five hundred and twenty pears; a virgoule bore five hundred and eighty pears. And he adds, that the branches of the four last trees spread nearly in the same proportion as the first three. He also states that a young burre, the second year after heading, bore two hundred and thirty pears; and a St. Germain four hundred. All the above trees stood in the same aspect and the same wall, and the fruit was numbered in the same year. A great many pears which dropped from the trees are not reckoned. The trees that were pruned according to the old practice covered at least one-third more wall than the other.

From this statement it appears that the trees headed down bore upwards of five times the quantity of fruit that the others did; and that it keeps increasing in proportion to the progress of the trees. This is an important statement in the culture and management of old trees of this sort; and the following fact with respect to standards is deserving of great attention: On the 20th of June he headed several standards that were almost destroyed by the canker; some of them were fo loaded with fruit the following year, that he was
PYRUS.

was obliged to prop the branches, to prevent their being broken down by the weight of it. In the fourth year after these standards were headed down, one of them bore two thousand eight hundred and forty pears. There were three standards on the same border with the above, two of which were St. Germain; the old tree was of the same kind. One of these trees, twenty years old, had five hundred pears on it, which was a great crop for its size: so that there were on the old tree, which had been headed down not quite four years, two thousand three hundred and forty pears more than on the tree of twenty years' growth. When the men numbered the pears, there was near a barrowful of wind-falls at the bottom of the old tree, which were not included. These and other statements are given in his useful treatise on the "Culture of Fruit-Trees."

The following is the method he pursues in training trees that are cut near to the place where they are grafted. In the month of March, every year, he shortens the leading shoot to a foot or eighteen inches, according to its strength: this shoot will, if the tree be strong, grow from five to seven feet long, in one seon; and, if left to nature, would run up without throwing out side-shoots. The reason for thus shortening the leading shoot is to make it throw out side-shoots, and if it be done clofe to a bud, it will frequently cover the cut in one seon, leaving only a cicatrix. When the shoots are very strong, he cuts the leading ones twice in one seon; by this method he gets two sets of side-shoots in one year, which enable him the sooner to cover the wall. The first cutting is performed any time during the spring, and the second about the middle of June. When you prune the trees, and cut the fore-right shoots, which should be done in February or March, always cut close to an eye or bud, oberving where you fee the greatest number of leaves at the lower bud, and cut at them; for at the footstalk of every one of these will be produced a flower-bud. The same will hold good in cutting the superfluous shoots on standard pears. He adds, that you will have in some sorts of pears, in a favourable seon, from five to nine pears in a chiot. This cutting should not be later than March, or the beginning of April, on account of the leading shoot beginning to grow: the next topping, when the leading shoot grows quick enough to admit of it, should be about the middle of June; and the length of the shoots should be according to their strength, having from three eyes or buds to fix on a side. It is added, that the cankerly part beginning to affect the new bark, he cut off all the canker at the bottom, and plastered the place with some cow-dung, mixed with wood-ashes and powder of burnt bones, put into as much urine and foapuds as would make it of the consistence of thick paint; this he laid on with a painter's brush. After it had been applied about three hours, he patted it gently down, with his hand, clofe to the tree. By so doing, he gets rid of all the air-bubbles that may be under the composition, and makes it adhere to the tree, preventing it from being washed off by heavy rains. And in the beginning of August he shortens the fore-right shoots to about four inches long; by this time the shoot will have made its full growth for the seon, and will produce fine strong eyes for the following year. Such shoots as grow near the flem of the tree, if any are wanted to fill up the wall, may be tucked-in as directed for peaches. This will prevent them from looking unftightly, and save them from the fury of the autumnal and winter winds. He further advises, that whenever the trunk is hollow, it be followed under ground till you have cut out all the decayed parts and rotten roots, otherwise you will lose the tree. By proceeding according to the foregoing directions, the roots will be renewed, while the tree is forming a fine handfome head. In the mean time the borders should be threnchd, taking up all the roots, and adding some fresh mould to them, if you can conveniently get it; if you cannot, remove all the four mould that is about the roots of the trees, and put in some taken from the border, at a distance from the wall; always remembering to lay the top spit next to the roots of the trees; also, to mix some vegetable mould, from the melon and cucumber beds, with rotten leaves, as a manure for the borders. He has headed down many trees that had not this preparation; and yet they thrive very well, but did not fend forth such fine roots and shoots as those that were so prepared. He concludes by obferving, that if the above directions be followed, more pears will be procured in three or four years than can be done in twenty-five years by planting young trees, and pruning and managing them in the common way. It is added, that if it should be found, that, before the pears arrive at half their natural size, they get fluted, after cold blighting winds, and frosty nights, he would recommend a new operation to be performed when the weather begins to grow mild, which is to take a sharp penknife, and with the point of it make an incision through the rind of the pear from the footstalk to the eye, in the fame way as in forcing a bark-bound tree, taking care to penetrate as little into the flesh of the pear as possible. At the fame time beat up some fresh cow-dung with wood-ashes, and with your fore-finger rub in a little of this composition where you made the incision; as the wound heals, the composition will be discharged from the fruit; this will prevent the pears from cracking and burling, which renders them good for nothing. The forts that are most liable to this disorder are, he obferves, the colmar, virgoule Rede, and cra- fane. He only, however, recommends this operation for wall pears, as it may be thought by some a troublesome operation, and it will certainly take up some time.

Signs of Ripeness in the Pears. — The maturity of the pear is generally known by its changing from a green to a yellow, or reddish colour, &c. and by the frequent falling from the tree; and when, with a gentle twirl or turn upwards, it easily quits its hold: but these signs of ripeness are more particularly observable in summer and autumn pears; as winter pears, not being maturely ripe when gathered, often require a good pull before they quit the branches.

The summer pears ripen in successiion in different sorts, from about the beginning or middle of July till the middle of September; many of the earlii ripening all at once, as it were, and continuing good but a few days, either on the tree or when gathered, nor will any of the sorts keep good long; and none of these sorts should hang on the tree till soft ripe, as in that case most of them would become mealy and inipid. These sorts should be gathered as soon as they are arrived to full growth, and just begin to colour and discover maturity, but before they become soft and mellow. For family use, they may be gathered from the tree according as they attain perfection; but the general crops of each sort should be always taken down before they ripen fully, and be laid in any dry room; none of the kinds will keep long, some only a few days, and scarcely any of them above a fortnight, though from different varieties ripening at different times, the sucession is continued for eight or ten weeks.

The autumn sorts ripen in different varieties, from about the middle of September till the end of October; some of the forwardest become edible on the tree, others requiring to lie some time after being gathered before they acquire perfection. The different sorts of these pears should be gathered according as they arrive to maturity; those defigued
to keep some time, may be gathered in dry weather, just when they have attained full growth, as shown by their frequent drooping, and by their readily quitting the trees on being handled, and laid in a dry close room, or in baskets, each lot separately.

The winter kinds attain their full growth on the trees about the end of October or beginning of November; but the eatable kinds do not acquire maturity for that purpose on the tree, or for some considerable time after they are gathered, some probably in a month, others two or three, and some more, and some lots not till the spring following. But the baking kinds may be used any time from October or November during their continuance. All winter pears should be indulged with as full growth on the tree as the weather will permit, even until the end of October, or first week in November; in the later kinds, if the season continues mild, be cautious, however, to get them gathered before attacked by much frost. And in gathering all the lots for keeping, dry weather should be chosen, and when the fruit is also quite dry, being careful not to bruise them. See Fruit.

Method of Forcing Pears.—These sorts of trees are sometimes forced by artificial heat, in some of the prime early kinds, to obtain a portion of fruit as early in the season as possible. This is effected by means of hot-walls and forcing-frames; having previously some trees of the choicest early summer pears, such as the jargonelle, or any other early lot, trained as wall-trees against a south wall, till advanced to some tolerable state of bearing; being then enclosed with glass frames, in the manner of forcing-frames or hot-walls, and having internally either flues for fire-heat, erected forward and extending long-ways, or otherwise a pit arranged in that direction, in the interval or space between the trees and the glass-work, for a bark or dung hot-bed; and by one or other of these methods a proper degree of artificial heat is produced internally to force an early growth in the trees, and forward them to early flowering and fruiting, managing them in the common way, as other trees in forcing-frames, so as to have some ripe fruit early in June, or some time in that month.

Method of Culture in the Apple Kind.—The whole of the varieties of the apple were first accidentally obtained by raising them from the kernels of the fruit; but as these cannot be dependent upon to continue the same sorts of fruit, grafting is the mode made use of to increase and continue the different varieties of them, which is performed upon crab, or any kind of apple stocks, raised from the kernels, for dwarfs as well as standards; and sometimes upon codlin and paradise apple stocks raised from cuttings and layers, when designed to have efpaliers and other dwarf trees, or for small standards, as low as possible, to be confined within a moderate space; some lots may also be raised by layers and cuttings, as the common codlin.

Stocks.—The method of raising the different sorts of stocks for the purpose is, in the crab and apple stocks, from the kernels of the fruit; but in the codlin and paradise stocks by cuttings and layers, to continue them with certainty of the same kinds and moderate growths. The crab and apple stocks may be raised from the kernels of any of the sorts, procuring them in autumn or winter, either from the fruit, or from such as have been pressed for vinegar and cider, clearing them from the grosser part of the pulp; then fowing them in beds of light earth, moderately thick, over the bed, or in drills, covering them about an inch deep. They come up in the spring; when, if the season prove dry, they should be watered occasionally, to forward and strengthen the growth of the plants; and in the autumn, winter, or spring following, the largest may be planted out in nursery-rows, shortening their tap-roots a little, and placing them in lines two feet and a half apart, to remain for grafting; after having from one to two or three years' growth, they will be fit for grafting upon, particularly for dwarfs, or even for full and half standards, if intended to form the item from the graft, which is an eligible method for these trees; but if the lot is to form the item, they require three or four years' growth, to rise to a proper height, four feet for full, and four or five for half standards. The modes of grafting all the forts is the same as for other fruit-trees, and should be performed in March, either by whip or cleft-grafting, according to the size of the stock. See Grafting.

Having provided proper grafts of the different sorts of apples intended to be raised, the stocks designed for dwarfs of all sorts must be grafted within six inches of the ground; and the standards may also be grafted low, one shoot from the graft being trained up for a item, or on tall stocks, at five or six feet in height, but for low and half standards, at from two or three, to four or five feet, and lower for dwarf standards. The grafts of all the forts should the same year; and, by the autumn following, the trees having formed little heads, of the same height, or as high, and about to ripen, they may then be planted out finally where they are to remain, or be retained a year or two, or longer, in the nursery, as may be requisite, training them for the purposes intended, as dwarfs, efpaliers, &c. &c., and uprights for standards, heading the dwarfs down in March following, within six inches of the graft, to force out more lateral shoots below to form a fuller head, proceeding immediately to turn them near the bottom, log as to fill the efpalier, &c. equally with branches, quite from within six or eight inches of the ground, regularly upward. In standards, these grafts low must be trained with one shoot upright, at full length, for a item, five or six feet high at least, for full standards before it is topped; though if grafted on tall stocks of height sufficient for a item, the shoots from the graft may either be headed to five or six eyes; or, if to form a more spreading head, remain entire, and aspire more in height, and assume a more upright growth: in all the modes of training, care should be taken to keep the items clear from all lateral shoots, displacing all such as soon as they appear, encouraging only a proper set of branches at top to form the head. When these trees have heads from one to two or three years old from the graft, they are of a proper age for planting out; though trees of four or five years old will also succeed very well, and even those of five or six years' growth may also be safely planted if required. The nursery-grounds are mostly furnished with all the varieties of these trees for sale, either quite young from the graft, or trained of several years' growth.

Choice of Trees.—In choosing the different kinds of trees for planting, care should be taken to have a collection of the principal varieties, both in efpaliers and standards, in proportion to the extent of the ground, as the trees of the best sorts are as easily raised and cultivated as the indifferent ones, allotting a smaller portion of the summer kinds, as such as ripen from August to about the middle of September, for immediate use off the trees, as they will not keep long; a larger supply of the autumn sorts, and most of all of the winter keeping apples: observing, in the summer kinds, that it is advisable to allot a principal supply of the common codlin in small standards, as being generally both a great bearer, and the fruit the most useful of the summer apples for culinary purposes, from its young green growth.
growth in June or July, till its full maturity in August and September, when it becomes also a good eating apple: and as the tree is a moderate grower, it admits of being planted in small standards closer or more abundant in a small extent of ground than most of the principal apple kinds.

In choosing apple-trees from the nursery, they should, Mr. Forsyth says, have strong, straight, and clean items. And he advises not to suffer the dwarf trees to run higher than twelve feet, as otherwise they become naked at bottom, the fruit is liable to be blown down, and the tops broken by high winds.

The proper season for planting all the sorts of apples is, in mild weather, from the end of October till March; but when planted in autumn, or early in winter, they establish themselves more firmly before the drought of the following summer. They succeed in any common soil and open situation, except in low very moist land, in which they are apt to canker, and soon go off: in a phialy, shallow loam they generally answer very well. The ground should be properly prepared, by good trenched, where the ranges of trees are to stand.

In the planting of espalier apple-trees they should be ranged at no less than eighteen or twenty feet distance; the latter especially for trees grafted on crab or apple flocks, which being free shoots, the branches readily fill that space. For the trees grafted on codlin and paradise flocks, fifteen or eighteen feet may be sufficient; though the latter, in particular, is sometimes planted only twelve or fifteen feet asunder, as being a very moderate shooter: it is, however, advisable to allow every forts full room, according to their growth, to have proper space to extend their branches always at full length. The trees should be planted with all their heads entire, only retrenching any very irregular growths, that do not range conveniently with the intended form, and pruning any broken roots. Then having opened a proper hole for each tree, plant them in the usual manner, being careful to place them with their branches ranging the way of the espalier. As soon as the earth of the holes and of the roots is properly settled, all the branches should be trained in horizontally to the right and left, an equal number on each side at full length, as above.

The general culture in espalier trees thus planted and trained, as the same branches or bearers continue fruitful many years, is to continue them as long as they remain of proper growth, constantly giving them a summer and winter pruning annually, as explained above. In wall-trees also, any of the principal choice varieties of eating apples may be trained, to forward and improve the growth, beauty, and flavour of the fruit; such as jennetings, Margaret apple, golden pippins, golden rennets, pearmain, &c. or any other approved eating kinds, a tree or two of a fort, against a south-west, or east wall.

Standard apples, when planted in the garden, should be arranged thinly, to admit of under crops growing freely, without being shaded by their spreading branches. Full standards should be chiefly planted for the general crops, and half and dwarf standards for variety. The standards, when trained as above, should be planted out with all their heads entire, when in the kitchen garden, at thirty feet distance in the rows; and for an orchard, thirty feet distance every way. In planting, for each tree a wide hole should be opened, trimming any long fragglings and broken roots, leaving all the others entire, and planting them with the usual care. As soon as planted out, every tree should be well flaked to support them firmly upright, and prevent their being disturbed in rooting by winds. See Orchard and Planting.

Smaller growing standards, such as codlins, or other low standards grafted upon codlin flocks, and dwarfs upon these or paradise flocks, may, if required, be planted only at fifteen or twenty feet distance in the rows, and not less than twenty-five feet between the lines of trees; though, if there be room to allow a greater distance both ways, it will be advantageous, especially in planting in kitchen gardens, in which it would be proper to allow double that distance between the rows of trees, of the larger growths of these kinds. The standards thus planted with their heads entire, should be suffered to advance with their branches at full length, and in general take their natural growth, when they soon form numerous natural spurs in every part for bearing.

In respect to pruning these standards, little is required, only the occasional retrenching any irregular cross-placed bough, or the reducing to order any very long rambler; or when the head is become greatly crowded and confused to thin out some of the most irregular growths, likewise all strong shoots growing upright in the middle of the head, and all dead wood, and suckers from the stem and root.

As to half and dwarf standards of these trees, they may be differed in different parts of the garden to cause variety, managing them as the full standards. The former on dwarf paradise flocks, being very moderate shooters, may be planted in a little compass, and are sometimes planted in pots for curiosity, to place on a table, amidst a defect, with the fruit growing on them. See Dwarf-Trees.

It is observed by Mr. Forsyth, that in heading down old decayed apple-trees, for the sake of symmetry, it will be necessary to cut at the forked branch as near as can be to the upper side of the fork, cutting them in a sloping manner to carry off the wet, at the same time rounding the edges. To begin at the lower branch, cutting still above the lower fork; and proceeding upwards, cutting the rest of the branches from one to fix joints, or forks, according to their strength, till you have finished cutting-in the whole head. If any of these branches should have the canker, all the infected part must be cut out. When the tree is all prepared, the composition should be immediately applied, beginning at the top of the tree, and finishing with the powder of wood-ashes and burnt bones as you descend, which will serve it from being rubbed off during the operation; and the composition will prevent the sun and air from injuring the naked inner bark. A tree thus prepared, will in the course of three or four years, produce more and finer fruit than a maiden tree that has been planted upwards of twenty years.

These directions, if properly attended to, will be sufficient, it is supposed, to enable any one to bring old decayed trees into a healthy bearing state.

It is believed, that in large orchards and gardens, it may be necessary, at first, to head down only every other tree; cutting some of the branches of the rest, which are in a decayed and cankerly state, and which bear no fruit. This will be preparing them to throw out new wood, and furnish the tree much sooner with bearing branches. He recommends the performing of the operation as early as possible; as by so doing the wood will be the stronger, as in May, or the two following months.

And it is added, that when the trees are become hollow, the same method should be followed as directed for plums; but by no means to cut them down unless the tops are quite decayed; observing to cut the loose rotten wood clean out of the hollow and other decayed parts, applying the composition; at the same time to open the ground, and cut out
PYRUS.

all the rotten parts that may be found in the lower part of the limb, together with all the decayed roots, which, if this be not done, will infallibly injure the fresh wood and bark, and prevent a cure from being effected. He would recommend heading down all apple-trees that are much cankered and have ill-shaped heads; as by so doing much labour will be saved, and the trees will amply pay the proprietor. He advises never to shorten the young branches, except they are very thin, when it will be necessary to do so to fill the trees with young wood: nor prune any of the young wood: nor prune any of the young shoots the second year (he means the year after they are cut), as many of the eyes, almost to the end of the shoot, will, if it be strong, become fruit-buds next year; and so on every year. It is contended, that in the month of May in the fifth year after the trees have been so cut, it will be necessary to go over them, and rub off with your finger and thumb all the superfluous young shoots; leaving from three to five eyes on each shoot, according to the size and strength of the branch cut. These shoots will bear from three to four years; by which time they will be pretty much exhausted by the great quantity of fruit produced from them: they should then be cut down to two eyes to produce new wood. He always leaves three different years' branches on the tree, when the first shoot is cut off. This is fully shown in a plate in his useful work; and the next shoot will be full of fruit-buds, if it has not been shortened: when it begins to grow weak, it should be cut off; and the next cutting must be made when the former branch is tired of bearing: by proceeding thus all over the tree with care and attention, the advantages of this method of pruning, above the common mode, will soon be perceived; as by it you will be able to keep the trees in a constant state of bearing, which, if left, to nature, would only produce a crop of fruit once in two or three years. When the shoot that is done bearing is cut off, the composition should constantly be applied, rubbing off the shoots where they are too numerous.

It is supponed, that the best time to prune apple-trees is in the month of April, or in May, after the operation has been performed on the peaches, nectarines, and cherries: and that soon after this pruning, about the middle of May, it will be proper to look over the trees, and to pick off any caterpillars that may be on them. It will then be seen what shoots are infected with the canker, and which might have escaped your notice at the time of pruning; and wherever you observe the least appearance of infection, which may be known by the wood appearing of a brownish colour, the shoot must be cut down till you come to the sound white wood. The small shoots that cross each other should be cut off, leaving the strongest to fill up the tree, and make a fine handsome head. The suckers that spring from the root should be carefully grubbed up, and the side-shoots from the stem cut off; for, if left to grow, they greatly weaken the tree. The knobs, where old branches have been cut off, should also be pared away, leaving the surface of the tree as smooth as possible; after which, the composition should be applied: the young bark will soon begin to grow, and by degrees cover the old wounds with a fresh smooth surface, and thus prevent the canker from gaining ground on the tree. He has seen some old wounds of considerable size, headed over in one year: and he adds, in confirmation of the utility of this practice, that the trees which he pruned and dressed, as above directed, in the course of the summer, 1795, are all perfectly cured, the wounds being filled up with sound wood, and covered over with new bark: they all continue in a healthy state, and bear fine handsome fruit. And he has advised several nurseriesmen to follow the practice, heading down their apple-trees after the season of drawing her bales is over. Mellers Gray and Wear have headed a great many of such trees as were formerly thrown into the figgote pile, and have been amply repaid for their trouble. Trees thus headed down, provided the limbs be strong, will, he thinks, in the third and second year, produce as much fruit as well refund the purchase-money; besides, a great deal of time will be saved, which would be lost by planting younger trees: as, where you can procure tree of the above description that have been headed down three or more years, they will be all covered with fruit buds: and, if carefully taken up and planted in the autumn, if the season proves favourable, they will have a tolerable crop of fruit the fifth year. Such trees must not be headed down like maiden trees, but only thinned off where the branches run across and rub against one another, which should never be suffered in these cases. He says, he would never recommend training apple-trees as espaliers; as by doing so the air is kept from the quarters of the garden; and by constant pruning and cutting off all the side-shoots which you cannot tie to the espaliers, you prevent them from bearing, and, moreover, bring on the canker. And when the dwarf trees have handsome heads, more and much finer fruit will be gotten from one of them than from the espaliers; at the same time, a free air is admitted to the crops in the quarters, and the constant expense of the flakes and labour, in laying the trees to the espaliers is saved. Espaliers may, he observes, be converted into dwarf standards by shortening the branches at different lengths, so as that they may be able to support themselves without the flakes: but not to shorten them all regularly; and if cut with judgment, as near to a leading shoot, or an eye, as possible, they will in the course of two years form fine heads, and in the third year bear six times the fruit as they did in their former state, and of a finer flavour. The same method of pruning as already laid down for standard apple-trees is also applicable to espaliers.

It is remarked, that the borders where you make your croffings in gardens should be six or eight feet broad at least, to let the trees spread on each side, at the distance of twelve feet from tree to tree, and they should be well trenched, two feet and a half deep at least. If there should be gravel, or four clay, it must be taken out, and good mould put in its place; leaving the ground as rough as possible for the frost and rain to melt it. When you level the ground it should be done after rain; you may then sow some small crops in the border; such as lettuce or spinach, or cabbage for transplanting; but let not any of the brassica tribe come to full growth. Leaving cabbage and broccoli on borders, near fruit-trees, draws the ground very much, fills the borders with insects, and also prevents the sun and air from penetrating into the ground. And when the sun can have free access to the border, it adds much to the flavour of the fruit. If you can spare the ground on the crofs-borders in winter, it will be of great service to the trees to rid it up as loose as you can, and let it lie in that state all winter, to mellow and sweeten.

Where the soil is strong, he would recommend planting of apple-trees that are grafted on paradise stocks; but if the soil be light, free stocks will do much better; and when the ground is light clay or brick-earth, it should be mixed with old lime-rubbish or coal-ashes, street-dung, or sand: but what he uses for the borders against the walls, and which he prefers to every other manner, is a vegetable mould produced from leaves of trees. Of this a good coat should be given once in two or three years, which will be sufficient, he thinks, for the borders where the wall-trees stand, and much better than dung, which he by no means approves.
approves of for trees, unless it be perfectly rotten and mixed up with mould.

In respect to grafting old apple-trees, he says, it frequently happens, that through some mistake or other, after waiting ten or twelve years for a tree to come into a bearing state, it is found that the fruit is neither fit for the table nor kitchen; in such cases they should always be grafted the following spring, observing to graft on the finest and healthiest shoots, and as near as possible to the old graft, and where the crofs-flouts break out; as by fo doing you will have some fruit the second year; and in the third, if properly managed, you will have as much as on a maiden tree of fifteen years standing; the canker, if any, must be carefully pared off the branch, and the icion must be taken from a sound healthy tree. Whenever an incision is made for budding or grafting, from that moment the canker begins. He would, therefore, recommend to those employed in budding or grafting, as soon as the incision is made, and the bud or graft inflected, to rub in with the finger, or a brush, some of the composition before the buds is tied on; then to cover the buds all over with the composition as thick as it can be laid on with a brush, working it well in. If this operation be performed in a proper manner, and in a moist scaven, it will answer every purpose without applying any grafting clay: as he has frequently done it, and found it succeed perfectly to his wishes. The matting which is wrapped round the bud should not be slackened too soon; for in that case you will find the incision opened, which very often occasions the death of the bud. If, says he, nurserymen and gardeners would give this method a fair trial, and use the same composition as he uses for curing defects in trees, instead of loam and horse-dung (which binds so hard as to prevent the rain and moisture from penetrating to the graft to moisten the wood and bark), they would find that the grafts would succeed much better. The composition, for this purpose, should be rather softer than grafting clay generally is; and instead of applying so large a mass as is generally done of clay, it need not, in moist cafes, be more than two or three inches in circumference, to effect the purpose.

Apples come to full growth in different forts successively, from July until the end of October: the summer kinds continue but a short time, but the autumn and winter apples keep from two or three to six or eight months and longer, in different varieties. The signs of perfection or full growth of the different sorts of apples, are by their affinming a lively colour, emitting a fragrant odour, frequently falling from the tree, and by quitting their hold easily on being handled.

Gathering.—In the gathering of all the sorts of apples for keeping, dry weather should always be chosent, and when the trees and fruit are also perfectly dry: observe likewise, in gathering apples for the table, and all kinds of apples designed for keeping any considerable time, that they be pulled one and one by hand. See Fruit.

The other species may be increased by grafting and budding them upon the common crab-stock: they should have sheltered situations, as they are rather tender while young. These trees afford ornament and variety in the clumps and shrubbery parts of pleasure-grounds.

Method of Culture in the Quince Kind.—These trees may be raised from the kernels of the fruit grown in autumn; but there is no depending on having the same sort of good fruit from seedlings, nor will they soon become bearers. But the several varieties may be continued the same by cuttings and layers; also by suckers from such trees as grow upon their own roots, and likewise be increased by grafting and budding upon their own pear-flouts, raised from the kernels in the same manner as for apples.

The raising by cuttings, layers, and suckers, is performed in autumn, winter, or spring, choosing young wood for the cuttings and layers, which should be planted and laid in the common method, when they will be rooted by the following summer, then planted out into nursery rows two feet asunder; plant the suckers also at the same distance, and then train the whole for the purposes intended: if for standards, run them up with a stem to any desired height, from three to five or six feet, then encourage them to branch out at top, to form a head; and those designed as dwarfs must be headed near the ground, and trained accordingly for espaliers, or dwarf standards, as directed under those articles: the grafting or budding is effected on quince or pear-flouts, and trained as above. When they have formed tolerable heads, they should be planted out finally.

Mr. Forfyth advises that the layers or cuttings should be planted in a shady place, in rows at about a foot distant from each other, and about three inches from plant to plant in the rows; mulching them with rotten leaves, or horse-dung, which will keep the ground about them moist; and watering them frequently in hot weather. About Michaelmas those that are well rooted may be planted out, and those that are not should remain another year. They may also be propagated by budding or grafting; and these trees will bear sooner, and be more fruitful than those raised by any other method.

He observes, that the quince-tree may be pruned much in the same way as an apple-tree, taking care to cut out all the old diseased and dead wood, and the crofs branches in the middle of the tree, which are apt to injure each other by friction. In general you will find old trees much hurt by injudicious pruning; in that case they should be headed down, cutting out all the cankery parts, and also all the diseased and dead wood where the tree is hollow, or where large branches have been cut or broken off, applying the composition as for apple-trees: and as quince-trees are very apt to have rough bark, and to be bark-bound, in these cases it will be necessary to have off the rough bark with a draw-knife, and to scarify them when bark-bound, brushing them over with the composition. It is also advised to plant quince-trees at a proper distance from apples and pears, as bees and the wind may mix the farina, and occasion the apples or pears to degenerate.

Standard quinces, designed as fruit-trees, may be shook in the garden or orchard, and some by the sides of any water, pond, watery-ditch, &c. as they delight in moisture, suffering the whole to take their own natural growth: and as espaliers, they may be arranged in assemblage with other moderate growing trees, such as apples and pears on paradise and quince-flouts, cherries, &c. being trained as directed for apples and pears in espaliers. They may also be planted in shrubberies, either as full or low standards, and permitted to take their own way of growth. See Orchard.

PYSTERA, in Ancient Geography, an island situated on the coast of Asia Minor, over-agamit Smyrna. Play. Pythagoras, in Biography. See Pythagoreans.

Pollution has been very liberal to this philosopher, in bestowing upon him all such inventions as others had neglected to claim, particularly in music; for there is scarcely any part of it, as a science, with which he has not been involved by his generous followers in biography.

Musical ratios have been assigned to him, with the method of determining the gravity or acoustic of sounds by the greater or less degree of velocity in the vibrations of strings;
the addition of an eighth to the lyre (Pliny, lib. ii. cap. 2); the harmony of the spheres (Plato); and the Greek musical notation (Boethius). His right, indeed, to some of these discoveries has been disputed by several authors, who have given them to others with as little reason, perhaps, as they had been before bestowed upon him.

But there is one discovery, relative to music, that has, at all times, been unanimously ascribed to him, which, however, appears to us extremely doubtful, not only whether it was made by him, but whether, in the manner it is related, it was ever made by any one.

We are told by Nicomachus, Gaudentius, Jamblichus, Macrobius, and all their commentators, "that Pythagoras, one day meditating on the sound of a man's rule, hit upon a string of such a pitch as would produce sound, in the proportion of 5 to 4. Upon this he fastened upon the nearest strings of equal length, and observed that the strings, which were four in number, formed a very harmonious sound, and found them to be in the proportion of 6, 8, 9, and 12. Upon this, he fastened upon the nearest strings, of equal length and thickness, &c. and found, that they gave the same sound. But he had not yet fixed upon the strings of equal lengths, and found that the hammer were not equal to the hammer used before, for the Greeks had not a greater hammer than the tetarch, or seven strings, till that time." Principles and Power of Harmony, p. 8.

This is the substance of the account, as it has been lately abridged by Mr. Stillingelet, who points out many incapable circumstances with respect to the story in general, and denies that the weights 6, 8, 9, 12, would give the intervals pretended; but seems not to have seen the difficulty in the fact, relative to different hammers producing different sounds upon the same string. The frontispiece to M. Mar- pargi's History of Music, represents the Samian lute in the act of weighing the hammers.

But though both hammers and anvil have been swallowed by ancients and moderns, and have passed through them from one to another, with an oltrich-like digestion, upon examination and experiment it appears, that hammers of different size and weight will produce different tones upon the same string, than bows or clappers of different sizes, will from the same string or bell.

Indeed, both the hammers and anvils of antiquity must have been of a construction very different from those of our degenerate days, if they produced any tones that were strictly musical. Of the millions of well-organized mortals, who have passed by blacksmiths' shops, since the time of Pythagoras, we believe no one was every detained by a single note, much less by an harmonious concord, from those Vulcanian instruments. A different kind of noise, indeed, will be produced by hammers of different weights and sizes; but it seems not to be in the power of the most subtle ear to discover the least imaginable difference with respect to gravity or acuteness. But though different noises may be produced from different bodies, in proportion to their size and solidity, and every room, chair, and table, in a house, has a particular tone, yet these noises can never be ascertained as melodic tones, which depend upon reiterated and regular vibrations of the aliquot parts of a string, or other elastic body; and in wind instruments, upon the undulations of the air conveyed into a tube. Noise may, indeed, be forced from a musical string, or instrument, by violence; but noise proceeding from bodies non-dissipative, or immusical, can never be fastened into sound. M. Roufliu (Dict. de Mus. art. Brilli) has ingeniously imagined that noise is of the same nature as sound, with this difference, that to produce sound, the one

PYTHAGORAS.

tone, with its consonant harmonics only, should be heard; such as the 8th, 12th, 15th, and 17th; whereas noise is produced by a jarring multitude of different tones, or even by one tone, when its vibrations are so violent as to render audible a considerable number of dissonant tones, of which the vibrations foment or never coincide; such as the 7th, 9th, 11th, &c.

The long belief of this story proves that philosophers themselves have sometimes taken facts upon truth, without verifying them by experiment. And as the tone of the hammers was affected without proof, so was the effect of their different weights fastened to strings; this Galileo discovered. The numbers 6, 8, 9, 12, applied to different lengths of strings, would, indeed, give the intervals mentioned. But it is proved, that to produce these intervals by the tension of different weights, the weights must be the squares of those numbers; that is, 36, 64, 81, 144. It is astonishing how the blunder had been echoed from author to author, without experiment, till the time of Galileo. And Bontempi, in trying the power of weights upon strings in the Pythagoric proportions of 6, 8, 9, 12, found, that instead of giving the 4th, 5th, and 8th of the grave tone, they produced only the minor 3d, major 3d, and tritonus; so that the whole account falls to the ground. But though modern incredulity and experiment have robbed Pythagoras of the glory of discovering musical ratios by accident, he has been allowed the superior merit of arriving at them by meditation and design. At least the invention of the harmonical canon, or monochord, has been ascribed to him both by ancient and modern writers. (See Monochord.) See Arif. Quint. p. 116. Prin. and Power of Harm. Hilt. des Mathem. par. Montucla. Euler, Tentamen nova Theor. Mus. and all the writers upon harmonics and temperament.

We shall enter no deeper into this subject here, than is absolutely necessary to explain the nature of the discovery attributed to Pythagoras, to which music is indebted for the honourable appellation of science.

Pythagoras supposed the air to be the vehicle of sound, and the agitation of that element occasioned by a similar agitation in the parts of the sounding body, to be the cause of it. The vibrations of a string, or any other sonorous body, being communicated to the air, affected the auditory nerves with the sensation of sound; and this sound, according to him, was acute or grave, in proportion as the vibrations were quick or slow. It was also known, by experiment, that of two strings equal in everything but length, the shorter made the quickest vibrations, and gave the acuter sound; in other words, that the number of vibrations made in the same time by two strings of different lengths, were inversely as those lengths; that is, the greater the length, the smaller the number of vibrations in any given time. By these discoveries it was that sound, considered in the vibrations that cause it, and the dimensions of the vibrating or sonorous body, was reduced to quantity, and as such, became subject to calculation, and explicable by numbers. Thus, for instance, the two sounds that form an octave are explicable by the numbers 1 and 2; which represent either the number of vibrations in a given time, or the length of the strings; and mean nothing more mysterious than that the acuter sound vibrates twice, while the graver vibrates once; or, that the string producing the lower sound is twice the length of that which gives the upper. If we consider the vibrations, the higher found is as 2, the lower as 1; or if you consider only the length. In the same manner, and in the same fende, the 5th is expressed by the ratio of 2 to 3, and the 4th by that of 3 to 4.
PYTHAGORAS.

Such was the ancient philosophy of sounds, of which Pythagoras is recorded as the first teacher. But how much of this theory was founded on experiment and demonstration, and how much of it upon hypothesis; how much of it was known, and how much taken for granted, cannot certainly be determined. The story just now discussed is too much embroiled with absurdities and impossibilities to guide us to any probable conjecture, as to the method by which Pythagoras actually arrived at his conclusions.

The discovery, as far as it relates to the length of strings, was easily made, because it depended upon an obvious experiment. It was, likewise, easily perceived, that a short string vibrated with more velocity than a long one; but between the certainty of this general fact, and the certainty that the vibrations were in a ratio exactly the inverse of the lengths, there is a considerable gulph. (See Smith’s Harmonics, sect. ii. art. 7, and note f.) We have no account of the bridge upon which Pythagoras got safely over. Experiment, here, is out of the question; for the lowest vibrations that produce musical sound, are far too quick to be counted or distinguished. The inference, however, was natural, though it does not appear that the ancients were able to support it by strict and scientific proof.

Indeed it was so late as the beginning of the present century, (1714. See Phil. Trans. and Methodus incrementorum directa et inversa, by Dr. Brook Taylor,) before this ancient theory of sound was fully confirmed, and the laws of vibrations, and the whole doctrine of musical strings, established upon the solid basis of mathematical demonstration.

The second musical improvement attributed to Pythagoras, was the addition of an eighth string to the lyre, which, before his time, had only seven, and was thence called a heptachord. It is supposed by several ancient writers, that the scale of this instrument, which was that of Terpander, consisted of two conjoint tetrachords, E F G A B b C D; and that Pythagoras, by adding an eighth found, at the top, and altering the tuning of the fifth, formed this scale: E F G A, B C D E, or a similar scale, confining of two disjunct tetrachords.

How this scale was generated by the triple progression, or feries of perfect 5ths, the abbé Rouffier has lately very well diffected, in his “Memoire sur la Musique des Anciens.” We shall endeavour to explain what is meant by the triple progression in music, which is the basis of this ingenious hypothesis; referring the reader to the Memoire itself for his proofs, as inferring them here would require too much time and space for a work of this nature.

Let any found be represented by unity, or the number 1; and as the 3d part of a string has been found to produce the 12th, or octave of the 5th above the whole string, a series of 5ths may be represented by a triple geometric progression of numbers, continually multiplied by 3, as 1, 3, 9, 27, 81, 243, 729; and these terms may be equally supposed to represent 12ths, or 5ths, either ascending or descending. For whether we divide by 3, or multiply by 3, the terms will be in the proportion of a 12th, or octave to the 5th, either way. The abbé Rouffier, imagining that the ancients sung their scale backwards, as we should call it, by descending, annexed to his numbers the sounds following:

<table>
<thead>
<tr>
<th>Term</th>
<th>I</th>
<th>II</th>
<th>III</th>
<th>IV</th>
<th>V</th>
<th>VI</th>
<th>VII</th>
</tr>

</table>

out of which series of 5ths, by arranging the sounds in diatonic order, may be formed the heptachord, or 7th, B C D E F G A; and to these, adding the duple of the highest found, in the proportion of 2 to 1, the abbé supposes that Pythagoras acquired the octave, or profunamemnos. This is throwing a mite into the charity-box of poor Pythagoras, without, however, telling us in what reign the obolus was coined; for we have met with no ancient author who betoys the invention of profunamemnos upon this philosopher. The abbé does not let him or his followers step here, but supposes an 8th term, 2187, added to the progression given above, by which a B b was obtained, which furnished the minor femitones below B b. The system of Pythagoras, according to the abbé, was bounded by this 8th term, and the principle upon which it was built being lost, the Greeks penetrated no farther into the region of modulation, where they might have enriched their music, but contented themselves, in after-times, with transpositions of this series of found.

The abbé Rouffier imagines, however, that though Pythagoras went no farther than the eighth term in triple progression, yet the Egyptians, in very high antiquity, extended the series to twelve terms, which would give every possible mode and genus perfect. A curious circumstance is observed by the same author, p. 28, § 47, with respect to the musical system of the Chinefe, which well deserves mention here.

"In collecting," says he, "what has already been advanced concerning the original formation of the Chinese system, it appears to begin precisely where the Greek left off, that is, at the VIIIth term of the triple progression, which is purfed as far as the XIIth term, by which feries, arranged dia- tonally, the Chinese acquire their scale, e b, D b, B b, A b, G b, E b, in defcending: or, as Rameau exprefles the fame intervals, in flarps, defcending, G #, A #, C #, D #, E #, G #."—It is observable that both these scales, which are wholly without fermities, are Scotifh, and correspond with the natural scale of the old fimple enharmonic, given p. 34. M. Jamard, a late French writer on music, pulling calculation till further than either the Egyptians or Chinese, has obtained, by purfuing the harmonic feries, 1, 2, 3, 4, &c. &c. not only the enharmonic diesis, but even the minute intervals in the warbling of birds; it is wonderful he did not apply his ratios to human speech.

After musical ratios were discovered and reduced to numbers, they were made by Pythagoras and his followers, the type of order and just proportion in all things: hence virtue, friendship, good government, celestial motion, the human soul, and God himself, were harmony.

This discovery gave birth to various species of music, far more strange and inconceivable than chromatic and enharmonic, such as divine music, mundane music, elementary music, and many other divisions and subdivisions, upon which Zarlino, Kircher, and almost all the old writers, never fail to expatiate with wonderful complacency. It is, perhaps, equally to the credit and advantage of music and philosophy, that they have long descended from these heights, and taken their proper and separate stations upon earth: that we no longer admit of music that cannot be heard, or of philosophy that cannot be understood.

Arifides Quintianus affirms us, that music comprehends arithmetic, geometry, physics, and metaphysics, and teaches every thing, from founding the scale, to the nature and construction of the soul of man and the soul of the universe. To confirm this, he quotes, as a divine saying, a most curious account of the end and beginning of music, from one master Panacmus, which informs us that the province of music is not only to arrange musical sounds, and to regulate the voice, but to unite and harmonize every thing in nature. This writer, p. 102, in solving the question, whence it is that the soul is so easily affected by instrumental music, acquaints us, in the Pythagorean way, how the soul, frisking about, and playing
playing all kinds of tricks in the purer regions of space, approaches by degrees to our gross atmosphere; gets a taint for matter and fondness, and at length acquires a warm and comfortable body to cover her nakedness. Here the picks, up nerves and arteries; there membranes, here spirit or breath; and all in a most extraordinary manner; especially the arteries and nerves; for what should they be made of, but the circles and lines of the spheruses, in which the soul gets entangled in her paffage, like a fly in a spider’s web. Thus, continues he, the body becomes similar in its texture to instruments of the wind and stringed kind. The nerves and arteries are stringing, and at the same time they are pipes filled with wind. “What wonder, then,” says Arilides Quintilanius, “if the soul, being thus intimately connected with a body similar in construction to those instruments, should sympathize with their motions.”

Maiter Thomas Mace, author of a most delectable book, called *Musick’s Monument,* would have been an excellent Pythagorean; for he maintains that the mystery of the *Tri
ty is periphrastically made plain by the connection of the three harmonical concords, 1, 3, 5; that music and divinity are nearly allied; and that the contemplation of concord and discord, of the nature of the octave and unison, will so strengthen a man’s faith, that he shall never after degenerate into that *grof sub-bodified sin of atheism.*” P. 268.

Pythagoras is said, by the writers of his life, to have regarded music as something celestial and divine, and to have had such an opinion of its power over the human affections, that, according to the Egyptian system, he ordered his disciples to be waked every morning, and lulled to sleep every night, by sweet sounds. He likewise considered it as greatly conducive to health, and made use of it in disorders of the body, as well as in those of the mind. His biographers and secretaries even pretend to tell us what kind of music he applied upon these occasions. Grave and solemn, we may be certain; and vocal, say they, was preferred to instrumental, and the lyre to the flute, not only for its decency and gravity, but because instruction could be conveyed to the mind, by means of articulation in singing, at the same time as the ear was delighted by sweet sounds. This was said to have been the opinion of Minerva. In very high antiquity mankind gave human wisdom to their gods, and afterwards took it from them, to bestow it on mortals.

In perusing the life of illustrious men, who have sprung from the school of Pythagoras, it appears that the love and cultivation of music was so much a part of their discipline, that almost every one of them left a treatise behind him upon the subject.

**Pythagoras’s Table. See Table.**

**PYTHAGOREA, in Botany, received that appellation from Loureiro, in memory of the famous Pythagoras, who is said to have written a book on the qualities of plants.—Loureiro. Cochinh. 245. Clufs and order, Odontria Tetra
gynia. Nat. Ord. . . . . . . . . . .

Gen. Ch. Calc. Perianthus inferior, bell-shaped, of seven or eight linear, hairy, coloured leaves. Cor. superior, bell-shaped, of seven or eight lanceolate, concave, hairy petals, the length of the calyx. Stam. Filaments eight, awl-shaped, longer than the corolla; anthers roundish, two-lobed. Pet. German between the calyx and corolla, nearly ovate, hairy; styles four, awl-shaped, reflexed, flatter than the filaments; illiciacegs acute. Peric. Capsule ovate, of four cells. Seeds numerous, roundish.

Eff. Ch. Calyx of seven or eight leaves, inferior. Corolla of seven or eight petals, superior. Capsule of four cells, with many seeds.

1. P. Cochinchinensis. — Native of Cochinchina, where it is called *Xuông cát châm bò.* A small tree, with numerous branches. Leaves nearly sessile, ovato-lanceolate, serrated, serrulate; their longitudinal ribs red at the extremity. Chyffe
ters axillary, long, nearly simple, with short partial flacks. Flowers white.

Such is Loureiro’s account, but we have no knowledge of the plant he describes, nor can we offer any conjecture respecting its natural affinity. We have no faith in the existence of a genus inferior to the calyx and inferior to the corolla, the only influence of the kind which Linnaeus ever imagined, in *Sanguinaria,* proving not well founded.

**PYTHAGOREAN, or Pythagoric System, among the Ancients, was the same with the Copernican system among the moderns. See System.**

It was thus called, as having been maintained and cultivated by Pythagoras, and his followers; not that it was invented by him, for it was much older.

**PYTHAGOREANS, a sect of ancient philosophers, who adhered to the doctrine of Pythagoras.**

Pythagoras, the founder of this sect, was of Samos, the son of a lapidary, and a pupil of Phericydes, and flourished (fays Bayle) about five hundred years before Christ, in the time of Tarquin, the last king of Rome, and not in Numa’s time, as many authors have supposed. See Cicero Tufecul. Queri. lib. iv. cap. 1.

The time of his birth, however, has been much disputed. Dr. Bentley, in his *Dissertation on the Epitites of Phalaris,* relying chiefly on the authority of Eratosthenes, refers the birth of Pythagoras to the 41st year of the 436 Olympiad, B.C. 586. Lloyd, in his *Dissertation concerning the Chronology of Pythagoras,* ascribes his birth to the 39th year of the 488 Olympiad, B.C. 586. Dodwell places it in the 4th year of the 52d Olympiad, B.C. 569, relying in this date chiefly on the authority of Porphyry and Jamblichus. Upon the whole, the opinion of Lloyd seems to be the most probable, which is, that he was born about the year B.C. 586, and that he died about the 39th year of the 68th Olympiad, B.C. 569; so that it seems pretty certain, that he was not born earlier than the 49th year of the 436 Olympiad, B.C. 605, nor later than the 49th year of the 52d, B.C. 569. If we admit only the credible particulars of his childhood and early education, and pay no attention to the tales of Jamblichus and others, who even alleged that he was the son of God, we shall find that he was first instructed in his own country by Cresphilus, and afterwards by Pherecydes, in the island of Scyllus, and that after having paid his last tribute of respect to his preceptor, he returned to Samos, and pursued his studies under the direction of his first master. Jamblichus, and other later biographers, mention his journey into Ionia, and his interviews with Thales and Anaximander, but of this journey we have no authentic record, nor is any effect of it discernible in his doctrine, which is essentially different from that of the Ionic school. His first journey from the Greek islands was probably into Egypt, which was celebrated in his time for that kind of wildness which bell lent his genius and temper. In his way thither, Jamblichus asserts that he visited Phenicia, and conversed with the prophets and philosophers that were the successors of Mochus the Phylologus; which Mochus, Sado, and some others, will have to be Mosis.

Nor is it thought at all improbable that Pythagoras might, with a ready assent to the Iraochian philosophy, of which he must, without doubt, have received a general report from his father, and from other merchants who traded to this coast. But that he derived his knowledge of numbers from the Phenicians is not at all probable, because their acquaintance with numbers extended no further than
to the practical science of arithmetic. It has been said, indeed, that Pythagoras travelled, not only into Egypt and Chaldea, but even into the Indies, to inform his understanding with regard to all branches of science and prevalent customs; and that after returning to his own country, being unable to bear the tyranny of Polycrates, he retired into the eastern part of Italy, then called Magna Gracia, and established his sect, denominated from this circumstance the “Italic Sect,” or “Italic School.” Whatever opinion is entertained of this journey to the East, to which Le Clerc gives no credit, we must altogether reject other stories of his visiting the temple on mount Carmel, and remaining there for several days, without food, passing among the inhabitants for a good demon, and obtaining from them religious honours; and of his proceeding into India, and there passing through several ceremonies of the Moabic law.

Pythagoras, whilst he was in Egypt, was introduced by the recommendation of Polycrates, tyrant of Samos, to Amasis, king of Egypt, a distinguished patron of literary men, and thus obtained access to the colleges of the priests. Having found it difficult to gain this privilege, he performed many severer and troublesome preliminary ceremonies, and even submitted to circumcision, a preferred condition of his admission. He passed twenty-two years in Egypt, availing himself of all possible means of information with regard to the recondite doctrines of the Egyptian priests, as well as to their astronomy and geometry, and Egyptian learning in its most unlimited extent.

Many writers of reputation, both Pagan and Christian, who flourished after the commencement of the Christian era, relate, that after Pythagoras had left Egypt, he visited the Persian and Chaldaean Magi, and proceeded so far as to have intercourse with the Indian Gymnosophists. Jamblicus affirms, that he was taken captive by the Persian arms of Cambyses, and carried to Babylon, where he acquainted himself with the learning and philosophy of the East; and that after the expiration of twelve years, when he was in the 60th year of his age, he returned to Samos. The circumstance of his having visited the Persian magi is also mentioned by Cicero, Eusebius, Laertius, and Valerius Maximus, though they take no notice of his captivity. In this journey to the East, as some have maintained, he attended upon the instructions of the celebrated Persian sage, Zoroaster; and others, who have placed the life of Zoroaster in an earlier period than that of Pythagoras, have asserted, that he converted with certain Jewish prophets, who were at that time in Babylon, in a state of captivity, and thus became acquainted with the Jewish laws and customs. However, several objections, particularly of a chronological kind, have been alleged against the narrative of Pythagoras’s journey to the East. Chronologists unanimously agree, that Cambyses invaded Egypt in the fifth year of his reign, or the third year of the 63d Olympiad. According to Jamblicus, Pythagoras, after staying twelve years in Babylon, and visiting several other countries, went into Italy in the 62d Olympiad. The same date is affixed to this journey by Diidorus and Clemens Alexander; whilst others place it about fourteen years earlier. Hence it appears, that if Pythagoras left the East before the 62d Olympiad, after remaining there twelve years, he could not have been carried thither by Cambyses in the 63d Olympiad. Moreover, the whole narration of Pythagoras’s journey into the East is contradicted by the express authority of Antiphorus (quoted by Porphyry), who says that Pythagoras, after his residence in Egypt, returned into Ionia, and opened a school in his own country; and that, at the age of forty years, finding himself harassed by the tyranny of Polycrates, he withdrew into Italy; and according to this account, we have no interval for the supposed eastern expedition. The reality of this expedition is testified either by certain Alexandrian Platonists, who were defirous of exalting, as much as possible, the wisdom of those ancient philosophers, whom they considered as the oracles of wisdom, or by certain Jewish and Christian writers, who were disposed to credit every tale which tended to give probability to the opinion that the Pythagorean doctrine was derived from the Oriental philosophers, and ultimately from the Hebrew scriptures.

In either case the authenticity of the relation is liable to just suspicion; nor is there any probable argument to prove, that Pythagoras received instruction from any prophet of the Hebrew nation, during his supposed residence at Babylon. Drucker concurs with those writers who are disposed to reject this story of Pythagoras’s eastern journey as a mere fiction, and who concludes that, having never passed from Egypt to the East, he returned thence immediately to Samos. The story of his having visited the northern Druids is so delusive of probability and of evidence, as to merit no regard.

After his return from Egypt to his native island, he wished to communicate the benefit of his twenty years’ researches and studies to his fellow-citizens, and with this view he attempted to institute a school for their instruction in the elements of science; proposing to adopt the Egyptian mode of teaching, and to communicate his doctrines under a symbolical form; but the Samians were either too stupid or too indolent to profit by his instructions. Although he was obliged to relinquish his design, he did not altogether abandon it. In order to engage the attention of his countrymen by some other means, he repaired to Delos; and after presenting an offering of cakes to Apollo, he there received, or pretended to receive, moral dogmas from the priests, which he afterwards delivered to his disciples under the character of divine precepts. With the same views he also visited the island of Crete, so celebrated in mythological history; where he was conducted by the Corybantes, or priesets of Cybele, into the cave of mount Ida, in which Jupiter is said to have been buried. Here he conversed with Epimenides, an eminent pretender to prophetic powers, and was by him initiated into the most sacred mysteries of Greece. About the same time he visited Sparta and Elis, and was present during the celebration of the Olympic games, where he is said to have exhibited a golden thigh to Abaris, in order to convince him that he was Apollo. Besides other places which he visited during his stay in Greece, he repaired to Phlius, where he first assumed the appellation of philosopher. (See Philosopher.) Having thus added to the stores of learning which he had previously accumulated, and acquired a kind of authority which was calculated to command respect, he returned to Samos, and made a second attempt, more successful than his first, for establishing a school of philosophy. In a semicircular kind of building, which the Samians had used as a place of resort for public buffoons, he delivered with an assumed authority of a sacred nature, popular precepts of morality: and he also provided for himself a secret cave, into which he retired with his intimate friends and professed disciples, and here he gave his followers daily instructions, accompanied with a considerable parade of mystery, in the more abstruse parts of philosophy. His fame, and the multitude of his followers, increased. What he failed to accomplish by the mere force of learning and ability, he effected by concealing his doctrines under the veil of mysterious symbols, and infusing forth his precepts as reprobates from a divine oracle. About the beginning of the 59th Olympiad, Pythagoras, defirous of escaping the
the tyrannical government exercised in his native island by Sylfon, the brother of Polycrates, left Samos, and, as we have already hinted, passed over into Italy, and attempted to establish his school among the colonies of Magna Græcia. It is probable that, in order to obtain credit with the populace, he about this time pretended to possess a power of performing miracles, and practised many arts of imposture. The first place at which he arrived in Italy was Crotona, a city in the bay of Tarentum, the inhabitants of which were very corrupt in their manners. But such were his reputation and influence, that he was treated with great respect, and people of all classes assembled to hear his discourses; insomuch that the manners of the citizens were soon totally changed from great luxury and licentiousness to strict sobriety and frugality. It is said that 600 (some say 2000) persons were prevailed upon to submit to the strict discipline which he required, and to throw their effects into a common stock for the benefit of the whole fraternity. The influence of his philosophy extended from Crotona to many other cities of Magna Græcia, and obtained for Pythagoras from his followers a degree of respect little short of adoration. If he had contented himself with delivering doctrines of philosophy and precepts of practical wisdom, he might probably have continued his labours, without molestation, to the end of his life. But he manifested a strong propensity towards political innovations; and he employed his influence in urging the people to the strenuous assertion of their rights, against the encroachments of their tyrannical governors. This course of conduct raised against him a very powerful opposition, which he was unable to repel and contend against, and which obliged him to retire to Metapontum. Here he found himself still surrounded with enemies, and was under a necessity of seeking an asylum in the temple of the Muses, where, not being supplied by his friends with sufficient food, he perished from hunger. The time of his death is uncertain; but according to the Chronicon of Eusebius, he died in the third year of the 68th Olympiad, B.C. 506, after having lived, according to the most probable statement of his birth, to the age of 80 years. After his death his followers paid a superstitious respect to his memory. They erected statues in honour of him, converted his house at Crotona into a temple of Ceres, the street in which it stood was called the Muses, and appealed to him as a divinity, swearing by his name.

It appears, from the history of this philosopher, that with all his talents and learning, he owed much of his celebrity and authority to imposture. His whole manner of life confirms this opinion. Clothed in a long white robe, with a flowing beard, and, as some say, with a golden crown on his head, he preferred among the people, and in the presence of his disciples, a commanding gravity and majesty of aspect. He recurred to music for promoting the tranquillity of his mind, frequently finging, for this purpose, hymns of Thales, Hesiod, and Homer. He had such an entire command over himself, that he was never seen to express, in his countenance, grief, joy, or anger. He refrained from animal food, and confined himself to a frugal vegetable diet, excluding from his simple bill of fare, for mythical reasons, pulse or beans. By this artificial demeanour, Pythagoras appeared among the vulgar as a being of an order superior to the common condition of humanity, and persuaded them that he had received his doctrine from heaven. Pythagoras married Theano of Crotona, or, as some say, of Crete, by whom he had two sons, Telesuges and Mnefarchus, who, after his death, took the charge of his school. Whether this philosopher left behind him any writings has been a subject of dispute. Many works have been enumerated under his name by Laerlius, Jamblichus, and Pliny; but it is the declared opinion of Plutarch, Jophusus, Lucian, and others, that there were no genuine works of Pythagoras extant; and it appears highly probable, from the pains which he took to confine his doctrine to his own school during his life, that he never committed his philosophical system to writing, and that the pieces to which his name was affixed at an early period, were written by some of his followers, upon the principles imbibed in his school. The famous golden verses attributed to Pythagoras, and illustrated with a commentary by Hierocles, were not written by our philosopher, but are to be ascribed to Epicharmus, or Empedocles. They may, however, be considered as a brief summary of his popular doctrines.

His "Method of instruction," formed upon the Egyptian model, was "exoteric," and "esoteric," that is, public and private. Those auditors, who attended his public lectures, did not properly belong to his school; but followed their usual mode of living. His select disciples, called his companions and friends, were such as submitted to a peculiar plan of discipline, and were admitted, by a long course of instruction, into all the mysteries of his esoteric doctrine.

Previously to the admission of any person into this fraternity, Pythagoras examined his features and external appearance; inquired how he had been accustomed to behave towards his parents and friends; marked his manner of laughing, conversing, and keeping silence; and observed what passions he was most inclined to indulge; with what kind of company he chose to associate; how he passed his leisure moments; and what incidents appeared to excite in him the strongest emotions of joy or sorrow. Nor after this examination was any one admitted into his society, till he was fully persuaded of the docility of his dispositions, the gentleness of his manners, his power of retaining in silence what he was taught, and, in fine, his capacity of becoming a true philosopher. After the first probationary admission, the candidate was put to the trial by a long course of severe abstinence and rigorous exercises. The course of abstinence and self-denial comprehended food and drink, and clothing, all which were of the most plain and simple kinds; and the exercises prescribed were such as could not be performed without pain and fatigue. To teach them humility and industry, he exposed them, for three years, to a continued course of contradiction, ridicule, and contempt, among their fellows. In order to replenish the powerful passion of avarice, he required his disciples to submit to voluntary poverty; he deprived them of all command over their own property, by calling the possessions of each individual into a common stock, to be distributed by proper officers, as occasion required. After this sequestration of their goods, they lived together on the footing of perfect equality, and sat down together daily at a common table. If any one afterwards repeated of the connection, he was at liberty to depart, and might reclaim, from the general fund, his whole contribution. That his disciples might acquire a habit of entire docility, Pythagoras enjoined upon them, from their first admission, a long term of silence, called εὐχαρίστησις. This initiatory silence, which probably consisted in refraining from speech, not only during the hours of instruction, but through the whole term of initiation, continued from two to five years, according to the propensity discovered by the pupil towards conceit and loquacity. With regard to himself, this was a judicious expedient, as it checked impertinent curiosity, and prevented every inconvenience of contradiction. Accordingly his disciples silenced all doubts and refuted all objections,
PYTHAGOREANS.

jections, by appealing to his authority. *Ades εκατ. ἴπο γίγνεται, decided every dispute. Moreover, during the years of initiation, the disciples were prohibited from feering their master, or hearing his lectures, except from behind a curtain, or receiving instruction from some inferior preceptor.

To the members of the esoteric school (who were called *meta* *μεταπολεμείς* genuine disciples) belonged the peculiar privilege of receiving a full explanation of the whole doctrine of Pythagoras, which was delivered to others in brief precepts and dogmas, under the concealment of symbols. Disciples of this class were permitted to take minutes of their master's lectures, in writing, as well as to propose questions, and offer remarks, upon every subject of discourse. These were particularly distinguished by the appellation of the "Pythagoreans;" they were also called "Mathematicians," from the studies upon which they entered immediately after their initiation. Having made a sufficient progress in geometrical science, they proceeded to the study of nature, the investigation of primary principles, and the knowledge of God. Those who pursued these sublime speculations were called "Théorists," and those who devoted themselves more particularly to theology, were styled *περιπλούντες* religious. Others, according to their abilities and inclinations, were engaged in the study of morals, economics, and policy; and were afterwards employed in managing the affairs of the fraternity, or sent into the cities of Greece, to instruct them in the principles of government, or affitt them in the institution of laws.

The brethren of the Pythagorean college at Crotona, called *πρὶς ἔργον*, *κοινῆς* about 650 in number, lived together as in one family, with their wives and children; and the whole busines of the society was conducted with the most perfect regularity. Every day commenced with deliberation upon the manner in which it should be spent; and concluded with a retrospect of the events that had occurred, and of the business that had been transacted. They rose before the sun, that they might pay him homage; after which they repeated select verses from Homer and other poets, and made use of music, both vocal and instrumental, to enliven their spirits and fit them for the business of the day. They then employed several hours in the study of science. These were succeeded by an interval of leisure, which was commonly spent in a solitary walk for the purpose of contemplation. The next portion of the day was allotted to conversation. The hour immediately before dinner was filled up with various kinds of athletic exercises. Their dinner consisted chiefly of bread, honey, and water; for after they were perfectly initiated, they wholly denied themselves the use of wine. The remainder of the day was devoted to civil and domestic affairs, conversation, bathing, and religious ceremonies.

The "exoteric" disciples of Pythagoras were taught, after the Egyptian manner, by images and symbols, obscure and almost unintelligible to those who were not initiated into the mysteries of the school; and those who were admitted to this privilege were under the strictest obligation of silence with regard to the recondite doctrines of their master. The wisdom of Pythagoras, that it might not pass into the ears of the vulgar, was committed chiefly to memory; and when they found it necessary to make use of writing, they took care not to suffer their minutes to pass beyond the limits of the school.

Clemens observes, that the two orders above described corresponded very exactly to those among the Hebrews; for in the schools of the prophets there were two classes, *viz.* the sons of the prophets, who were the scholars; and the doctors or masters, who were also called *perfecti*; and among the Levites, the novice or tyros, who had their quinquennial exercises, by way of preparation. Lastly, even among the profelytes there were two orders; *exoteric*, or profelytes of the gate; and *interior* or *perfecti*, profelytes of the covenant. He adds, it is highly probable, that Pythagoras himself had been a profelyte of the gate, if not of the covenant.

Gale endeavours to prove, that Pythagoras borrowed his philosophy from that of the Jews; to this end producing the authorities of many of the fathers, and ancient authors; and even pointing out the tracks and footsteps of Moises in several parts of Pythagoras's doctrine.

After the dissolution of the assembly of Pythagoras's disciples by the fact of Cylo, a man of wealth and distinction at Crotona, it was thought necessary by Lyfis and Archippus, in order to preserve the Pythagorean doctrine from oblivion, to reduce it to a systematic summary; at the same time, however, strongly enjoining their children to preserve these memoirs secret, and to transmit them in confidence to their posterity. From this time books began to multiply among the followers of Pythagoras, till at length, in the time of Plato, Philolaus exposed the Pythagorean records to sale, and Archytas of Tarentum gave Plato a copy of his commentaries upon the aphorisms and precepts of his master. Of the imperfect records of the Pythagorean philosophy left by Lyfis, Archytas, and others, nothing has escaped the wreck of time, except perhaps fundry fragments collected by the diligence of Stobæus, concerning the authenticity of which there are some grounds for suspicion; and which, if admitted as genuine, will only exhibit an imperfect view of the moral and political doctrine of Pythagoras under the disguise of syllogistical and enigmatical language. The strict injunction of secrecy, which was given by oath to the initiated Pythagoreans, has effectively prevented any original records of their doctrine concerning Nature and God from passing down to posterity. On this head we are to rely entirely for information, and indeed concerning the whole doctrine of Pythagoras, upon Plato and his followers. Plato himself, while he enriched his lyceum with flowers from the magazine of Pythagoras, accommodated the Pythagorean doctrines, as he also did those of his master Socrates, to his own lyceum, and thus gave an imperfect, and, we may say, in many particulars, a false representation of the doctrines of the Samian philosopher. It was further corrupted by the followers of Plato, even in the old academy, and afterwards in the Alexandrian school. To which we may add, that the doctrine of Pythagoras itself, probably in its original state, and certainly in every form under which it has been transmitted to us, was observed, not only by syllogeial, but by mathematical language, which is rather adapted to perplex than to illustrate metaphysical conceptions. In this fault Pythagoras was afterwards imitated by Plato, even in the old academy, and afterwards in the Alexandrian school. To which we may add, that the doctrine of Pythagoras itself, probably in its original state, and certainly in every form under which it has been transmitted to us, was observed, not only by syllogistical, but by mathematical language, which is rather adapted to perplex than to illustrate metaphysical conceptions. PYTHAGOREANS.

contemplation. The whole course of mathematical science may be divided into four parts: two respecting numbers, and two respecting magnitude. Number may be considered either abstractedly in itself, or as applied to some object. The former science is arithmetic; of the latter kind is music.

Magnitude may be considered as at rest, or as in motion; the science which treats of the former is geometry, that which treats of the latter is astronomy.

Arithmetic is the noblest science; numbers the first object of study, and a perfect acquaintance with numbers the highest good. Numbers are either scientific or intelligible.

Scientific number is the production of the powers involved in unity, or the progression of multitude from the monad or unity, and its return to the same. Unity and one are to be distinguished from each other; the former being an abstract conception, the latter belonging to things capable of being numbered. Number is not infinite, but is the source of that infinite divisibility into equal parts, which is the property of all bodies.

Intelligible numbers are those which subsist in the divine mind before all things, from which every thing hath received its form, and which always remain immutably the same. It is the model, or archetype, after which the world, in all its parts, is framed. Numbers are the cause of all things of heavens: τὸ διδομένος ἀληθῶς τοῖς ἀληθείαις.

The monad, or unity, is that quantity, which, being deprived of all number, remains fixed; whence called monad, from τὸ μοῖρον. It is the fountain of all number. The duad is imperfect and passive, and the cause of increase and division. The triad, composed of the monad and duad, partakes of the nature of both. The tetrad, composed of the monad, duad, and triad, is the most perfect. The decade, which is the sum of the four former, comprehends all numerical and musical proportions.

According to some writers, the monad denotes the active principle in nature, or God; the duad, the passive principle, or matter; the triad, the world formed by the union of the two former; and the tetrad, the perfection of nature. Some have understood by this mysterious number, the four elements; others, the four faculties of the human mind; others, the four cardinal virtues; and others have been so absurd as to suppose that Pythagoras made use of this number to express the name of God, in reference to the word γαύδια, by which that name is expressed in the Hebrew language. But every attempt to unfold this mystery has hitherto been unsuccessful.

The most probable explanation of the Pythagorean doctrine of numbers is, that they were used as syllogistical or emblematical representations of the first principles and forms of nature, and particularly of those eternal and immutable essences, to which Plato afterwards gave the appellation of ideas.

Not being able, or not knowing, to explain in simple language the abstract notions of principles and forms, Pythagoras seems to have made use of numbers, as geometers make use of diagrams, to affist the conceptions of scholars. More particularly, conceiving some analogy between numbers and the intelligent forms which subsist in the divine mind, he made the former a symbol of the latter.

As numbers proceed from unity, or the monad, as a simple root, whence they branch out into various combinations, and assume new properties in their progress, so he conceived the different forms of nature to recede, at different distances, from their common source, the pure and simple essence of deity, and at every degree of distance to assume certain properties in some measure analogous to those of number; and hence he concluded, that the origin of things, their emanation from the first being, and their subsequent progression through various orders, if not capable of a perfectly clear explanation, might, however, be illustrated by symbols and resemblances borrowed from numbers.

Next to numbers, music had the chief place in the preparatory exercises of the Pythagorean school, by means of which the mind was to be raised above the dominion of the passions, and inured to contemplation. Pythagoras considered music, not only as an art to be judged of by the ear, but as a science to be reduced to mathematical principles and proportions. We have introduced, under the article PYTHAGORAS, the manner in which he is said to have discovered the musical chords, but shall here subjoin a more minute account. As Pythagoras was one day reflecting upon the subject, happening to pass by a smith's forge, where several men were successively striking with their hammers a piece of heated iron upon an anvil, he remarked, that all the sounds produced by their strokes were harmonious except one. The sounds, which he observed to be chords, were the octave, the fifth, and the third; but that sound which he perceived to lie between the third and the fifth he found to be discordant. Going into the workshop, he observed, that the diversity of sounds arose, not from the form of the hammers, nor from the force with which they were struck, nor from the position of the iron, but merely from the difference of weight in the hammers. Taking, therefore, the exact weight of the several hammers, he went home, and suspended four strings of the same substance, length, and thickness, and twined in the same degree, and hung a weight at the lower end of each, respectively equal to the weight of the hammers: upon striking the strings, he found, that the musical chords of the strings corresponded with those of the hammers. Hence it is said, that he proceeded to form a musical scale, and to construct musical instruments. His scale was, after his death, engraved in brass, and preserved in the temple of Juno at Samos.

Pythagoras conceived that the celestial spheres in which the planets move, striking upon the ear through which they pass, must produce a sound; and that this sound must vary, according to the diversity of their magnitude, velocity, and relative distance. Taking it for granted, that every thing respecting the heavenly bodies is adjusted with perfect regularity, he further imagined, that all the circumstances necessary to render the sounds produced by their motion harmonious, were fixed in such exact proportions, that the most perfect harmony is produced by their revolutions. This fanciful doctrine respecting the music of the spheres gave rise to the names which Pythagoras applied to musical tons. The last note in the musical octave he called hyper, because he supposed the sphere of Saturn, the highest planet, to give the deepest tone; and the highest note he called note, from the sphere of the moon, which being the lowest, or nearest the earth, he imagined, produced the shrillest sound. In like manner of the rest. It was said of Pythagoras by his followers, who hesitated at no allusion, however improbable, which might seem to exalt their master's fame, that he was the only mortal so far favoured by the gods as to be permitted to hear the celestial music of the spheres. Pythagoras applied music to the cure of diseases both bodily and mental. It was, as we have seen, the custom of his school, to compose their minds for rest in the evening, and to prepare themselves for action in the morning, by suitable airs, which they performed upon the lute, or other fringed instruments. The music was, however, always accompanied with verse, so that it may be doubted, whether the effect was to be ascribed more to the music or
PYTHAGOREANS.

or to the poet. It is said of Clinius, a Pythagorean, that when he perceived himself inclined to anger, spleen, or other refractory passions, he took up his lute, and that it never failed to restore the tranquillity of his mind. Of Pythagoras himself it is related, that he checked a young man, who, in the midst of his revels, was meditating some act of Bacchanaalian madness, by ordering the musician, who had inflamed his passions by Phrygian airs, to change the music on a sudden into the slow and solemn Doric mode. If the stories which are related by the ancients concerning the wonderful effects of their music are to be credited, we must acknowledge we are strangers to the method by which these effects were produced.

Besides arithmetic and music, Pythagoras cultivated geometry, which he had learned in Egypt; but he greatly improved it, by investigating many new theorems, and by digressing its principles, in an order more perfectly systematic than had before been done. Several Grecians, about the time of Pythagoras, applied themselves to mathematical learning, particularly Thales in Ionia. But Pythagoras seems to have done more than any other philosopher of this period towards reducing geometry to a regular science. His definition of a point is, a monad or unity with position. He taught that a geometrical point corresponds to unity in arithmetic, a line to two, a superficies to three, a solid to four. Of the geometrical theorems ascribed to Pythagoras, the following are the principal: that the interior angles of every triangle are together equal to two right angles; that the only polygons which will fill up the whole space about a given point, are the equilateral triangle, the square, and the hexagon; the first to be taken six times, the second four times, and the third three times; and that, in rectangular triangles, the square of the side which subtends the right angle is equal to the two squares of the sides which contain the right angle. Upon the invention of this latter proposition (Euclid, I. i. prop. 47.), Plutarch says, that Pythagoras offered an ox, others, an hecatomb, to the gods. But this story is thought by Cicero inconsequent with the institutions of Pythagoras, which, as he supposes, did not admit of animal sacrifices. Pythagoras inferred the stature of Hercules from the length of the Olympic course, which measured six hundred of his feet. Observing how much shorter a course six hundred times the length of the foot of an ordinary-sized man was than the Olympic course, he inferred, by the law of proportion, the length of Hercules's foot; whence the usual proportion of the length of the foot to the height of a man enabled him to determine the problem. Pythagoras also applied geometrical ideas as symbolical expressions of bodies, and of natural principles; but nothing certain, or intelligible, is preferred on this head.

On astronomy, the doctrine of Pythagoras, or, however, of the ancient Pythagoreans, was as follows:

The term heaven either denotes the sphere of the fixed stars, or the whole space between the fixed stars and the moon, or the whole world, including both the celestial spheres and the earth. There are ten celestial spheres, nine of which are visible to us; namely, that of the fixed stars, those of the seven planets, and that of the earth; the tenth is the antichthon, or an invisible sphere opposite to the earth, which is necessary to complete the harmony of nature, as the decad is the completion of numerical harmony. And this antichthon may be the cause of the greater number of the eclipses of the sun than of the moon. Fire holds the middle place in the universe; or, in the midst of the four elements is placed the fiery globe of unity; the earth is not without motion, nor situated in the centre of the spheres, but is one of those planets which make their revolution about the sphere of fire. The revolution of Saturn is completed in thirty years, that of Jupiter in twenty, that of Mars in two, that of the Sun, and of Mercury and Venus, in one year. The distance of the several celestial spheres from the earth correspond to the proportion of notes in the musical scale. The moon and other planetary globes are habitable. The earth is a globe, which admits of antipodes.

From several of these particulars respecting the astronomical doctrine of Pythagoras, it has been inferred, that he was poffessed of the true idea of the solar system, which was revived by Copernicus, and has since been fully established by Newton.

From this preparatory study the disciples of the Pythagorean school were conducted to the knowledge of natural, theological, and moral science. Concerning wisdom, in general, Pythagoras taught, that it is the science which is conversant with those objects, which are in their nature immutable, eternal, and incorruptible, and therefore alone can properly be said to exist. The man who applies himself to this kind of study is a philosopher. The end of philosophy is, that the human mind may, by such contemplation, be assimilated to the divine, and at length be qualified to join the assembly of the gods. In the pursuit of wisdom, the utmost care must be taken to raise the mind above the dominion of the passions, and the influence of sensible objects, and to divest it from all corporeal impressions, that it may be inured to converse with itself, and to contemplate things spiritual and divine. For this purpose the affluence of God, and of good demons, must be invoked by prayer. Philosophy, as it is conversant with speculative truth, or with the rules of human conduct, is either theoretical or practical. Practical philosophy is only to be studied so far as may be necessary for the purposes of life; theoretical philosophy is the perfection of wisdom. Contemplative wisdom cannot be completely attained, without a total abstraction from the ordinary affairs of life, and a perfect tranquillity and freedom of mind. Hence the necessity of instituting a society, separated from the world, for the purpose of contemplation and study.

Active or moral philosophy, which prescribes rules and precepts for the conduct of life, according to Ariotoph, was first taught by Pythagoras, and after his death by Socrates. Among the moral maxims and precepts ascribed to Pythagoras are the following:

Virtue is divided into two branches, private and public. Private virtue respects education, silence, abstinence from animal food, fortitude, sobriety, and prudence. The powers of the mind are reason and passion; and when the latter is preferred in subjection to the former, virtue is prevalent. Young persons should be inured to subjection, that they may always find it easy to submit to the authority of reason. Let them be conducted into the best course of life, and habit will soon render it the most pleasant. Silence is better than idle words. A wise man will prepare himself for every thing which is not in his own power. Do what you judge to be right, whatever the vulgar may think of you; if you despise their praise, despise also their censure. It is inconsistent with fortitude to relinquish the station appointed by the Supreme Lord, before we obtain his permission. Soby is the strength of the soul, for it preserves its reason unclouded by passion. No man ought to be esteemed free, who has not the perfect command of himself. Drunkenness is a temporary phrenzy. That which is good and becoming is rather to be pursued, than that which is pleasant. The desire of superfluity is foolish, because it knows
PYTHAGOREANS.

The ancient Pythagoreans had a profound influence on Western philosophy, mathematics, and science. Their teachings were centered around the beliefs that all numbers and relationships were fundamentally divine and that the universe was governed by numerical and geometric principles.

Their philosophy was marked by a deep respect for the natural world and a belief in the interconnectedness of all things. They believed in the power of numbers and mathematics to reveal the truths of the universe, and they developed a system of numbers that they believed could explain the natural world.

The Pythagoreans were also known for their intense pursuit of knowledge and their rigorous method of inquiry. They believed that the soul was eternal and that education was essential for the development of the mind.

Their ideas were passed down through generations and influenced many of the great thinkers of the Western world, including Plato, who was one of the most prominent admirers of the Pythagoreans. Their influence can still be seen in the fields of mathematics, science, and philosophy today.

The Pythagoreans' work and teachings continue to inspire and influence generations, and their legacy remains a testament to the power of knowledge and the importance of pursuing truth and understanding.
contains spheres, which revolve with musical harmony. The atmosphere of the earth is a grofs, immutable, and morbid mass; but the air, or ether, which surrounds it is pure, heathful, serene, perpetually moving, the region of all divine and immortal natures. The sun, moon, and stars, are inhabited by portions of the divinity, or gods. The sun is a spherical body. Its eclipses are caused by the passing of the moon between it and the earth; those of the moon by the intervention of the antichthon, before explained. The moon is inhabited by demons. Comets are stars, which are not always seen, but rise at stated periods.

Concerning man, the Pythagoreans taught, that, consisting of an elementary nature, and a divine or rational principle, he is a microcosm, or combindium of the universe; that his soul is a self-moving principle, composed of two parts, the rational, which is a portion of the soul of the world, seated in the brain, and the irrational, which includes the passions, and is seated in the heart; that man participates in both these with the brutes, which, from the temperance of their body, and their want of the power of speech, are incapable of acting rationally; that the sensitive soul, ψυχή, perishes, but the rational mind, λογις, is immortal, because the source whence it is derived is immortal; that after the rational mind is freed from the chains of the body, it assumes an ethereal vehicle, and passes into the regions of the dead, where it remains till it is sent back to this world, to be the inhabitant of some other body, brutal or human; and that after suffering successive purgations, when it is sufficiently purified, it is received among the gods, and returns to the eternal source from which it first proceeded.

The doctrine of the Pythagoreans, respecting the nature of brute animals, and μεταφορα, the tranmigration of souls, were the foundation of their ablution from animal food, and of the exclusion of animal sacrifices from their religious ceremonies. The latter doctrine is thus beautifully represented by Ovid, who introduces Pythagoras as saying:

"Morte caret animal: semperque priore reliquit
Sede, novis domibus habitant, vivuntque receptae.
Omnia mutantur; nil aliut erat et illinc.
Huc venit, hic illic, et quotlibet occupet artus.
Spiritus, eque feris humanas in corpore transt.
Inque feras nona: nec tempore derelit utero.
Utque novis fragilis signatur cera figuris,
Nec manet ut fuerat, nec formas servavit exstrem.
Sed tamen ipsa eadem eit, animam lic cemer amidem,
Elle, sed in variis doceo migrate figuris."

"What then is death, but ancient matter dried
In some new figure, and a varied velt:
Thus all things are but alter'd, nothing dies;
And here and there the unbodied spirit flies,
By time, or force, or sickness dimples'd,
And lodges where it lights, in man or beast;
Or hunts without, till ready limns it find,
And actuates those according to their kind;
From temenent to temenent is toll,
The soul is still the fame, the figure only loit:
And as the foften'd wax new foals receives,
This face affumes, and that impression leaves;
Now call'd by one, now by another name.
The form is only chang'd, the wax is still the fame;
So death, thus call'd, can but the form deface,
Th' immortal soul flies out in empty space,
To seek her fortune in some other place."
"Periplus of the World," and he is supposed to have written a treatise "De Oceano," none of these pieces have reached modern times, though some of them were extant in the fourth century. From fragments collected out of Strabo, it appears that Pytheas introduced into them, as the testimony of others, a number of marvellous and incredible circumstances, which drew on him the censure of that author and Polybius. The last named author maintained it to be utterly impossible for a private person, who was even in want, to have travelled so far as he pretended to have done by sea and land. He, however, probably visited all the countries of Europe that are situated upon the ocean, discovered the island of Thule, or Iceland, and penetrated a considerable distance into the Baltic. This fact has been proved by Gaflendi, who shews, that Pytheas was well acquainted with the northern countries, and accurately marked the distinction of climates, by the difference which he observed in the length of the days and nights in different latitudes. He also attempts to prove that Eratosthenes and Hipparchus improved their geographical works by availing themselves of the labours of Pytheas, without due acknowledgments of their obligations. There is no doubt that Pytheas was a skilful observer of the heavens, for he taught that there is no star in the precise situation of the pole, and he rendered himself famous among astronomers, by being the first calculator of the meridian altitude of the sun at the summer solstice at Marseille. This fact he ascertained by erecting a gnomon of a given height, and finding the proportion between that height and the length of the meridian shadow. The result was found to correspond exactly with that of an observation made by Gaflendi, at the same place, in the year 1636. To obviate such objections as that advanced by Polybius against the reality of Pytheas' voyages, it has been said, that he probably was furnished with the means of prosecuting them at the public expense. For as the republic of Marsilles was then powerful at sea, largely engaged in commercial pursuits, and lent Euthymenes to make such discoveries in the southern parts of the world, as might lead to the extension of its trade, it seems very probable, that Pytheas was dispatched on the public account into the northern regions for the same purposes.

PYTHEUM, in Ancient Geography, a town of Macedonia, in the country of the Pelignitores. Ptolemy places it between Azorium and Gonnas.

PYTHIA, or PYTHIAN, in Antiquity, the priestesses of Apollo, by whom he delivered oracles. See DELPHI.

She was thus called from the god himself, who was entitled Apollo Pythius, from his slaying the serpent Python; or, as others will have it, αφων τε πυθιανος, because Apollo, the fun, is the caufe of rotenness; or because the carcasse of Python was left there to putrefy; or, according to others, πυθιανος, I enquire, because people went to hear and consult his oracles.

This priestess was to be a pure virgin. She sat on the cocusf, or lid, of a brazen vessel, mounted on a tripod; before she ascended which, after fasting three days, she used to wash her whole body, and especially her hair, in Castalia, a fountain at the foot of Parnaiss, where the poets, men inspired by the same deity, used to wash, and drink; and thence, after shaking the laurel-tree that grew by it, and sometimes eating the leaves, which were supposed to conduco to inspiration, and were succeeded by a violent enthusiasm, she delivered her oracles, or rather explained those of the god; i.e. she reheared a few ambiguous and obscure verses, which were taken for oracles. The oracle being pronounced, she was taken down from the tripod and conducted back to her cell, where she continued for several days, to recover herself from the violent agitation and conflict. Lucan informs us, that speedy death was frequently the consequence of her enthusiasm. See ORACLE.

Diodorus Siculus (lib. xvi.) informs us, that these priestesses were at first virgins, but that after one of them was delivered by Echeocrates, a Thessalian, choice was made of women above fifty years of age; that fo they might either be secured from the attempts of lust, or if they should at any time be forced to the violation of their chastity, having passed the time of child-bearing, they might remain undiscovered, and not bring the oracle of religion into contempt; nevertheless they wore the habit of virgins, thereby to signify their purity and virginal modesty.

All the Pythiae did not seem to have had the same talent at poetry, or to have memory enough to retain their lesson. Plutarch and Strabo make mention of poets, who were kept in pay, as interpreters of Jupiter, &c.

PYTHIA, or PYTHIAN Games, were solemn games instituted in honour of Apollo, and in memory of his killing the serpent Python with his arrows.

The Pythia were celebrated in Macedonia, in a place called Pythium. They were next in fame after the Olympic games, but were more ancient than they; for it is pretended they were instituted immediately after the defeat of the serpent. The Pythia were also celebrated at Delphi; and they were thefe that were the most renowned. Their first founder, and the precise time of their institution, are not known.

The Pythian games, according to Pausanias, were first instituted by Jafon or Diomedes, king of Etolia, and restored by Eurylochus of Theifaly, in the third year of the 48th olympiad, or the year of the world 3364, and 584 years before the birth of Christ; from which time the Greeks reckoned sometimes by Pythiades, as they had been accustomed to do by Olympiads. They were at first celebrated every eight years, but afterwards every four years, in the third year of each olympiad; so that the pythiade, which was a term of four years, served as an epocha for the inhabitants of Delphi. At first they consisted of poetical and musical contests, but in process of time they confin'd of the other exercies of the pnesacrarium, which were performed in the Olympic games. The victors were crowned with branches of laurel; though, at the first institution, the crown was of beech-leaves. The Romans are said to have adopted these games in the year U.C. 642, and to have given them the name of Apollinaires ludi.

A part of Pindar's poems was composed in praise of the victors in the Pythian games. See GAMES.

The critics are divided on the subject of the serpent Python. The poets say, that Juno made use of it to persecute Latona, and prevent her bringing into the world Apollo and Diana, whom she had conceived of Jupiter; and that it was for this reason that Apollo afterwards killed it.

Strabo says, it was no other than a famous villain, one Draco, that Apollo freed the world from. Dickinison, in his "Delphi Pheniceizantes," maintains the Python of the Greeks to be the Typhon of the Phenicians; and the Typhon of the Phenicians to be the Og of Scripture; and Apollo, who slew it, he will have to be Jofhua. See TYPHON.

PYTHON, in Ancient Geography, a name anciently given to the city of Delphi.

PYTHOPOLIS, a town of Aia Minor, in Bithynia, on the river Solonnt, according to Plutarch, founded by Thefeus.
PYX

Thefeus.—Alfo, a town of Aria Minor, in Caria; afterwards called Nifia.—Alfo, a town of Afismatic Myfia.

PYULCON, from πυξις, πυξ, and ἄλλως, to draw, an old surgical instrument anciently employed for drawing the matter out of ulcers.

PYURIA, in Medicine, from πυξις, πυξ, and υρος, υριν, a term used by Sauvages and others to denote all purulent and mucous discharges from the bladder. See CATTARRHUS Vefier.

PYXIDANTHERA, in Botany, from πυξις, a box, and ἀνθήρα, an anther, becaufe, according to Michaux, each cell of the anthers opens by a port of lid; see Diaphorhia, to which genus the plant in question is referred by Mr. Pursh, in his Fl. Amer. Sept. v. 1. 148, under the name of D. cuneifolia, after Mr. Salisbury.

PYXIS Nautica, in Navigation, the feaman’s compass. The word πυξις, literally signifies a box.

Pyxis, among Anatomists, is also used for the cavity of the hip-bone. See Acetabulum.

PYXIS, a small metal cafe for containing the consecrated species in the Catholic church. Anciently it was made in the form of a dove and fulpended over the altar.

PYXUS, in Ancient Geography, a small river of Italy, in Lucania; which took its rife northward towards Sonitia, and running southward discharged itself into a gulf of the fame name, E. of Pyxus, or Pyxuntum.

Pyxus, or PYXUNTUM, Poli-Caffro, a town of Italy, belonging to Lucania, situated at the bottom of a small gulf, E. of a small river of the fame name. It was founded by Mirathus, prince of Zanele and Rhegium, in the year 471 B.C. It became a Roman colony in the year 194 before the fame era.

PYXUS Promontorium, a small cape of Italy, E. of a peninsula of Laconia, which had on the W. the promontory Paliurnum. This promontory is found at the entrance of a small gulf of the fame name.

PYZENENIN, in Geography, a town of Bohemia, in the circle of Bolefau; 12 miles E. of Jung-Duntzel.

Q.

A confonant, borrowed from the Latin or French, for which the Saxons generally used cp, cow; and the sixteenth letter of the alphabet.

The name of this letter is cu, from queue, Fr. tail; its form being that of an O with a tail.

The Q has this peculiarity to it, that it is always followed by an U, and is therefore reckoned among the mutes.

The Q is formed from the Hebrew, q, koph; which most other languages have borrowed; though some of them have rejected it again, particularly the Greeks, who now only retain it as a numeral character, called μονετα ιωνικουν.

In effect, there is that resemblance between the Q and the C, in some languages, and the K, in others, that many grammarians, in imitation of the Greeks, banish the Q as a superfluous letter. Papas even affirms, that all the Latin words now wrote with a Q, were written among the ancient Romans with a C; but we want better authorities for this.

For, though that may hold in many cafes, inomuch that some write indifferently quer, or cu; cum, or quam; quotidie, or continet, &c. yet it does not thence follow, that they ever wrote cita, cæ, cid, for quis, quer, quid. What inscriptions authorize such a reading?

Far from this, the ancients sometimces substituted Q for C; and wrote quojus, quasi; for cujus, cui, &c.

Varro, however, and some other grammarians, as we are told by Cenorumus, &c. would never use the Q. The truth is, its use or dilute seems to have been so little settled, and agreed on, that the poets used the Q or C indifferently, as belt suited their measures; it being a rule, that the Q joined the two following vowels into one syllable; and that the C imported them to be divided.

Hence it is, that Lucretius ues ecuit for three syllables, in lieu of quirit; aequus, for aequa, and that Plautus ues rellicum, for reliquum; as in quod debil,datum non vellem reliquum.

Vol. XXIX.

PYZ.

Q, where the cum must be two syllables, otherwise the trochaic verse will be lame of a foot.

In the French, the sound of the Q and K are so near akin, that some of their neice authors think the former might be spared. Ramus adds, that, till the establishment of royal professors in the university of Paris, under Francis I., they always used Q in the Latin the fame as in the French; pronouncing his, kalis, kantus, &c. for quis, qualis, quantus. See K.

Some very learned men make Q a double letter, as well as K and X. According to them, Q is evidently a C and U joined together. It is not enough that the sound is the fame, but they see the traces of the C U in the figure of the Q; the V being only laid obliquly, fo as to come within the cavity of the C; as c <.

To confirm this, they say the ancients wrote qi, qua, quid. Though Jof. Scaliger, Littleton, &c. think this is no proof of the point; for in Gruter’s inscriptions we find not only the Q, but also the C, put for Q U; as Cintus, Quintus; feius for fiquis, &c. Yet nobody ever imagined the C a double letter.

Q, among the Ancients, was a numeral letter, signifying 500; as in the verse,

"Q velut A cum D quingentos vult numerare."

A dash over it, as $\bar{Q}$, denoted it to signify five hundred thousand.

Q is also ued as an abbreviation in several arts. Q. pl. in physicians’ bills, stands for quantum placet, or quantum vis, as much as you please of a thing; q. f. for quantum sufficit, or as much as is necessary.

Q, in the proper names of the Romans, signifies Quintus, or Quintus. Upon the French coins this letter denotes that they were struck at Perpignan.
Q. D. is frequently used, among Grammaticus, &c. for quæst dition, as if it were laid, &c. or as who should say.

Q. E. D. among Mathematicians, signifies quod erat demonstrandum, which was to be demonstrated.

Q. E. F. quod erat factandum, which was to be done.

QUAB, in Ichthyology, the name of a Ruffian fish, which some report to be at first a tadpole, then a frog, and at last a fish. Dr. Mooney, who made many enquiries concerning these pretended changes, apprehends that they are all fabulous. He had an opportunity of seeing the fish itself, and found that they spawn like other fishes, and grow in size, without any appearances to justify the report. He adds, that they delight in very clear water, in rivers with sandy or stony bottoms, and are never found in running lakes, or in rivers palling through marshy or morly grounds, where frogs choose most to be. Phil. Trans. vol. xlv. p. 175.

QUABES, in Geography, a people of Africa, in the interior country between Río Seffer and Sierra Leona, inhabiting the southern banks of the river Seffer. They had been formerly conquered by Flanlto, king of Folgia; but having thrown off their subjection, they have since remained a free people, though under the protection of the emperor of Monon, or Manou; which empire is called by English geographers, and also by M. d’Aville, Mendi Manouo.

QUACHA, or Quaga, in Zoology. See Equus.

QUACHILTO, in Ornithology, the name of a very beautiful Braziland bird, of the moor-hen kind, called also yacaciuli, and porphyro Americanus. It is the Fulica Purpurea, (which fee;) and is of a fine blackish purple colour, variegated with white; its beak is white while young, but becomes red as it grows older, and has a naked space at its basis, resembling, in some sort, the coot; its legs are of a yellowish green; it lives about the waters and feeds on fish, yet is a very well-tasted bird. It imitates the crowing of a common cock, and makes its music early in the morning. Marggraves’s Hift. Brazil.

QUACHY, in Zoology, a name given to the Coati, or Viverra Naja; which fee.

QUACK, in Medicine. See Empiric.

QUACKENBRUCK, in Geography, a town of Westphalia, in the bishopric of Osnabruck, situated on the river Hafo, which runs through it in seven streams, that unite in two below the town; 20 miles N. of Osnabruck. N. lat. 52° 42;' E. long. 8° 30'.

QUADIANS, Quadi, in Ancient Geography, a people of Germany, whose territories extended from the Danube to Moravia, and the northern part of Austria. They are comprehended by some writers under the ancient name of Suevi, part of whom forced their way into Spain, and formed a kingdom there. Their country is at present known by the name of Moravia; for it extended from the mountains of Bohemia to the river Marus, now the March, and consequently comprised that province. Ptolemy mentions the following cities in the country of the Quadi; viz. Eburodum, Eburum, Medofalnium, and Celemantia, now, according to Cluerius, Briu, Omlutz, Zasim, and Kalminz. The Quadians were a warlike people, had kings of their own, and agreed in customs, manners, and religion, with the other German nations. They, without doubt, joined their countrymen against Lollius, Germanicus, Caius, and Galba, who attempted to reduce Germany, and to subdue the several nations which inhabited that extensive country. The emperor Domitian marched against them, but was defeated by the Marcomann, and put to flight. The Quadians submitted to the emperor Titus Antonius, and it appears by his coins, supposing to have been struck about the year 139, that they acknowledged, as sovereign, a king appointed by that prince. They joined the Marcomans, in the famous war made by that people on the empire under the reign of Marcus Aurelius; but being reduced to great distresses they sent ambassadors to sue for peace, and with them they restored all the Roman defeters, and about 13,000 prisoners, whom they had taken during the war. They thus obtained peace, upon condition, that they should not traffic, for the future, within the Roman dominions, nor settle within six miles of the Danube; but, differing these conditions, they again joined the Marcomans, and renewed the war. In the prosecution of this contest, which was long and languid, they were totally defeated by their king Ariodes, but the emperor spared his life, confining him to the city of Alexandria, the metropolis of Egypt. The Quadians, however, seem to have continued in arms till the reign of Commodus, who granted them peace upon the following terms: that they should keep at the distance of five miles from the Danube; that they should surrender their arms, and supply the Romans with a certain number of troops when required; that they should assemble but once a month in one place, and in the presence of a Roman centurion; and that they should not make war upon the neighbouring nations without the consent of the people of Rome. In the year 214, the king of the Quadians was Gaio compost, who was affiliated by order of Caracalla. In the 4th year of the reign of the emperor Valerian, the Quadians joined the Sarmatians, and invading Illyricum, ravaged that province; but they were defeated by Probus, then tribune of a legion, and afterwards emperor. In the year 260, the 7th of the emperor Gallicius, they made a sudden irruption into Panon, but they were expelled, without their booty, by Regilianus. Upon the death of Probus, who had kept the barbarians in awe, A.D. 283, the Quadians, in conjunction with the Sarmatians, broke into Illyricum and Thrace, and having ravaged those provinces, and advancing towards Italy, they were met by Carus, the successor of Probus, on the borders of Illyricum, and totally defeated: 16,000 being killed on the spot, and 20,000 being taken prisoners. In the 15th year of the emperor Constantinus, the Quadians made an irruption into Pannonia and Media; and having pillaged both provinces, returned home with an immense booty. They returned again in two years, and laid waste Valeria. Constantinus was provoked by these invasions, and leaving Milan, advanced to the confines of the Quadians, and conferred with their chiefs, who excused past hostilities, and promised, for the future, to live in peace and amity with the emperor. They soon, however, forgot their promise; and in the following year joined the Sarmatians, and laid waste a part of Pannonia and Media; but at the approach of Constantius, they repulsed the Danube, and returned home. The emperor determining to punish them for their treachery, sailed the Danube on a bridge of boats, and began to destroy their country. The Quadians, unable to resist, fled for peace, and obtained it, upon delivering up hostages, and setting at liberty all the prisoners they had taken. In the year 374, their king Gabinhus being treacherously murdered by Marcellianus, duke of Valeria, they crossed the Danube in the utmost rage, and falling upon the reapers, in harvest time, killed the greatest number of them, laid waste the country, and took many captives. They afterwards followed Equius, general of the troops in Illyricum, who had been
accessory to the murder of their king, into Valeria, and
committed dreadful devastations in the countries through
which they passed. In their way they met with two legions,
the Pannonian and Macedon, who had been sent to oppose them,
and taking advantage of a contest which subsisted among
them about precedence, they cut them both in pieces.
In this irruption the Quadians had been joined by the Sar-matians; but the latter were defeated with great slaughter
by Theodosius, then duke of Media, and afterwards em-
peror. Against the Quadians Valentinian I. marched in
person; and having made great preparations for his pro-
posed expedition into their country, he took the field;
passed the Danube at Acinicum, now Gran, or Buda, in
Lower Hungary, entered the enemy's country, and de-
stroyed it with fire and sword. At length, the Quadians
fued for peace; but whilst the emperor was speaking to the
messenger with great warmth, and threatening to extirpate
their whole nation, he fell to the ground in a fit, and soon
afterwards expired. Upon his death a treaty was con-
cluded with the Quadians. Their refiepts spirit and dis-
position for war manifested themselves again in the year 379,
when they invaded Illyricum; but they were driven out,
with some losSs, by the emperor Gratian. In 457 they
entered Gaul with the other barbarians, over-ran its pro-
vinces, and committed dreadful ravages. From this time
no farther mention is made of the Quadians; so that they
were either subdued, or utterly extirpated by the Goths,
vol. xviii.

QUADRISME, a term sometimes used for
the time of Lent, because confusing of forty days.

Hence some monks are said to lead a quadragesimal life;
or to live on quadragesimal food all the year.

QUADRAGESIMA Sunday is the first Sunday in Lent; so
called because it is about the fortieth day before Easter.

On the same account, the three preceding Sundays are
called Quinquagesima, Sexagesima, and Septuagesima.

QUADRAGESIMALS, QUADRAGESIMALIA, denote
Mid-lent contributions, or offerings.

It was an ancient custom for people to visit their mother-
church on Mid-lent Sunday, and to make their offerings at
the high altar; and the like was done in Whit-fen-week.
But as these latter oblations, &c. were sometimes commut-
ed for by a payment of pence to florins, or Whit-fen-farthings; so
were the former also changed into a customary payment,
known as graduals, denarii quadragesimalia; and sometimes
Letare, Jerusalem, from a hymn so called, sung on that
day, beginning "Jerusalem, mater omnium," &c.

QUADRANGLE, in Geometry, a quadrangular, or
quadrilatera figure; or a figure which has four sides, or
four angles.

To the class of quadrangles, or quadrangular figures,
belong the square, parallelogram, trapezium, rhombus, and
rhomboids.

A square, &c. is a regular quadrangle; a trapezium, an
irregular one.

Quadrangular figures are not proper for fortification; the
flanks, and flanked angles, being too small.

QUADRANGULARIS Pisces, the Square-fish, in
Ichthyology, the name of a fish, which, in its most usual size,
is about fifteen inches long, four inches high in the middle,
and three inches and a half over; the forehead is square, a
little hollow, and, by the eminence of the eye-brows, two
inches and a half over; the nose blunt, and not very steep,
with two holes in the place of nostrils, and the mouth very
small; the back is a little convex toward the tail, and on the
sides a little obtusely angled; as is also the belly, which is
plain and flat, and a little rising toward the tail; it has five
fins, two near the gills, two near the tail, and the tail-fin,
which is considerably long. Part of the head and tail are
covered with a soft skin, the rest of the body with a kind
of cloth, adorned all over with little round knots, reduced
for the most part into hexagonal figures, and subdivided

QUADRANS, in Antiquity, the fourth part of the as,
or pound. See As.

QUADRANS, in our Cents, is the fourth part of a penny,
or a farthing.

QUADRANT, QUADRANS, in Geometry, an arc of a
circle, containing 90 degrees, or one-fourth of the entire
periphery.

Sometimes, also, the space, or area, included between
this arc and two radii, drawn from the centre to each ex-
tremity thereof, is called a quadrant, or, more properly, a
quadrantal space; as being a quarter of the entire circle.

QUADRANT also denotes a mathematical instrument, of
great use in navigation and astronomy, for the taking of al-
itudes, angles, &c.

The quadrant is variously contrived, and furnished with
different apparatus, according to the several uses for which
it is intended; but they have all this in common, that they
confist of a quadrant, or quarter of a circle, whose limb is
divided into 90 degrees; and that they have a plummet sus-
hended from the centre; and are furnished with pinnules
or sights, through which to look.

QUADRANT, the Common, or Surveying, (represent-
ed Plate VI. Surveying, fig. 13.) is made of brass, wood, or
other matter, usually twelve or fifteen inches radius. Its
circular limb is divided into 90°, and each of these subdivi-
ded into as many equal parts as the space will allow, either
diagonally or otherwise. On one edge, or semi-diameter,
are fixed two immovable sights; and in the angle, or centre,
is hung a thread, with a plummet. To the centre is like-
wise, sometimes, fixed a label, or moveable index, bearing
two other sights, like the index of a telescope. And, in
lieu of the immovable sights, there is sometimes fitted a
telephone; though this more peculiarly belongs to the as-
umetrical quadrant.

On the under side, or face, of the instrument, are fitted
a ball and socket; by means of which it may be put in any
position, or use.

Besides the essentials of the quadrant, there is frequently
added on the face, near the centre, a kind of compartiment,
called the quadrat, or geometrical square; as in the figure
this, in some measure, making a distinct instrument of itself.
See its description and use under the article Quadrat.

The quadrant is to be used in different situations, ac-
tording to the dimensions to be taken. To observe heights
and depths, its plane is disposed at right angles to the ho-

Heights and distances, again, may be taken two ways;
QUA

by means of the fixed sights and plummet, and by the label.

**Quadrant, Use of the Surveying.** To take the height or depth of an object with the fixed sights, and plummet.—Place the quadrant vertically, and the eye under the sight next the arc of the quadrant; thus direct the instrument to the object, e.g. the top of a tower, till the visual rays of it strike through the sights upon the eye.

This done, the portion of the arc intercepted between the thread and the semicircle, on which the sights are fastened, shows the complement of the object's height above the horizon, or its distance from the zenith; and the other portion of the arc intercepted between the thread and the other semicircle, shows the height itself of the object above the horizon.

The fame arc likewise gives the quantity of the angle made by the visual ray, and a horizontal line, parallel to the base of the tower.

Note, to observe depths, the eye must be placed over that light next the centre of the quadrant.

From the height or depth of the object in degrees thus found, which supposeth 35' 35", and the distance of the foot of the object from the place of observation carefully measured, which supposeth 47 feet; its height or depth in feet, yards, &c. is easily determined by the most common cafe in trigonometry.

For we have here, in a triangle, one side given, viz. the line measured, and we have all the angles; for that of the tower is always supposeth a right angle; the other two, therefore, are equal to another right angle; but the angle observed is 35° 35", therefore the other is 54° 25'.

The cafe, then, will be reduced to this: as the sine of 54° 25', is to 47 feet, so is the sine of 35° 35' to a fourth term, viz. 35 feet; to which add the height of the observer's eye, supposeth 5 feet; and the sum, 38 feet, is the height of the tower required.

**Quadrant, the farther use of the, in taking of altitudes of objects, both accessible and inaccessible, lie under the article Altitude.**

**Quadrant, Use of the, in taking heights and distances by the index and sights.**—To take, e.g. a height, as that of a tower whose base is accessible; place the plane of the instrument at right angles to the plane of the horizon, and one of its edges parallel to it, by means of the plummet, which, in that cafe, will hang down along the other. In this situation turn the index, till, through the sight, you see the top of the tower; and the arc of the limb of the quadrant between that side thereof parallel to the horizon and the index will be the height of the tower in degrees; whence, and from the distance measured as before, its height in feet, &c. may be found by calculation, as in the former cafe; or, without calculation, by drawing from the data, on paper, a triangle similar to the great one, whose base is the distance; and its perpendicular, measured on the scale, is the height of the tower.

**Quadrant, Use of the, in measuring horizontal distances.**—Though the quadrant be a lefs proper instrument for this purpose than a theodolite, semicircle, or the like, because angles greater than quadrants cannot be taken by it, yet necessity sometimes obliges persons to have recourse to it.

The manner of its application is the fame with that of the semicircle; all the difference between the two instruments consisting in this, that the one is an arc of 180°, and can therefore take an angle of any quantity; and the other is only an arc of 90°, and is therefore confined to angles of that quantity. See, therefore, Semicircle.

**Quadrant, in Astronomy, is an instrument by which the altitude of a heavenly body is measured, and is composed of one-quarter, or one-eighth of a circle, accordingly as the measurement is made by means of direct vision, or by the reflected image of the object to be viewed. When a suffused circle was made use of with revolving sights, called an astrolabe, the accuracy of an observation could never be depended on, partly because the radius was small, and partly because the instrument vibrated when suffused by the hand, and was otherwise inconvenient to use, as well as liable to have its equinoctial disturbed by the various positions of the index and sights: therefore, such a portion of the circle was adopted as was competent to measure the greatest possible altitude, and an increase of radius was thereby obtained, which promised to contribute to accuracy, without affecting the portability of the instrument. But though the construction was varied by different ingenious men, the quadrant was but little, if at all, conducive to the improvement of nautical or of astronomical science, till the application of telescopic sights, and an improved mode of graduating the limb, together with the addition of a vernier scale, gave it powers on which the mariner and astronomer could confide. Quadrants have been constructed of different materials, such as wood, ivory, brass, &c. and of various dimensions, agreeably to the uses for which they were intended, in order to accommodate purchasers of every denomination; but as it is not our province to notice every plaything that has usurped the appellation of quadrant, we will confine our account to such instruments chiefly as have been of actual service in navigation and astronomy. We have, however, already anticipated the history, we might here have introduced, of the various improvements successively made in quadrants, at the beginning of our article Circle; and under the article Graduation we have given, at considerable length, the different methods of dividing and subdividing astronomical instruments in general; to which articles we beg to refer our readers, who wish for information on those points, and which may be read in conjunction with our present article.

Our arrangement of quadrants will be most systematic, if we divide them into two classes, viz. those which measure altitudes by direct vision, and those which determine measurements in all directions, vertically, horizontally, and obliquely, by means of reflection. The former classes have been found useful in astronomy chiefly, and the latter in navigation, where the motion of a ship interferes with the readiness of any fixed position of an instrument.

The first quadrant, in its rude form, was probably a quarter of the astrolabe enlarged, with fixed sights placed in, or parallel to, the vertical line passing through zero; and a fine thread, or wire, stretched by a plummet, indicated the altitude on the divided limb, according to the representation in fig. 4, of Plate I. of Astronomical Instruments. This construction might be used in observations of the sun, without injuring the eye of the observer, by allowing the solar rays to pass through the first sight-vane, or hole, so as to fall on the second, at some distance from the former, while the thread rested nearly in contact with the elevated limb; but the want of minute, and at the same time accurate subdivisions, and the sensible thickness of the thread, were impediments to accuracy that did not admit of remedy, until another mode of reading the altitudes was devised, and until a method was contrived of rendering the light of the sun tolerable to the eye of an observer. The form of these reflectors was accomplished first by diagonal scales, with a fiducial edge of an index, and afterwards by that admirable contrivance, sometimes called a Nonius, but more properly denominated a Vernier, from the name of its inventor;
QUADRANT.

DISTINCTION; the latter was effected by semi-opaque glasses, introduced at first without, but afterwards, with better effect, with telescopic sights; at the same time, enlarging the visual angles subtended by the fun, and yet diminishing the intensity of his light by a partial transmission through the smoked or coloured glasses.

Davis's Quadrant, or Back-Staff.—In the year 1590, captain John Davis, a native of Sandridge, near Dartmouth, previously to his falling into the south seas under the command of Mr. Cavendish, contrived that instrument, which is represented in fig. 2, of Plate I. of Astronomical Instruments, and which has been called the English quadrant, or back-staff. This instrument dispensed with the use of the plumb-line, and consequently was better adapted to nautical purposes than the old quadrant, or the fore-staff, that preceded it; but wanted the telescopic fights, which have given subsequent instruments the advantage over it. It was, however, probably the first quadrant in which the horizon was used as one of the objects in a back observation, and from which the reflecting images afterwards borrowed an useful principle, where altitudes are concerned; though it was in the use of the fore-staff, (described under our article CIRCLE,) that the horizon was first made one of the extreme limits of an altitude, taken by a forward observation. Captain Davis found that near-tree answered very well as the material on which his instrument was constructed, and an ingenious arrangement of two divided arcs and three vanes constituted his plan, according to the following description. The vane at A was called the horizon-vane; the one seen at B the shade-vane, because its shadow fell on the horizon-vane during the instant of completing an observation; and the third, at C, was denominated the fight-vane, by reason of its being the vane to which the eye was applied in taking an observation. The arc of smaller radius, DE, contained 60°, and the other, FG, of larger radius, contained only 30°, in continuation of the former, making together the whole quadrant. The arc DE was divided into whole degrees only, on account of the smallness of its radius; but the arc FG had its degrees subdivided by concentric and diagonal lines, as seen in the figure. The manner of ascertaining the altitude of a heavenly body, by the joint use of these two arcs, is not obvious at first sight of the instrument, but may be thus explained. When the altitude of the fun is taken, the horizon-vane is fitted to the extreme end or centre A of the quadrant, and the shade-vane B is put to within about 10° or 15° of the supposed co-altitude, but to a less quantity than the co-altitude, while the fight-vane remains for adjustment on the arc FG. Things being in this state, the back of the observer is turned to the fun, and the quadrant is so elevated, that the shadow of the upper edge of the shade-vane B falls upon the upper edge of the slit in the horizon-vane A, when viewed through the small hole in the fight-vane. If now, in this situation, the horizon is seen through the said slit, the observation is exact; but if not, the fight-vane is moved backwards or forwards on the arc FG, accordingly as the sky or sea is seen, till the horizon appears in its place, while the shadow of the shade-vane rests on the required slit in the slit of the horizon-vane, and then the observation is finished; and the sum of the two readings on the respective arcs, B and C, as read by the fiducial edges of the vanes, is the co-altitude or zenith distance of that limb of the fun, upper or lower, which was observed from the corresponding limb of the shadow. If a lens, of a focal length equal to the radius of the smaller arc, were used, the focal luminous point occasioned thereby would be a better object to measure the place of, than a shadow with an edge not sufficiently defined. This instrument, it should seem, was not capable of taking the altitude of a star or planet, nor of the moon, unless her disc was large enough at the time to project a shadow.

Elton's Quadrant.—An index bearing a spirit-level, with a vernier scale near the sight-vane, was added to the quadrant of Davis some time afterwards, by one Elton, the use of which was to take altitudes without an horizon; but the similarity of the two instruments renders a more particular description of this addition superfluous. An inspection of fig. 8. Plate I. will sufficiently explain the difference.

Gunter's Quadrant.—Among the numerous and useful contrivances of the ingenious professor of astronomy in Gresham college, was a portable quadrant, which now claims our attention, and which was contrived in, or a little before, the year 1618. The object of the inventor was not to construct an instrument capable of measuring altitudes more accurately than that of captain Davis, which we have just described, but to make a quadrant so comprehensive in its uses, that, like the logarithmic scale, which he divided, it might thence by inspection results, which had previously required long and tedious calculations; and in this point of view it is still to be considered. Besides the quadrantal arc for measuring altitudes, this instrument has various curves stereographically projected on it, such as the equator, the tropics, the ecliptic, and the horizon, on a supposition that the eye is situated in one of the poles, all which are represented in fig. 3. of Plate XXIII. of Astronomical Instruments. The projection, according to Bion, is thus effected: when the quadrantal arc BC has been graduated, from its centre A, with a convenient radius AT, describe the arc TD to represent one of the tropics; and let the line AT be taken as the tangent of 56° 46', or half the sun's greatest declination (supposed here to be 31° 32'), added to the radius or tangent of 45°; then to find the point E in this line for the equinoctial, there will be this proportion, as the tangent of 56° 46' : 1000 :: radius : 655; and therefore, if 4900 parts of the line AT be taken, it will be the proper radius of the arc EF, or equinoctial.

To find the centre of the occult arc ED, which represents the ecliptic, let the meridional line AD be divided by the point G, that if AF be taken as radius, AG may be the tangent of 23° 31', the sun's greatest declination; in which case AG will be 27° of the line AF, and the occult arc ED described from the point G will be one-fourth of the ecliptic, which may be divided into signs and degrees thus: as radius is to the tangent of any degree's distance from the nearest equinoctial point, so is the co-line of the sun's greatest declination, to the tangent of that degree's right ascension; for example, supposing the right ascension of the first point of A to be 25° 54', draw a line from A, the centre of the quadrantal arc, to this degree and minute on the said arc, and note where it intersects the occult arc of the ecliptic, and this point will be the beginning of the sign; and in like manner any other part may be inferred.

The line ET, or line of declination, may be divided thus: that the radius for the radius of the equinoctial, or tangent of 45°, let the tangents of 46°, 47°, 48°, &c. up to 68° 30', be successively taken and laid down on the line ET, and the points of excess above the tangential point of 45° will be the dividing lines of the scale for 1°, 2°, 3°, &c. up to 23° 32', or greatest declination.

When the scale of declination is finished, the quadrantal arc may be taken as the measure of right ascensions, and then the place of a star or any other heavenly body may be inferred on the plane of the quadrant thus: let a line be drawn

9
drawn from A to the degree and minute of right ascension, counted from B towards C, and the point in this line, where an occult arc, drawn through the declination from the centre A, intercepts it, will be the place of the heavenly body in question.

The two parallel arcs contained between the tropic T D and the quadrantal arc B C, are the scales of days and months, which are divided by the aid of a table of meridian altitudes of the sun for each day, calculated for the particular latitude, for which the quadrant is constructed. It is hardly necessary to observe, on the construction of such table, that if the latitude and declination be both north, or both south, the declination must be added to the co-latitude for the greatest altitude; but if of contrary denominations, subtracted. The degrees and minutes contained in such table are transferred into the scale of months by a line extending across it from the centre A to the quadrantal arc, as before.

The centre of the horizon will be in the meridional line A C, and if a point H be taken such, for the co-latitude 38° 28' for instance, that A H may be the corresponding tangent to radius A F, then \( \frac{28}{28} \) of that radius will be its distance from A, and the occult arc described from H in the extent HE, begins at E in the equinoctial, and ending at the tropic T D, will be the required horizon. This horizontal arc may be divided thus; as radius is to the sine of the latitude, so is the tangent of any number of degrees in the horizon, to the tangent of a corresponding arc in the quadrant; and from a table thus constructed any point in the horizon may be put in by intersecion of a line drawn from A to the tabular number as read on the quadrantal arc, as in the former cases.

A third table of the sun's altitude for inferring the hour lines may be calculated thus; when the sun is in the equator, as radius is to the co-sine of the latitude, so is the co-sine of any hour from the meridian, to the sine of the sun's altitude at that hour; but when the sun has declination, say, as the co-sine of the hour from the meridian is to radius, so is the tangent of the latitude, to the tangent of a fourth arc; then if the latitude and declination have like denominations, and the hour fall between noon and six o'clock, subtract the declination from the said fourth arc, and the remainder will be a fifth arc; but if the latitude and declination have unlike denominations, or the hour be between six and midnight, add the declination to the fourth arc, and the sum will be a fifth arc, which must be thus used; as the sine of the fourth arc, is to the sine of the latitude, so is the co-sine of the fifth arc, to the sine of the altitude sought. The determina-

fication of such table by this fundamental method is however opaque, and Margett's horary tables, which give the successive altitudes in any given latitude, would greatly shorten the labour, by giving the results by inspection, which may at the same time be inferred by transfers from the quadrantal arc, similar to those we have already described. When the horary points are put in for each successive hour, when the sun is in the equator, at each tropic, and at a few intermediate places, the horary lines may be drawn through the said points, which will give the hour for any given day, when the instrument is used as hereafter described.

A fourth table, for putting in the azimuth lines, will require the sun's altitude to be calculated for each degree of azimuth, when the sun is at the equator, at each tropic, and at other intermediate places, which may be done thus: when the sun is in the equator, as radius is to the co-sine of the azimuth from the meridian, fo is the tangent of the latitude, to the tangent of the sun's altitude at the azimuth in the equator: but out of the equator the rule is, as the sine of the latitude, is to the sine of the declination, so is the co-sine of the sun's altitude at the equator at a given azimuth, to the sine of a fourth arc.

The latitude and declination have the same name, in all azimuths from the prime vertical to the meridian, add this fourth arc to the arc of altitude at the equator; but when the azimuth is above 90°, subtract the altitude at the equator from this fourth arc; also when the latitude and declination have unlike names, subtract the said fourth arc from the arc of altitude at the equator, for the altitude at the proposed azimuth. The points corresponding to the tabular numbers, thus ascertained, must be inferred by intersection of lines drawn from A, as before, to the quadrantal arc B C, and lines uniting those points will be the lines of azimuth for each hour in every day of the year. But to complete the instruments, two sights or vanes must be fixed on the meridional line A C, and a small plumbline, with an adjustable head, must be suspended from the point A of the quadrant.

In addition to the lines already described, Gunter's quadrant has sometimes a square under the angular point A, called a quadrat, as seen in the figure, two sides of which are divided into ten equal parts each, and these again subdivided into others, the use of which is to measure angular distances; and sometimes the large square is subdivided into a number of smaller ones, for the purpose of performing arithmetical proportions by inspection. See BIOL on the Construction and principal Uses of Mathematical Instruments.

It would be tedious to enumerate all the uses of this quadrant, and to exemplify all the problems that it is capable of performing, or rather of illustrating (for great accuracy cannot be expected in the indication of so small an instrument); but we will specify a few of the most useful, which may be varied by reversing the process, and by altering the data, to a great extent.

**Problem I.** To find the Sun's Right Ascension.

Stretch the thread from the point A over the sun's place, as marked in the graduated ecliptic, and the degree cut by it in the quadrantal arc will give the corresponding right ascension.

**Problem II.** To find the Sun's Declination.

Stretch the thread as before, and slide the bead till it rests on the sun's place for the given day, and then turn it to the scale of declination, where the corresponding degree will be seen under the bead.

**Problem III.** To find the Sun's Meridian Altitude on any Day.

Extend the thread over the day of the month given, in its proper scale, till it reaches the quadrantal arc, and the sun's greatest altitude for that day will be indicated thereby.

**Problem IV.** To find the Hour of the Day.

Extend the thread over the day of the month, and, holding it there, slide the bead till it lies on the line of twelve o'clock; then elevate the quadrant so that the solar ray may pass through the upper right-hole exactly upon the second, and allow the plummet to rest, and then the bead will indicate the hour, before or after noon, as the case may be. In a similar manner the sun's altitude may be measured by the thread falling on the quadrantal arc, when the solar rays pass as above described.

**Problem V.** To find the Sun's Amplitude.

Let the bead be rectified for the given time, and be brought
brought afterwards to the horizon, while the thread remains stretched, and it will indicate the rising or setting amplitude, as the case may be.

Prob. VI.—To find the Ayscnzional Difference.

Rectify the head as in the last problem, and bring it to the horizon, in which situation the thread, extended to the quadrant, will shew the ascensional difference in degrees, which converted into time will shew how much the sun rises before fix in summer, and after fix in winter, and consequently will give the exact length of the given day.

Prob. VII.—To find the Sun’s Azimuth.

Rectify the head for the given time, and observe the sun’s altitude as explained in prob. 4. Then extend the thread to the complement of that altitude, and the bead will indicate the azimuth corresponding, and vice versa.

Prob. VIII.—To find the Hour of the Night by a Star.

Put the bead on the thread to the distance that will indicate the star’s declination, and look through the sight for the star till the plummet rests on the plane of the quadrant, and in that situation the bead will shew, in the hour lines, the star’s distance in time from the meridian of the place; in the next place subtract the sun’s right ascension in time from that of the star, as given in some catalogue, and to the remainder add the observed distance from twelve o’clock in sidereal time, and the sum will be the hour nearly, or the approximate distance of the sun from noon, which may be corrected by applying the sun’s variation of right ascension since the preceding noon, which in every six hours will be about a minute.

Sutton’s quadrant, and Collins’s facet on a quadrant, are very similar, both in construction and use, to the quadrant we have here described, and the dial on a card, by Ferguson, is nearly related to it, particularly as it has been lately improved by the Rev. W. Pearson.

Of Astronomical Quadrants.—The quadrants which we have hitherto described may be considered as by no means perfect, but as approximating only to an instrument, that is really useful in an observatory for determining the exact place of a heavenly body; hence the quadrant which we propose next to describe, has obtained the name of astronomical, from its superior pretensions to accuracy in the measurement of altitudes taken above the horizon, and therefore merits our more particular attention.

An astronomical quadrant may be either portable or fixed; in the former case it is usually mounted on a tripod, with adjusting screws in the feet, and has a horizontal motion as well as a vertical one, in order that it may take altitudes in any azimuth, or be made to follow the body observed in its apparent path; but in the latter case it is fixed against a steady wall, with its plane in, or very nearly in the meridian, and is therefore denominated a mural quadrant.

The first astronomical quadrant, of which we have any account left us, is that which Ptolemy used; it was the fourth part of a circle placed upright against a stone pier, or quadrangular log of wood, with zero of the arc in the horizontal line, and a pin of wood projecting from the central point throw a shadow on the limb when the sun shone, which shadow was used by way of index; but it is obvious that such accuracy was not to be expected from such an instrument, however well constructed or divided. We might mention here the quadrants of Tycho Brahe and Hevelings, but the former has been noticed under our article Circle, and the latter was destroyed in the conflagration of the owner’s house in Dantzie. In more recent times, astronomical quadrants have been made on accurate principles, and with great care, especially by Graham, Sisson, Bird, Rambo- den, Cary, and Troughton, several of whose instruments we will now describe, as far as any difference in their construction renders distinct accounts necessary. We will proceed, as we have done on former occasions, chiefly in the order of time, which, generally speaking, will be found to be also in the order of successive improvements.

Mural Quadrant by Graham.—Before we proceed to describe the mural quadrants, contrived and made by Graham, and fixed at the well side of the stone pillar in the middle room at the Royal Observatory at Greenwich, at the expense of King George I., and for the use of that eminent astronomer Dr. Halley, it may be proper to mention that Flamsteed, and his assistant Sharp, had previously used an arc of a circle fixed against a stone pier in the meridian, which they had themselves contrived, and which was removed at Flamsteed’s death. We must, therefore, consider their instrument as having been the prototype of Graham’s mural quadrant, or arc, as it has been also called sometimes. In fig. 4. of Plate XXIII. of Astronomical Instruments, is given a representation of the mural quadrant of Graham’s construction, which will equally represent that of Bird, contrived after the same model, and is the same that both Dr. Smith, and Stone, the editor of Eion’s work, have given in their respective accounts.

The body of this quadrant is composed chiefly of bars of iron united together, as seen in the figure; some, to form the plane of the quadrant, placed flat-ways; and others, to give strength and stability, fixed edge-ways. These bars are all of the same dimensions, namely 2.5 inches wide, and 0.175 thick, and are united together by right-angled bent bars in various places, both at the interferences made by the sides of the small squares, and at other situations, so that while great firmness is obtained, great weight is avoided. The quadrantal arc is composed of two bars, one of iron, united to the iron frame, and the other of brass, on which the divisions are made, as described under our article Graduation; this brass bar is pinned fast to the iron one, and being more slender than the iron, accommodates itself thereto, and, as time has proved, does not alter the shape of the arc, as we have lately been assured by Mr. Troughton. The breadth of the limb is 2.2 inches, the brass limb being more remote than the anterior edge of the iron arc by 1.2 inch, and the surface was planed, or rather sanded, by a tool fixed to a radial bar, that revolved on a vertical axis of motion, placed in the centre of the arc, and relling with its superior end in a fixed beam above the plane of the quadrant, when this plane was lying in a horizontal position, it being impracticable to put so large a body in any ordinary lathe. The original divisions of Graham were incised on two separate arcs, one graduated into 90° and its subdivisions, and the other divided into 90 parts and its subdivisions, as we have before explained in the article just referred to; but the divisions, being laid down by rough dividing, are not now made use of, but a quadrantal arc of 96, with its subdivisions, put in by Bird in 1753 between the two arcs of Graham, is that which all observations taken by Graham’s quadrant are now referred to, and the readings are transformed into degrees, minutes, and seconds, by an appropriate table. The readings were at first obtained by a double vernier-piece carried by the telescope, that revolves round the centre of the arc, one side of which vernier-piece read with the arc 90°, and the other with the arc of 96 parts, or grand divisions; the degree was subdivided into 12 parts, or 57 parts, and 10 parts on its vernier equalled 11 out of the said 12 parts, so that
degree, the pieces coincidence fcrcw-pin the and 01 did. That 96.85 but fere the this, and this lower the 30", brafs any and fupported the fince celebrated to the read, and this 16. Hence in the firft vernier its number 11 is one left than its equivalent arc contains on the limb of 90°; but in the second, the number 17 is one more than its equivalent arc contains in the arc of 96 parts, on which account the reading of one vernier is in the direction from right to left, but that of the other, on the contrary, from left to right; one meets, and the other overtakes the dividing strokes of the divided limb; and for the fame reafon, in the common Hadley's quadrant, or rather ochant, sometimes 19 subdivisions, and sometimes 21 on the limb, act againft 20 in the vernier, but then the readings are not in the fame direfion. The telecope is clamped to the arc in any situation by the mechanism for flow motion in the ufual way, which probably was firft adopted in one of the large quadrants, and its counterpoife beyond the centre of the arc, gives it the advantage of remaining in any position. It has crofs hairs in the focus of the eye-glas. When the lines of the vernier are none of them coincident with any one on the limb of either quadrantal arc, the portions less than what the verniers prove to indicate were exclaimed by the eye, by examining the situation of other pairs of dividing lines, to the right and left of the near to a coincidence; and to a want of a micrometrical nut to the fcrew of flow motion may be attributed the remark, that has been made, that the readings thus taken, even with fo large radii as 96.85 and 95.8 inches, were not to be depended upon to 10'. That the motion of the telecope might be quite easy, and that the centre of the quadrant might be relieved of its weight, the following contrivance was introduced: ab repreffible an iron axis laid across the top of the wall, having two brafs plates fixed perpendicularly to its ends, with notches cut in them for this aim to turn in, which axis points to the centre of the quadrant at right angles to its plane: to that end of it next to the quadrant, at a, an iron arm, e d, is fixed, having two brafs plates, e, f, d/; almost perpendicular to it; to these are riveted two flender slips of deal, whose remote ends meet at g, near the eye-piece of the telecope, and are held together by a brafs cap. Through a small plate fixed to one fide of a collar, embracing this lower end of the telecope, there paffes a fcrew-pin at 88 parallel to the telecope; which pin, being fcrewed into the cap at the end of the faid slips of deal, holds up the telecope againft the centre-work, while the slips are braced by other crofs slips of the fame light wood. The counterpoife i is supported by the rod h i at l, the retiring end of the axis a b; and a pair of brafs rollers k, l, acting againft the limb of the instrument, give freedom to the motion of the telecope thus counterpoife, and complete the construction. The quadrant being thus put together, some strong but small plates of brafs are made fast to its posterior face, and bent fo as to fall into as many hold-fails in the wall, into which they are refpectively fereved; but the weight of the whole is supported chiefly by two pins or bolts inferted into the holes A and B, made in pieces of metal attached to fuch angular points of the iron bars, as best support the centre of gravity of the whole: the pin A is made fast into the wall, but allows a motion round it, and the pin B fixes the quadrant after its extreme radii are adjusted, one horizontal, and the other vertical: this position was given by means of a plumb-line of fine silver-wire, that at firft was fo fupended as to be fice both the centre of the quadrantal arc and the point 90° on the limb, but which was transferred afterwards to an adjustable point of fufpenfion out of the centre, with a corresponding dot made on the arc of excess of the limb. The plane of the quadrant was made vertical, as compared with the plumb-line, by the fcrews of the hold-fails; and the telecope was adjusted parallel to this plane by comparison with a tranit telecope viewing together both high and low fars in fucception; but the line of collimation of the telecope could not be fixed properly, as it regarded the true horizontal line of the quadrant paffing through its zero, without the aid of Graham's factor. This factor was, therefore, fo adjusted to a far near the zenith, that it measured the fame zenith-diftance, with its plane turned to the eafit, as it did when turned to the west, and had its error atermined in this way, and afterwards an altitude, taken with the quadrant, was made to correspond with fuch corrected altitude of a far taken with the defignified factor in revered positions, which property the mural quadrant does not polifh. The method of performing this adouiment for collimation will be understood from our directions hereafter given, when treating of Ramsden's portable astronomical Quadrant.

Bird's Mural Quadrant.—After the defcription we have given of Graham's mural quadrant, we shall have no occafion to dwell long on the structure of Bird's, which was made of brafs entirely, after a fimilar model, but divided in both its arcs, of 90°, and of 96 grand parts, with more skill than Graham proved himfelf matter of in this part of his labours. Smith and Stone deferibe Graham's quadrant as fixed to the eafit fide of the pier at Greenwich, and looking to the fouth, which was the situation for taking meridian altitudes of the greateft number of fars; but fince the year 1753, it has been placed on the welf fide, looking towards the north, and Bird's then took its original place.

This quadrant, which was procured in the time of Dr. Bradley, was firft placed on the welf fide of the pier, in 1750; and the obervations of himfelf and of Dr. Malkeleyn, taken by it firft it was placed on the eafit fide, have contributed largely to complete the hefet catalogues of the heavenly bodies, which otherwise must have been very defective. While, however, Mr. Pond, the preffent astronomer royal, was engaged in making his well-known table of declinations, with one of Trughton's circles, at Weftbury, he found reafon to fupject the accuracy of the total arc of this quadrant, from a compariion of his own determinations with those previously made with Bird's quadrant; and a fubjecftent examination of the arc by Troughton justified his fupicion. With an apparatus exprifely contrived for the occafion, this celebrated mathematician and instrument-maker measured the total length of the quadrantal arc, and found it too fmall by 7", exclusive of another fimilar error of 2°, occasioned by the wear of the axis of motion; though, on a rigid trial of the intermediate divisions, he did not detect more than one fecdnd of error, or rather of inequality, among the neighbouring divisions in any part of the arc. This trial was made in the prefence of the preffent astronomer royal, in the year 1807; and the refult, while it ferves to correct pupil obervations, by the addition of 1" to every fucceffive 10° of altitude, would have tended to correct all future obervations by a like addition, had not the large tranit-circle, lately made and fixed in the fame obfervatory by Troughton, superfeded...
fuperfeded the ufe of both the quadrants by its superior accuracy. The quadrantal arc of Graham's quadrant has not lately undergone a fimilar trial; but Troughton thinks it probable that the iron instrument has preserved its figure better than the brafs one, and that confequently the addition of the brafs arc on the face of the iron one has had no undue influence in altering either its temporary or permanent dimensions. At firft, the telecope of Bird's quadrant was not braced; but after a trial, it was found to bend a little by a counterpoife of 80 pounds, and was afterwards braced by frame-work furrounding it, that prevented its yielding. A trial was made by Dr. Bradley of the total arc, in January 1753, after it had remained three years on the weft side of the pillar; and though its weight is eight hundred pounds, the error was found to be not more than two seconds. He did the fame again in July, in the year 1759, when it had remained fix years and half in its new ftuation, on the eafi side of the pillar, and found the arc exactly 90°. These examinations, having been made in the extremes of cold and heat, fhow that change of temperature did not a fect the total arc; and that, therefore, the 7" diminution of the arc, detected by Troughton, is occasioned by a change of figure in the space of 48 years. The difference of the readings of the two arcs has never yet amounted to 4", which is a fanding proof of the accuracy and flill of Bird as a divifer. Near the eye-piece of the telecope is a good micrometer, that not only gives flow motion in taking obfervations, but measures the number of seconds that the reading lines of the vernier is short of coincidence in any obfervation; and formerly the quantity indicated by the vernier had three fconds added, to obtain the whole meafure; but, by Smeaton's advice, the vernier is now disregarded, and the addeement, obtained by feveral turns of the micrometer-fcrew alone, is used to complete the fimple reading of the divisions and fud bifctions, or 5' spaces; in other words, the fcrew, and not the vernier, subdivides the laft 5' space in the obferved arc, and gives what is due to the obfervation. The adjuftlement of this instrument, which was made of eight feet radius, on purpofe to take the place of Graham's, are made in all refpects as they are made in its predecessor; and the fector, which ferves for adjufting Graham's line of collimation by fars near the zenith, is used for the fame purpofe in Bird's quadrant. If any of our readers with to feethe the original plan of all the separate parts of Bird's quadrant, and to read his decription of them, we beg leave to refer them to his quarto pamphlet, entitled "The Method of constructing Mural Quadrants," published by order of the commissioners of the Board of Longitude, in the year 1760. In this pamphlet, however, it is not mentioned that the vernier of the arc of 90° subdivides the space of 5' into ten parts of 30" each, by having ten divisions thereon, reading with eleven subdivisions of the limb; but we know that this was the original reading of the vernier.

Jeremih Siffon's Mural Arc.—Perhaps it would have been more confonant to the order of time, if we had fpoken of the younger Siffon, who was Bird's contemporary, and at one time his employer, next after Graham; but the histories of the two mural quadrants at Greenwich being connected, demanded that these instruments should follow each other in immediate succession. In the year 1768, Jeremiah Siffon, the fon of Jonathan, made the large mural arc at the king's private observatory in Richmond gardens, which extends 45°, or more, beyond a quadrant, and consequently reaches beyond the north pole; which circumstance gives it the advantage of being put in the meridian, by an obfervation of the pole-star. The divisions of this arc are into degrees and its sub-divisions, but the frokes are not cut very neatly; and the reading, as was the cafe with Bird's quadrant at firft, is performed partly by a vernier, and partly by a micrometer-fcrew. We have felectcd this instrument, as a fpecimen of Siffon's construction, principally on account of a power that it poifefles, which is very important, but which probably was not contemplated, and confequently not intended by the maker himself: the extenfion of the divided limb, to feveral degrees beyond the north pole, affords the means of using this instrument in the manner that Troughton's large mural circle is now ufed, at Greenwich Observatory, by the prefent aftronomer royal; namely, to meafure the polar distances of the fars directly from the true polar point, without any reference to the lati- tude of the observatory, which method is one of the greateft modern improvements in making aftronomical obfervations. It is much to be defired that this mural arc fhould be divi- ded again by Troughton, or fome other superior divider, and that it have micropic micrometers applied to it, which may be placed by adjuftement over any optional part of the divisions, and at any affumed distance from each other; for though it would not then, as it does not now, poifefs the valuable property of oppofite readings, and of a motion in altitude to reverse the oppofite arcs, by reafon of its being lefs than a femicircle, yet being compactly made, and of large radius, it is capable of receiving divisions fuperior to thofe on the quadrants which we have juft defcribed; and as the fitation and flructure of the observatory are excellent, the appointment of a regular observer to co-operate with the aftronomer royal would be highly conducive to the interefts of aftronomy. We hope that this hint may be taken up in a quarter where the power exifts of realizing our wishes in this refpect. Aftronomical clocks, and various other auxiliary instruments, are already in the observatory; fo that the principal expeffes of instruments, as well as of an appropriate and elegant building, is already incurred.

Portable Aftronomical Quadrant by Ramflen.—It frequently happens that fuperior artifices vary the construction of their instruments to fuit the views of the purchaser, or the fcale on which they are to be constructed. We will fealet out of the quadrants made by the late ingenious Mr. Ramflen, that which he made for Dr. Shepherd for the observatory of Chrift-college, Cambridge, and which profeffor Vince has defcribed at confiderable length in his "Treatife on Practica1 Aftronomy." The figure exhibiting this quadrant is the 5th of Plate XXIII. of Aftronomical Instruments, which requires but little explanation. The tripod on which the quadrant is mounted has fcrews of adjuftement to fix the fem, on which the horizontal motion is performed, perpendicular, which is proved to be fo in all directions when the plum-line bifects both the superior and inferior dots during the whole revolution round a horizontal circle. The visible fem is a brafs tube, and through it ascends a folid steel vertical axis, which fitting closely at the superior and inferior ends, has not the leaft shake, and pre- ferves the position once given it fo long as the feet fcrews are unmoifled. The telecope is of the achromatic conftuction, and has the ufual apparatus for flow motion, the fem of which is made a micrometer to subdivide the small reftidum of the angle that the vernier alone will not indi- cate, when the coincidence is not perfect. The telecope lies on a bar that carries the counterpoife, and in which is the centre of its motion. It has a fystem of wires in the focus of the eye-glas, which are adjuftable by fcrews, both upwards and fideways, as well as in a circular direction, fo that the adjuftlements for collimation, and for zero in the alti- tude circle, may be effected thereby. The point of fuf- pension of the plum-line is also adjuftable by a proper fem apparatus.
QUADRANT.

apparatus. At the top of the vertical tube, or stem, is a small horizontal circle with a clamping apparatus for slow horizontal motion, by means of which the whole quadrant, with its attached telecope, turns gradually round in azimuth. When observations are made in or near the zenith, the plumb-line falls in the way of the telecope, and is obliged to be removed, on which account the large quadrant made by Ramfden for the duke of Marlborough, and now placed at Blenheim, has the plumb-line suspended at the posterior face of the instrument. This inconvenience is, however, remedied by the addition of a spirit-level suspended from an adjustable horizontal brass rod, under the uppermost radial bar of the quadrant, and this level not only supplies the place of the plumb-line when taken off, but at all times serves as a check on its adjustment, and, when furnished with a graduated scale, may very well be made its substitutive.

The construction of Ramfden's portable quadrant was probably borrowed from Bird's, as well as his method of dividing the larger instruments that exceeded the reach of his dividing engine; but the instrument before us has no other horizontal or azimuth circle, except what is used plain, for the purpose of giving motion. Neither is there a second horizontal telecope fixed permanently in that situation by which the telecope of observation may have its collimation determined, and the zero of its vernier adjusted.

The vernier of this quadrant reads with two sets of divisions, like that of the mural quadrant by Bird, but the radius being small, the subdivisions are made into four parts each; the inner arc is divided into 90°; and the subdivisions into 15° each, but the outer one into 90 parts, or grand divisions, and these again each into four parts, or subdivisions; and those two arcs operate as a check on each other. The micrometer sub-divides the 15° into 30°; but it is necessary to convert the reading of the arc of 90 grand divisions into a corresponding quantity, expressed in degrees, minutes, and seconds, which may be done by direct proportion, or, which is more feasible, by a table that we have fulljioned, calculated for this purpose. The readings of the arc of 90 are put down with titles divisions, sub-divisions, and vernier, where 16 (and sometimes 32) on the vernier are equal to one sub-division, and four sub-divisions to one division; for example, suppose the reading to be thus, 21 div, 2 sub.

When, however, the coincidence of the vernier is not perfect, the quantity brought up by the micrometer-screw must be added as a fractional portion of 52° 15', which is the value of one step of the vernier, when 16 is the number of steps, but if 32 are infected, then 26° 4 would be the value of one step forwards from zero.

A Table for the Reduction of the Grand Divisions, Sub-divisions, and Vernier, of the Arc of 90, into Degrees, Minutes, and Seconds.

Adjustments.
QUADRANT.

Adjustments.—1. To adjust the axis of the pendial vertical.—This adjustment may be performed either by the plum-line or by the level, both which methods we will explain in succession. We have already said that when the wire of the plum-line will continue to bisect both the upper and lower dot, while the instrument is turned quite round in azimuth, its axis is vertical in all directions, but this could not be effected unless the plum-line passing through the two dots were also parallel to the axis; this adjustment, therefore, is made partly by the screws at the feet of the tripod, and partly by the screw that moves the piece bearing the upper dot in a lateral direction. In the first place then turn the quadrant in azimuth till its plane, or, which is the same thing, the telescope lies parallel to a line joining any two of the three feet, and turn one of these two screws till the wire bisects the lower dot, and with the proper screw bring the upper dot to the same wire; then reverse the telescope by turning $180^\circ$ in azimuth, and if both dots are again bisected, the axis is vertical in the direction that the telescope has pointed; in the next place turn the telescope the space of a quadrant till it points in the same direction as the third foot of the tripod, and make the wire bisect the lower dot by the screw of this foot, and it will be found to bisect the upper dot also, if the first adjustment of the dot was properly made, but if not, repeat the operation till both dots are bisected in all the reverted situations of the telescope, and then the axis will be vertical in every direction.

In making this adjustment by the level alone, the proceeds must be thus; first, the level must be made parallel to the rod on which it hangs, and secondly, this rod must be put perfectly horizontal, and the level will then be horizontal also, with the bubble in the middle. In order to make the level parallel to the rod, place it parallel to a line joining two of the feet screws, and bring the bubble to the middle by one of the feet screws in question; then take off and revive the position of the level, and if the bubble is found in the middle now, the parallellism is perfect, if not, one half of the error must be rectified by the screw-foot-screw, and the other half by the adjusting screws at the end of the rod, by releasing one and screwed up the other. A repetition or two of these processes will make the bubble stand in the middle in both of the reverted situations. In the next place, with the level thus parallel to the rod of the instrument, turn the quadrant round its axis an entire semicircle as nearly as can be estimated, and if the bubble will now rest in the middle, the rod is level, and being at right angles with the axis of the quadrant's motion, proves that this axis is vertical in every direction; but if the bubble is found to run to one end of the tube, bring it one half way back by the rod's adjusting screws, releasing one and fixing the other, as the case may be, and the other half by the proper foot-screw. A repetition of these processes will soon settle the bubble in the middle during a whole revolution in azimuth, and then the adjustment of the axis is perfect, as well as of the rod and level.

2. The second adjustment is that by which the line of collimation of the telescope is made parallel to the horizontal line that passes from the centre of the quadrant to zero on the limb, or quadrantal arc, at the same time that zero on the vernier coincides with zero on the limb. This important adjustment may be made in several ways, some of which are tedious and otherwise objectionable; but we will confine ourselves to two which apply, one to the vertical, and the other to the horizontal line of the quadrant, which two methods, when duly effected, will not only check each other, but detect the error of the total arc, if there is any, at the same time; which is an acquisition of the utmost importance. First then, to adjust by the vertical line, let the axis of the quadrant be first made truly perpendicular in all directions by the adjustment we have already described, and fix on a star within a few degrees of the zenith, when exactly on the meridian, and measure its altitude by the crosf-wire in the field of view in the usual way, and note down the result; do the same on a successive night soon after, if possible, on an evening of similar temperature, with the quadrant turned half round in azimuth, and note again the result; if these readings prove to be at equal distances from the point $90^\circ$, one on the quadrantal arc, and the other on the arc of excess beyond $90^\circ$, the horizontal wire is truly placed in the eye-piece, but if not, half of the difference of the readings must be corrected by the proper screw for raising or lowering the said wire. This may be done by directing the telescope to a distant mark till the crosf-wire bisects it, then by moving the screw of flow motion of the vernier the half quantity required, and by bringing back (up or down) the crosf-wire thus displaced to its original mark again. This operation repeated will place the crosf-wire in such situation, that zero on the vernier will be in its proper place with respect to the point $90^\circ$; or the half difference thus ascertained may remain, without altering the crosf-wire, as an error of adjustment to be constantly applied with the sign $+$ or $-$, as the case may be, in all subsequent observations. Again, to adjust by the horizontal line passing through zero of the quadrantal arc, it will be necessary to have a second telescope turning on pivots in adjustable Y's attached to the back of the quadrant, on the same level with the said horizontal line of the quadrant. This telescope may be called the adjusting telescope, and may be also used to 'swatch' a distant mark, before and after an altitude is taken, in order to detect any deviation in the position of the vertical axis, that may happen during the operation of measuring. Let the adjusting telescope bisect a fine distant mark with its crosf-wire, and turn the tube of the telescope round one halfway on its pivots, as it lies in a horizontal position, and if the wire now bisects the same mark it is truly fixed, if not, look out for a new mark a little higher or lower, as the case may be, and make it cut that in the reverted positions of the crosf-wire, by means of the proper screw for this purpose; now this adjusting telescope will be adjusted for collimation: in the next place, put zero on the vernier to zero on the limb, and direct the telescope of observation to the same distant mark, by which the adjusting telescope had its wire adjusted, and let this mark be bisected by both telescopes, the level and plum-line at the same time shewing that the vertical axis is perpendicular; now turn the quadrant half round in azimuth, and reverse the adjusting telescope so as to view the same distant mark again, and if it is found to bisect it as before, the horizontal line of the quadrant is right, and also the quadrantal arc without error, supposing the telescope of observation to have its adjustment for collimation as fixed by the point $90^\circ$, above described; but if this adjustment of the point zero on the limb be first made, half the apparent error must be rectified by the screw at the eye-piece, by means of reversed positions and new marks; and then afterwards the adjustment by a star near the zenith will detect the error of the whole arc. If, however, no error in the total arc exists, then the adjustment for collimation may be made either from the horizontal or from the vertical measurement, as may be most convenient; one of which is more practicable by day, and the other by night. When this delicate and very essential adjustment is finally settled, the object-glass of the telescope should not be disturbed, and therefore it would be advisable to have its interior surface well cleaned previously.

It was taken for granted that the crosf-wire was perfectly horizontal.
horizontal during the time the preceding adjustment was made, or, which is the same thing, that the parallel vertical wires were perpendicular to the horizon. This is proved by simply removing the direct telescope to a fine small distant mark, and make the adjustment for vision, if necessary; then if one of the vertical wires will continue to bisect the said mark through the whole field of view while the telescope is elevated or depressed, the wires are right, but if not, they must be made so by the proper screws for that purpose, near the focus of the eye-glasses. This preparation ought to precede the last adjustment, and when once made, seldom requires altering, except in case of accidental injury.

It has also been assumed in the preceding adjustment, that the maker of the instrument placed the plane of the quadrant parallel to the axis of its motion, and also the line of collimation of the telescope parallel to the said plane. The former may be known to be true thus; if, when the plumb-line is adjusted, at its centre of suspension, just to escape touching the limb, (which should always be the case,) the quadrant's motion in azimuth will not alter it in this respect, the plane is truly fixed; but if not, the fences, that fix the quadrant to its axis, must be referred to for the alteration, which is best done by the maker. When there is no plumb-line, a small spirit-level, fixed at right angles to the plane of the quadrant, will answer the same purpose; for the raising of the bubble during the quadrant's revolution in azimuth, will be a proof that the plane to which it is at right angles is vertical. With respect to the parallel position of the telescope, as this is guided by the vernier sliding on the limb, it is the business of the maker to adjust it properly, which he will best do by a comparison with a good transit instrument of the parallels of a high and of a low star in each of the two instruments; but a small deviation of the telescope with respect to parallelism, though to be avoided if practicable, will not sensibly affect the measurement of altitudes, which is the sole business of this instrument. If, however, this deviation is considerable, the eye-end of the telescope must be set nearer to or farther from the limb, as the case may be, by the maker himself. We have been the more minute in describing these adjustments, not only because they are indispensably necessary in making good observations, but because they will apply, one or other of them, by means of the plumb-line, or of the spirit-level, to all other astronomical quadrants that have a motion in azimuth.

We have before us the drawing of a large and beautiful quadrant made by Mr. Cary, for Leopold, the late grand duke of Tuscany, with two telescopes and a graduated azimuth circle, but the description we have given of Ramfden's instrument will equally apply to his, except as to the dimensions.

Portable Astronomical Quadrant by Troughton.—Though we have described Ramfden's portable astronomical quadrant with much minuteness, and have detailed the most useful methods of making such adjustments as will apply to the other portable quadrants that have a motion in azimuth, yet we should do violence to our own feelings, as well as to the ingenuity of an excelling artist of the first eminence, if we withheld from the public eye the great improvements that he has made in this instrument since the death of Ramfden. Fig. 6, of the same plate that contains Ramfden's instrument, is a reduced perspective view of the improved astronomical quadrant of Troughton, which was made by him and sent to Bilboa in Spain, about the time that astronomical circles began to be constructed. It has been ascertained, under our article Circles, that this instrument, as constructed by Troughton, (and we may now add, by Thomas Jones, who has learnt his mode of dividing,) is greatly superior to any quadrant that can be made, on account of properties which the circle exclusively possesses; but so far as a quadrant's accuracy can be depended on, Troughton's improved construction is to be preferred to all others. And, indeed, when we consider that simplicity, fleetness of performance, and permanence of the adjustments once made in this instrument, are properties which it peculiarly possesses, along with comparative cheapness, it is probable that there will always be purchasers, when such an instrument is on sale, provided the improver will content to make such instrument with limited powers, when he can have rapid sale for those which he now constructs, with all the advantages that the circle affords.

The radius of this quadrant is three feet, and the body is made double, that is, of two quadrantal frames united into one, by small pillars holding their planes parallel, and enfuring the two properties, not often united in other men's instruments, of lightness and strength at the same time. The tripod, on which the quadrant is supported, is a frame of mahogany, braced in different directions, so as to resist any ordinary preflure; when the quadrant is put in motion, or the telescope used. The three feet-crews are furnished with each a Hooke's joint and long handle, so that the observer may make an adjustment with any of these screws without flopping, and consequently without withdrawing his attention from the plumb-line apparatus, or spirit-level, that indicate the quantity of adjustment that may be necessary from any individual screw. About the middle of the pedestal, or frame-work of the tripod, is a three-armed horizontal bracing piece, on which the item of the quadrant rests; and this item is kept vertical by a socket of brass made fast to the centre of the table, that surmounts the pedestal, in which socket the vertical axis turns both steadily and freely, while it rests on the three-armed bracing piece below. The azimuth or horizontal circle is centered on this axis, but so as to admit of a motion round it of about two degrees, for the purpose of putting the zero of the quadrant right when the telescope is in the plane of the meridian. This small motion is produced by the tangent screw seen in front, and the other tangent screw regulates the flow motion of the telescope and vernier, by taking hold of the solid vernier plate, that reads at opposite points, and that may be clamped, when in use, to the azimuth circle, which is also a solid circular plate of brass, subdivided into 10° spaces, and reading by the verniers alone to 10'.

The vernier or index-plate is of considerable depth, and hollow, terminating with a chamfered edge below, and contains in it a triangular frame not seen, foleder to it, and opposed, for the sake of strength, by another similar frame seen above its plane. From the frame within the hollow index-plate arise three small pillars, which support the upper triangular frame at the three corners, and palling through it receive so many milled nuts on their tapped ends, by which means the whole are compactly united. These milled nuts are useful for adjusting the plane of the quadrant parallel to the vertical axis of the quadrant's motion in azimuth; and it is here where the quadrant is to be secured from the wind for close package. Upon the upper triangular frame is folded fast a short but strong conical tube, that supports the long column that terminates with a supplementary cone. From nearly the lower extremity of this long column a couple of braces ascend about twenty inches to the upper part of the body of the quadrant, and, by being made fast to it, complete the adjustments of the structure in an admirable manner. The telescope, which is about forty-two inches long, and achromatic, as well as furnished with an adjustable fly-wheel of Spider's threads, tapers from the object-glasses down-
downwards, to prevent any inclination to bending by its weight, and has an axis of motion of four inches and a half long, that passes through the thick pillar, that connects the two quadrantal portions of the double frame at the exact centre of motion, and of the divided arc. The counterpoise is applied at the redundant end of the telescope, and the vernier borne by its end, near the eye-piece, divides the 5 spaces of the vertical arc into 50, while a micrometrical microscope, attached to the metal of the telescope, subdivides this half quantity into single seconds. A nicely ground spirit-level hangs on the horizontal bar, with its proper adjustment apparatus, which alone will ascertain the position of the quadrant to a second; but, as if this were not sufficient, a plumb-line is made to descend, free from dail, or agitation by the wind, from an adjustable point of suspension through the hollow column, where there is little or no disturbance from a motion in azimuth, and ensures the position still more certainly. The water vessel in which the plummet is immersed, to prevent vibration, is contained in the hollow short cone before described, as containing a triangular frame within it, and the situation of the wire is examined in two directions, at right angles to each other, by microscopes looking across the bore of the column, at a convenient height for the observer to see without a change of position of his body, when he has been just observing at the telescope. The mark used for each wire to designate a luminous face, known by the name of Ramfisk’s glass, from its being only the image of a luminous point without substance, occasioned by a contracted aperture of a tube, fixed at the remote side of the column into which light enters, and by which it is directed without parallax. Besides these appendages, there is a secondary or adjusting telescope, such as the elder Sillons made for his spirit-level, and such as we have already described, as furnishing the means of adjusting the horizontal line of a quadrant that moves in azimuth, and of ascertaining the error of the whole quadrantal arc, by comparison with the adjustment by a flat near the zenith. (See Portable Astronomical Quadrant by Ramfisken, before described.) Lastly, the radial bars that bear the quadrantal arc, taper downwards from the centre, thereby giving strength to the part most liable to alter its figure by weight, as it is supposed Bird’s mural quadrant has done in a small degree for want of such precaution. This quadrant has an arc of excess at each end, and is capable of all the adjustments we have above described in an exquisit degree.

Of Nautical Quadrants, measuring by Reflection.

Sir Isaac Newton’s reflecting Quadrant.—A manuscript account of a quadrant, measuring altitudes and distances by reflection, of the hand-writing of Sir Isaac Newton, was found among the papers of Dr. Halley after his death, which quadrant, according to Stone, was actually made in the year 1672, when Dr. Halley was preparing to go to the South seas, to make an addition to his catalogue of fixed stars; but the manuscript account was not produced, or even mentioned, when Halley’s instrument was shewn to the Royal Society, nor was made known till the year 1742. (See Phil. Trans. N. S. 465.) Hence some doubt has been entertained whether Sir Isaac Newton or Halley was the first inventor of the reflecting quadrant. The most probable inference is, that each invented his own, seeing that though the principle is the same in both constructions, yet the mode of applying it is different, as will be seen from a comparison of the figures, and from our description of each in succession.

Sir Isaac Newton’s quadrant was preferred for several years at the house of Mr. Heath, who was a mathematical instrument maker in the Strand, London, and it is probably in existence at this time. Dr. Hooke is also laid, by Dr. Pratt, to have invented a quadrant that was, or might be, used at sea with one reflection only; and, indeed, he is asserted to have been the first man who proposed the use of a mirror in a nautical instrument. See Circle.

Sir Isaac Newton’s quadrant, represented by fig. 7 of Plate I. of Astronomical Instruments, consists of an entire sectoral plate of brass, PQR S, to the plane of which the telescope A B is fixed and lies parallel, and an index, which is moveable about an axis of motion at A. The limb D Q was accurately divided into half degrees, and, as is laid, half minutes, on a scale of four feet radius, and was subdivided by a diagonal scale into 1/40th of a minute. The principle on which this semi-division is founded is this; viz.

"If a fixed ray of light be reflected at a plane reflector, and if the reflector be made to revolve about an axis perpendicular to the plane passing through the incident and reflected rays, which may be called the plane of reflection, the angular velocity of the reflected ray will be double to the angular velocity of the reflector." See Vince’s Practical Astronomy, p. 7, &c.

Hence one small mirror, G, is made fast to the plane of the sectoral plate, and perpendicular thereto, but inclined in an angle of 45° to the axis, or length of the telescope, and in such a way, as to cover one half of the aperture, while another similar mirror is borne by the index, in such a position, that when the index is at zero, both the mirrors are not only perpendicular to the plane of the quadrant, or rather octant, but are parallel to each other. Now, according to the principle that we have just mentioned, when the index is moved forward, a ray of light from any fixed luminous body, when caught by the index mirror, will be reflected on the fixed mirror, and an eye directed through the fixed telescope towards the said body, will see it divide into two bodies the instant that the index begins to move; that is, the body itself will be seen stationary through one half of the telescope’s aperture, and its image will be seen in the other half in motion, and this motion has double the velocity that the index has, which bears the revolving reflector; and on this account it is, that the divisions for half degrees and half minutes, are read as whole degrees and whole minutes, as well as the 1/40th read as 1/80th by the diagonal scale. From this short explanation of the principle and structure of Sir Isaac Newton’s reflecting quadrant, it is easy to perceive that the construction is derived immediately from the principle in the simplest, though in practice not the best manner; for the instrument itself illustrates the principle in the most obvious way; but, from its magnitude and mode of being used, it is very inconvenient to be supported without a stand, which on board a ship is inadmissible.

Perhaps it might be on this account that Dr. Halley did not pay more attention to it than he appears to have done, according to the information that we at this distance of time possess. However, it is evident, that the instrument before us is capable of measuring either vertical, horizontal, or oblique angles, in the way it professes.

Cole’s Quadrant by single Reflection.—Fig. 2. of Plate XXIII. of Astronomical Instruments, is the figure of an instrument, which, like Dr. Hooke’s contrivance, measured altitudes by single reflection, as we conceive, the drawing having fallen into our hands without the description. An arc is composed of an entire quadrant, and an index with a single mirror fixed to it at its centre of motion, constitute its leading features, while a light-vane, at the remote end of the prolonged index, instead of a telescope, has a plane hole, through which the sun is viewed after reflection from the index-glass, his rays having first passed through a coloured glass.
QUADRANT.

glafs. This contruction, with the addition of ir Isaac Newton’s second mirror, would constitute an union of two instruments, that would greatly resembfe the combination adopted by Mr. Hadley, which follows next in our list of quadrants; but which may not have been copied from such union; for Cole has got the vernier scale, which is preferable to the diagonal one adopted by Hadley, and therefore probably he followed Hadley, though the quadrant before us, has not recommended itself to general use, as being an improvement.

Hadley’s Quadrant.—As we cannot help considering Hadley’s quadrant, or more properly octant, as a near relative at least to his friend ir Isaac Newton’s, we will describe it next in order, while the principle of its construction is freth in the reader’s memory. The circumstance of Mr. Hadley’s being president of the Royal Society was favourable to the early notice of his instrument; and the interest that the British nation took, and must ever take, from its infular situation, in nautical improvements, contributed to its early adoption, at a time when such an instrument was greatly wanted.

Mr. Hadley, we learn, tried various modifications in the construction, but that which has been approved from long usage is the one we shall select for description. Fig. 1. in Plate XXIII. of Astronomical Instruments, is the representa­tion of Hadley’s octant, as it is now constructed with a vernier, which it had not at first, and which is preferable to the diagonal divisions at first applied by Hadley, as well as by ir Isaac Newton. For the sake of lightness, united with strength, the frame of the instrument, when made of any of the hard woods, is put together usually as is represented in the figure, but when made all in brafs, and particularly when the limb is extended to 120 half degrees, reading as 120°, in which case it is called a sextant, the best modern makers make it double; that is, have two separate light frames, united by short pillars, flanding at right angles to their planes, which thus become parallel. This construction, we believe, was introduced by Mr. Troughton, and allows a more steady motion to all the moveable and adjustable parts, by lengthening their axes of motion, which penetrate acrofs both parts of the double frame, and by that contrivance have longer bearings. But we are now pro­posing to describe a quadrant of Hadley’s own contruction. A B C is a frame of some hard wood, such as ebony, which may be of any convenient radius, from eighteen inches downwards to three, or less, if required for the pocket, and A D is the index bearing the vernier at D, together with the usual clamping apparatus for flow motion, in making the contact in any observation. This apparatus, together with the powers of the vernier, and mode of using it, have been explained under our article: CIRCLE, (see also VERNIER,) and therefore may be referred to by the reader unaquainted with their uses. When the radius is very small, the vernier subdivides half degrees, and has thirty divisions on it, but has twenty or fifteen, accordingly as the degree of the limb is subdivided into thirds or fourths of a degree. The peculiar excellence of this instrument, either in the form of an octant or sextant, is, that all sorts of angles can be measured with it on board a ship, even while the ship is tossed by the waves; and also, that it requires no other auxiliary means, than the natural horizon, which at sea is always, or moftly present, when a heavenly body can be seen. The plummet-line and spirit-level are equally depended on; to which may be added, that, if any accidental injury be received, a circumstance not improbable in the hands of sailors, the adjustments are to finiple, that, generally speaking, the derangements may be easily rectified. In the best instruments, a small telescope is screwed into the fright-vane, which not only prevents parallax, by limiting the line of fight between two parallel wires, but affifts the sight greatly in obtaining exact contacts. There is usually an arc of excess at each end of the limb, one of which is useful in adjufting the index-error by the fun or moon, and the other is serviceable when angular diftances are measured beyond a quadrantal arc; indeed it would be well if the arc were always extended to measure 120°; or more, for then a sextant would be competent to measure all sorts of angles that the mariner can require, to find his latitude, time, and longitude.

When the octant has not the tangent screw of flow motion for adjustment in making the contact, the index is nicely moved by hand, and then fixed by a screw behind it for this purpose, and in either cafe the examination and noting down of the altitude, or horizontal angle taken, may be read at any time, for hours afterwards, which is another important advantage that this instrument possfies in common with the sextant; for where more obervers than two are not preffent, one oberver may thus manage to take both an altitude and a distance in a lunar observation with two separate instruments in quick succession, while another oberver is taking the altitude of the second object; or with the help of Margett’s horary tables, the second altitude may be had by inspection, when the hour, latitude, and declination of the body are known, in which cafe one oberver can take a lunar observation with tolerable accuracy. The limb of the instrument is best of metal, such as brafs, silver, or platina, when made and divided in the bralz way by a superior dividing engine, such as Troughton’s; but in ordinary instruments a piece of ivory is frequently let into the wood, and sometimes the divisions are made even on the wood itself, which is liable to be affected by moisture. The index is most frequently entirely of brafs, and wider as it ascends to the centre of motion, to prevent lateral bending, which would destroy the accuracy of the readings. When an observation is made by the larger fort, the right hand should be applied to the lower extremity of the index to give it steady motion, while the left holds the lower end of the remote radial bar; and the plane of the instrument must be kept in the line that joins the two objects, of which the horizon is one, when an altitude is taken, and then the instrument is held vertical. In bringing down the image of an object to the horizon by a fore observation, the body of the oberver must gradually incline towards the horizon, and a little vibrating motion will assist in determin­ing the exact plane of contact; but in taking a ho­rizontal angle, the oberver will handle the instrument as befits his convenience. The mirror at A is placed over the centre of motion of the index, in a direction pointing to zero on the vernier, and perpendicular to the flat face of the index; this index-glas, being completely silvered, reflects the light it receives directly at right angles on the glas E, when the zero of the vernier is at the zero of the limb; but as the limb proceeds forwards, this angle alters, and, as we have said, is double of the measure of the real angle to be measured and indicated. This glas E is also fixed perpendicular, and has screws of adjufment for perpendicularity above its socket of brafs, and a tail-piece with a fixing-screw behind the frame, for fixing the parallelism; the want of which is called the index-error: one half only of this glas, which is called the fore-horizon glas, is silvered, and the other half remains unsilvered, in order that both the direct rays transmitted through the unsilvered part, and the reflected rays coming from the silvered part, may meet at the eye, on which account the middle of this glas, where the line of separation crosses, is the part to be viewed
viewed in making a contact, otherwise both the image of one object, and the substance of the other, could not be seen at the same instant. F is the sight-vane, with two holes, usually an upper and a lower, inserted into the first radial bar of the frame, so that the holes are at the same distance from the plane of the instrument as the line of separation in the half-merced glass E, to prevent parallelism of the reflected rays, and in the belt instrument this vane, with its telescope, has an adjustable motion to and from the plane, in order that more or less light may fall on either of the bodies observed, which is not only useful, but necessary, in taking a lunar distance; for by this adjustment the image of one body may be made as luminous as the real body of the other, by increasing the light of one, while it decreases that of the other; that is, by making more of the covered, or of the unmerced part of glas E, fall before the object-glas of the small telescope, when this adjustment is necessary. It may be necessary to observe here, that every merced glass of sensible thickness has two refractions, one on the anterior, and the other, which is the principal one, on the posterior or merced face, and in many cases errors may be occasioned by these double refractions; to remedy which, Dr. Makleyne proposed, that the merced portion of the posterior face should be ground rough and painted black, taking care that the grinding be so performed, that the line of separation between the polished and unpolished parts be parallel to the plane of the octant. In the back merced-glas, which is that seen with its sight-vane at G, with adjustments similar to those of the fore merced-glas E, the whole posterior face is merced, except a slit, that divides it in a line parallel to the plane of the frame, through which slit the body is observed in a back observation. But when the sun is the body observed, his light is generally too intense for the eye to bear, particularly when the small telescope is used; to render the rays tolerable to the eye, a coloured glas, or glases, must be interposed, and a blank tube instead of a telescope be used, by which means the sun may be viewed without doing injury to the eye; and usually a system of coloured glases are slipped into a square hole, as at H, and a joint in each allows them, or any one of them, to be brought forwards into the situation where the direct rays must pass to the eye. The same remedy is also sometimes applied at the eye-piece of the blank tube, when the sun alone is observed. The plane of the back merced-glas is placed not only parallel to the plane of the frame, but at right angles to the plane of the fore merced-glas, in order that the frame readings may apply in both kinds of observation, and this object was effected by the maker by the simple rectangular position of the two merced glasses to each other, and by reversing the position of the body in making a back observation; for as the inclination of the index-glas to the fore merced-glas gives double the angle directly measured; so twice the complement of this inclination to the back merced-glas gives the same quantity, and on the same part of the graduated limb, when measured in a reversed position.

Adjustments.—The adjustments of every instrument are of the utmost importance to the accuracy of observations taken thereby, but they are particularly so in the instrument before us, because a small deviation from parallelism in the fore merced-glas, or from perpendicularity in the back merced-glas, as compared with the index-glas, (with the vernier at zero of the limb,) will double the error occasioned by it in the quiescent situation, as soon as motion is given to the index-glas. 1. The first adjustment is, to set the index-glas perpendicular to the plane of the instrument: this is done by first sliding the index to about 40° or 45° of the limb, while the octant is held with its plane nearly parallel to the horizon, then a glance into the index-glas will shew, whether the sharp edge of the limb seen by reflection, is an exact and straight continuation of the same edge of the limb seen by direct vision, and if this is not the case, it must be made fo by the screws that adjust the bed of the mirror; and in all cases where two screws are to be used, one must be released as much as the other is screwed inwards. Dr. Mackay proposes to place two small pieces of metal as adjusting tools, with each a horizontal line drawn on it, at equal heights from the plane of the limb, at some distance from each other, so that the horizontal line of one may be a continuation of the horizontal line of the other, when one is viewed by reflection, and the other by direct vision, but the sharp edge of the inner part of the limb will answer all ordinary purposes. 2. The second adjustment is, to set the fore merced-glas perpendicular to the plane of the instrument: this is done by first fixing the zero of the vernier at zero on the limb, and while the plane of the frame is held parallel to the horizon, by applying the eye to the lower hole of its sight-vane; then if the horizon, or any distant horizontal line, appear to be a straight line, the glas is placed perpendicular already; but if the parts seen by reflection and by direct vision do not constitute a straight line, they must be made to do so by the screws at the back of the glas, one or other of which must be screwed in or out, as the fracture of the line demands; that is, if the line seen by reflection appear above that seen by direct vision, that screw must be urged indeads, which is on the other glas, and vice verfa, until the fractured line be straight. 3. The third adjustment is, to rectify for the index-error of the fore merced-glas, or to place it parallel to the index-glas, when the zero of the vernier is placed at zero on the limb. To do this properly, a bright distant object must be chosen, such as the sun, moon, or star, and while the zero coincides, look through the vane, or telescope, and observe if the body and its image coincide; that is, if the image is invisible: in this case, the fore merced-glas is parallel to the index-glas, or is truly adjusted; but if not, release the tail-piece or lever behind this merced-glas, and with the thumb-piece give it a small motion, till the body and its image coincide, in which situation it must be fixed by the fixing nut before released. Sometimes the act of screwing will displace, in some degree, the tail-piece, and thereby again occasion a sensible index-error. When this cannot be completely avoided, the error must be ascertained and allowed for with its sign + or − in every subseuent observation, while it remains unaltered. This error may be ascertained by measuring the diameter of the sun, first forwards on the limb, and then backwards on the arc of excess, and one half of the difference of the measures will be the index-error + or −, as the case may be. 4. The fourth adjustment is, to set the back merced-glas perpendicular to the plane of the instrument: this adjustment is similar to the second, and may be performed by the directions there given, supposing them to be for the back merced-glas, and its vane, instead of the fore merced-glas. 5. The fifth and last adjustment is, to set the back merced-glas perpendicular to the plane of the index-glas produced, the zero of the vernier being placed at zero on the limb: this adjustment at sea is performed thus: let the vernier be put as much to the right of zero, as is equal to twice the dip of the horizon, in the situation where the observer stands, then hold the quadrant in a vertical position, and apply the eye to the back horizon vane: now, if the horizon seen by reflection happen to coincide with that seen by direct vision, the glas is already right; but if not, the lever or tail-piece behind the frame at this place must be released by the proper fixing screw,
ferow, and turned slowly by the thumb-ferow or nut, till
this coincidence is perfect, and then the lever must be made
fast again; the reflected horizon will be inverted when
viewed in the manner here described. When the instrument
is used in a back observation on the land, which is not likely
to happen often, the adjutment will require some artificial
aid; by Dollond’s method, an index is applied to the back
horizon-glares, by which it may be put parallel to the fore
horizon-glares, by the third adjutment applied thereto, and
then, by a graduated arc of 90°, inserted on purpose, the
index of the back horizon-glares is set perpendicular to its
former situation, and consequently is made perpendicular
to the plane of the fore horizon-glares. By Mr. Blair’s
method, the under edge of the index-glares is ground and
polished, so as to be at right angles to the plane of the
glares, and hence the back horizon-glares is adjusted, by
making the direct and reflected horizons agree, while the
vernier stands at zero on the limb, exactly as is done in the
third adjutment. But we are to suppose the instrument
not furnished with either of the above named auxiliary
means; when this is the case, a long level space must be
chosen in some common or park, where three staves can be
put up in the same straight line exactly, and at an interval
from each other of not less than 500 yards, but if 600 or
700 the better; then, the vernier being truly placed at
zero, let the plane of the octant be held horizontally with
its back horizon-glares exactly on the top of the middle
staff, and let one of the rods be viewed directly through
the back right-vane, then if the other rod, seen by reflec-
tion, coincide with it, the position of the back horizon-
glares is true, but if not, it must be made so, by the tail-
piece behind, as before directed; if in fixing the tail-
piece a derangement should take place, which cannot be exactly
done away by a second or third trial, then the index-error
for the back observation must be ascertained.

This error may be obtained by reverred observations by
two methods; thus, let the coincidence of the two extreme
staves be made from the middle staff as just directed, by
a motion of the vernier, instead of the tail-piece of the back
horizon-glares, and read the quantity moved forwards or
backwards; then turn the downward face of the frame up-
wards, and repeat the operation, and read again; now, if
these two readings are found to be one on the limb, and the
other on the arc of excess, half of their difference will be
the error found, + or --; but if they both are read on
the same side of zero, half their sum, + or -- will be the
error; when they are both read on the limb, or if the greater
quantity be read on the limb, when the less is on the arc of
excess, the sign will be --, and vice veza. By the second
method, instead of revering the plane of the instrument,
let the observer rever his position, making the right-hand
staff to be the left-hand one, and vice veza, and then let
him repeat his first observation, with the same face of his
instrument up that he had in that, and the same refult will
follow, that was obtained by revering the plane of the in-
strument. These two modes of obtaining the error in
question, by reverred observations, may be made to check
each other, and will then give an average of the two results,
for the error to be applied to each subsequent observation,
taken with the back horizon-glares in its last determined
position.

Examination of the Instrument.—These several adjutments
being finished, the observer might proceed to make his
observations, provided he could rely on the skill and credit
of the maker of his instrument; but if not, he would act
prudently to examine the materials of which it is composed,
before he relies on its performance, and allo to put to same
test the accuracy of the divisions on the vernier and limb,
as well as the care that has been taken in selecting glases
of uniform thicknes, and of good polishi. The exactnes
of the total arc may be ascertained from comparison with
measurements taken with a circle, or some well-known su-
perior instrument; or by careful trigonometrical measurement
on some level and extensive ground, where the sides of the
triangle can be accurately measured, for which purpose
Troughton’s new chain of five-foot links is admirably cal-
culated; but the intermediate divisions must be examined
on the vernier itself, by flepping the arc with it; and if all
parts of the arc are found alike divided, when examined by
the coincidence of the extreme strokes of the vernier, the
intermediate strokes of the vernier itself may likel be ex-
amined by the strokes on the limb taken in various places.
Dr. Mackay recommends a table of corrections to be made,
in case of errors being detected in the dividing, but we
should rather recommend new divisions from a good engine,
the inverting of which can now be performed at a trifling
expenee. When the planes of the mirrors are examined,
try if a candle reflected appears in two images; if it does,
the two faces of the glases are not parallel, and consequently
the glases is not fit for its purpose.

To try whether the surfaces of the mirrors be perfect
planes, bring two distinct dilatant objects into good con-
tact, and let them be seen at the upper edge of the silvered
part; then move the instrument in its own plane, and move
the image and body along the line of separation or edge of
the silvered part, and if the coincidence is not disturbed
the plane is perfect, but not otherwise. Also, when an obser-
vation is taken of the fun, and the vernier has been fixed by
the fixing ferow, read the altitude, as the dark glases, or
glases, may have been used; then remove them from the
socket that holds them, and rever their planes, by putting
their remote faces nearer; and if, after this change, the
same altitude is given, the planes are parallel, otherwise half
the difference must be applied, in all such cases, as an error
of the coloured glases. This examination is best made exactly
at noon, when the sun’s altitude is not sensibly changed dur-
ing the examination; unless a good chronometer or regula-
tor, duly regulated, and put to exact time, be at hand;
for, then the successive examinations may take place at equal
distances from noon. Or the same thing may be done by
means of a luminous object placed at a distance, and so
elevated, that an artificial horizon may give its double altitude
before and after the coloured glases are revered in position.
The best artificial horizons are either a vellum of pure mer-
cury, with a roof of good glases framed over it to prevent ag-
itation by the wind; or otherwise a piece of black glases, well
polished, and placed on scres of adjutment, with a good
spirit-level in a glases tube, so ground, that it will revvere in
position, and will place the glases in a perfect level in the
two requisite directions, at right angles to each other.

It may be proper to examine further if the two holes in
the right-vane are so made that the fun or other luminous
body dazzles the eye more in looking through one, than in
looking through the other, the intention being that one shall
take in more of the silvered part, and the other more of the
unsilvered part of the glases, so as to accommodate the quant-
y of direct light to the strength of the eye.

Illustration of the Use.—When Hadley’s octant, or sextant,
is used for altitudes at sea, the fun, moon, or star, as the
case may be, must be viewed in the way that the eye can best
bear, with or without the dark glases, telescope, &c. as
occasion may require, and as experience will dictate; and in
a fore observation the body observed must have its image
brought gradually down, so as to be in exact contact with
the
the horizon: if the sun or moon be observed, either the upper
or lower limb must be substituted for the centre, and
the observation must be afterwards reduced to the centre, by
applying the semi-diameter, + or −, from the proper column
for the given day, as given in the Nautical Almanac, or Ephe-
meris; in doing this, the face of the observer must be turned
towards the object whose altitude is to be measured, and
while the index is gradually moved forward along the limb,
the image will defend till it approaches the horizon; in
this situation, care must be taken that the contact of the
image be made with the visible horizon at the line of separa-
tion, between the silvered and unsilvered parts of the fore
horizon-glass, that both objects may be visible together;
and also that the index may not be pulled too far, so as to
require a retrograde motion in finifhing the contact: there-
fore fix the clamping piece, if there is a tangent screw, and
complete the contact by a flow motion, and the altitude will
remain unaltered till the vernier has been examined by a
magnifying glass, which ought always to be at hand, to affix
the eye in examining the coincidence of some one line of the
vernier with some line of the limb; or, when there is not an
exact coincidence, in estimating the quantity that is beyond
coincidence, as compared with the contiguous quantity that
is short of it. To succeed well in perfecting a fore observa-
tion taken at the horizon, the observer must learn to give a
vibratory flow motion of his body to the right and left, his
heel being the centre of motion, that the image observed may
be made to move backwards and forwards in the arc of a
circle, of which the horizon is a tangent, in order that the
altitude may not be taken at one fide of the tangential point,
and consequently be too great. Care must also be taken
that the faint secondary image reflected from the posteri-
or face be not mistaken for the primary image, reflected
from the proper, or anterior face of the mirror. When the alti-
itude is marked down, as read on the limb and vernier, the
corrections must be applied, for either the sun or moon, for
parallax, refraction, dip of the horizon, and semi-diameter,
before the true altitude of the centre is obtained; but for a
star no parallax is wanted, nor yet allowance for semi-
diameter; these apparently diminutive bodies being situated
at such an immense distance from the earth, as to subtend no
feasible angle, nor to have any perceptible parallax in
altitude.

It is from meridian altitudes thus taken, that, by the ap-
lication of a heavenly body's declination, + or −, as the
body may be below or above the equator, the co-latitude,
and consequently the latitude, is readily determined; and also,
the latitude being known, from an altitude taken towards the
east or west, that the time is determined at one obser-
vation, but more accurately by a series of equal altitudes
taken at opposite sides of the meridian; the reduction, how-
ever, for the sun's change of declination during the interval,
must, in this case, be taken from tables of correction for
equal altitudes, such as are contained in the pamphlet of the
late Mr. Wales.

In making the back observation, the coloured glass, or
glasses, must be selected, as before, to fuit the eye, and
the plane of the instrument held vertically, as in the fore ob-
ervation, but the face of the observer must view the point of
the horizon opposite the sun, or that pointed to by his own
shadow; first, let the eye be directed through the vane of
the back horizon-glass to the transparent slit that divides the
mirror, and let it view the horizon, then move the index till
the image of the sun is just seen on the silvered part of the
glass; a vibratory motion given to the ocele from the
to the centre of motion, will make the sun's image move
in a curve of which the convex part appears uppermost; in

Vol. XXIX.
Mr. Wales, in captain Cook's Voyage, applied it to measuring the quantity eclipsed in an eclipse of the sun; in which operation it answers the purpose of a micrometer, to a great degree of certainty. See an account of the improvements suggested in the construction of these instruments, and also of the various uses to which they may be applied, in Magellans's Description des Oéants & Sextants Anglais, &c. 4°.

Other quadrants have been contrived since, by some ingenious artists, all of which have their merit; but the particulars of their construction are too many for this place; and perhaps, on the whole, nothing preferable to Mr. Hadley's invention has yet been found.

Quadrant, Herodotical, is a pretty commodious instrument; thus called from its use in telling the hour of the day.

Its construction is so simple and easy, and its application so ready, that we shall describe both, for the use of some who may want other conveniences.

Quadrant, Conduction and Use of the Herodotical. From the centre of the quadrant, C, (Plate XIX. Almanac, fig. 8.) whole limb A B is divided into 90°, describe seven concentric circles at intervals, at pleasure; and to these add the signs of the zodiac in the order they are represented in the scheme.

2. Applying a ruler to the centre C, and the limb A B, mark upon the severer parallels the degrees corresponding to the altitude of the sun when therein, for the given hours; connect the points belonging to the same hour with a curve line, to which add the number of the hour. To the radius C A fit a couple of lights, and to the centre of the quadrant C, tie a thread with a plummet; and, upon a thread, a bead to slide.

If, now, the bead be brought to the parallel in which the sun is, and the quadrant be directed to the sun till a visual ray pass through the lights, the bead will show the hour.

For the plummet, in this situation, cuts all the parallels in the degrees corresponding to the sun's altitude. Since, then, the bead is in the parallel which the sun then describes, and through the degrees of altitude to which the sun is elevated every hour there pass hour-lines, the bead must show the present hour. Some persons, who are not very nice, represent the hour-lines by arcs of circles, or even by straight lines; and that without any sensible error.

Quadrant, Sinical, is an instrument of use in navigation. It is represented Plate II. Navigation, fig. 4, and consists of several concentric quadrant arcs, divided into eight equal parts by radii, with parallel right lines crossing each other at right angles.

Now any of the arcs, e. gr. B C, may be accounted a quadrant, of any of the great circles of the sphere, chiefly of the horizon and meridian: if, then, B C be taken for a quadrant, e. gr. of the horizon, either of the sides, e. gr. A B, may represent the meridian; and the other, A C, will represent a parallel, or line of east and west; and all the other lines parallel to A B will also be meridians; and all those parallel to A C will be east and west parallels, or east and west lines.

Again, the eight spaces into which the arcs are divided by the radii, represent the eight points of the compass in a quarter of the horizon; each containing 11° 15'.

The arc B C is likewise divided into 90°, and each degree is subdivided into 12', diagonalwise.

To the centre is fixed a thread, as A L; which being laid over any degree of the quadrant, serves to divide the horizon.

If the final quadrant be taken for a fourth part of the meridian, one side thereof, A B, may be taken for the common radius of the meridian and the equator; and then the other, A C, will be half the axis of the world. The degrees of the circumference, B C, will represent degrees of latitude, and the parallels to the side A B, affinmed from every point of latitude to the axis A C, will be radii of the parallels of latitude, as likewise the fine-complements of those latitudes.

Suppose, then, it be required to find the degrees of longitude contained in 83 of the lesser leages, in the parallel of 48°. Lay the thread over 48° of latitude, on the circumference, and count thence the 83 leagues, on A B, beginning at A; these will terminate at H, allowing every small interval four leagues, and the interval between the broad lines twenty leagues. Then tracing out the parallel H G, from the point H to the thread; the part A G of the thread shews that 125 greater, or equinoctial leagues, make 6° 15', allowing twenty leagues to a degree, and three minutes for one league; and therefore that 83 lesser leagues A H, which make the difference of longitude of the course, and are equal to the radius of the parallel G I, make 6° 15' of the said parallel.

If the ship fall on an oblique course, such course, besides the north and south greater leagues, gives lesser leagues easterly and westley; to be reduced to degrees of longitude of the equator. But these leagues being made neither on the parallel of departure, nor on that of arrival, but in all the intermediate ones, we must find a mean proportional parallel between them.

To find this, we have on the instrument a scale of crofs latitudes. Suppose, then, it was required to find a mean parallel between the parallels of 40° and 60°. With your compasses take the middle between the 40th and 60th degree on the scale; this middle point will terminate again to the 51st degree, which is the mean parallel required.

Quadrant, Use of the Sinical. There are formed triangles upon this instrument similar to those made by a ship's way, with the meridians and parallels; the sides of which triangles are measured by the equal intervals between the concentric quadrants, and the lines N. and S.E. and W.

The lines and arcs are distinguished, every fifth, by a broader line; so that if each interval be taken for one league, there will be five between one broad line and another; and if every interval be taken for four leagues, then there will be twenty leagues, which make a 5th degree, from one broad line to the other.

Now, suppose a ship to have sailed 150 leagues north-east, one fourth north; which is the third point, and makes an angle of 33° 45' with the north part of the meridian. Here are given two things; viz. the course, and the distance failed; by which a triangle may be found on the instrument, similar to that made by the ship's course, and her longitude and latitude; and hence may the unknown parts of the triangle be found.

Thus, supposing the centre A to represent the place of departure; count, by means of the concentric arcs, along the point the ship sailed on, as A D, 150 leagues from A to D; then is the point D the place the ship is arrived at, which note. This done, let DE be parallel to the side A C; and then there will be formed a right-angled triangle A E D, similar to that of the ship's course, difference of longitude, and latitude; the side A E gives 125 leagues for the difference of latitude northward; which makes 6° 15', reckoning twenty leagues to a degree, &c. and the side D E gives 83 lesser leagues answering to the parallels; which
QUAD

which being reduced, as shown above, gives the difference of longitude. And thus is the whole triangle found.

QUADRANT, in Gunnery, called also the gunner's square, is an instrument serving to elevate or point cannons, mortars, &c. according to the places they are to be levelled or directed to.

It consists of two branches, made of brass or wood; one about a foot long, eight lines broad, and one line in thickness; the other four inches long, and of the same thickness and breadth as the former. Between these branches is a quadrant divided into ninety degrees, beginning from the shorter branch, and furnished with a thread and plummet. See its figure represented in Plate I. Gunnery, fig. 5.

The use of this instrument is easy; nothing more being required but to place the longest branch in the mouth of the cannon or mortar, and elevate or lower it, till the thread cuts the degree necessary to hit a proposed object. See Pointing of a Gun.

Sometimes, also, on one of the surfaces of the long branch, is noted the division of diameters, and weights of iron bullets; as also the bores of pieces. See Caliber.

QUADRANT OF ALTITUDE. is an appendage of the artificial globe, consisting of a lamina or flipp of brass, the length of a quadrant of one of the great circles of the globe; and divided into ninety degrees.

At the end, where the divisions terminate, there is a nut riveted on, and furnished with a screw, by means of which the instrument is fitted on to the meridian; and is moveable round upon the rivet, to all points of the horizon. See its figure in Plate XIX. Astronomy, fig. 9.

Its use is to serve as a scale in measuring of altitudes, amplitudes, azimuths, &c. See the manner of its application under the Use of the Globe.

QUADRANTAL, in Antiquity, a vessel in use among the Romans for the measuring of liquids.

It was at first called amphora; and afterward quadrantal, from its form, which was square every way, like a die.

Its capacity was eighty libras, or pounds of water, which made forty-eight sextaries, two urnae, or eight congii.

QUADRANTAL SPACE, in Geometry. See Quadrant.

QUADRANTAL TRIANGLE, is a spherical triangle, one of whose sides at least is a quadrant of a circle, and one of its angles a right angle.

QUADRANTATA TERRA, in our Ancient Law Books, is used for a quarter of an acre, now called a rood; which see.

QUADRAS ISLES, in Geography, islands situated on the W. coast of North America, between Pintard's found and the straits of Fuca; among which lies Nootka's found, which see. They were so called by Capt. Ingraham, after the name of a Spanish commander of two schooners, who passed through this channel in the year 1792.

QUADRAT, Quadratum, called also geometrical square, and line of shadows, is an additional member on the face of the common Guater's and Sutton's quadrants; of some use in taking altitudes, &c.

The quadrant more distinctly exhibited in Plate VI. Surveying, fig. 13. has each of its sides divided into a hundred equal parts, commencing from the extremes; so that the number 100 falls on the angle, representing tangents to the arc of the limb.

The divisions are distinguished by little lines from 5 to 5, and by numbers from 10 to 10; and the divisions being occasionally produced across, form a kind of lattice, consisting of 10,000 little squares.

The proportion here is, as radius is to the tangent of the angle of altitude at the place of observation (i.e. to the parts of the quadrant cut by the thread), so is the distance between the station and the foot of the object, to its height above the eye. See Altitude.

Use of the Quadrat, Geometrical Square, or Line of Shadows. 1. The quadrant being vertically placed, and the sights directed to the top of the tower, or other object, whose height is required; if the thread cut the side of the quadrant marked right shadows, the distance from the base of the tower to the point of station is less than the tower's height. If the thread falls on the diagonal of the square, the distance is equal to the height. If it fall on that side marked verted shadows, the distance exceeds the height.

Hence, measuring the distance, the height is found by the rule of three; inasmuch as there are three terms given. Indeed, their disposition is not always the same; for when the thread cuts the side of right shadows, the first term in the rule of three ought to be that part of the side cut by the thread; the second, the side of the square; and the third, the distance measured. If the thread cut the other side, the first term is the whole side of the square; the second, the parts of the side cut by the thread; and the third, the distance.

For an instance of each. Suppose, e.g. in looking at the top of a steeple, the thread cut the side of right shadows in the point 40, and that the distance measured 20 poles, the case then will stand thus: as 40 is to 100, so is 20 to a fourth term, which we find to be 50; the height of the steeple in poles. Again, supposing the thread to fall on the other side, in the point 60, and the distance to measure 35 poles; the terms are to be disposed thus: as 100 is to 60, so is 35 to a fourth term, viz. 21, the height required. See Altitude.

Use of the Quadrat without Calculation.—The preceding cases may be formed without calculation, where the divisions of the square are produced both ways, so as to form the area into little squares.

Thus, suppose, 1. The thread to fall on 40 in the side of right shadows, and the distance be measured 20 poles; seek among the little squares for that perpendicular to the side which is 20 parts from the thread; this perpendicular will cut the side of the square next the centre, in the point 50, which is the height required in poles.

2. If the thread cuts the side of verted shadows in the point 60, and the distance be 35 poles; count 35 parts on the side of the quadrant from the centre; count also the divisions of the perpendicular from the point 35 to the thread, which will be 21, the height of the tower in poles.

Note. In all cases the height of the centre of the instrument is to be added. See Altitude, and Shadow.

QUADRAT, in Astrology, called also Quadriles, an aspect of the heavenly bodies, in which they are distant from each other a quadrant, or ninety degrees. See Aspect.

QUADRAT, in Printing, is a sort of space; that is, a piece of metal, cast like the letters, to be used occasionally in composing, in order to form the intervals between words, at the end of lines, &c. See Printing.

There are quadrats of divers sizes, as m quadrats, n quadrats, &c. which are respectively of the dimensons of such letters.

QUADRATA, in Ancient Geography; a town of Higher Pannonia, placed on the banks of the Save by Antonine's Itinerary.

QUADRATA, in Geography, a town of Naples, in the province of Bari; five miles N.W. of Ruvo.

QUADRATA is the Italian term in canto fermo for Gregorian or square black notes.

U 2
QUADRATA Legio, among the Romans. See Square Legion.

QUADRATIC EQUATION, in Algebra, is an equation of which the highest power of the unknown quantity rises only to the second degree. If this power enters alone, it is called a simple quadratic; and when the second power and simple quantity both occur, it is termed an affixed quadratic equation, thus:

\[ x^2 + a x = b, \]

is an affixed quadratic, and

\[ x^2 = b, \] or \[ a x^2 = b, \]

is a simple quadratic equation.

Some authors classify all such equations as contain two different powers of the unknown quantity, the one being the double of the other, under the general term quadratics, such as \( x^2 + a x^3 = b, \) \( x^2 + a x^n = b, \) &c. each of which is called a quadratic equation, because their solutions depend upon precisely the same principles as the former.

Every quadratic may be reduced to the form \( x^2 + a x = b; \)

in which it is, however, to be understood, that \( a \) and \( b \) may be either positive or negative; and the general solution of it is expressed by the formula

\[ x = \frac{-a}{2} \pm \sqrt{\left(\frac{a^2}{4} + b\right)}. \]

If we give to \( a \) and \( b \) all the variety of signs they admit of, quadratic equations may be divided into four distinct classes, viz.

1. \( x^2 + a x = -b; \)
2. \( x^2 - a x = -b; \)
3. \( x^2 + a x = +b; \)
4. \( x^2 - a x = +b; \)

and their several roots will be exhibited by the following formulas, viz.

1. \[ x = \frac{-a}{2} \pm \sqrt{\frac{a^2}{4} - b}; \]
2. \[ x = \frac{a}{2} \pm \sqrt{\frac{a^2}{4} - b}; \]
3. \[ x = \frac{-a}{2} \pm \sqrt{\frac{a^2}{4} + b}; \]
4. \[ x = \frac{a}{2} \pm \sqrt{\frac{a^2}{4} + b}. \]

See Equations.

From these forms it is obvious that every quadratic equation has two roots arising out of the ambiguous sign \(+\), prefixed to the second member of the root. It is also obvious, that if in the 1st and 2d form, \( b \) be greater than \( \frac{a^2}{4}, \) the two roots in both forms are imaginary, or impossible; but if \( b \) be less than \( \frac{a^2}{4}, \) then they are in each form both real, being in the 1st both negative, and in the 2d both positive; because the quantity exhibited under the radical form is, in both equations, less than that without the radical; and consequently both the sum and difference will have the same sign as \( \frac{a}{2}. \)

In the 3d and 4th forms, the roots are necessarily both real, but one positive and the other negative; the 3d form having its greatest root negative, and 4th its greatest root positive; as is obvious by inspection.

It is, however, not necessary to consider quadratic equations under these four forms, as the solution of them all may be reduced to one general rule, as exhibited in the preceding part of this article, and which may be given in words as follows. Having reduced the proposed equation to any one of the above forms, the roots of it will be equal to half the co-efficient of the second term, with its sign changed; plus and minus the square root of the square of that half co-efficient prefixed to \( b, \) with its proper sign, whether plus or minus. The principles on which the preceding formulae are obtained, are the following, viz. \( (x \pm \sqrt{\frac{a}{2}})^2 = x^2 \pm a x + \frac{a^2}{4}; \) therefore, if an equation be proposed under the form \( x^2 \pm a x = \pm b, \) by adding \( \frac{a^2}{4} a \) to both sides, we will preserve the equality, and render the first side a complete square, that is, we have

\[ x^2 \pm a x + \frac{a^2}{4} = \frac{a^2}{4} \pm b; \]

and, by extraction,

\[ x \pm \sqrt{\frac{a}{2}} = \pm \sqrt{\left(\frac{a^2}{4} \pm b\right)}; \]

consequently

\[ x = \frac{-a}{2} \pm \sqrt{\left(\frac{a^2}{4} \pm b\right)}, \]

which form includes all the preceding formulae. We shall not here give the solution of any examples, as the reader will find sufficient exercises under the article Equation; but it may not be amiss to shew other methods of obtaining the roots of quadratic equations, viz. by sines and tangents, continued fractions, &c.

The Solution of Quadratic Equations by means of a Table of Sines, Tangents, &c.—Here, referring to our preceding forms, the solution of them may be exhibited as follows:

**Form 1.** \( x^2 + a x = -b. \)

Put \( \frac{2}{a} \sqrt{b} = \sin z; \) then

\[ x = \left\{ -\sqrt{b} \times \tan \left(\frac{1}{2} z\right) \right\} \quad \text{or}, \]

\[ x = \left\{ -\sqrt{b} \times \cot \left(\frac{1}{2} z\right) \right\} \]

**Form 2.** \( x^2 - a x = -b. \)

Put \( \frac{2}{a} \sqrt{b} = \sin z; \) then

\[ x = \left\{ +\sqrt{b} \times \tan \left(\frac{1}{2} z\right) \right\} \quad \text{or}, \]

\[ x = \left\{ +\sqrt{b} \times \cot \left(\frac{1}{2} z\right) \right\} \]

**Form 3.** \( x^2 + a x = +b. \)

Put \( \frac{2}{a} \sqrt{b} = \tan z; \) then

\[ x = \left\{ +\sqrt{b} \times \tan \left(\frac{1}{2} z\right) \right\} \quad \text{or}, \]

\[ x = \left\{ +\sqrt{b} \times \cot \left(\frac{1}{2} z\right) \right\} \]

**Form 4.** \( x^2 - a x = +b. \)

Put \( \frac{2}{a} \sqrt{b} = \tan z; \) then

\[ x = \left\{ +\sqrt{b} \times \cot \left(\frac{1}{2} z\right) \right\} \quad \text{or}, \]

\[ x = \left\{ +\sqrt{b} \times \tan \left(\frac{1}{2} z\right) \right\} \]

The above formulae result immediately from the construction of quadratic equations. Thus, in the two first forms, let \( A B, \) (Plate X11, fig. 6. Analytik), represent \( a, \) and \( C D = \sqrt{b}, \) then \( A D \) and \( D B \) will be the required roots from the known construction of equations. See Construction.

Now here it is obvious that the sin. \( z \) represents the sin. of CED.
QUADRATIC EQUATION.

C E D, and therefore angle D C B, which is \(\frac{1}{2}\) angle C E D, is \(\frac{1}{2}\) angle \(z\). Consequently \(D B = C D \times \tan \frac{1}{2} z\), and \(A D = C D \times \cot \frac{1}{2} z\), because the angle C A D = the angle B C D; which agree with the leading formulæ above given. As to the two latter formulæ for the two first cases, they are obvious without any explanation.

In the 3d and 4th cases, let A B represent \(a\), and D C = \(\sqrt{b}\), then A D and D B will represent the two roots; join B C, and draw D E parallel to B C, so shall C E = B D, and the angle C D E = \(\frac{1}{2}\) the angle B O C. Now here the tan. \(z\) will represent the tan. of B O C, and \(\frac{1}{2} z = C D E\); but C E = B D is obviously equal to D C \times \tan \frac{1}{2} z \times \cot \frac{1}{2} z\); and in the same manner A D = \(\sqrt{b}\) \times \tan \frac{1}{2} z\). The two latter formulæ require no illustration.

The same results might have been obtained, though not perhaps quite so obviously, from the preceding analytical solution.

There are but few cases in which it is advisable to employ the methods above described to the solution of quadratics, and therefore one example will be considered a sufficient illustration.

Exam.—Given \(x^2 + 7 = \frac{1695}{44}\), to find the two roots of the equation by sines and tangents.

Here tan. \(z = \frac{88}{7} \sqrt{1695}\).

\[
\begin{align*}
\log 1695 & = 3.2291967 \\
\log 12716 & = 4.1043505 \\
\log \sqrt{1695} & = 2.0.1248192 \\
\log 88 & = 1.9444827 \\
\log 7 & = 0.8459020 \\
\log \tan z & = 10.697943 \\
\text{whence } z & = 77° 42' 32'' \\
\log \tan \frac{1}{2} z & = 9.9061115 \\
\log \sqrt{1695} & = 1.5624096 \\
\log \sqrt{12716} & = 1.4685211 \\
\text{deduct radius} & = 10.0000000 \\
\log x & = -1.4685211 \\
\text{or } x & = .2941176 \\
\text{the positive root; \ and if cot. } \frac{1}{2} z \text{ be taken} & = \frac{1.5624096}{\sqrt{1695}} = .5183285. \text{ See Bonnycastle's Algebra, vol. i. p. 141.}
\end{align*}
\]

For the solution of quadratic equations by the method of continued fractions, we must refer the reader to the "Élai fur la Théorie des Nombres," by Le Gendre.

The root of a quadratic equation may be exhibited under the form of a continued fund, as follows:

Let \(x^2 - ax = b\), or \(x^2 = ax + b\); then

\[x = \sqrt{b + ax}\]

Or, by substituting for \(x\), under the radical, its whole value \(\sqrt{b + ax}\), we have

\[x = \sqrt{b + ax}\]

Substituting again for \(x\) as above, we obtain

\[x = \sqrt{b + a} \sqrt{b + a} \sqrt{b + ax}\]

and by continuing thus our successive substitutions for \(x\), we have

\[x = \sqrt{b + a} \sqrt{b + a} \sqrt{b + a} \sqrt{b + a} + \&c.\]

which is an analytical expression for the positive value of \(x\) in the proposed equation.

It is obvious, however, that such an expression as this is of little or no use for solving quadratic equations; but we have by means of the latter, a very ready means of finding the ultimate value of such a continued fund. Suppose, for example, the value of the following continued fund were required, viz.

\[\sqrt{12 + \sqrt{12 + \sqrt{12 + \sqrt{12 + \&c.}}}}\]

Assume

\[x = \sqrt{12 + \sqrt{12 + \sqrt{12 + \sqrt{12 + \&c.}}}}\]

By squaring both sides

\[x^2 = 12 + \sqrt{12 + \sqrt{12 + \sqrt{12 + \&c.}}} + \&c.\]

Or, since the latter part

\[\sqrt{12 + \sqrt{12 + \sqrt{12 + \sqrt{12 + \&c.}}} = x}\]

this becomes

\[x^2 = 12 + x, \text{ or } x^2 - x = 12\]

whence \(x = \frac{1}{2} \pm \frac{\sqrt{125}}{2} = 4\), which is the value of the infinite fund proposed.

Again, let there be proposed the following infinite fund, viz.

\[\sqrt{5 + 4 \sqrt{5 + 4 \sqrt{5 + 5 + \&c.}}}
\]

Assume the infinite sum = \(x\), then by squaring

\[x^2 = 5 + 4 \sqrt{5 + 4 \sqrt{5 + 5 + \&c.}, \text{ or}}\]

\[x^2 = 5 + 4 x, \text{ or } x^2 - 4 x = 5\]

whence \(x = 2 \pm \sqrt{4 + 5} = 5\), the value sought. For other examples of this kind, see SURDS.

QUADRATING of a Piece, among Gnomers, is the finding that a piece of ordnance be duly placed, and poised in its carriages; and that its wheels be of an equal height, &c.

QUADRATO, in Music. See QUADRO.

QUADRATO-CUBUS, QUADRATO-QUADRATO-CUBUS, and QUADRATO-CUBO-CUBUS, are names used by Diophantus, Vieta Oughtred, and others, for the fifth, seventh, and eighth powers of numbers. See POWER.

QUADRATO-QUADRATUM, or BIQUADRATUM, the fourth power of numbers; or the product of the cube multiplied by the root.

QUADRATRIX, in Geometry, a mechanical line, by means of which we would find right lines equal to the circumference
cumference of circles, or other curves, and of the several parts of it.

Or, more accurately, the quadratrix of a curve is a transcendental curve described on the same axis, the semi-ordinates of which being given, the quadrature of the corresponding parts in the other curve is likewise given. See CURVE.

Thus, e.g. the curve AND (Plate XIII. Analytis, fig. 7.) may be called the quadratrix of the parabola AMC, since it is demonstrated, that $\text{APMA} = \text{AP} \times \text{PN}$, or $\text{APMA} = \text{PN} \times a$, a constant quantity, &c.

The most eminent of these quadratrices are, that of Diocles, and that of Mr. Tschirnhausen, for the circle; that of Mr. Perks for the hyperbola.

The quadratrix of Diocles, is a curve $\text{AM} \cdot \text{m} \cdot \text{m}$ (fig. 8.) by which the quadrature of the circle is effected, though not geometrically, but mechanically; it is thus called from its inventor Diocles.

Its genesis is thus: divide the quadrant arc ANB into any number of equal parts, in $N$, $n$, &c. by a continual bissection; divide the radius AC into the same number of parts in the points $P$, $p$, &c. Draw radii $CN$, $nN$, &c. Lastly, on the points $P$, $p$, &c. erect perpendiculars $PM$, $pm$, &c. The curve formed by connecting these lines is the quadratrix of Diocles.

This curve may be described by continual motion; if we suppose the radius CN by its extreme N to describe uniformly the arc AB, and at the same time a ruler PM, always parallel to itself, to move uniformly along AC, in such a manner that when the ruler PM arrives at C, the radius CN may coincide with CB; and thus the continual intersections of CN with the ruler PM will describe the quadratrix AMD.

Here, from the construction, $\text{ANB}:\text{N}:\text{CA}::\text{AP}$; and therefore, if $\text{ANB} = a$, $\text{AC} = b$, $\text{AN} = x$, $\text{AP} = y$; $a \cdot y = b \cdot x$. See Quadrature.

The quadratrix Tschirnhausiana, is a transcendental curve $\text{AM} \cdot \text{m} \cdot \text{m}$ (fig. 9.) by which the quadrature of the circle is likewise effected; invented by Mr. Tschirnhausen, in imitation of that of Diocles.

Its genesis is thus conceived: divide the quadrant ANB, and its radius AC, into equal parts, as in the former; and from the points $P$, $p$, &c. draw the right lines $PM$, $pm$, &c. parallel to CB; and from the points $N$, $n$, &c. the right lines $NM$, $nm$, &c. parallel to AC. The points A, M, m, being connected, the quadratrix is formed; in which $\text{ANB}:\text{N}:\text{AC}::\text{AP}$. And therefore, if $\text{AB} = a$, and $\text{AC} = b$, $\text{AN} = x$, and $\text{AP} = y$; $a \cdot y = b \cdot x$. See Quadrature.

This curve may be also described by continued motion, if two rulers, $\text{N}$ and $\text{PM}$, perpendicular to each other, be made to move uniformly and parallel to themselves, the one along the quadrant of the circle AC, and the other along the radius.

The term quadrature has now a more indefinite signification; implying, in general, the determination of the area of a figure, without any reference to the geometrical exhibition of it, in a square or other rectilinear form.

All rectilinear figures being immediately reduced to, or dependent upon, the area of triangles, their quadratures have been known from the highest antiquity; but the quadratures of curvilineal spaces are, with very few exceptions, of modern date, two only having been known till near the beginning of the eighteenth century.

The first curvilinear space whose quadrature was accurately determined, was the lune of Hippocrates, of which an account will be found under the article Lunar. Archimedes next found the area of the common parabola; which he obtained in a very ingenious manner, by inscribing an isosceles triangle in the parabola, then two isosceles triangles on the equal sides of the former, four others on thefe, and so on, which he found to have a certain relation, decreasing in the proportion $\frac{1}{3}$, $\frac{1}{4}$, &c. the infinite sum of which series would therefore express the area of the parabola, or the area of all the triangles of which he thus conceived it to be composed; and which sum he found to be $\frac{1}{3}$ or $\frac{1}{4}$ of the circumscribing rectangle. After this time, a period of near two thousand years elapsed, without producing the quadrature of a single curvilinear figure, although the subject seems to have engaged the attention of the most eminent mathematicians during that long interval, particularly the quadrature of the circle. This figure, being the most simple in appearance and construction of any contained under a curve line, was well calculated to excite the curiosity of mathematicians. Archimedes doubtless attempted the solution of this problem; but failing in producing the exact quadrature, he contented himself with giving an approximation, having by the inscription and circumfererion of a polygon of ninety-fix sides, that the diameter being 1, the circumference was greater than $\frac{3}{2} \pi$, but less than $\frac{11}{4} \pi$; and as it was known, even before the time of Archimedes, that the area of a circle is equal to that of a right-angled triangle, whose altitude is equal to the radius, and bisequal to the circumference of the circle, it follows, that the area would be greater than $\frac{3}{4} \pi$, but less than $\frac{7}{4} \pi$.

It would be useless to attempt in this place to enumerate the various absurd quadratures which have been, from time to time, published by minor geometers, with all that conceit and confidence which seldom fail to accompany inferiority. Some attributed their success to divine inspiration; others to their own superior talents: some offered large sums of money to those who should discover any error in their investigation, while others expected great rewards from their government, as a recompence for their discovery, foolishly attaching great importance to a problem, which, if it could be accurately solved, would serve no other purpose but to gratify the curiosity of mathematicians. Many of these attempts, however, have been rendered somewhat amusing by an excess of absurdity. This is particularly the case with regard to the work of Jaime Falcon, a Spaniard of the order of Notre Dame, of Montefia, published at Anvers in 1587. This treatise opens with a dialogue in verse between himself and the circle, which thanks him very affectionately for having squared him; but the good and modest knight attributes all the honour of the discovery to the holy patron of his order. See Montucla's "Histoire des Recherches fur la Quadrature du Cercle;" or his "Histoire des Mathematiques," vol. iv. p. 619.

Referring those readers who have the curiosity to examine the reveries above-mentioned to the two preceding works, we propose to give here an abridgment from the same, of what has
QUADRATURE.

has been done on this subject, by way of approximation. We have already observed that Archimedes was the first who gave an approximation of the ratio of the diameter to the circumference of a circle, placing it between the limits 1 to \(3^{1/8}\) and 1 to \(3^{1/7}\); and it is said that Apollonius and Philo found more accurate approximations, which, however, have not been transmitted to us.

Towards the year 1585, Metius, combatting the false quadrature of Simon Duchène, gave the ratio of 113 to 355, which is very exact, being only \(\pm 0.00027\) in excess. Vieta found a still nearer approximation, carrying it to ten decimals, whereas the former is true only to six places. He also gave a kind of series, the infinite sum of which was equal to the entire circle.

Adriamus Romanus carried the approximation to seventeen figures, and Ludolph van Ceulen to thirty-six; which he published in his work "De Circulo et Adscriptis," and of which Snellius published a Latin translation in 1619. He afterwards verified Van Ceulen's approximation by some theorems of his own invention, which greatly facilitated the computation, and which he published in 1621, under the title of "Willebrordi Snellii Cyclopicus de Circuli Dimensione, &c."

Descartes found a geometrical construction from which it was easy to draw an expression in the form of a series; and Huygens afterwards discovered some curious theorems connected with this subject, but did not advance the approximation, though he made some useful rules for approximating towards the length of the circular arc.

One of the most curious discoveries connected with this subject, which had yet been published, was that given by Wallis in his "Arithmetica Infinitorum," in 1655: where he shews that the ratio of a circle to the square of its diameter, is truly expressed by the infinite fraction

\[
\frac{1}{2 + \frac{1}{2 + \frac{1}{2 + \frac{1}{\ddots}}}}
\]

If we limit ourselves, as we must do, to a finite number of terms, we shall have a ratio alternately too great and too small, according as we take an even or an odd number of terms:

<table>
<thead>
<tr>
<th>Numbers</th>
<th>Approximation</th>
</tr>
</thead>
<tbody>
<tr>
<td>2, 4, 6, 8, 10, 12, &amp;c.</td>
<td>3.14...</td>
</tr>
<tr>
<td>2, 4, 6, 8, 10, 12, &amp;c.</td>
<td>3.1415926535...</td>
</tr>
</tbody>
</table>

We shall have for the ratio sought, alternately in excess and defect.

In excess, \(3.14159265358979...\)

In defect, \(3.14159265358979...\)

Prior to the above series of Dr. Wallis, however, something of an equivalent expression, though given under a different form, was discovered by lord Brounker, which is as follows. The circle itself being 1, the square of its diameter is expressed by the infinite continued fraction.

\[
1 + \frac{1}{2 + \frac{1}{2 + \frac{1}{2 + \frac{1}{\ddots}}}}
\]

of which the law of the denominators is obvious. See Circle.

Such was the progress which mathematicians had made towards the solution of this interesting problem prior to the invention of fluxions, which, by reducing the quadrature of all curves to one general principle, again revived the hopes of mathematicians with regard to the circle, notwithstanding some pretended demonstrations of its impossibility; and its quadrature was accordingly again attempted with the greatest eagerness. The quadrature of a space, and the rectification of a curve, were now reduced to that of finding the fluent of a given fluxion but still the problem was found to be incapable of a general solution in infinite terms. The fluxion of a given fluent was found to be always divisible, but the converse proposition, viz. of finding the fluent of a given fluxion, could only be effected in particular cases; and amongst the exceptions, to the great regret and disappointment of geometricalians, was included the case of the circle with regard to every form of fluxion under which it could be obtained. Some exceedingly near approximations have, however, since been made towards the true ratio of the diameter to the circumference of the circle, and these belonging rather to the article Rectification than to Quadrature, we shall enter again upon the subject under the former term, and shall occupy the remainder of the present article on the quadrature of curves in general.

On the Quadrature of Curves by Fluxions. In order to exhibit more distinctly and at large the use of fluxions, according to the modern method of notation, in finding the areas of curves, we shall premise the two following cases.

Case 1.—Let \(A R C\) (Plate XIII. Analytis, fig. 10.) be a curve of any kind, whose ordinates \(b, C, B\), are perpendicular to an axis \(A B\). Imagine a right line \(b R\) perpendicular to \(A B\), to move parallel to itself from \(A\) towards \(B\); and let its velocity, or the fluxion of the abscisse \(b\), in any proposed situation of that line, be denoted by \(b d\); then will the rectangle \(b a\) express the fluxion of the generated area \(A B R\), which (if \(A B = a\) and \(b R = y\)) will be \(\frac{1}{2} y x\); whence, by substituting for \(y\) or \(x\) (according to the equation of the curve,) and taking the fluent, the area itself will become known.

Case 2.—Let \(A R M\) (fig. 11.) be any curve whose ordinates \(C R, C C\), are all referred to a point or centre; and conceive a right line \(C R H\) to revolve about the given centre \(C\), and a point \(R\) to move along the said line, so as to describe the curve live \(A R M\). If this point were to move from \(Q\), without changing its direction or velocity, it would proceed along the tangent \(Q S\) (instead of the curve,) and describe areas \(Q C\), \(Q SC\), about the centre \(C\), proportional to the times in which they were described; because, having the same altitude \(C P\), they are as the baces \(Q S\) and \(Q S\). Consequently, if \(R S\) be taken to denote the value of \(\frac{1}{2}\) the fluxion of the curve line \(A R\), the corresponding fluxion
QUADRATURE.

The fluxion of the area $A R C$ will be truly represented by the uniformly generated triangle $Q C S$; which, expressing $C P$ by $t$, will be $\frac{Q S \times C P}{2} = \frac{z'}{2}$; whence the area itself may be determined. But since, in many cases, the value of $z$ cannot be computed (from the property of the curve) without trouble, the two following expressions, for the fluxion of the area, will be found more commodious, viz.

$$\frac{y^2}{2} = \frac{z'}{2} t$$

and

$$\frac{2 S a}{2 a} = \frac{z'}{2} t$$

where $t = R P$, and $x = \text{arc}$ the $A B N$ of a circle, described about the centre $C$, at any distance $a = C B$. These expressions are derived from that above in the following manner; viz. $z = f (C R) = t (R P)$; therefore $z = \frac{y^2}{2}$; consequently $\frac{2}{2} = \frac{z'}{2} t$. Moreover, because the celerity of $R$ in the direction of the tangent is denoted by $z$, that in a direction perpendicular to $C Q$ (whereby the point $R$ revolves about the centre $C$), will, therefore, be $\frac{C P}{C R} \times \frac{x}{y} = \frac{z'}{2}$; which, being to $z$ the celerity of the point $N$ about the same centre as the distance or radius $C R$ ($y$) to the radius $C N$ ($a$); we shall, by multiplying extremes and means, have

$$\frac{a}{y} = \frac{y}{2}$$

and, consequently, $\frac{z'}{2} = \frac{x^2}{2}$. In the examples subjoined, the letters $a$, $y$, $x$, and $u$ shall be used to denote the abscissa, ordinate, curve-line, and area respectively.

**Quadrature of a Right-angled Triangle.** Let the base $A H$ (fig. 12.) be $a$, the perpendicular $H M = b$, and the $A B$ ($x$) be any portion of the base, considered as a flowing quantity, and $B R$ ($y$) the corresponding ordinate. Then, the triangles $A H M$ and $A B R$ being similar, we shall have

$$a : b :: x : y = \frac{b x}{a}$$

Whence $y x$ (the fluxion of the area $A B R = \frac{b x}{a}$; and its fluent (see Inverse Method of Fluxions) or the area itself $= \frac{b x}{2 a}$, which, when $x = a$, and $A B$ coincides with $H M$, becomes $\frac{a b}{2} = \frac{A H \times H M}{2}$

the area of the whole triangle $A H M$. See Mensuration of Triangles.

**Quadrature of a Circular Sector.** Let $A O R$ (fig. 13.) be the sector; $A O$ or $O R$, its radius $= a$, the arc $A R$, considered as variable by the motion of $R$, $z = z$, and $R r = \frac{z}{2}$; the fluxion of the area will be $\frac{a z^2}{2}$; the triangle $O R r$: whence the area itself is $\frac{a z}{2} = A O \times \frac{1}{2} A R$:

that is, the area of any circle is expressed by a rectangle under the half circumference and half the diameter. See Circle.

**Quadrature of a Semicircle.** Let the semicircle be $A R E H$ (fig. 14.); its diameter $A H = a$, $A B = x$, and $B R = y$, &c. and we have $y^2 (B R) = a x - x^2$ ($A B \times B H$), and, consequently, $u (y x) = \frac{x^2}{a} (a x - x^2) = \frac{x^2}{a} \left(1 - \frac{x}{a}\right)$; which expression being resolved into an infinite series, we shall have

$$u = a^2 x^2 \times (1 - \frac{x}{2 a} - \frac{x^2}{8 a^2} - \frac{x^4}{16 a^4} - \frac{5 x^6}{128 a^6} + \&c.) = a^2 x^2 \times (1 - \frac{x}{2 a} - \frac{x^2}{8 a^2} - \frac{x^3}{16 a^3} - \frac{5 x^5}{128 a^5} + \&c.)$$

Whence, the fluent of every term being taken, there will arise $u = a^2 x^2 \times (1 - \frac{x}{2 a} - \frac{x^2}{8 a^2} - \frac{x^3}{16 a^3} - \frac{5 x^5}{128 a^5} + \&c.)$

$$= \text{the area } A B R$$

When $x = \frac{a}{2}$, the ordinate $B R$ will coincide with the radius $O E$; in which case the area becomes $\frac{1}{4} a^2 \times (\frac{a}{2} - \frac{a}{2} - \frac{a}{2} + \frac{a}{2} - \frac{a}{2} + \frac{a}{4})$ and the arc

$$\sqrt{a x} \times \left(1 - \frac{x}{2 a} - \frac{x^2}{8 a^2} - \frac{x^3}{16 a^3} - \frac{5 x^5}{128 a^5} + \&c.\right)$$

of the radius $B R = \frac{1}{4} a^2 \times \left(1 - \frac{x}{2 a} - \frac{x^2}{8 a^2} - \frac{x^3}{16 a^3} - \frac{5 x^5}{128 a^5} + \&c.\right)$

and we shall have

$$\frac{a}{2} \times \frac{x^2}{a} = \frac{y^2}{2 a^2} + \frac{a}{4} \times \frac{x^2}{a^2}$$

and hence, for the whole area of the sector $A O R$; the treble of which, or $0.7853974$ ($A B = \frac{1}{2} A E$), will be the content of the whole quadrant $A O E$; which number, found by taking only four terms of the series, is true to the last decimal place.

We might have found a series of more rapid convergency, but shall here refer that part of our investigation for the article Rectification.

**Quadrature of the Ellipse.** See Lunes.

**Quadrature of the Parabola.** The curve $A R M H$ (fig. 15.), be the common parabola, in which $y^2 (B R)$ $= a x$ ($A B \times a$, the parameter). See Conic Sections. Whence we have $y = a^2 x^2$ and $u (y \times x) = a^2 x^2 \times x$; and, therefore, $u = \frac{a}{2} \times a x^2 \times x = \frac{2 a x^2}{3}$ $\times x = \frac{2 a x^2}{3}$ $\times x = \frac{2 a x^2}{3}$ $\times A B \times B R$. Hence a parabola is $\frac{1}{2}$ of a rectangle of the same base and altitude.

The value of the area may also easily be found in terms of $y$. Thus $x$ being $= \frac{y^2}{a}$, we have $x = \frac{2 a y}{a}$, and $u (y \times x) = \frac{2 a y^3}{3}$ $\times x$; whence $u = \frac{2 y^3}{3 a} \times \frac{2 y}{3} = \frac{2 x^2}{3} \times a x = \frac{2 y^3}{3} x = \frac{2 y^3}{3}$ $\times A B \times B R$. See Parabola.

In the cubic parabola, whose equation is $p^3 x = y^3$; we have
have \( y = \rho^3 x^3 \); multiply this by \( \dot{x} \), and we have \( y \dot{x} = \rho^3 x^3 \dot{x} \), for the fluxion of the area. Therefore fluent \( y \dot{x} = \frac{1}{2} \rho^3 x^4 = \frac{1}{2} \) of \( xy \), that is, area = \( \frac{1}{2} \) of circumscribing rectangle.

And in the same manner, it will be found that in the general parabola, whose equation is \( a^2 x y = c^2 \); the area = 

\[
\frac{a}{n+1} \text{ x circumscribing rectangle.}
\]

**Quadrature of the Hyperbola.** The analytical quadrature of this curve was first given by N. Mercator of Holstein, the first inventor of infinite series. But Mercator finding his series by division, Sir Isaac Newton and M. Leibnitz improved upon his method; the one seeking them by the extraction of roots, the other by a series prefaced. See Hyperbola.

**Quadrature of the Asymptotic Spaces in an Hyperbola.** Let \( D E F (fig. 16.) \) be an hyperbola, of which the asymptotes are \( CM \) and \( CN \); to find the area \( E G H F \), comprehended between the ordinates \( GE \) and \( FH \).

Let \( CG = a, GE = b, GH = x, FH = y \); then by the property of the hyperbola, \( CG \times GE = CH \times HF \), or \( a b = (a - x) y \); or \( y = \frac{ab}{a + x} \); and, therefore, \( y \dot{x} = \)

\[
\frac{a b \dot{x}}{a + x} \text{; the fluent of which is } a b \times \text{ hyper. log. } (a + x),
\]

which fluent, however, requires a correction, for when \( x = a \), the area = 0; but the above expression when \( x = a \) is \( ab \times \text{ hyper. log.} \) of \( a \); therefore, the correction is \( -ab \times \text{ hyper. log.} \) of \( a \); that is, the correct fluent which expresses the area is \( ab \times \text{ hyper. log.} (a + x) - ab \times \text{ hyper. log.} a \).

\( CG \) and \( GE \) each = 1; \( y \dot{x} = \frac{\dot{x}}{1 + x}, \) the fluent of which is \( \text{hyper. log.} (1 + x) \), which requires no correction.

**Quadrature of the Cycloid.** Let \( CAL (fig. 17) \) be a cycloid, \( AD \) the axis, \( A B D \) the generating circle, \( AF \) a tangent at the vertex, \( C F \) parallel to \( AD \). Take any point \( P \) in the arc, and draw \( PM \) perpendicular to \( AM \). Then the fluxion of the external area \( APM = PM \times \text{ the fluxion of } AM \).

Let \( AE = x, AD = 2a; \) then \( BE = \sqrt{(2a x - x^2)} \)

and the fluxion of \( BE = \frac{(a - x) \dot{x}}{\sqrt{2a x - x^2}} \).

Also \( PB = \text{ the arc } BA; \) therefore the fluxion of \( PB = \frac{a \dot{x}}{\sqrt{2a x - x^2}} \); and the fluxion of \( PB + BE \), or of

\[
AM = \frac{(2a - x) \dot{x}}{\sqrt{2a x - x^2}}; \text{ the fluxion of the area}
\]

\( APM, \text{ or } PM, \times \text{ by the fluxion } AM = \frac{(2a x - x^2) \dot{x}}{\sqrt{2a x - x^2}} \).

But the fluent of this fluxion is the same as that found above for a circle, whose radius is \( a \), and verified fine \( x \); that is, the area \( AB \); and, therefore, when \( x = 2a \), the whole external area \( CFA \) is equal to the area of the semicircle \( ABD \). But \( CD \) being equal to the semicircumference \( AD \), the whole rectangle \( CDAF \) = four times the semicircle \( ABD \), and consequently the internal area \( ACD \) = three times the semicircle \( ABD \); or the whole area of

\[
\text{Vol. XXIX.}
\]

the cycloid equal three times the area of its generating circle.

**Quadrature of the Logarithm.** Let the subtangent \( PT (fig. 18) = a, PM = x, P = d \); then will

\[
y \dot{x} = a \\
y \dot{x} = a^2 \\
y \dot{x} = a^3
\]

and fluent of \( y \dot{x} = a y \).

Therefore the indeterminate space \( HPMI \), is equal to the rectangle of \( PM \) into \( PT \).

Hence, 1. Let \( QS = z \); then will the indeterminate space \( ISQH = a z \); and, consequently, \( S \times PM = a^2 \), \( a z = a (y - z) \); that is, the space intercepted between the two logoric featherettes is equal to the rectangle of the subtangent into the difference of the featherettes.

2. Therefore the space \( BAPM \) is to the space \( PMSQ \) as the difference of the featherettes \( \overline{AB} \) and \( PM \) is to the difference of the featherettes \( PM \) and \( SQ \). See Logarithmic Spiral.

**Quadrature of the Logarithmic Spiral.** Let \( CBAC (fig. 19) \) be the area proposed; let the right line \( AT \) touch the curve at \( A \), upon which, from the centre \( C \), let fall the perpendicular \( CT \); then, since by the nature of the curve, the angle \( TAC \) is every where the same, the ratio of \( AT \) to \( CT \) will be constant; and, therefore, the fluent of \( \frac{1}{1} \times \frac{y^2}{2} = \frac{1}{1} \times \frac{y^3}{3} = \) the required area.

**Quadrature of the Spiral of Archimedes.** Let \( CR (fig. 20) \) be the curve, whose area \( CRG \) is required. Let \( AC \) be a tangent at the centre \( C \), about which centre, with any radius \( CA \), suppose a circle \( AG \) to be described; then the arc or abscissa \( AG \) corresponding to any proposed ordinate \( CR \), being to that ordinate in a constant ratio (viz. as \( m \) to \( n \)) we have \( x \) (\( AG \)) = \( \frac{m y}{n} \); therefore \( u = \frac{y^2 \dot{x}}{2a \dot{a}} \); consequently \( u = \frac{y^2 \dot{x}}{2a \dot{a}} = \frac{y^2 \dot{x}}{2a \dot{a}} = \frac{6a n}{2a \dot{a}} \).

Since \( b \dot{y} = bx^2 + x \) \( y = \frac{(bx^2 + x^3)}{b} \)

\[
y \dot{x} = \frac{(bx^3 + x^4)}{b^2} \]

flu. \( y \dot{x} = x^3 \)

\( x^3 + 3b - x^4 + 4b^3 \).

**Quadrature of all Curves comprehended under the general Equation, \( y = x^p \times (x + a) \).**

Since \( y = (x + a)^p \)

\[
y \dot{x} = \dot{x} (x + a) \]

Make \( (x + a)^p = v \)

Then \( x + a = v^p \), or \( x = v^p - a \)

Whence \( b = m v^{p-1} \)

\[
y \dot{x} = m v^{p-1} \]

the fluent of which is

\[
\frac{m}{m + 1} = \frac{(x + a)^{p+1}}{m + 1} - \frac{(x + a)^p}{m + 1} \\
\]

Let \( x = 0 \); the remainder will be

\[
\frac{m}{m + 1} \times a \quad \text{Whence,}
\]

vol.

\[
XXIX.
\]
Whence, the area of the curve $\frac{m}{m + 1} \sqrt[4]{(x + a)^2 - (x + a)}$

See on the subject of this article Maclaurin's Fluxions, and Simpson's Fluxions, vol. i. sect. 7, p. 121, &c.

Quadrature, in Astronomy, that aspect, or situation of the moon, when she is 90 degrees distant from the sun.

Or, the quadrature is when she is in a middle point of her orbit, between the points of conjunction and opposition; which happens twice in each revolution, viz. in the first and third quarter.

When the moon is in her quadrature, the exhibits that phases which we call the half-moon, i.e. the phases with just half her face; and is said to be bisected, or dichotomized.

In the moon's progress from the first syzygy, her gravity towards the earth is continually increasing by the action of the sun; and her motion is retarded for the same reason. Her motion then, in her orbit, is slower as her gravity to the earth is greatest when in the quadratures.

In her recess from the quadratures to the first syzygy, the gravity continually decreases, and the velocity increases. The ratio is thus: as radius is to the sun, or difference of one and a half the cosine of half the distance of the moon from the first syzygy, and half the radius; so is the addition of gravity in the quadratures to the diminution or decrease of it in any other situation. See Syzygy.

Hence the moon's orbit is more convex in the quadratures, than in the first syzygy; and hence the circular figure of the moon's orbit is changed into an oval, whose greater axis goes through the quadratures; and hence, also, the moon is less distant from the earth at the first syzygy, and more at the quadratures.

It is no wonder, therefore, that the moon should approach nearer to the earth when her gravity is diminished; so that accses not being the immediate effect of this diminution, but of the inflexion of the orbit towards the quadratures.

In the quadratures, and within thirty-five degrees of them, the apsidal line of the moon goes backwards, or move in antecedentia; but they move forwards in the first syzygy. See Apsides.

The moon's orbit undergoes various alterations in each revolution. Its eccentricity is the greatest when the line of the apsidal line is in the first syzygy; and the least, when in the quadratures.

Considering one entire revolution, the nodes move slower and slower as the moon approaches the quadratures, and they set the time is in them; but considering several revolutions, the nodes go back faster in the quadratures.

The inclination of the plane of the moon's orbit increases as the nodes go from the first syzygy, and is greatest when the nodes are in the quadratures. See Moon and Nodes.

Quadrature, or Lines of Quadrature, are two lines frequently placed on Gunter's sector.

They are marked with the letter $Q$, and the figures 5, 6, 7, 8, 9, 10; of which $Q$ signifies the side of a square, and the other figures the sides of polygons of 5, 6, 7, &c. sides. $S$ there stands for the semi-diameter of a circle; and $90$ for a line equal to ninety degrees in circumference.

Quadratus, in Biography, an early Christian writer, who flourished under the reigns of Trajan and Adrian. He is styled by Jerome and Eusebius "a disciple of the apostles," and he was reported to have been endowed with the gift of prophecy. According to Eusebius, Quadratus presented to the emperor Adrian, in the year 126, an apology for the Christian religion, with a view of mitigating the sufferings inflicted upon the professors of that period. This is supposed to have been the first written apology presented on the same subject to any of the Roman emperors, and it produced a considerable effect on the mind of Adrian. Of this work only a fragment remains, which is preferred by Eusebius, and which is extremely valuable on account of the testimony which it affords to the reality of the miracles of Christ and his apostles, by asserting that some of those miracles were wrought on persons who were living at the time when Quadratus wrote. Nothing is known respecting the time and manner of his death. Lardner.

Quadratus, in Anatomy, a name given to several muscles of the body, on account of their form.

Quadratus Femoris, le carré, is the trochanteric muscle; it is situated at the upper and back part of the thigh, and extends from the tuberosity of the ischium to the great trochanter. It is flattened, quadrilateral, and tolerably thick. The posterior surface is covered by the gluteus maximus, the iliacus, and the semi-membranosus; the anterior surface covers the obturator externus, the extremity of the tendon of the psoas magnus, and the head of the trochanter minor. The superior edge is parallel to the inferior geminus; and the inferior to the upper fibres of the adductor magnus. The inner edge, or origin of the muscle, is fixed to the outer side of the tuberosity of the ischium, in front of the semi-membranosus; the outer is attached to the bony ridge, which runs from the great to the small trochanter. It is tendinous at its two attachments, and fleshy in other parts. It will rotate the thigh outwards upon the pelvis; or, if the former be fixed, it will move the pelvis upon the thigh. When the thigh has been carried upwards and outwards, it will restore the limb to its natural position.

Quadratus Genae, a muscle of the lower lip; see the article Deglutition, where it is described under the name of depressor labii inferioris.

Quadratus Lumbrorum. See Lumbrorum.

Quadratus Occipitalis, a name of the posterior or occipital portion of the Epicanthus; which see.

Quadrella, in Geography, a town of Naples, in Lavora; 20 miles E.N.E. of Naples.

Quadrels, in Building, a kind of artificial stones, perfectly square, whence their name. They are made of a chalky, or whitish and pliable earth, &c. dried in the shade for at least two years.

They were formerly in great request among the Italian architects.

Quadriceps, in Anatomy, a name under which it has been proposed to describe the extensors of the knee-joint, viz. the vastus internus and externus, the crurinus, and rectus; and the adductors of the thigh, with the peltinahs.

Quadriga, formed from quadrus, four, and jugum, yoke, in Antiquity, a car, or chariot, drawn by four horses, haraselled abreast.

Various are the accounts we have of the inventor of the quadriga. Cicero makes it the invention of Minerva. Hyginus attributes it to Erichthonius IV. king of the Athenians; which sentiment Virgil also follows in his Georgics, lib. iii. ver. 111. Eufebius gives Prometheus the honour of it. Tertullian, De Spectac. lib. ix. says, it was invented among the Argians, by Trochilus, in honour of Juno; and at Rome, by Romulus, in honour of Mars, or Quirinus. Ado of Vienna, Chronic. act. iii. will have it to have been invented by one Proclus, about the time of the establishment of the kingdom of Athens. Laziardels, Hist.
Hifi. Univerf. Epitom. lib. xxiv. says the fame of Triptolomus. Latly, if there be not opinions enough already, Herodotus gives us another; and says, the Greeks borrowed it from the Libyans. Pliny tells us, that his feat was a quadriga, lib. xvi.

On the reverses of medals we frequently fee Victory, or the emperor, in a quadriga, holding the reins of the horses; whence these coins are called, among the curious, nummi quadrigratis, and victorlatis. See Bigat.

Quadriga, from quadrat and juga, yokes, in Surgery, a bandage for the sternum and ribs, so called from its resemblance to the trappings of a four-horse car. It was formerly employed in cases of fractured ribs; but, as it is not now in use, a more particular account of it seems unnecessary.

Quadrigemina Corpora, in Anatomy, a part of the brain, known more commonly by the terms nates and telles. See Brain.

Quadrilateral, in Geometry, a figure whose perimeter consists of four right lines, making four angles; whence it is also called a quadrangular figure.

If the several angles be right, the figure is a rectilinear quadrilateral. If oblique, an oblique-angular quadrilateral.

If the sides of a quadrilateral be equal, and the angles right, the figure is a square.

If the sides be equal, but the angles unequal, the figure is a rhombus.

If the angles be equal, and the sides unequal, the figure is a rectangle.

If only the opposite angles and sides be equal, the quadrilateral is a rhomboid.

If the opposite angles and sides be unequal, the quadrilateral is a trapezium.

If any side of a quadrilateral, inscribed in a circle, be produced out of the circle, the external angle will be equal to the opposite, internal angle.

Hence, the two opposite angles of any quadrilateral figure inscribed in a circle, always make two right angles; and, therefore, no oblique-angled parallelogram can have a circle described about it, because its opposite angles being equal, must together be greater or less than two right angles. See Circle.

Quadrill, Quadrilla, a little troop or company of cavaliers, pompously drest and mounted; for the performance of caroufels, julls, tournaments, running at the ring, and other gallant divertisements.

The word is borrowed from the Italian, being a diminutive of quadrata, a company of soldiers ranged in a square: for quadrare is, properly, to dispose any thing square; whence their quadrilla, the French squadrille and quadrille, and our quadrill. The French formerly wrote squadrille, and squadrille.

A regular caroufal is to have at least four, and at most twelve, quadrills.

Of these quadrills, each is to consist of at least three cavaliers, and at most of twelve. The quadrills are distinguished by the form of their habits, or the diversity of their colours.

Quadrille, a well-known game at cards, and whatever has been, in several cafes, the object of mathematical computations. See M. de Moivre’s Doctrine of Chances, 3d edit. p. 97, &c.

Quadrrio, Francesco Saverio, in Biography, a Jesuit, author of a voluminous history and description of every kind of Italian poetry, “Della flora e della Ragione d’ogni Poesia,” eight vols. 4to. published at Bologna between the years 1739 and 1752.

The author seems a mere compiler, without selection, taste, or accuracy. It is a heavy work, hardly interesting enough to stimulate a regular perusal; and from the disorder of arrangement, very difficult to consult. Crecimbeni is as superior to Quadrrio in every requisite of an historian of literature, as Tiraboschi is to Crecimbeni.

Quadripartition, the dividing by four; or a taking of the fourth part of any number, or quantity. Hence quadripartite, &c. something divided into four.

Quadrireme, Quadrigemina, a galley, or vessel, with four oars on a side; the invention of which was attributed by the ancients to the Carthaginians.

Quadrisetæ, the four-haired flies, a term used by the writers in natural history to express those flies of the feticuda or hair-tailed kind, which have four hairs or bristles growing from the tail, as the others have three, two, or one.

Quadrivium, the centre of four ways, where four roads meet and cross each other. By statute, pofts with inscriptions are to be set up at such cross-ways, as a direction to travellers, &c. 8 & 9 W. III. c. 10.

Quadrivium, besides the centre of four ways, was a scholastic division, used in the middle ages in our universities, to express the highest clafs of philosophical learning and science; comprehending arithmetic, geometry, astronony, and music. as the trivium did grammar, rhetoric, and logic. During this period, music, such as it was, must have been highly prized to be ranked with the most sublime sciences, and thought an essential part of a learned education.

Quadro, Ital. literally means square, and in music, at present, it implies a natural, $,$ or Gothic $B$, in opposition to $t$ondo, round, or the round $b$, used for a flat. The durum hexachord is sometimes called the quadro hexachord, from the circumstance of $B$ being $\hat{b}$.

It was the opinion of Padre Martini and the prince abbot of St. Blasius, that accents and points, enlarged, disfigured, and lengthened, became musical characters for time as well as tune. At first, when lines and spaces were used, from their being chiefly employed in a square form for writing the chants established by St. Gregory, they acquired the name of Gregorian notes, quadrata, and in barbarous Latin, quadracta. As the church is now in receiving new doctrines, and generally a century later in admitting those improvements or corruptions in music (the reader may call them which he pleases) that are adopted by the laity as the fortunate efforts of cultivated genius, the notation of chants was at first cenfured and prohibited by several councils; and figurative harmony being regarded as a crying sin by pope John XXII., was formally excommunicated by a bull from the conclave 1321. See Notes, and Time-table.

Quadrugata Tere, in Old Law Records, denotes a team-land; or so much as can be tilled by four horses.

Quadrula, in Natural History, a word sometimes used in the same sense as tessel, and spoken of the cubic pyrites. Sometimes it is used also as the name of those little spangles of shining matter that are mixed among fand. These are generally fragments of tale; and are of various colours, white, yellow, and blackish.

Solinus has used the word quadrula to express the fragments of yellow tale that are found in that sand called ammobrytus, or golden fand. He mistakes these shining particles for mafles of real gold, and makes the sand itself a kind of precious subftance ranked among the gems, and brought from Persia; but in this he does not agree with the rest of the ancients.

Quadruped. The essential character of quadrupeds...
Quadrupeds.

Quadrupeds are distinguished by the number of their feet, from other animals, which have only two feet, as birds; from those which have no feet, as fishes and reptiles; and from those which have more than two feet, as insects.

Aristotle distinguishes quadrupeds into three classes: denominating those whose feet are terminated by a hoof in one piece, *fossipedes*; those which have a cloven hoof he distinguished by the name of forked or cloven-footed; and those whose feet are digitated he called *fipppedes*. With this general division he contented himself, without descending to a methodical distribution of each class into their several orders, genera, &c. Gesner, Aldrovand, Jonston, and many other naturalists, have adopted the distribution of Aristotle: but we are indebted for the regular systematic arrangement of quadrupeds to Mr. Ray, who published his "Synopsis Methodica Animalium Quadrupedum et Serpentini Generis," &c. in 1693. According to this writer, quadrupeds are divided into those which are hoofed, *ungulata*; and those which are clawed, or digitated, *ungulacta*.

1. *Whole-hoofed, *fossipedes, *muropeda, *muropoda, *sole冬dungula*; as the horse and ass, the onager or wild ass, the mule; and the zebra of Africa, or the fine striped Indian or African ass, almost like a mule in form and figure.

Of the whole-hoofed kind, Aristotle has observed, that no one hath two horns (he might have said any horns); no one hath the talus, or *grallagalus*, nor hath the males any appearance of teats.

2. *Cloven-footed*: and that either, 1. Into two divisions only: as the *saoen*, of the bifoliate kind; which are again subdivided into such as are.

First, *Ruminants, *guaprazo; that is, such as chew the cud; and these either have hollow and perpetual horns, as the bull, sheep, and goat kind; or decision horns, as the hart and deer kind, which usually shed their horns annually.

Of the *bull kind* are reckoned these: the common bos or bullock, of which the male is taurus, the female vacca; the German urus, urochs, or urochus; the bifon; the bonasus; the bubalus, or bullaffo; and the bos Africanus of Bellonius, Obs. lib. ii. c. 90, which he takes to be the bubalus of the ancients.

Of the *fleap kind*, besides the common fорт, are reckoned the Arabian ovis laticauda, whose tail is sometimes of thirty pounds weight; the ovis ferox capricorn Cretica Bellonii; the ovis Africana, with short hair instead of wool; and the ovis Guineens, or Angolensis, of Marcgrave, Hist. Brasiil. lib. vi. c. 10.

Of the *goat kind* are, besides the common capra domestica, the ibex, or German steinbock, found on the tops of the Alps; the rupicapra, French chamois, or German gems; the gazella Africana, or antelope; the gazella Indica; the gazella Africana with shorter, annulated, and bent horns; the capra fulvifrons Africana Grinnelli; the capra Mambrina, or Syriaca of Gesner; the bucephalus, or mofehelaphus Caifi, in Gesner; the tragelaphus Caifi, in Gesner; and the tragelaphus of Bellonius.

Of the *hart, or deer kind*, are reckoned, the cervus, *boides*, or red deer; the cervus platyceros, or palmas, the fallow deer; also, or the elk; rauheller, the rein deer; the axis Plinei, according to Bellonius; the caprea Plinei, the euouacu-ate, and euouacu-apa, of Marcgrave; the caprea Groenlandica.

Secondly, of animals whose feet are divided into two parts only, and which do not chew the cud, there is only the hog and swine kind. Under this head, besides the common swine, are reckoned the wild boar, or swine; the Guineens Marcgravii; the porcus Indicus, or babirusa; the tajacu or aper Mexicax mouffierus of Dr. Tyfon, called, by Marcgrave, tajacu casigora; by others, quashita coymat, and quaipizotl; and by Acosta, and some others, zaino.

2. There are some quadrupeds, whose hoof is cloven into four divisions, and these seem to be not ruminant; as the rhinoceros, the hippopotamus, the tapirjere of Brasil, the capy-bar of Brasil, and the animal mouffierian.

Quadrupeds, *Hoofed or Digitate*. Of this kind, there is, first, a fort whose claws are not divided or separated, but adhere to one another, and are covered with one common skin, but with obtuse nails, ficking out round the margin of the foot; as the elephant, which is anomalous, and not clearly referrible to this kind, or to that of cloven-footed quadrupeds.

A second species of this digitate kind of quadrupeds, which has only two claws, is the camel; and though these have no horns, they both ruminate, and have also the four romachs of horned ruminant animals.

Of the camel there are two forts; one having but one hunch on the back, the other two.

To this kind also belong the Peruvian glama, which some have reckoned among the sheep kind; as also the pacos, the ovis Indica, or Peruviana vulgo, which is much less than the glama.

A third species of this ungulate kind includes such animals as the Greeks called *palaeonyes*, and *Achdionyes*, which have the foot divided into many claws, with broad nails on them; as the ape and monkey kind.

Of these, some have no tails, and are called fime, or apes: others have tails, and are called monkieys, cercopitheci; and such as have either long or short tails, if they are of a larger size, are called papiones, or baboons. There are great numbers and varieties of this species of quadrupeds; of which naturalists have described these, viz. the orang-oustang, or homo sylvestris of Dr. Tyfon, described by him in a particular disconue; the guariba of Brasil, Marcgravii; the rupi of Brasil, greater and lesser; the cae of the fame region, described by Lertius; the catina of the fame country; the cercopithecus barbatis Guineenfis, two or three forts of it; the cercopithecus Angolensis major; the cercopithecus non barbatis Clufi; the cercopithecus Cluf. called jagown. Lastly, if apes and monkieys have their foons very prominat, like dogs, they are called cynocephali.

A fourth species of this ungulate kind is, when, though the claws are many, yet they are not covered at the end with broad flat nails, like monkieys or apes; but are rather like the talons of hawks, &c. crooked and sharp-pointed.

Thefe, in respect of their teeth, may be divided into fuch as have many dents primum, or incifors (that is, cutting teeth) in each jaw, of which there are two forts; a greater, which either have a short, round head, as the cat kind; or a leffer fort, having a long flender body, with very short legs, as the weael or vermin kind. There are also some of this species of quadrupeds which have only two large remarkable teeth in each jaw: these are the hare kind; and these live only upon herbs, grans, &c.

Of the *cat kind* of quadrupeds are reckoned to be the lion; the tyger; the pardalis, whole male is pardus, and female panthera; the leopard; the lupus cervarius, or lynx; the catus pardus, or cat-a-mountan; the common cat; and the bear.

Of the *dog kind* are reckoned the wolf; the lupus arceus, or jackall; besides the common dog, of which kind they
they enumerate the mastic, or mallif; the canis venaticus Graius, Græcus, or Scoticus, the greyhound; Graius Hibernicus, or the Irish greyhound; the canis venaticus sagax, indagator, sectator ferarum, &c. the hound; canis venaticus Hispanicus, or aviarious, the spaniel for land or water; vertagus, or tumbler; canis Ovis, or domesticus, the houfe-dog; canis melitæus, or the lap-dog; canis Getulus, or Ilicanius, the fchock: and of all these forts there are many varieties of mongrels, and hybridos breeds.

Other species of the dog kind are, the fox; the animal zibethicum, or civet-cat, as it is corruptly called, but by its teeth and snout is plainly of the dog tribe; the American coati, or rackoon, or rattoon; the yziquepatli; the carigueya, marinucca, carigoy, ropoza, or opolium; the taubii; the taxus, or meles, the badger, grey, or pate; the lutra, or otter. To these some add the phoca, sea-calf or seal; the equus marinus, morfe, or sea-horse, muitaken by fome for the hippocopotamus; the Dutch call him walrus, the Danes and Icelenders rofmarus; laifly, the manti, or vacca marina, the sea-cow.

Of the vermin, or weafel kind of quadrupeds, is, firft, the muftela vulgaris, the common weafl, in Yorkshire called founmart, or flicht; ydak the vijerra Indica, called quill and quirpele; another fort called mungo, and mugathia, of a reddifh-grey; the muftela, ermine, or float, and muftela fylverfis, the ferret; putorius, the pole-cat; martes, or foyna, the martin, or martlet; muftella zibellina, the fable: laifly, the genetta; and the ichneuromon Bolloni.

Of the bare kind of quadrupeds are, firft, the lepus, or the common hare; cuniculus, the rabbit, or coney; tapeti, or Brail coney, and the aperea of Brail; the hylinus, or porcupine, and the hylinus Americanus, or cuanda of Brail; caflor, fiber, or the beaver; fciurus vulg., or fquirrel; the virginianus, Zeylandic, Barбary, and Americanus flying fquirrel; the mus domelificus, major and minor, the common rat and mouse: to these alfo may be referred mus major aquaticus, the water-rat; the mus-chat, mus avellanarum, major and minor; the dormouse or fleepier, mus Noricus, Crictetus, Alpinus, feu marmotta; the cavia cobaya, or cuniculus Americanus, the Guinea-pig; the aguti, and paca of Brail; the mus Norwegicus, or leming; the glis Gfneri, or the rill; the mus Indicus, &c.

QUADRUPEDS, ANOMALOUS. To these feveral kinds, the following anomalous ones mufl also be added:

1. Such four-footed viviparous animals as have a longifh snout, with their feet divided into manv claws, and toes, and having teeth; as the echinus teretirrus, or common urchin, or hedgehog; erinaceus Indicus albus; tatu or armadillo prima of Marcgrave; tatuete of Brail, or the second fpecies of the armadillo, according to Marcgrave; tatu apara, his third fpecies of armadillo; tatu muftelinus, Soc. Rég. Muf. the weafl-headed armadillo; talpa, the mole-warp, or mould-warp; and the mus araneus, flrew, hardy flrew, freamoufe.

2. Quadrupedous and viviparous animals with a longifh snout, having their feet divided into many claws or toes, but without teeth; as the tamandua guacu of Brail, Maregraui, urius formicus Cardani, the great ant-bear; the tamandua of Brail, or Maregraves, the etter ant-bear.

3. Anomalous flying quadrupeds, with a shorter snout, and their feet divided as above; being of the bat kind, or fitter-mice, of which there are severall fizes, and of different forms.

4. There is one very anomalous animal, which has but three claws on each foot; and that is the ai or ignavus of Marcgrave, the floth or fluggard.

5. Viviparous and fanguineous quadrupeds, breathing with lungs, but having only one ventricle in the heart; as the rana aquaticus, the frog, or fpli; rana arborea, the small tree or green frog; bufu, five rubeta, the toad; coldudo, the tortoise, in Greek χελως; of thefe there are land and water ones, and many different species in foreign parts.

6. Oviparous quadrupeds, with a long tail ftreched out horizontally. Such are the lizard kind; as lacertos omnium maximus, the crocodile; cordylus, five caudiverbera, uromatix Græcis, larger than the green lizard; tapayaxin Nove Hispamuce, or lacertos orbicularis of Hernandez; lacertos vulgaris, the common eft, swift, or newt; lacertos viridis, the green lizard; lacertos fuetanum Aldrovandi, at Rome and Naples called the tarantula; lacertos Indicus, called fenembi and ignava; lacertos Brasiliensis, called tejuguaco, and temapara by Marcgrave; the taraguara ameia, the taraguito Arcuraba, Americima, Curapopba, Tiunhama, &c. of Marcgrave; the lacertos Indicus; lacertos venaticus Indicus; lacertos venaticus. This fystem of Mr. Ray obtained very generally among naturalifts, till, in the year 1735, Linnaeus firft published his fystem. This was followed by feveral others, varying in the arrangement of the animal kingdom, even to the laft edition of 1797. Under the clafs, which he denominates Mammalia, (which fee,) he comprehends not only all the animals which we call quadrupeds (the lizard genus, or rather the reptiles pedati excepted), but also the cetaceous order, or whales, cachalots, and porpelles; juftifying this arrangement of whales with quadrupeds, from the agreement of the animals in the structure of the heart, in the repiration by means of lungs, in their having moveable eye-lids and ears, in being viviparous, furrhed with teeth, and other particulars, by which they differ fo materially from fhies, as more than to counterbalance their living with them in the fame element. The mammalia are divided into feven orders, the diûuctions of which are principally eftabhlished on the difference in the numbers, situation, and form of the three kinds of teeth, viz. the primate or incifiers, called fore-teeth, or cutting-teeth; the laniarii or canini, called dog-teeth, canine or lacerating teeth; and the molares, double teeth or grinders. But Linnaeus does not entirely neglect the feet. See the characters of the feveral orders under Primates, Brute, Feræ, Glis, Pecora, Belliu, and Cete or Whale. This part of the Linnean fystem, including a few species defribed in the Appendix of the third tome, and in the Mantilla of 1771, contains about two hundred and thirty species.

Mr. Pennant, in his "Synopfis of Quadrupeds," and professor Martin, in his "Elements of Natural Hislory," by including fome animals that were unknown to Linneaus, and giving the rank of species to feveral that were confidered by him as varieties, have extended the number of mammalia to two hundred and eighty-nine species. Mr. Klein, in 1751, published a new fystem of quadrupeds, intituled "Quadrup. Diplopho brevifique Hil. Natur," in which he distributes them into two orders, the firft comprehending those whole feet are terminated by one or more hoofs, and the second those which are divided, in which of these orders is subdivided into five families or classes. In his firft order he follows the general arrangement of Mr. Ray, which he has considerably improved; but in the second, by a fervile regard to a method founded on the number of toes, he has combined very opposite animals; the camel and the floth, the mole and the
Mr. Buffon, in 1756, published another system, in which he has arranged animals by the number or defect of their teeth; beginning with those that are toothless, such as the ant-eater, and ending with those that have the greatest number, such as the opossum. By this arrangement, some quadrupeds, very distant from each other in their manners, are too nearly connected. We shall lay nothing of Mr. Buffon's "History of Quadrupeds," though it contains much valuable information, because he seems to have disregarded that, fystematic arrangement. Mr. Pennant has introduced some useful alterations in his "History of Quadrupeds;" this ingenious naturalist has followed Mr. Ray in his greater division of animals into bovied and digitated; but, after the manner of Mr. Klein, he has formed separate genera of the rhinoceros, hippopotamus, tapir, and musk. The apes are continued in the rank in which Mr. Ray placed them, and are followed by the mausoeus. The carnivorous animals are arranged according to the system of Linnaeus, omitting the seal, mole, shrew, and hedge-hog. The herbivorous or frugivorous quadrupeds occupy the class assigned to them by Mr. Ray, to which he has allotted likewise the shrews, the mole, and the hedge-hog. The fourth section of digitated quadrupeds confides of those which are absolutely destitute of cutting teeth, such as the sloth and armadillo. The fifth section is formed of those which are destitute of teeth of every kind, such as the manis and ant-eater. The third and fourth orders or divisions which Mr. Pennant has added, are the pinnated and the winged quadrupeds: the first comprehends the walrus, the seals, and (in conformity to preceding writers) the manati. But these, he observes, seem as the links between the quadrupeds and the cetaceous animals. The bats are winged quadrupeds, and form the next gradation from this to the class of birds. See Pennant's Hist. of Quadrupeds, ed. 8vo. 1781. Preface. See Classification.

Quadrupeds, Alated. Among the many fabulous things with which natural history has been loaded, stories of flying quadrupeds seem to claim a very high rank; the griffon, the quadruped dragon, and a great many other imaginary animals, having been introduced so seriously among the descriptions of real animals, that too many have been taught to believe them. Schenck, in his "Phyfica Sacra Jobi," has done much toward disconfounding such relations; and Hyacinthus Gemma, who has written expressly "De Fabulis Animalibus," has added much on the same occasion; yet all is not done. The world have late histories of lemmas and baiflifs, which never existed but in the imagination of the relator, or in the futile contrivance of the fabricator; as is evidently the case in the baiflifs which we find in the museums of the curious, and which are all made out of the ray-fifth. And the generality of readers are so fond of any thing that is marvellous, that these things are sure to be remembered, while perhaps all the truths in the book are forgotten.

Upon the whole, the standard of the flying or alated quadrupeds seems to be properly enough reducible to this: that the words flying and alated are not synonymous terms, and that there are three kinds of flying among the quadruped clafs: the first absolute and swift, flying as perfect as in birds; this peculiarly belongs to the bat; which is the only alated or winged quadrupod, properly speaking.

2. An imperfect flying by means of certain membranes serving as wings, but imperfectly, and not turning quick, or enduring long flights: such is the flying of the lizard, which is not properly an alated animal. And lately, the imperfect flying of the squirrel kind, which even in that species, by way of eminence, the flying squirrel, is not properly flying, but only long leaping: the creature being able to turn but very little out of a right line, and only to suspend itself during a short time in a leap from a high place to a lower. Phil. Trans. N. 247. p. 34.

Quadrupeds, in Agriculture, all such animals as walk on four legs, and are of the domestic kind, as horses, neat cattle, sheep, swine, and many other forts, which are beneficial either for the purposes of working, fattening, or in any other way. Some animals of this nature are disposed of for one of these purposes in preference to others; while others are capable of being made to serve more than one of them. Thus, horses of the lighter and more active kind are adapted to the plough, and some forts of road work, and those of the more heavy fort to all descriptions of team work in the field or other places. And next cattle of the ox kind, in the least heavy breeds, as the Devonshire, Herefordshire, and some others, are well suited to team labour as well as fattening; while those of the more heavy forts, as the Lancashire breed, or long hores, &c. are better calculated for feeding only. Among sheep, some breeds are valuable for their mutton as well as their wool; some for the former, or latter, of these articles only; and others again for their ready disposition in taking on fleec. In swine, some breeds are much better formed than others; require much less food, in proportion to their sizes, in keeping and fattening, and are more disposed to feed, &c.

The fame is likewise the cafe with some other animals of this description, which should constantly be taken into the account in feeding and choosing them for the use of the farmer.

Quadrupeds of all sorts, should also, in all cafes, he well adapted in their numbers, nature, and kinds, to the qualities of the lands as farms, their extents, and the quantities of labour to be performed upon them, as much in the success of farming depends on this being properly done. They should likewise be constantly well kept and in proper condition, according to the different intentions for which they are designed, as badly fed or half-starved animals never answer any good purpose for the farmer, they always requiring a much larger proportion of food for rearing or bringing them again into proper order and for fattening them, than would otherwise have been necessary; and they never ultimately turn out so well, or produce so much advantage, as might have been the cafe under other circumstances. And, in labouring animals, where this is the cafe, they are never capable of performing nearly so much work, in conformance of which a vaft continual los is fubfained, though scarcely perceived. See Live-Stock, and Team.

Quadruplatores, among the Romans, were formers, who had the fourth part of the confiscated goods for their pains.

Quadruple, a sum or number multiplied by four, or taken four times.

Quadruple is particularly used for a gold coin, worth four times as much as that of which it is the quadruple.

The quadruple of the Spanish pitole is a piece of four pifoles, called also the double doubloon.

The quadruple of the louis d'or is a piece of gold coined in the reign of Louis XIII. in 1641. The legend on one side is CHRISTUS VINCIT, REGNAT, IMPERAT; and on the middle of this side it has a crofs with four crowns, and en- can toned in four fleurs-de-lis; on the other side it has the legend, LUDOVICUS DECIMUS TERTIUS DEI GRATIA FRANCO- RUM REX, with the head of Louis XIII. Its value under this king was twenty livres.

Quadruple Groche, in French Muffe, is a note with four hooks or four ties, one degree quicker than our demi-semiquaver,
QUA

feniquaver, and for which we have no name. The term
raab, in French a quaver, is not derived from crochet, but
from the tail being crooked. And why our crochet, with a
straight tail, has its name, is a whimsical absurdity, for which
we are unable to account.

QUELA, in Pleading, is used to supply the want of
a traverse. (2 Litt. Abs. 405.) In a clausum frigat
such a day, the defendant pleads the plaintiff's libence
to him to enter on the same day, and that vice versa he entered;
he need not say, que el cadem transgredi.

QUELA Plura, a writ that anciently lay where inquisition
had been made by an escheator, of such lands or tenements
as any man died seised of, and all was supposed not to
be found by the office or inquisition.

This writ was to inquire what more lands or tenements
the parties died seised of. But it is now made ufeles, by
taking away the courts of wards and offices post mortem.

QUIR. See Pers quaerita.

QUERENS non inventi peccatum, a return made by
the sheriff upon a writ directed to him with this clause, in
v. Si A. accuserit B. secumur de clamoribus pro suo profugendo, &c.
F. N. B. 38.

QUAERENS, in Geography, a town of Norway; 55
miles N. of Romfal.

QUESTA, in our Ancient Writers, denotes an indulgence,
or remission of penance, exposed to sale by the
popes.

QUESTIONARII, in our Ancient Law Books, were
people who went about with indulgences from door to door,
defining charity either for themselves or others.

Matt. Well observes, 1240, that the king, "Terram fuan
per papae quminarios, depauperari, &c. permitit."

QUESTOR. See Questor.

QUESTUS, in Laws, is that eflate, or those effects,
which a man hath by acquisition or purchase; in contradifion
to hereditas, which is what he hath by descent. See
Acquirt, and Goods.

Glanv. lib. vii. "aut habet hereditatum tantum, vel
quemquam, aut hereditatem & quemam."

QUAG, in Agriculture, a name given to any fort of wet,
wampy, moras, or boggy situation in land, which has a
tremulous or shaking feel under the foot, and which
produces nothing but a coarse grasy herbage that is unfit
for the food of animals. Low as well as high grounds are sub-
ject to spots of this kind where water is confined and ret-
tained near the surface. They are to be removed by proper
means of draining, and the application of solid earthy matters
of different kinds upon the surfaces of them, with the ufe
of rollers in order to consolidate the whole. See Bog and
Swamp.

QUAGGA, in Zoology. See Equus.

QUAGLIATI, PAOLO, in Biography, the music-maker
of the celebrated traveller, Pietro della Valle, at Rome, in
the beginning of the 17th century. His disciple, della
Valle, says, that he was an excellent maestro di cappella,
who introduced a new species of music into the Roman
churches, not only in compositions for a fingle voice (mono-
dio), but for two, three, or four, and very often more voices,
in chorus, ending with a numerous crowd of many choirs or
chorusles, finging together; specimens of which may be seen
in many of his motets that have been fince printed.
And the music of my ear, or moveable-flage, composed
by the fame Quagliati, in my own room, chiefly in the man-
ner he found most agreeable to me, and performed in walks
through the streets of Rome during the carnival of 1696,
was the first attempt at an opera, or fucular drama in music,
which had been heard in that city." See Opera, Reci-
tative, and Pietro della Valle.

QUAGMIRE, in Agriculture, the name of a fort of soft
merry flaeking or quaking bog, swamp, or moras, which is fre-
quently and commonly met with in low hollow situations,
where there is none, or very little decant, for the discharge
of the flagnant water or wetnesses. They are formed in
many different ways according to the nature of the circum-
stances which first gave rise to them, and of that of the places
in which they are found. The author of the "Treatise on
Landed Property" has remarked, that besides the common
moory quagmires or bogs, there is a species which is con-
stantly charged with moisture, yet does not accumulate a
thick covering of moory earth, owing probably, it is sup-
pofed, to the want of fertility in the water by which it
fed. These forts of quagmires are, in his opinion, for the
moll part, found in mountainous and hilly situations. Other
kinds are occasionally seen on large peat mofts, and hollow
meadows, in spots where the water is confined and kept
up nearly to their upper parts, and where there is much
decay of vegetable production on their surfaces, and the
reception of earthly materials from other places. These
quagmires occupy large spots of ground in many different
situations, and are, of course, a great loss to individuals
and the public, as little or nothing of any ufe is ever pro-
duced by them. (See Morass.) They are, for the most
part, capable of being readily drained by proper means,
a fort of improvement which ought never to be neglected
where it can be performed with any chance of success.

QUAHU, in Geography, a district of Africa, on the
Gold Coast, in the kingdom of Accambo, or Aquambo;
which fee.

QUAHVITLA, in Botany, a name used by some au-
thors for the tree from which the resin commonly called gun
copal is procured.

QUAICHA, in Geography, a town of Africa, in Sen-
nar; 38 miles E.S.E. of Gischam.

QUAIL, Coturnix, or Tetrao coturnix of Linnaeus, in
Ornithology, the leaf of all the birds of the gallinaceous kind.
They have, however, the genius of the cock kind, and may
be bred to fight like our game cocks.

This was an old custom among the Athenians, and is still
kept up in some parts of Italy, and in Afa.

Quails are birds of paflage, some entirely quitting our
island, others shifting their quarters from one county to an-
other, and sheltering themselves among the weeds near the
sea-fide; with us they frequent the corn-fields, and some-
times the meadows. They begin to finge in April, and make
their nests in the month of May, building on the ground,
and seldom lay more than from five or seven whitifh eggs,
marked with ragged earth-coloured spots.

Quails are to be taken by means of the call during their
whole whole winter time, which lasts from April to Augulf.
The proper times for using the call are at fun-rising, at nine
o'clock in the morning, at three in the afternoon, and
at fun-set; for these are the natural times of the quail's call-
ing. The notes of the cock and hen-quail are very different,
and the sportsman who expects to succed in the taking of
them, must be expert in both; for when the cock calls, the
answer is to be made in the hen's note; and when the hen
calls, the answer is to be made in the cock's. By this
means they will come up to the person, so that he may, with
great ease, throw the net over them, and take them. If a
cock-quail be finge, on hearing the hen's note he will imme-
diately come; but if he have a hen already with him, he
will not forfake her. Sometimes, though only one quail
answers to the call, there will three or four come up; and
and then it is best to have patience, and not run to take up the first, but stay till they are all entangled, as they will soon be.

The quail is a neat cleanly bird, and will not run much into dirty or wet places: in dewy mornings they will often fly instead of running to the call; and in this case, it is best to let them go over the net, if it so happens that they fly higher than its top, and the sportsman then changing sides, and calling again, the bird will come back, and then will probably be taken in the net.

The calls are to be made of a small leather pursé, about two fingers wide, and four fingers long, and made in the shape of a pear; this is to be stuffed half full of feathers and at the end of it is to be placed a small whistle, made of the bone of a rabbit's leg, or some other such bone; this is to be about two inches long, and the end formed like a flageolet, with a little soft wax. This is to be the end fastened into the pursé; the other is to be closed up with the same wax, only that a hole is to be opened with a pin, to make it give a distinct and clear sound. To make this sound, it is to be held full in the palm of the hand, with one of the fingers placed over the top of the wax: then the pursé is to be pressed, and the finger is to shake over the middle of it, to modulate the sound it gives into a fort of thake. This is the most useful call; for it imitates the note of the hen-quail, and seldom fails to bring a cock to the net, if there be one near the place.

The call that imitates the note of the cock, and is used to bring the hen to him, is to be about four inches long, and above an inch thick; it is to be made of a piece of wire, turned round and curled, and covered with leather; and one end of it must be closed up with a piece of flat wood, about the middle of which there must be a small thread or strip of leather, and at the other end is to be placed the same sort of pipe, made of bone, as is used in the other call. The noise is made by opening and closing the spiral, and gives the same sound that the cock does when he gives the hen a signal that he is near her.

Quakers, in Ecclesiastical History, the common denomination of a society of Christians, who appeared first in England about the middle of the seventeenth century, and who continue to be distinguished from others by peculiar tenets and practices. They call themselves Friends. They are remarkable for affecting the continuance, to the present time, of immediate revelation, or the communication of divine instruction to the mind, by the testimony of the spirit of God. This revelation they affirm to be necessary for the production of true faith, and that it neither does nor can contradict the outward testimony of the scriptures, or right and found reason. Their doctrine on this subject has been often misunderstood, even by theological writers; and they have in consequence been subjected to much obloquy. It is, however, the principal feature in that peculiar view of Christianity, which has occasioned their separation from other churches.

Origin and History.—Before the period above mentioned, many serious persons, satisfied with none of the modes of religion which the reformation brought forth, had withdrawn from the communion of every visible church, to cultivate in retirement, impressions which they attributed to the operation of the spirit of Christ on their own minds: it is chiefly from such, when brought to recognize each other by the ministry of an individual, that the Quakers consider their society to have been originally gathered. George Fox, the individual in question, was born in 1624. He has left a journal of his own life, written with a simplicity of style, which proves that he has fairly laid open his own character. In this work, the peculiar principles of Quakerism may be satisfactorily explored in their early beginnings, which it may be worth while briefly to review. Fox's parents, who were pious members of the church of England, had intended him for the priesthood, his character affording very early promise of fitness for religious service; but others perceiving to the contrary, he was put under a matter to a country business. Being engaged herein at a fair, when about the age of nineteen, a cousin of his, with another professor of religion, attempted to engage him in drinking to intoxication. "The Lord had shown me," says George, "that I might not eat or drink to make myself wanton, but for health, using the creatures in their service, as servants in their places, to the glory of Him who created them."

Accordingly, on perceiving the design of his companions, he rose up; paid for the refreshment they had had, and departed, with emotions of virtuous indignation. Returning home, he paced a sleepless night, walking up and down, and crying to the Lord; who, he affirms, said unto him, "Thou feest how young people go together into vanity, and old people into the earth; thou must for sake all, young and old, keep out of all, and be as a stranger unto all." The reader will understand this, and generally all revelations professed to have been received by Quakers, as confounding not in an outward voice, but in an internal communication to the mind. Taking the command literally, he detached himself from his connexions; and having some property of his own whereon to subsist, removed from place to place, observing the religion and professors of the age, without engaging in close fellowship with any. He devoted much of his time to fasting, solitary prayer, and reading the bible.

He became at length quite detached in his affections from the world, distrait at the spiritual condition of his fellow men, and in much anxiety, bordering on despair, about his own; yet was not without intervals of heavenly joy and comfort. Such a state of mind naturally led him to seek for spiritual counsel from others, and he had conferences with many of the clergy, beginning with his own parish priest. In answer to a question from the latter, we find him professing faith in Christ, who, by his death as man, (for he died not as he was God,) became an offering for the sins of the whole world. The general result of these conferences was, however, unsatisfactory to him; "for," he observes, "they could not reach my condition." Pursuing, therefore, his meditations on the subject as before, he came to be satisfied respecting several propositions which it involved, such as the following:—that although it was said that all Christians are believers, both Protestants and Papists, yet that none were truly such, but those who were born of God, and who had palled from death unto life. Again, that to be bred at Oxford or Cambridge, was not enough to fit and qualify men to be ministers of Christ. At this he wondered, because it was the common belief that such qualification was sufficient. "At another time," he says, "it was opened to me, that God, who made the world, did not dwell in temples made with hands. This at first seemed strange, because both priests and people used to call their temples or churches dreadful places, holy ground, and the temples of God; but the Lord showed me clearly that he did not dwell in those temples, which men had commanded and set up, but in people's hearts." George Fox now ceased to attend the established preachers; at which his relations being offended, he shewed them from the scriptures, "that there was an anointing within man to teach him, and that the Lord would teach his people himself."
QUAKERS.

Observing, as he thought, more of the fruits of this internal teaching among the "diligent people," he went for a while among them; but, he continues, "as I had forborne the preachers, so I left the separate preachers also, and those called the most experienced people; for I saw there was none among them all that could speak to my condition. And when all my hopes in them, and in all men, were gone, so that I had nothing outwardly to help me, nor could tell what to do, then, I then, I heard a voice, which said, 'There is One, even Christ Jesus, that can speak to thy condition.' When I heard it my heart did leap for joy. Then the Lord let me see why there was none that could speak to my condition, namely, that I might give him all the glory. For all (he continues, alluding to Rom. xi. 32.) are concluded under sin, and shut up in unbelief, as I had been, that Jesus Christ might have the pre-eminenence, who enlightens and gives grace, faith, and power."

The preceding is a specimen of Fox's own account of the manner in which the doctrine he afterwards preached arose in his mind. The reader will perceive that he refers all his real edification to the means which have been already indicated, immediate revelation. He says, "though I read the scriptures, that spoke of Christ, and of God, yet I knew Him not but by revelation, as he who hath the key did open, and as the Father of life drew me to his Son by his Spirit." Yet that he was sensible of the importance of the holy scriptures, as the source from whence, under this influence, Christian instruction must be drawn, is evident, both from his declaration that they were very precious to him, and from his having incessantly used, and continually appealed to them, both before and after beginning to promulgate his system.

Having at length attained to a view of Christianity in which he found peace of mind, he believed himself required and divinely commissioned to become a teacher of it to others: and from the year 1647, the reader may conceive him always engaged in this office. He travelled as before, preaching first to small companies of enquiring persons, then to public congregations, such as upon his appearance among them were willing to hear him, and at length to large assemblies of people, convened on purpose. This he did with the courage and perseverance of a reformer; in the face of opposition from the national and diocesan preachers, of frequent personal abuse from their hearers, and occasional severe treatment by the magistrates. In most places where he came, he met with persons who received his doctrines, a proportion of whom, after associating with him for a time, became imprest with the like apprehensions of duty to propagate their principles; which they attempted by similar methods. Thus, although interrupted at different periods by imprisonment, he found himself, before many years had elapsed, in connection with a numerous band of fellow-labourers, and a widely diffused and respectable society of religious friends. No inconsiderable number of these quitted, for the sake of their principles, livings in the church, commissions in the army, or seats as magistrates.

When we consider that this happened in an age equally remarkable for religious zeal and political turbulence, it will appear that some deviations from Christian propriety, some fruits of the mixture of imagination with good intentions, could scarcely fail to be exhibited among them. If the new society, from a regard to its principle of internal impulses to particular duties, was slow to condemn thefe, it was careful, on the other hand, not to engratify them, by imitation on its practice. Individuals, therefore, were alone responsible for such acts, and the general conduct of the members, from the period of their first associating together, was found in no mean degree conformable to the morality of the gospel.

The most serious instance of misconduct occurred in the case of James Nayler and his followers. This fell out in 1656. and was magnified beyond its real importance by being suffered to occupy for ten days the attention of parliament. Nayler had been an Independent, and a quarter-master of horse under major-general Lambert. He was one of George Fox's earliest converts, and for some years an able preacher and disputant in the same cause. Coming to London, he found a set of people who extolled him in his office above measure. His friends, and George Fox among the rest, seeing his danger, gave him suitable cautions; but flying thence, he became exposed to the flatteries of a train of followers, chiefly women, whom he suffered, at length, from a delusive notion of its being done to Christ in him, to address him with the name and titles of the Saviour, and with acts amounting to worship. In particular, his entrance into Bristol was conducted, by these intimated people, in imitation of the procession of Christ into Jerusalem. The parties implicated in this transaction were committed to prison; but Nayler alone was elected by parliament, after examination and long debates on his cafe, for punishment as a blasphemer. Cromwell kept aloof from the proceedings, which, by their excessive severity, moved great commotion in the public. The culprit was twice scourged through the streets, twice pilloried, branded in the forehead, and bored through the tongue with a hot iron; all which he endured with surprizing patience and fortitude.

His punishment ended with two years' close imprisonment in Bridewell, during which he attained to repentance, and a founder mind. Having given proof of this by several public confessions, the Quakers, who had disowned both him and his followers, received him back into their communion, in which he lived circumspectly the short remainder of his life.

Quakerism prevailed at first chiefly in the northern counties; but many preachers having risen up here, who travelled in different directions, it was not long in spreading to the metropolis, and the remoter southern and western parts. Wherever its professors appeared, the ordeal of suffering awaited them; for which their negative tenets commonly furnished the occasion. They refused to the priests every kind of payment, to the government military service, to the magistrate's oaths, and to all persons the customary, and at that time much looked for worship, of kneeling or bowing with the head uncovered. They adhered too, in every instance, to their northern English of thou and thee, judging the plural mode of addressing one person to have originated, together with all empty titles, in a spirit of flattery unbefitting Christian. These peculiarities were a check to superficial conversions; since an upright conformity to the profession was in most cafes purchased by the loss of friends, contempt, and hardships. Even the privilege of meeting to worship, apart from the national congregations, was acquired only by persevering in the practice, through almost every kind and degree of coercive obstruton, down to the period of complete toleration, the revolution of 1688. Hence their history confits in great part of a detail of buffettings, imprisonments, and spoiling of goods. So early as 1639 they flated to parliament, that in the preceding six years about two thousand individuals had suffered in prison and exile, for being Quakers: and this representation was accompanied by one of the most extraordinary public acts on record. One hundred and sixty four Friends offered themselves by name to the house, to be imprisoned in the places of an equal number, who from sickness or the hardships...
ships of their confinement, were conceived to be in danger of perishing. The house, however, rejected this proposal, and expressed some displeasure at "the reflections on magistracy and ministry," said to be contained in the memorial. It will be proper to give some particular instances of their sufferings.

James Parnell, a youth of good parts and education, going to see George Fox in a dungeon at Carlisle, became a convert to his principles: and, preaching in Erex, was the means of rousing many congregations of Quakers in that county. He was imprisoned in Colchester castle, and at the age of nineteen under the cruel treatment there inflicted on him. In 1656, two Quaker women arrived at Boston, New England. They were apprehended 'ere they could land, committed to close prison, and searched in a brutal manner, by flapping them naked, lest they might also be "slices"; an object to the colonists of equal and equally rational dread. These two, with eight others who arrived afterwards, were forcibly sent away: but the precaution was in vain, their principles entered the colony. An aged citizen, and church member of Boston, was first found favourably inclined to them; he was fined, imprisoned, and banished in the depth of winter. In Rhode Island he was hospitably received by an Indian chief, who offered, if he would live with him, "to make him a warm house;" observing, "What a God have the English who deal so with one another about their God?" So far is intolerance from recommending the religion of those who practice it. Penal laws against Quakerism soon followed the appearance of this people in New England. The scourge was first applied, without regard to age or sex: mutilation, by cutting off the ears, followed: but these being found insufficient, cruelty proceeded through another intermediate step, banishment on pain of death, to its dreadful extreme; and four Quakers were hanged at Boston. Their names were William Robinson, Marmaduke Stevenon, William Leddra, and Mary Dyar. Their cases, as related by Sewel, in his "History of the Quakers," form an interesting piece of martyrology.

Charles II., on notice of these proceedings, granted a mandamus, which prevented further executions in the colonies; but he was not equally ready to reinstate persecution at home. The Quakers had several meeting houses in London. When assembled at these, they were often disturbed by soldiers, under the direction of the magistrates; these effected their purpose by severe beatings with their arms. One John Trowel being evidently mortally wounded in this way, a coroner's inquest was held, but the verdict of the jury was suppressed: and the king, on being informed of the facts, evaded interference, telling the complainants to prosecute the law against the soldiers! Similar proceedings took place at Colchester; where the congregation, being kept out of their house, met for many weeks in winter standing in the street. Here they were assailed by soldiers on horseback, who wounded many of them, and a man of seventy lost his life in consequence. On one of these occasions a soldier's sword, by violent ufage, came out of the hilt. The man he had been beating handed it up to him with these words, "I dare the Lord may not lay this day's work to thy charge." In this instance, as in others, the patience of the sufferers at length triumphed, and they were quietly allowed their right of meeting.

In 1665 a hundred and twenty Quakers were in Newgate, sentenced to transportation, under an act recently made "to prevent and suppress felonious conventicles." The matters of ships generally refusing to carry them, an embargo was laid, and it was made a condition of failing to the West Indies, that some Quakers should be taken thither by every vessel. A mercenary wretch being at length found for the service, the Quakers, unwilling to be active in their own banishment, refused to walk on board, as did also the seamen to hoist them in. By the help of soldiers from the Tower, fifty-five of them were at length shipped. But the matter was now in prison for debt: and the ship, after seven months' detention, quitting the coast, was immediately taken by a Dutchman, and twenty-eight of the prisoners (the remainder having died of the plague) were liberated in Holland and sent home. Other parties of Quakers were set on shore again from different vessels, so that the number actually sent to the West Indies was small.

The preceding instances may serve to shew the kind of persecution which this society endured for many years; it may be observed in conclusion, that the court (or rather the clergy) of Charles, in their eagerness to suppress the growing society, actually defended to the measure of inflicting a formal order of council for demolishing their meeting-house in Southwark, which was addressed to no less a person than Christopher Wren, esq., surveyor-general of his majesty's works; but it was executed by the military, by whom the congregation, who had the courage to meet on the ruins, were dragged on as often as they assembled, for nearly three months together, without however overcoming their firmness.

Though the Quakers never sent out missionaries, in the manner of some other societies, we have seen that individuals went, under apprehensions of religious duty, to distant parts. Several of these visited Italy, where they did not conceal their dislike of superstition; and one John Love, being detained at Rome on this account, died (as it seems a violent death) in the prison of the inquisition. Catherine Evans, and Sarah Cheever, after three years' confinement, and many sufferings in the inquisition at Malta, were released and returned to England. But the most extraordinary enterprise, in this way, was performed by Mary Fisher, a maiden, and one of the two who had been so ill treated at Bolton. She, apprehending she had a message from God to Fulton Mahomet IV., actually made her way from England to his camp before Adrianopolis, where she delivered, through his interpreter, what was on her mind, was treated with respect, and offered an escort to Constantinople, which she declined, and returned, as he had gone, alone and in perfect safety. A young man, named George Robinson, went, through still greater difficulties, to Jerusalem, where, speaking against the superstition of the pilgrims, the friars persuaded him to be forced into a mosque, whence the Turks, on his refusing to turn Mahometan, led him out to be put to death, as for wilfully violating the place: but a sudden change taking place in their sentiments concerning him, he also was permitted to return.

In 1666 the Quakers held their first general meeting, for the care of their poor and other concerns of the society, at Skipton in Yorkshire; within a few years after which, meetings for discipline were established throughout England and Ireland, chiefly by the incautious personal labours and epistolary recommendations of George Fox. At this period the society received a considerable accession of respectability by the conversion of William Penn and Robert Barclay. The celebrated Apology of the latter gave the world an opportunity of fairly appreciating doctrines till then but partially known, and on this account the more decried: and the settlement of the Jerseys, and subsequentially, of Pennsylvanian, under the auspices of Penn, opened to the Quakers a new and promising field of increase, which they did not fail speedily to occupy. Another peril of con-
QUAKERS.

Credible learning, George Keith, after associating with them for near thirty years, became the author of a fchism, the circumstances of which it will be proper to notice. Keith was a native of Scotland, and educated at Aberdeen; he was imprisoned, as a Quaker, in 1664, and in 1675 assisted Barclay in a public difputation againft the students at Aberdeen; he wrote much in defence of the principles of the Quakers, which he thoroughly understood, and was employed in the education of their youth; but is thought by them to have indulged too much in curious and ufeful speculations, which his brethren did not encourage. Being again repeatedly imprisoned, about 1684, he removed to America in difgrace. Here, after some previous general cenfure of his friends, he accused several, in particular, of gross error in doctrine; the pretext for which was, their holding (as he himself had done) that the knowledge and belief of the history of Chrift is not neceffary for the salvation of thofe who have no poffible means of acquiring it. His complaints againft individuals leading to more general cenfure, the Friends in England interfered, and the parties were heard before the yearly meeting in London, which decided the caufe againft Keith, and he remained under the "difownment" pronounced againft him in America. He now set up a feparate Quakers' meeting in London, attacked the principles he had formerly defended, (on which occasions the Quakers replied by quotations from his own works,) and finally entered into the church of England. He was foon after ordained priet, and made a millionaiy to America, to bring over his former brethren. But his efforts, though for a while troublefome to the Quakers, were attended with very little succefs; he returned to England, funk into obscurity on a small living in Suflefs, and his party gradually disappeared.

The jeopardy in which the Quakers almost conftantly flood on account of their principles, very early introduced them to an immediate intercourse with the throne; and they thus acquired the privilege, which they fill exercise, of prefent- ing public addresses to the king, by a deputation from their body, in a manner which does not violate their confequences fcruples. The accession of a new sovereignt, the conclusion of a peace, or an impending war, have commonly been drawn from them addresses, in which sentiments not unworthy of their Chriftian profession, are conveyed in fimple but re- fpeftful language. And very recently (1814,) they availed themfelves of the prefece in this country of the emperor of Russia, and the king of Prufia, to address each of their monarchs in favour of a perfect toleration in their re- fpective dominions; in which they met with a favourable reception. Another great and interesting object, the abolition of the slave trade, has fuddenly brought them forward to government in this way. In the caufe of humanity, as it regards the opprefled Africans, they have proved themfelves ftrong and indefatigable: the reproach, even of holding a fellow man in slavery, was wiped away from the members of this fociety many years before the abolition of the trade was decreed, either in England or America. This was ef- fected by their discipline; and it was made a part of this, in confequence of that view of Chriftianity, which regards every individual of the human race as a fit object of its benefits, and as entitled to the charitable regard which it incalculates. Much was done on the Negroes' behalf, in America, by Anthony Benezet, whose character is well known to the world; and by John Woolman, a minifter of the fociety, whose writings difcover a mind of uncommon purity, simplicitv, and tendernefs.

The Quakers as a body have been long relieved from actual perfecution; yet they are fuil involved by their principles in occasional trouble as individuals. The refufal to bear arms, or to pay military fines, subjects them to legal diftrait on their goods, and if none of these be found, to improprefion. Tithes and other ecclefeal claims, enforced upon them, likewise render diftrait a very common, and fometines an oppreflive occurrence; and if the profeétor be more rigorous, they may be imprisoned for an indefinite time. In America they are exempt from ecclefeal but not from military defigures; by which, during the war for independence, many of them were impoverifhed. It is obvious that, refusing to swear, they cannot fill any office of profit or trust under government. Except for these purpofes however, for serving on juries, and in cafes of criminal prosecution, their folemn afurance before the magiftrate has the legal force of an oath.

The Quakers are dispersed over the united kingdom, and most of the fates of North America; from the southern fates of the latter they have mostly emigrated of late to the Ohio. In America they are chiefly engaged in agriculture; and for a series of years have been making judicious and fuccesful efforts to introduce this, with the other arts, and the manners of civilized life, among the Indian natives. There are a few Quakers in Germany, and their principles are entertained by fome perfons in France.

In this country they are found chiefly in the middle clafs of citizens, and in trade or manufacture. Their general dif- rellition of agriculture feme to have refulted from the im- pediments offered by the tithing fystem: a yoke which, under their fcruple, becomes doubly heavy on the farmer. There is a greater approach to equality in the civil condition of the Quakers, than obtains in almof any other body: the children of fuch as become very rich are apt to quit the fociety, either by marrying perfons not in its communion, or for the fake of liberties which it prohibits: and the children of the poor commonly get a plain but folid education, fuperior to their condition, by means of which they rife in civil fociety to a higher level. They have feveral excellent eftablifhments for this purpofe: the principal of which, fituated at Ackworth in Yorkshire, contains, of both sexes, three hundred children, and was founded in 1778, at the infiance of Dr. Pothergill. With provision for mathematical and claffical learning, the Quakers, though they have fome good private fchools, are yet flanderly furnished; and they have in confequence few accomplished men in these branches. They are by no means deficient in general information, and of late years many of them have cultivated natural philofophy with fuccefs. The fociety in its earlier stage, including many men of regular fcholafhic education, who had joined it on principle, had of confequence the advantage, in point of theological knowledge, over the modern Friends, who chiefly inherit their profeflion, and whose education has but of late begun to include fystematic instruction in the doctrines of Chriftianity at large.

In morals they are allowed to excel: their youth is watched over in this respect with more than ordinary care; and when grown up, their discipline prohibits, to all conditions, those amufements which refer to the mind the ready means of dilipating ferious impreffions. Habitual offenders againft their peculiar regulations forfeit their membership, as well as thofe who violate the more obvious rules of juftice and morality: their moral character, and confiftency as a body, are thus kept up. But it is alleged, that they are not equally well guarded againft a money-getting spirit; which is apt to grow upon thofe who intently preferue trade and commerce to the exclusion of all other pursuitis. From the occasional tenor of the fociety's advices to its members, it shoud seem that this is in a certain degree true; and that it

behaves
behaves them to seek for an adequate remedy. They are not, however, chargeable with the love of money for its own sake; no class of men being more beneficent, or more prompt to contribute their time and substance to various public institutions, which the spirit of the Christian religion has at length roused up, for relieving the distressed, promoting the comforts, and improving the moral and religious condition of mankind.

As to the minuter features of their character, the Quakers are prudent and methodical in their business; generally good economists of time and money. Their conversation has many peculiarities; some of which flow from their principles, others merely from their associating chiefly among themselves. They were early thought to be habitually crafty ("the Quaker fly," says Pope); but there seems no other ground for this, than the extreme caution with which they incur engagements, or make prophecies and promises. Viewed at a distance, they appear cold, formal, and reserved in their manners; and have been unjustly concluded void of domestic cheerfulnes, and incapable of the enjoyments arising from social converse, and the intercourse of cultivated minds. They are plain in their dress; the peculiarities observable in which result, not from any regulations on the subject, but from an indigitation to vary with the fashion; they have, however, slowly followed changes which have proved general and permanent, and thus become less conspicuously singular. Mourning habits they reject on principle: and with a people whole ordinary dress is so grave, the moral reason for them seems not to exist. They are averse to splendour in furniture and equipage: though the rich among them, in these articles, and most of their females in drefs, have contrived, without ceasing to be known as Quakers, to refine considerably upon absolute simplicity.

Doctrine.—A recent publication on behalf of the society, entitled, "A Summary of the History, Doctrine, and Discipline of Friends," ascribed to one of the society, held in high estimation, viz. Mr. J. G. Bevan, who died while this article was in the press, states their doctrine as follows:

"We agree with other professors of the Christian name, in the belief of one eternal God, the creator and preserver of the universe; and in Jesus Christ his Son, the Messiah, and mediator of the new covenant.

"When we speak of the gracious display of the love of God to mankind, in the miraculous conception, birth, life, miracles, death, resurrection, and ascension of our Saviour, we prefer the use of such terms as we find in scripture; and contented with that knowledge, which divine wisdom hath been meet to reveal, we attempt not to explain those mysteries which remain under the veil; nevertheless we acknowledge and assert the divinity of Christ, who is the wisdom and power of God unto salvation.

"To Christ alone we give the title of the Word of God, and not to the scriptures; although we highly esteem these sacred writings, in subordination to the Spirit, from which they were given forth; and we hold with the apostle Paul, that they are able to make wise unto salvation, through faith which is in Christ Jesus.

"We revere those most excellent precepts, which are recorded in scripture to have been delivered by our great Lord, and we firmly believe that they are practicable and binding on every Christian; and that in the life to come every man will be rewarded according to his works. And further it is our belief, that, in order to enable mankind to put in practice these sacred precepts, many of which are contradictory to the unregenerate will of man, every man coming into the world, is endued with a measure of the light, grace, or good Spirit of Christ; by which, as it is attended to, he is enabled to distinguish good from evil, and to correct the disorderly passions and corrupt propensities of his fallen nature, which mere reason is altogether insufficient to overcome. For all that belongs to man is fallible, and within the reach of temptation; but this divine grace, which comes by Him, who hath overcome the world, is, to those who humbly and sincerely seek it, an all-sufficient and present help in time of need. By this, the snares of the enemy are detected, his allurements avoided, and deliverance is experienced through faith in its effectual operation: whereby the soul is translated out of the kingdom of darkness, and from under the power of Satan, into the marvellous light and kingdom of the Son of God.

"Being thus persuaded that man, without the spirit of Christ inwardly revealed, can do nothing to the glory of God, or to effect his own salvation; we think this influence especially necessary to the performance of the highest act of which the human mind is capable; even the worship of the Father of lights and of spirits, in spirit and in truth: therefore we consider all oppositions to public worship, all forms which divert the attention of the mind from the secret influence of this unction from the Holy One. Yet, although true worship is not confined to time and place, we think it incumbent on Christians to meet together, in testimony of their dependence on the heavenly Father, and for a renewal of their spiritual strength; thus, 'Each not only partakes of the particular refreshment and strength which comes from the good in himself, but is a share of the whole body, as being a living member of the body, having a joint fellowship and communion with all.' Barclay.

"Nevertheless, in the performance of worship, we dare not depend, for our acceptance, on a formal repetition of the words and experiences of others; but we believe it to be our duty to lay aside the activity of the imagination, and to wait in silence to have a true light of our condition bestowed upon us; believing even a single light, arising from such a tenue of our infirmities, and of the need we have of divine help, to be more acceptable to God, than any performances, however specious, which originate in the will of man. If any should object the difficulty of laying aside the activity of the imagination, let such consider the following statement—That it is our duty to maintain a watch over our thoughts, by endeavouring to preserve our attention from being carried away by such as manfully originate in our own natural will or habits, and to wait patiently for the arising of the life of Christ, which by bringing every thought into subjection, produces a true inward silence, and therein affords a true sense of our condition.

"From what has been said respecting worship, it follows that the ministry we approve must have its origin from the same source; for that which is needful for a man's own direction, and for his acceptance with God, must be eminently to enable him to be helpful to others. Accordingly we believe, that the renewed affiance of the light and power of Christ is indispensably necessary for all true ministry; and that this holy influence is not at our command, or to be procured by study, but is the free gift of God to chosen and devoted servants. Hence arises our testimony against preaching for hire, in contradiction to Christ's positive command, 'Freely ye have received, freely give,' and hence our conscientious refuial to support such ministry, by tithes or other means.

"As we dare not encourage any ministry, but that which we believe to spring from the influence of the Holy Spirit, we neither dare we attempt to restrain this ministry to persons of any condition in life, or to the male sex alone; but,
as male and female are one in Christ, we hold it proper that such of the female sex as we believe to be endued with a right qualification for the ministry, should exercise their gifts for the general edification of the church; and this liberty we esteem a peculiar mark of the gospel dispensation, as foretold by the prophet Joel, and noticed by the apostle Peter.

Three are two ceremonies in use among most professors of the Christian name, water-baptism, and what is termed the Lord's supper. The first of these is generally esteemed the essential means of initiation into the church of Christ; and the latter, of maintaining communion with him. But as we have been convinced that nothing short of his redeeming power, inwardly revealed, can set the soul free from the thraldom of sin: and this power alone we believe salvation to be effected. We hold that as there is one Lord and one baptism, so his baptism is one, in nature and operation; that nothing short of it can make us living members of his mystical body; and that the baptism with water, administered by his fore-runner John, belonged, as the latter confessed, to an inferior and decreasing dispensation.

With respect to the other rite, we believe that communion between Christ and his church is not maintained by that, or by any other external performance, but only by a real participation of his divine nature through faith: that this is the supper alluded to in the Revelation; Behold I stand at the door and knock: if any man hear my voice, and open the door, I will come in to him, and will sup with him, and he with me, and that where the substance is attained, it is unnecessary to attend to the shadow: which doth not confer grace, and concerning which, opinions so different, and animosities so violent, have arisen.

Now, as we thus believe that the grace of God, which comes by Jesus Christ, is alone sufficient for salvation, we can neither admit that it is conferred on a few only, while others are left without it; nor, thus affrighting its universality, can we limit its operation to a partial cleansing of the soul from sin, even in this life. We entertain worthy notions both of the power and goodness of our heavenly Father, and believe that he doth vouchsafe to afflict the obedient to experience a total surrender of the natural will, to the guidance of his pure unerring Spirit: through whose renewed affixture they are enabled to bring forth fruits unto holiness, and to stand perfect in their present rank.

There are not many of our tenets more generally known than our testimony against oaths, and against war. With respect to the former of these, we abide literally by Christ's positive injunction, delivered in his sermon on the mount, 'Swear not at all.' From the same sacred collection of the most excellent precepts of moral and religious duty, from the example of our Lord himself, and from the correspondent convictions of his Spirit in our hearts, we are confirmed in the belief that wars and fightings are, in their origin and effects, utterly repugnant to the gospel; which still breathes peace and good-will to men. We also are clearly of the judgment, that if the benevolence of the gospel were generally prevalent in the minds of men, it would effectually prevent them from oppressing, much more from enslaving, their brethren (of whatever colour or complexion), for whom, as for themselves, Christ died; and would even influence their conduct in their treatment of the brute creation, which would no longer groan, the victims of their savor, or of their false ideas of pleasure.

Some of our tenets have in former times, as hath been shewn, subjected our Friends to much suffering from government; though to the falterere principles of government, our principles are a security. They inculcate submission to the laws, in all cases wherein conscience is not violated. But we hold, that as Christ's kingdom is not of this world, it is not the business of the civil magistrate to interfere in matters of religion, but to maintain the external peace and good order of the community. We therefore think perfection, even in the smallest degree, unwarrantable. We are careful in requiring our members not to be concerned in illicit trade, nor in any manner to defraud the revenue.

It is well known that the society, from its first appearance, has diffused those names of the months and days, which having been given in honour of the heroes or false gods of the heathen, originated in their flattery or superstitious; and also the custom of speaking in a jargon in the plural number, as having likewise arisen from motives of adulation. Compliments, superfluity of apparel, of furniture, and of provision for the table, outward shows of rejoicing and mourning, and the obsequies of days and times, we esteem to be incompatible with the simplicity of a Christian life; and public diversions, gaming, and other vain amusements of the world, we cannot but condemn. They are a waste of that time which is given us for nobler purposes; and divert the attention of the mind from the sober duties of life, and from the reproofs of instruction, by which we are guided to an everlasting inheritance.

To conclude, although we have exhibited the several tenets which distinguish our religious society, as objects of our belief; yet we are sensible that a true and living faith is not produced in the mind of man by his own effort; but is the free gift of God in Christ Jesus, nourished and increased by the protracted operation of the Holy Spirit in our hearts, and our proportionate obedience. Therefore, although for the preservation of the testimonies given us to bear, and for the peace and good order of the society, we deem it necessary that those who are admitted into membership with us, should be previously convinced of those doctrines which we esteem essential; yet we require no formal subscription to any articles, either as a condition of membership, or a qualification for the service of the church. We prefer judging of men by their fruits, and depending on the aid of Him who, by his prophet, hath promised to be for a spirit of judgment to him that heareth in judgment. Without this, there is a danger of receiving numbers into outward communion, without any addition to that spiritual sheep-fold, whereof our bled Lord declared himself to be both the door and the shepherd; that is, such as know his voice, and follow him in the paths of obedience.

To this statement may be added the following extracts, the first of which is from a declaration issued on behalf of the society in 1693.

We sincerely profess faith in God by his only-begotten Son Jesus Christ, as being our light and life, our only way to the Father, and also our only Mediator and Advocate with the Father:—that God created all things, he made the worlds, by his Son Jesus Christ, he being that powerful and living Word of God by whom all things were made; and that the Father, the Word, and the Holy Spirit, are One, in divine Being inseparable; One true, living, and eternal God blessed for ever;—yet that this Word or Son of God, in the fulness of time, took flesh, became perfect Man, according to the flesh descended and came of the seed of Abraham and David, but was miraculously conceived by the Holy Ghost, and born of the Virgin Mary, and also, farther, declared powerfully to be the Son of God, according to the Spirit of sanctification, by the resurrection from the dead—that, as Man, Christ died for our sins, rose again, and was received up into glory in the heavens; he having, in his dying for all, been that one, great, universal offering and sacrifice for peace, atonement, and reconciliation between God and man; and he is the propitiation.
QUAKERS.

The doctrine of the resurrection of the dead is so connected with the Christian religion, that it will be also proper to say something on this subject. In explaining our belief of this doctrine, we refer to the 15th chapter of the Epistle to the Corinthians. In this chapter (verses 46, 47, 48, 49, 50) is clearly laid down the resurrection of a body, though not of the same body that dies. Here we rest our belief in this 'mystery,' without desiring to pry into it beyond what is revealed to us; remembering that secret things belong unto the Lord our God, but those things which are revealed belong unto us and to our children. Principles of Religion, as professed by the Quakers, by Henry Tuke.

Discipline: from the "Summary," with some abridgment.—"The purposes which our discipline hath chiefly in view, are, the relief of the poor, the maintenance of good order, the support of the testimonies which we believe it is our duty to bear to the world, and the help and recovery of such as are overtaken in faults: in a few words, the promotion of piety and charity.

In the practice of discipline, we think it indispensable that the order recommended by Christ himself be invariably observed. If thy brother shall trespass against thee, go and tell him his fault between thee and him alone: if he shall hear thee, thou hast gained thy brother; but if he will not hear thee, then take with thee one or two more, that in the mouth of two or three witnesses, every word may be established; and if he shall neglect to hear them, tell it unto the church.

To effect the faithful purposes of discipline, meetings were appointed, at an early period of the society, which, from the times of their being holden, were called quarterly meetings. It was afterwards found expedient to divide the districts of those meetings, and to meet more frequently; from whence arose monthly meetings, subordinate to those held quarterly. At length, in 1660, a Yearly Meeting was established, to superintend, assist, and provide rules for the whole; previously to which general meetings had been occasionally held.

A monthly meeting is usually composed of several particular congregations, situated within a convenient distance from each other. Its business is to provide for the subsistence of the poor, and for the education of their offspring; to judge of the sincerity and fineness of persons appearing to be convinced of the religious principles of the society, and desiring to be admitted into membership; to excite due attention to the discharge of religious and moral duty; and to deal with disorderly members. Monthly meetings also grant to such of their members as remove into other monthly meetings, certificates of their membership and conduct; without which they cannot gain membership in such meetings. Each monthly meeting is required to appoint certain persons, under the name of overseers, who are to take care that the rules of their discipline be put in practice; and when any case of complaint, or disorderly conduct, comes to their knowledge, to see that private admonition, agreeably to the gospel rule before mentioned, be given, previously to its being laid before the monthly meeting.

When a case is introduced, it is usual for a small committee to be appointed, to visit the offender, to endeavour to convince him of his error, and to induce him to forswear and condemn it. If they succeed, the person is by minute declared to have made satisfaction for the offence; if not, he is divested as a member of the society.

In disputes between individuals, it has long been the decided judgment of the society, that its members should not sue each other at law. It therefore enjoins all to end their differences by speedy and impartial arbitration, agreeably to rules laid down. If any refuse to adopt this mode, or, having adopted it, to submit to the award, it is the direction of the yearly meeting that such be divested.

Weekly meetings also belong to the union of marriages; for our society hath always ered to acknowledge the exclusive authority of the priest in the solemnization of marriage. Those who intend to marry, appear together, and propose their intention to the monthly meeting; and if not attended by their parents or guardians, produce a written certificate of their consent, signed in the presence of witnesses. The meeting then appoints a committee to inquire whether they be clear of other engagements respecting marriage; and if, at a subsequent meeting, no objections be reported, they have the meeting's consent to solemnize their intended marriage. This is done in a public meeting for worship, towards the close whereof the parties stand up, and solemnly take each other for husband and wife. A certificate of the proceedings is then publicly read, and signed by the parties, and afterwards by the relations, and others as witnesses. Of such marriages the monthly meeting keeps a record: as also of the births and burials of its members. A certificate of the date, of the name of the infant, and of its parents, signed by those present at the birth, is the subject of those here mentioned records; and an order for the interment, counter signed by the grave maker, of the other. The naming of children is without ceremony. Burials are also conducted in a simple manner. The body, followed by the relations and friends, is sometimes, previously to interment, carried to a meeting; and at the grave a pause is generally made; on both which occasions it frequently falls out, that one or more friends present have somewhat to express for the edification of those who attend; but no religious rite is considered as an essential part of burial.

Several monthly meetings compose a quarterly meeting. At the quarterly meeting are produced written answers from the monthly meetings, to certain queries respecting the conduct of their members, and the meeting's care over them. The accounts thus received, are digested into one, which is sent, also in the form of answers to queries, by representatives, to the yearly meeting. Appeals from the judgment of monthly meetings are brought to the quarterly meetings; whose business also it is to assist in any difficult case, or where remissions appear in the care of the monthly meetings over the individuals who compose them.

The yearly meeting has the general superintendence of the society in the country in which it is established: and therefore, as the accounts which it receives discover the state of inferior meetings, as particular exigencies require, or as the meeting is impressed with a sense of duty, it gives forth its advice, makes such regulations as appear to be requisite, or excites to the observance of those already made; and sometimes appoints committees to visit those quarterly meetings which appear to be in need of immediate advice. Appeals from the judgment of quarterly meetings are here finally determined, and a brotherly correspondence, by epistles, is maintained with other yearly meetings.

"In this place it is proper to add, that, as we believe
women may be rightly called to the work of the ministry, we
also think that to them belongs a share in the support of our
Christian discipline; and that some part of it wherein their
own sex is concerned, devolve on them with peculiar pro-
propriety. Accordingly they have monthly, quarterly, and
yearly meetings of their own sex, held at the same time with
those of the men; but separately, and without the power of
making rules.

In order that those who are in the situation of ministrers
may have the tender sympathy and counsel of those of either
sex who, by their experience in the work of religion, are
qualified for that service, the monthly meetings are advised
to select fish among the denomination of elders. These,
and ministers approved by their monthly meetings, have
meetings peculiar to themselves, called meetings of ministers
and elders; in which they have an opportunity of exciting
each other to a discharge of their several duties, and of ex-
tending advice to those who may appear to be weak, without
any needful exposure. Such, it may be here observed, as
believe themselves required to speak in meetings for worship,
are not immediately acknowledged as ministers by their
monthly meetings; but time is taken for judgment, that the
meeting may be satisfied of their call and qualification. It
will also sometimes happen, that such as are not approved
will obtrude themselves as ministers, to the grief of their
brethren; but much forbearance is used towards those, before
the disapprobation of the meeting is publicly testified.
These meetings of ministers and elders are generally held in
the compass of each monthly, quarterly, and yearly meeting.
They are conducted by rules prescribed by the yearly meet-
ing, and have no authority to make any alteration or addition
to them. The members of them unite with their brethren in
the meetings for discipline, and are equally accountable to
the latter for their conduct.

It is to a meeting of this kind in London, called the se-
cond-day's morning meeting, that the revifal of manuscripts
concerning our principles, previouseiy to publication, is in-
terested by the yearly meeting held in London: and also the
granting, in the intervals of the yearly meeting, of certificates
of approbation to such ministers as are concerned to travel in
the work of the ministry in foreign parts; in addition to those
granted by their monthly and quarterly meetings.

The yearly meeting of London, in the year 1675, ap-
pointed a meeting to be held in that city, for the purpose of
advising and affilting in cafes of suffering for conscience-fake,
which hath continued with great use to the society to this
day. It is composed of friends under the name of corre-
pondents, chosen by the severa quarter meetings, and who reside in or near the city. The same meetings also ap-
point members of their own in the country as correspondents,
who are to join their brethren in London on emergency.
The names of all these correspondents, previously to their
being recorded, are submitted to the approbation of the
yearly meeting. Such men as are approved ministers are also members of this meeting, which is called the Meeting
for Sufferings; a name arising from its original purpose, and
which is not yet become entirely obsolete.

The yearly meeting has intrusted the meeting for suffer-
ings with the care of printing and distributing books, and
with the management of its flock; and, considered as a
standing committee of the yearly meeting, it hath a general
care of whatever may arise, during the intervals of that
meeting, affecting the society, and requiring immediate at-
tention: particularly of those circumstances which may oc-
casion an application to government. The fice of the yearly
meeting, just mentioned, is an occasional voluntary contri-
bution, expended in printing books, salary of a clerk for
keeping records—the passage of ministers who visit their
brethren beyond seas—and some small incidental charges;
but not, as has been falsely supposed, the reimbursement
of those who suffer distress for tithes and other demands with
which they were to comply.” — G. Fox's Journal. Sewel's
History of the Quakers. Gough's History of the Quakers.
Belle's Sufferings of the Quakers. Barclay's Apology.
Clarkson's Portraiture of Quakerism.

The editor is indebted for the historical part of the pre-
ceding article to a respectable member of the society of
Friends. Mr. Clarkson's work, which was composed in
consequence of his intimate personal acquaintance with many
of its leading members, produced by his labours for the aboli-
tion of the slave trade, may be consulted for a more ample ac-
count of the manners, practices, and opinions of this society.

QUAKER-TOWN, in Geography, a poit-town of Ame-
rica, in Bucks county, Pennsylvania; 184 miles from
Washington.

QUAKING-Bog, in Agriculture, a name usually given
to a fort of soft pulpy, flexible, earthy depositions, which
are formed in hollow moist situations, in consequence of the
fotation of water in them in some manner or other. Bags
of this kind differ much in their nature, qualities, and pro-
perities, according to the difference of circumstances and
situations, but they have all a tremulous motion under the
foot, when capable of being trodden upon. See Bog and
Quagmire.

Draining is here equally necessary, as in all other cafes
of a similar kind, and may most be carried into execution
without any great difficulty.

QUAKING-Grass, in Botany, so called from the trembling
of the little pendulous spikelets, occasioned by their capil-
lar zigzag walks. See Briza.

QUAKING-Grass, in Agriculture, the common name of a
fort of grases, which is laid to thrive and flourish well on
most kinds of poor cold land, and which cattle eat in a
greedy manner; but which is not much adopted for cultivation
in grases grounds, though it makes tolerably good hay.
See Briza.

QUAKU, or Quaqua, in Geography, a district of
Africa, on the Gold Coast.

QUALATCHE, a town of the state of Georgia; 40
miles W.N.W. of Tegusco.

QUALE, in Botany, a Caribbean name, used by An-
blet, and inadvertently adopted by Schreber; possibly be-
cause, as it appears, he suspected the genus not to be suf-
ciently distinct from *Viych* of the same author, his own Cu-
cullaria; see that article. Wildenow, however, has fol-
lowed him; and thus one name more is added to dunghill,
which some future botanical Hercules must sweep away,—
—Clafs and order, Monandria Monogynia. Nat. Ord. per-
haps Gutifera. Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, in four very
deep ovate, concave, concave, unequal segments; the two
lowermost larger, spreading widely. Cor. Petals two, un-
curled, inserted into the calyx; the uppermost erect, round-
ilip ed, emarginate, terminating at the base behind, in a short,
obtuse, horn-like nectary, projecting between the upper seg-
ments.
ments of the calyx; lowermost largest, flapping downward. Stem. Filament solitary, short, ascending, bent with the lower petal and the germ; anther oblong, furrowed, recurved. Pis. Germin superior, globose; style thread-shaped, ascending, the length of the stamens; stigma obtuse. Peric. Berry? of one cell. Seeds numerous, imbedded in pulp. Obs. The corolla is, as it were, two-lipped. This genus is akin to *Cucullaria*. Schreb.

1. Q. *rofus*. Labl. Guian. 1. 1. *Wild*. n. 1. — Lower petal undivided. Leaves elongated at the point. — Native of the wood of Guiana, flowering in September. The inhabitants call this species *Labaco*. A tree, whose trunk is fixt for or more in height, terminating in large spreading branches. Wood red, compact. Leaves opposite, in pairs crouching each other, on shortish stalks, elliptical, three or four inches long, entire, smooth, with an elongated blunt point; their transverse veins very numerous, straight and parallel. *Steptou* deciduous. Panicles terminal. Flowers numerous, two inches long, powerfully and agreeably scented, white on the outside, rose-coloured, and finally yellowish, within.

2. Q. *carules*. Labl. Guian. 1. 2. *Wild*. n. 2. — Petals two-liped. Leaves with a short point. — Native of the Guiana forests. This species flowers in October, and is known by the name of Qualé. It differs from the former in having smaller flowers, of a grey or blueish colour, but fragrant like those of *Q. rofus*. Their petals are emarginate, or almost obcordate. Points of the leaves less elongated.

**QUALIFICATION for killing game, for jurors, judges, members of parliament, and electors of members.** See Game, Jury, Justices, and Parliament.

**Qualifications for a complete musician, required by Zarlingo.** This venerable theorist had very exalted ideas of a perfect musician, and tells us (Inlit. vol. ii. part iv. p. 342, et seq.) that it is necessary he should have a knowledge in arithmetic, for the calculation of musical proportions; of geometry, to measure them; of the monochord and harmonichord, to try experiments and efficacies; that he should be able to tune instruments, in order to accustom the ear to distinguish and judge of intervals; that he should sing with truth and taste, and perfectly understand counterpoint; that he should be a grammarian, in order to write correctly, and yet words with propriety; that he should read historie, to know the progress of his art; be a master of logic, to reason upon, and investigate the more abstruse parts of it; and of rhetoric, to express his thoughts with precision; and, further, that he would do well to add to these sciences acquaintance with natural philosophy, and the philosophy of sound; that his ears being perfectly exercised and purified, may not be easily deceived. And adds, that he who aspires at the title of perfect musician, has occasion for all these qualifications, as a deficiency in any one of them will frequently render the rest useless. An additional qualification is now become necessary to be added to those enumerated by Zarlingo, which is a perfect knowledge of the genius and powers of all the instruments for which a musician writes; otherwise he will not only embarrass a performer by ufeles and unmeaning difficulties, but lose opportunities of producing effects by the bow of a violin, the coup de langue of flutes, and a selection of the purest and best tones on other wind instruments.

**Qualifications of Land-managers, &c.** The requisite acquirements which are proper and essential to them in order to the due and full performance of all the different forts of business in which they may be engaged or employed. In this view, a considerable knowledge of the principles and practices of different forts of farming and farm-management, some acquaintance and experience in surveying land, in mechanics, in rural architecture, and in the business of planting; are indispensably necessary, as well as a notion of the various mineral and other substances contained in the bowels of the earth, and a ready facility in arranging the management of different forts of accounts.

They should at the same time possess mild, conciliatory dispositions, exact upright principles, and strict moral character. See Land-Recever, Land-Steward, and Office of Bailiff.

The duties and uses of these forts of managers, besides those of regulating and directing the husbandry, management, and other matters, are, the preventing all forts of encroachments from taking place; the seeing that a proper and right method of flocking is pursued on the commonable lands; the guarding against the turf or foil being injured by being broken up or pared off; the looking after the public and private roads, lanes, and driveways, to see that the fences on the sides of them are properly cut and pruned as occasion may require, the travellable parts of them kep: free from obstructions, and in a suitable state of repair, and that the farm-ways are well calculated to the ufe and intentions for which they were designed; the duly attending to the open drains, water courses, and common ditches, to take care that they are kept clear and free at all times, without doing injury to any one; the considering the state of the natural streams and running waters as fit for the purposes of watering live flock at home or in other places, those of irrigating land, the turning of mills, &c.; the examining the borders of rivers, brooks, &c. to see that they are not carried away, or their courses altered in any injurious manner; the taking care of plantations, and all forts of woodlands, as well as timber-trees and young plants, by seeing that they are preferred in a proper manner, and no damages committed by cutting them down, or in any other ways; the attending to the situation of the fences, gateways, &c. to see that the live hedges, with their banks, be duly cut, weeded, pruned, and kept up, as well as the gates, dikes, pales, and other dead fences properly preferred and in repair; the keeping the barn buildings, farm cottages, and garden grounds, belonging to them, in proper condition, with their tenants in a full state of industry; and lastly, the regulating the order of the different occupiers, by preventing improper meetings of all kinds, the reprefing of bad houses, and all forts of irregularities that have a tendency to lessen industry and frugality.

Besides these, there are many other duties which properly belong to them, but which need not be mentioned in this place. See Bailiff.

**Qualifications of Tenants,** the necessary properties and circumstances which render them fit for holding lands as farms. The importance of having persons perfectly qualified as tenants, is very great, in the superintendence and management of all landed property, being, in a great measure, the basis, or principal bearing, on which its uniform and lasting prosperity depends.

The proper qualifications of a good tenant, according to the author of the "Treatise on Landed Property," are the having capital, skill, industry, and character. And he contends, that without a sufficient capital, the rest are unavailing; but that, at the same time, an industrious, frugal, good farmer will thrive with difficulties, and get on with less money than a man of contrary qualifications. But if he has not sufficient strength to work his land, nor a sufficiency of live-flock to raise manure, or money whereby to purchase it, he must, under ordinary circumstances, live in a state of poverty and hard labour; and, on the first attack of misfortunes, or the first failure of season of crops, he will probably sink.
Further, that in regard to the proper ratio or proportion between the rent and capital, it depends on the existing state and circumstances of the farms, and the style of management in which they are intended to be conducted; as well as on the number and strength of the occupiers' families, and their industry and frugality. However, in order to afford some general notions on the matter, it may be said that, for farms of size, as those of from one to five hundred pounds a year, the occupiers should have at their commands from five hundred to a thousand pounds of capital, for every hundred pounds of rent which they may pay. Yet still, on the greater number of farms, the first proportion is too small to manage them with full advantage and profit. And, if they be farmed with spirit, and the higher order of improvements be attempted, particularly the introduction of the best breeds of live-stock adopted by modern farmers, the last will not be found too large for the purpose.

It may be remarked, that it is constantly the belt way for tenants to farm somewhat within their capitals, as a few pounds kept in their pockets enables them to embrace and take the advantage of every favourable opportunity that may offer, and to sell or buy with the greatest benefit. While such as are straightened for money, are forced to take the chance of markets, and liable to make bargains of a loosing and disadvantageous nature, as well as experience many other inconveniences of different kinds.

Notwithstanding, where there is a want of sufficient experience and skill in the art, and different branches of practical husbandry, tenants cannot farm or manage their lands with the most profit, either to themselves, or the proprietors of them. Where, however, their capitals and exertions are great, they may, by observation and practice, acquire skill; and by this means be enabled to perform the business in a tolerable manner, and in some measure do justice to their farms, whatever they may do for their families in the way of getting money for their benefit. But where, with a want of skill, scanty capitals are joined, it is not all the exertion, industry, and frugality in the power of man, that can save or prefer the families or the farms from injury and inconvenience.

However, without industry, capital and skill may be said to be thrown away. In the management of rural business, in which so much depends on the nature of seasons and weather, idleness is a vice of the darkest cast. Every instance of negligence is not only injurious in itself, but operates as a dangerous and had example; serving as an apology or excuse for the half indolent, with whom every farm or estate is incumbered in a greater or less degree.

In consequence of the intimate connection which necessarily subsists between the proprietors and the occupiers of land, and seeing how advantageous and profitable it is to prefer good order and regularity upon farm lands, as giving thereby full liberty and freedom to the exertions of their tenantry, it becomes a matter of some importance, in the selection of farm-tenants, to make proper and necessary inquiries into their characters for morality, and particularly as they relate to habits of sobriety or extravagance, as well as to a peacefulness or queruloseness of disposition.

And it is farther to be remarked, in respect to the proper selection of tenants for farms, that nothing of interest, or any other consideration whatever, that is not intimately connected with the above qualifications, can properly warrant the choice; unless in particular cases and circumstances, as in providing for the widows and orphans of deceased tenants, &c. A farm-manager should not suffer himself to be influenced by any sort of family connection, favour, fee, or reward. Superintendents of this kind, merely as such, cannot have any true interests separate and distinct from those of the farms or lands they may overlook. It, therefore, becomes a dishonourd act in any agent of this sort, to put an inferior tenant into the possession of a farm, through his own interest, even at a fair rent for the same.

Lastly, it may be noticed, that in a district which stands forward in a prominent manner in the ranks of rural improvements, merit should be looked for and encouraged near home. But to advance or bring up a farm or estate which remains in the rear of modern practices, two or more tenants of the higher classes should be sought for, at a distance, in such districts as are of a kindred nature, but in which the more modern and profitable management of farming prevails, in order to lead and direct the native tenantry of the situation.

These are some of the principal and leading qualifications which ought in all cases to direct and regulate the choice of farm-tenants; there are, however, many others which should have an influence in certain circumstances, and particular methods of farm-management, otherwise the full interests and advantages of the proprietors of the lands may be overlooked and neglected.

QUALIFICATOR, in the Canon Law, a divine appointed to qualify, or declare the quality of, a proposition brought before an ecclesiastical tribunal; chiefly before the inquisition.

The qualicators of the office are not judges; they only give their sentiments on the propositions presented to them. They are the inquirers that judge.

QUALITY, Qualitas, that affection of a thing, whence it is denominated such; or that which occasions a thing to affect our fenses in this or that manner, and gives it this or that denomination. Accordingly quality is said to be an attribute, from which no sublimate is exempt. See Mode.

Thus, that power in fire, whatever it be, by which it excites in us the sensation of heat, since it is that whence the fire is denominated hot, is called the quality of fire.

The word quality, qualitas, is said to have been first introduced into the Latin by Cicero; till his time the Romans studiously avoided using a term which denoted an abstract; and the only of it only considered concrete, signified by quale. The like is observed of the ancient Greeks, who did not use conceptus, but conceptum.

Quality, it is to be observed, is an ambiguous term; and has been applied to some things which ought rather to have been looked upon as states of matter, or assemblages of several qualities; as life, health, beauty, &c.

There are, also, other attributes, as size, shape, motion, and rel, usually reckoned among qualities, which might more conveniently be ranked among the primary modes of the parts of matter; since, from these simple attributes, all the qualities are derived.

The ancient school-philosophers distinguish quality in the general, which they call metaphysical and predicamental quality, into essential and accidental. The moderns more usually divide it into spiritual and corporeal.

Qualities, Spiritual, or Qualities of the Soul, are affections of the mind, considered as in this or that habitude or disposition. Of these they make two kinds; the one belonging to the understanding, the other to the will; of the former kind are knowledge, opinion, certainty, doubting, &c. Of the latter are all the moral virtuous and vices.
QUALITIES, *Corporal* or *Physical*, are what we chiefly consider under this denomination, and to which the definition above laid down is accommodated.

Philosophers are divided as to the nature of these qualities, or what they are in the body. The general language of the Peripatetic school is, that they are things distinct from the bodies themselves; and are superadded to them, or flow from their substantial forms: on which principle, they hold qualities to be real, and denominate them *accidents*; supposing them to be inherent in substances, though not in the relation of parts, but to be fullained by them as in a subject, and incapable of subsisting without them. In effect, the Thomists define qualities to be accidents following or arising from the form; in the same manner as quality is an accident following or arising from the substance.

The moderns absolutely explode the notion of qualities distinct from the body; and insist, that the powers by which bodies exist in us the ideas of such qualities, are no other than the mechanical affections of the bodies themselves, e.g. the figure, magnitude, motion, &c. of the parts of which they consist.

The principal considerations inquired on by the retainers to real qualities are, that these powers may be actually separated from the substances they inher in; as we see in light, heat, &c. That from these very qualities, considered as so many determinations, there arises a very great diversity in bodies; and that bodies, according to the diversity of their qualities, affect our senses very differently.

The adherents to the experimental way, on the contrary, account for all the qualities of bodies from mechanical causes. Thus all the phenomena of a clock, the motion of its wheels, its hands, &c., by which it strikes the hour, points the minute; day, moon’s age, &c. do all evidently arise from the single spring; which we never imagine to have any particular powers by which it should be enabled to make such discoveries; nor any other principle but that of elasticity.

Why, then, may we not conceive, as to sensible qualities, that though, by virtue of a certain congruity or incongruity in point of figure, texture, or other mechanical properties, the portions of matter they modify are enabled to produce various effects, on account of which the bodies are said to be endowed with qualities; yet these are not, in the bodies endowed therewith, any real or distinct entities, or differing from the matter itself of such a determinate being, shape, and other mechanical modifications? Thus, though the modern goldsmiths and refiners reckon it among the most distinguished qualities of gold that it is diffusible in aqua regia, whilst aqua fortis will not work upon it; yet these attributes are not in the gold any thing distinct from its peculiar texture; nor is the gold we have now of any other nature than it was in Pliny’s time, when aqua fortis and aqua regia were unknown.

We all know that the sun hath a power to harden clay, soften wax, melt butter, thaw ice, turn water into vapour, make air expand itself in weather-glasses, contribute to blanch linen, render the white skin of the face swarthy, and mowed grass yellow, ripen fruit, hatch the eggs of insects, caterpillars, &c. and perform many other things, none of which seem contrary to others; yet these are not distinct powers, or faculties in the sun, but only the production of its heat, diffusified by the different textures of the body it chances to work on, and the condition of the other substances concerned in the operation. And, therefore, whether or not the sun, in some cases, has any influence at all distinct from its light and heat, we see that all the phenomena mentioned are producible by the heat of common

fire, duly applied and regulated. Some of the ancients, and particularly the Peripatetics, have distinguished qualities into *sensible* and *insensible*.

QUALITIES, *Sensible*, or *Manifold*, are those arising from certain modifications of matter, and which become immediately the objects of our senses. Such are all those above-mentioned.

Though, in strictness, those only are said to be sensible qualities which affect some one sense alone; as colour does the eye, sound the ear, &c.

These are sometimes also, called *tangible* qualities, because they only produce their effect, i.e. excite their idea in us, when contiguous, or in contact with the organ.

QUALITIES, *Sublimate*, are certain latent powers arising from the specific forms of things, of which no rational solution can be given on any principles of physics.

Sensible qualities are usually subdivided into *primary* and *secondary*. See Ideas.

QUALITIES, *Primary*, or *General*, are such as are found in all bodies; or which agree to all matter, considered as matter, and therefore to the elements themselves. Such are extension, figure, motion, heat, solidity, impermeability, and number.

QUALITIES, *Secondary*, or *Particular*, are such as result from a composition or mixture of elements, and do not agree to body as body, but as a mixt. Such are light, heat, cold, colour, found, taste, smell, hardness, softness, fluidity, firmness, roughness, smoothness, opacity, transparency, &c.

According to Aristotle, and the Peripatetics, the primary, or elementary qualities, are those of the four elements themselves; viz., heat, cold, moisture, and dryness.

The secondary qualities, according to the same, are all the remaining; which are combinations or assemblages of the former elements; as colour, odour, taste, &c.

To give an idea of Aristotle’s method of accounting for these secondary qualities from these primary ones, we shall indulge in his account of colour. All colours, then, says he, are generated of a mixture of the four elementary qualities: white, e.g., is produced when the humidity mounts the heat, as in old men, whose hair grows grey; black is produced when the humidity dries off, as in walls, ciphers, &c. red, &c.

Among the school-philosophers we meet with other divisions of qualities; as *active*, and *passive*; and *real*, and *intentional*.

**Qualities, Active**, are those by virtue of which effects and operations are actually produced on other bodies duly disposed with respect to them. Such are the heat of fire, the moisture of water, &c.

**Qualities, Passive**, are those by which bodies are disposed to receive the action of others. Such are inflammability in oil, &c.

**Qualities, Real**, are those which remain in the subject, and only act on things adjacent to it. As fire in a piece of iron not ignited, &c.

**Qualities, Intentional**, are those which issue from the subject, and operate at a distance. Such is the light emitted from the sun, &c.

But the moderns are agreed, that either all qualities are real, or all alike intentional. So that the distinction is imperceptible. See on the subject of quality, its various species, and its different properties, Harris’s Philosophical Arrangements, chap. viii.

However ignorant we may be of the nature of qualities, or of the manner of their operation, yet we know the laws of their intention and result. Dr. Keil demonstrates, that every quality which is propagated in a medium, such as light,
light, heat, cold, odour, &c. has its efficacy increased, or abated, in a duplicate ratio of the distances from the centre of radiation, or exertion of the quality, reciprocally.

Thus, let $A$ (Plate XII. Geometry, fig. 1.) be a centre from whence any quality exerts itself round about, according to the right lines, $A_c$, $A_f$, &c. The efficacy of the quality be it heat, cold, odour, &c. will be $(at \text{equal distances from } A)$ as the $sp$uititude or density of the rays, $A_b$, $A_c$, $A_d$. But the rays within the inner circle, or rather spherical supericies, $b c d H$, when they come to be extended to the other spherical surface, $e f g K$, will be much less close than they were before, and that in the reciprocal proportion of the spaces they take up; that is, if the outer surface be the double of the inner, the rays there will be but half as thick; but since spherical supericies are as the squares of their radii, therefore the efficacy of the quality in the inner surface will be to that of the outer, as $A e$ square to $A b$ square. Q. E. D.

Sir Isaac Newton lays it down as one of the rules of philosophizing, that those qualities of bodies which are incapable of being intended and remitted, and which are found to obtain in all bodies in which the experiment could ever be tried, are to be esteemed universal qualities of all bodies. See Philosophizing.

Qualities, Cognitive. See Cosmical Qualities.

Qualities is also used for a kind of title, or degree of eminence given to certain persons, in regard to their territories, figuriaries, or other pretensions.

Thus the king of Great Britain used to take the quality of king of France; the king of Poland that of king of Sweden; the king of Sardinia that of king of Cyprus and Jerusalem; the czars of Russia, and kings of Spain, have the whole pages of qualities. The emperor of China affirms the quality of son of the sun.

Quality of Curvature. In Geometry, is used to signify its form, as it is more or less inequal, or as it is varied more or less in its progress through different parts of the curve. Newton's Meth. of Flux. and Inf. Ser. p. 75. Maclaur. Flux. art. 369. See Curve.

Qualities of Trees, and Plants. In Agriculture and Gardening, are the properties which are peculiar to them, in relation to their magnitude, modes of growth, textures or consistencies, forms, colours, tastes, smells, means of propagation, culture, uses, and values.

In regard to the fir, as soon as the simple constituent fibres of plants are evolved and increased, as far as the nature of them and the arrangement of the primary nutritive substances will permit, they cease to receive any more for their further increase; the primary matters merely replacing the inos which is occasioned by the performance of the natural functions of the plants; consequently they have each a particular prescribed increase or measure of growth. Some are very large, others extremely small. The Indian fig, in consequence of ramifications being sent off, which connect with the primitive trunk, by innumerably degrees acquires a very considerable bulk or thickness, being frequently twenty, or even thirty cubic feet in its diametrical section. And there are accounts given of particular plants, which are scarcely visible to the naked eye; and of some trees, which are so large as to cover with their branches two hundred persons, or more.

In this country, some trees and shrubs of the ornamental fort are either very high, or very low; of the former kind are the horfe-chefnut, larch, cornelian cherry, snowdrop-tree, and many others; and of the latter, the mountain-ah, hemlock, fir, Scotch rofe, butchers' broom, and many more. There are some trees which are very broad, in proportion to their height, as the oak, Spanish chefnut, &c.; others which are very narrow, as the larch, spruce fir, &c.

And there are still some others, in which there is a medium between these extremes, preferred and kept up, as in the ash-leaved maple, the evergreen oak, the Virginian rasperry, the Guelder rose, and a number of others.

The modes or habits of growth in trees and shrubs are also extremely different; some finding out their branches in a horizontal manner, as in the oak; in others they have an upward direction, as in the Huntingdon willow; while in a few they fall downwards, as in the lince, acacia, and others. Again, there are some which have an oblique inclination, as may be seen in the Scotch fir; or they recline, and then rise up again, as in the larch kind; and there are still others, in which they hang directly downwards, as in the weeping ash, weeping willow, &c.

There are likewise some shrubby plants, which creep along the surface of the ground, as the periwinkle; others which clasp themselves to trees, as the passion-flower; and a few which fix and attach themselves to buildings, walls, &c. as the ivy. Farther, there are some trees that, in whatever way they may be placed, cut, or pruned, constantly allume and take on one principal item, from which all the different branches proceed or go off, as rays from a centre, as in the fir tribe; while in others, the trunks divide themselves into arms, or large branches, which fend out boughs or smaller branches in an irregular manner, as in the oak and others. Some kinds of shrubs have merely one single item, as the althea; while other forts invariably spread and extend along the surface of the ground, throwing or leaping out a greater number, as the hypericum, and some others.

The texture or consistence of plants of different kinds is likewise very different, as hard, soft, membranous, carious, smooth, downy, thorny, &c. which are molly obvious to the feel. Plants of the young kind are commonly mucilaginous, becoming hard as they advance in growth; though many luxuriate in the date of continual softness, as the trebella; yet some are so hard as to sink in water, as the iron wood of the island of Ceylon, &c.

Thus among trees and shrubs, some have a soft smooth appearance, as the lime, the corporon fenna, &c.; while others have a hard, rough, firm appearance, as the evergreen oak, the holly, &c. There are some also which have a smooth, silky appearance, as the tamarisk, &c.; while others have a downy, woolly appearance, as the hoary poplar, &c. And some appear wholly beft and covered with thorns or prickles, as the furze, hedgehog holly, &c.; while others, again, appear wholly composed of thready fhoots, as the Portuguese broot, &c. Besides these, there are many other forts, which fur- nish different appearances from any of thefe.

The forms in the different forts and varieties are still equally, if not more, various; some being apparently solid and compact, from being thick fet with branches and foliage, as in the horfe-chefnut, the Englifh elm, the lilac, the syringa, &c.; while others are of a more light, airy, elegant form, being thin of boughs, branches, and leaves, as the alh, the hoary poplar, the bird cherry, the Canadian mepilus, &c.; and there is a middle degree between these extremes, in the broad-leaved euonymus, the alh-leaved maple, and some others. They may also be further distinguish'd into those whose branches begin from nearly the surface of the ground, as in the fir tribe of trees, and most shrubs; and into those which shoot up into a stem before their branches are begun to be fent off, as in the mountain-ah, the althea frutex, &c. It may likewise be noticed in respect to those whose branches begin from the ground, that some of them ride in an elegant cone, as the larch, the

Z 2

holly,
holly, &c.; others in a cone, whose base is very broad, as in the cedar; or whose base is very small, as in the upright cypresses. There are some which swell out in the middle of their growth, and diminish or contract at both ends, as in the Weymouth pine, &c.; while others are broadest at the top, as in the raspberry, the alpine honeyuckle, &c.; and some few irregular and bushy throughout, as in the evergreen oak, the snowball tree, &c. Among those which shoot up into a stem before their branches are fent off, there are some which are in the shape of slender cones, as in the deciduous cypresses; others in those of broad cones, as in the balsam poplar. Still others assume a globular form, as in the mountain-ash; while many are irregular throughout, as in the Scotch elm, the acacia, and several others.

As to colour, it appears to depend upon the colouring principle, the proportion of vital air and light which is contained, and is proper to different parts of the same tree or plant: hence, when exhalation is prevented, and light intercepted, the green colour is changed into white. In trees and shrubs it is either accidental or permanent: the latter including all the different shades of green in the summer months; the former, the different tints of red and yellow, which are peculiar to the autumnal and vernal seasons.

There are some of the permanent kinds of colour, which are of a dark green, as those in the horse-chestnut, the yew, &c.; while others are of a light green, as those in the ash, the common laurel, &c.; and others, again, which are of a blueish-green, as those in the Scotch fir, the bladder fenna, &c. Some trees have a green tinged with brown, as the Virginian cedar; others a green tinged with white, as the abelone and the Lapland willow. Also, in some trees the greens are tinged with yellow, as in the ashen-leaved maple, the Chinese Arbor vitae, &c.; in others with red, as in the scarlet maple, &c.; and in a few with purple, as in the purple beech. There are some greens which are spotted with white, yellow, and red, as in the variegated holly, privet, fycamore, box, and various others. The colours which arise from accident are almost infinite in number, each kind of which is liable to great variation; moly, however, it will be found that in autumn the wild cherry assumes a bright red, the birch a deep red, the beech a brownish-red, the scarlet oak a deep scarlet, the hornbeam a dull colour, the sugar maple a rich yellow, the common oak a reddish-yellow, the lime and ash a straw colour, the balsam poplar a black, the fycamore a dark brown, and others different forts of other colours.

In regard to taste and smell, the former depends upon the different principles which compose and constitute the juices or humours of the different kinds, and varies as well in the different sorts, as in the different parts of the same sort of trees or plants. The latter depends upon the volatile principle, or principles, which issue or exhalate from them, and differs in its nature, according to the kinds of plants, or the parts of them, in which it chiefly resides or is present. There are some trees and shrubs which have scarcely any smell, as the evergreen oak, platanus, &c.; others have a most grateful rich fragrance, as the birch, sweet-briar, honeyuckle, &c.; some again have a pungent, powerful smell, as the mezereon, the lirysinga, &c.; others a disagreeable nauseous smell, as the elder, &c.; in fome the smell is very sweet, as in the flowering limes; in others it is deleterious, as in those of the walnut, the art-misia, &c. There is also the greatest fragrance in some while they are in blossom, as in the hawthorn, and in some it is solely confined to it, as in the lilac; while in others it is equally diffused over or throughout the whole plant, as in the sweet-briar, and many others.

There may be considered as some of the most general characteristic qualities of trees and shrubs; but various other peculiarities incident to them present themselves, on a more minute investigation, which equally interest and deserve the attention of the ornamental planter and gardener, as well as the cultivator of all sorts of wood and timber; and which principally relate to differences in the barks, the buds, the leaves, the flowers, and the fruits. The appearance of the bark is very different in many different sorts of trees and shrubs, as red, white, black, brown, and green, as in the dogwood, birch, oak, Guelder rose, and holly. It differs also in its properties, as in some it is firm, in others spongy, in some thin, in others thick, brittle, glutinous, or thready, as in the oak, the cork-tree, the beech, the Scotch fir, the hornbeam, the holly, the lime, and the elm. It varies likewise in its duration, the outer bark or coat in some trees being thrown off annually, as in the arbutus, the Birch, &c.; while in others, for the most part, it is constantly retained or kept on. It differs equally in respect to its properties of taste, being in some alluring in its nature, in others sweet, bitter, pungent, &c., as in the oak and bramble, lime, abelone, fir, &c. In regard to buds, some trees have none at all, as the pine and evergreen forts; in some they are very large, in others very small, as in the horse-chestnut, and the willow. In some they are coated over with a covering of glutinous or resinous matter, as the horse-chestnut, &c.; in others they are overspread with a dry film or tegument, as in the beech, &c. There are likewise some buds which are of a red colour; others which are yellow, black, brown, or red and greenish; as in those in the lime, the willow, the ash, the beech, and the common fycamore, in the order in which they occur.

The variety in the leaves is still much greater: some being very broad, as those of the common laurel; others very narrow, as those of the larch. And there is a medium between these extremes, in those of the willow and the alder. In some they are entire, as in the bay; in others serrated, as in the cherry; and pinnatifid, as in the acacia, &c. In some again they are covered with down, as in the sea buckthorn; in others with wool, as in the hoary poplar; with prickles, as in the holly; with a glutinous matter, as in the gum ciftus, &c. They are of all the different shades of green in the summer season; and of all the different tints of red and yellow, in the autumnal and vernal seafons.

There are some which retain their leaves and colours during or throughout the whole year, as the pine tribe, &c.; others which lose their green colour in the autumn; but retain their leaves all the winter, as the beech, hornbeam, &c. in particular circumstances. A great number of trees, among which are the elm and the ash, drop their leaves in the autumn, and are naked all the winter. In general, the leaves have the same properties as the barks, but in a fainter and less perfect degree; which are of much importance in some points of view. Those of the elder, the box, &c. are refused by most sorts of cattle; those of the elm, the horn, &c. greedily devoured by them; while those of the fir tribe are offensive to many sorts of insects, which are liable to inflict hot-house, and other similar places.

And the flowers are much less various than the leaves. Thofe of some trees being large and showy, as of the rose, the honeyuckle, &c.; while thofe of others are small and obscure, as of the alaternus, &c. In some they cover the whole plant, and quickly fade away, as thofe of the hawthorn; while in others they are but thinly distributed, yet continue a considerable length of time, as thofe of the passion-flower, &c. There are some, which come into blossom at an early period, as thofe of the mezereon, almond, &c.;
and various other deciduous kinds; however, a year or more before their removal is to take place, they should have their roots cut in, and their tops thinned by the pruning knife, or other means, as such precautions are highly important and necessary, and should never be omitted, in removing trees of the latter of the above heights.

In respect to the uses of trees and shrubby plants, though the latter fort are commonly set out for the purpose of ornament, variety, &c., and the former for that of timber, as well as thefe and other uses; there are still some other ways in which they occasionally contribute, and become of utility and importance to the planter. There are different products of some of them, which are useful in different arts and professions. For instance, the bark of some is useful in chemistry, for the making of bird-lime, as that of the holly; that of others, as of the lime, the elm, &c. for the manufacturers of mats. The leaves of some, as those of the mulberry, for the growers and reapers of silk. The blossoms of others, as those of the rose, for the apothecary, and those of the syringa for the confectioner. Those parts of the leaves of the beech which are proper, are converted into bread. And the fruits of others, as those of the apple, plum, &c. are of very general utility and value. Some kinds of wood are of particular use and value for particular purposes, as the oak to ship-builders; and others might be trained for this application, as the larch, by bending down the stem when about twenty feet in height, securing it in that position, and then re-bending it again some considerable
able time afterwards, leaving the bole or trunk in a differently crooked state. The woody parts of the fir and pine are employed by house-carpenters, of the crab-tree by millwrights, of the ash by ploughwrights, of the beech, the walnut, the cherry, the plum, the box, the holly, the yew, and others, by the cabinet-makers. The lime is particularly useful to the carver, the fycamore to the turner, the box and holly to the mathematical instrument-maker, and the alder and the birch to the painter and the wheelmaker. Charcoal of any of the kinds is valuable for the iron-founders; that of the dogwood, fallow, elder, hazel, &c. for the gunpowder manufacturers. The larch, the silver fir, &c. afford the coarse turpentine and its spirit; the spruce and pine tribes, resin, tar, pitch, lampblack, &c. Most woods, but especially the beech, ash, elm, &c. afford potash. The sap-juice of some trees, as the birch, &c. yields a valuable liquor; and that of others, as of the sugar-maple, &c. affords sugar.

The value of wood as timber, and for other purposes, differs much according to local situation, and other circumstances; when near a dry-dock or shipyard, oak, elms, &c. suited to ship-building, are of much higher value than when at a great distance in the country. The under-growths of several sorts of trees, as dogwood, fallow, willow, alder, &c. are of the most value when near large manufactories of gunpowder, being of little utility, except as fuel, when at a distance. Some sorts of wood, however, from the generality of their application and employment, are of great value in all situations, as those of the oak, the elm, the ash, the beech, and perhaps the larch has still more value than any of them. Others, on account of their scarcity, are also valuable in all places, as the box, the holly, the yew, &c. All the lighter products of some sorts of trees, as those of bird-lime, potash, turpentine, tar, pitch, &c. may likewise be considered of equal value in all situations. But a tree which would be of the greatest value in a particular situation or place, may not find in it that sort of soil that is suitable to its nature or habits of growth; in which circumstances that which will come to the most perfection in it, will commonly be found of the most value. Such woods as may not be valuable in consequence of local circumstances, may be rendered a great deal more high in their value, by having them manufactured in the places where they are grown with, thus lessening the expenses of conveyance, &c. In consequence of the great improvements in roads, canals, &c. and the general promotion of them, woods and plantations for timber, maple, in almost all places, be valuable, and there can be few in which the other sorts of products will not be of great importance. In the measuring of standard trees for the purpose of ascertaining their value, though many think themselves fully qualified by being only able to measure them; it is only by the perfect knowledge of the use and application of the different shapes, boughs, and woods of them, that a correct estimate can be given; as a small portion of wood may be of little consequence in one sort of business, while it is of much in another, which is a secret of great interest and importance to the purchasers of timber of the standing kind.

In addition to these qualities, almost every tree and plant is possessed of various others, which excite emotions that have a relation to them, and which give their characters or expressions. For instance, the cypress is of a regular, invariable shape, or form, and always, in colour, of a dark green, having a full, foliose appearance; hence it has acquired the character of melancholy. A familiar, but somewhat fainter, train of emotions, is produced in the mind by the falling branches, dropping spray, and yellow greenish colour of the weeping willow; hence it suits with fenes of solitude, and induces meditation. In the light, airy form of the ash, and the bright white of the variegated holly, there are some traits of certain degrees of the cheerful kind; in the foliose of the virgin'sbower, eafe and gracefulness; in the myrtle, delicacy and neatness; and in the sweep of the stem, the curve of the branches, &c. of the larch, a peculiar elegance.

In the oak and the chestnut are forms which have long given the appearance of grandeur and nobility. Both these and other trees are particularly expressive of peculiar known characters, arising, in some degree, from their own nature, and in part from associations in the mind. Those of the cypresses and yews have been planted in burying grounds, and other similar places; the weeping willow, as the shade of urns; the laurel used as the crown of warriors; and the chestnut introduced in landscapes. Some accidental characters and expressions of plants are produced by novelty and singularity, either in their nature, forms, or appearances; hence exotics are at first distinguished from those of the indigenous kind, and called beautiful, elegant, fanciful, strange, rare, &c. according to circumstances. The creeping ash, the flone pine, &c. derive and retain their characters from their comparative scarcity and unusual shape; while others have that of elegance and novelty in a much less degree, as the cedar of Libanus and the cypresses; the hemlock spruce, and the scarlet oak, &c. Some trees and plants are common, and thought nothing of in one district or country, while, in others, they are uncommon, and thought highly of; thus, the weeping willow, the narrow-leaved elm, the acacia, &c., which abound, and are little valued, in the southern parts of the island; are scarce, highly esteemed, and termed elegant in those of the north; while the arbutus, the uva urb., the erica alba, and even the mountain-ash, which are plentiful, unnoticed, and common in the north, are held in estimation, and thought highly elegant in the south.

There are some of the more particular qualities of trees and plants, which are concerned in the classification and arrangement of them, as the materials by which the objects of planting and ornamental gardening are to be accomplished, but there are others which are peculiar to them in other points of view, that it is quite unnecessaiy to notice in this place, as they are fully explained in speaking of them individually under their proper heads.

More ample information on the above subject may, however, be obtained by consulting Mr. Loudon's work "On Forming, Improving, and Managing Country Residences," in which will be seen their particular utility, and their most appropriate modes of application in the business of planting and ornamenting different kinds of pleasure grounds, under all the various circumstances which may occur in so far as their nature, situation, soil, and other familiar particulars are concerned, as well as the picturesque effect which will be produced.

Qualities of Seeds, Sets, and Produce, the properties which are essential to them for the production of full and beneficial crops of the several different kinds, and the most perfect and advantageous states of growth and maturation of such crops, for their being consumed, either as food or otherwise. In all sorts of seeds of the grain kind, those which are the most fully bodied, bright, thinnell in the skin, and the most found, without being too long kept, are the most suitable for making use of as seed. Such as are small, lean, ill fed, and thrunk in their skins, or which have been in any way heated in the mow or stack, are wholly quite improper for this purpose. Some have, however, supposed the contrary to be the case, but they have hitherto added no proofs whatever, of the fact, while the former opinion is supported.
supported by the daily experience of the belt farmers in the country. There is another circumstance which is of some importance in this business, which is that of the grain for this use being constantly newly threshed out from the straw, as such, for the most part, sprouts and grows more expeditiously, and is less liable to rot and perish in unfavourable seasons and situations.

All sorts of disused grain, and such as is not perfectly free from the mixture of the seeds of weeds with it, should always be, as much as possible, avoided in this intention.

In regard to the smaller sorts of feeds for raising all kinds of plant-crops in the field, as well as those of the grasses, both natural and artificial, the principal necessary qualities, in each, are those of their being of a bright, lively, shining colour, perfectly found, and fresh, or lately collected from the plants. Such as are old, or kept more than a few months, are mostly improper for this application. The best sorts commonly slide freely over each other, without sticking or being heavy in the hand, and have a brilliant bloomy appearance.

In gardening, most sorts of feeds also are the best, and require to have these properties and qualities as much as possible; but there are a few which are apt to grow too luxuriantly for fruiting well, as some of the cucumber, melon, kidney-bean, and other kinds, which are better for being kept for some length of time, as this property is thereby in some measure corrected and restrained. Most sorts of nuts and stones, when used as feed, should, however, be employed in as fresh a state as possible.

Sets are different in their nature, being of the root or plant kinds. In the former, the sets or cuttings should have the eyes or buds in a perfect state, and be of a middling fixe, as both those which are very large and very small are objectionable. This is the case with the potato, and some other sorts. In the latter, the plants should not have too large growths, but be in a fine young state of vegetation, so that they can be set out with facility, and readily take root again, having their heads or upper parts, for the production of the produce, wholly in an uninjured condition. They should also be quite newly drawn up, cut or nipped from the stalks of the old plants, without any sort of clubbing near the roots in those which are drawn. Such as have riven the most quickly from the feed, are, in general, the best. They should none of them ever be kept any great length of time after being drawn, before they are re-planted. This is equally applicable to the field and garden kinds. See Seed, Set, and Sowing.

The produce in all the white or grain crops, which are employed either for the purpose of making or matting, should constantly be well ripened; but where the straw is to be made use of as cattle food, the crops are better to be cut before they have reached the state of full maturity, as this purpose is thereby more completely answered. There is no mistake in the produce of most sorts of field plant-crops, by taking them before they have formed their bulbs or heads in a perfect manner. But much of such like products, in the garden, are the best and most advantageously taken in such imperfect states, being tough and coarse when full grown, and without the necessary tenderness. Others require to be cut or drawn early in order to have the proper degree of sweetness and flavour. The fruit kind of produce is taken both before and when nearly ripe, according to the uses for which it is intended. Some sorts of vegetable produce are used quite in their green state, as food; while others are best in a somewhat more advanced state; and others, again, in both these states. And there are those which require to be well ripened, and kept for some length of time before they are used in this way.

All sorts of produce of the grasses-kind, are cut and used to the most benefit, when they are taken a little before they become perfectly ripe, as they go the farther, whether they are to be consumed in the green state, or in that of hay. This is equally the case with the more luxuriant artificial sorts, as with those of least growth, of the natural kind. This is explained more fully in speaking of the different plants and crops individually, and in the article Hay; which see.

QUALO, in Geography, a town on the N.E. coast of Sumatra. N. lat. 2° 45′. E. long. 99° 40′.

QUALUGA, a town of Africa, in the country of Whidah; 18 miles N.W. of Sabi.

QUAM, a town of Norway, in the diocese of Drontheim; 68 miles N. of Drontheim.

Quam diu fe bene gofferit, a clause frequent in letters patent, or grants of offices, to secure them so long as the person they are granted to shall not be guilty of abusing the same.

Thus, e.g., we find it in those given to the barons of the exchequer; where it intimates, that they shall hold the same as long as they shall behave themselves well; which is to be restrained to matters of their offices; and signifies no more than the law would have implied, had the office been granted expressly for life. See Judge.

A grant therefore, with this clause, is equivalent to a grant for life.

QUAMASH, in Botany, a name given by the North American Indians, to a plant called Phalangium Quamoso, by Mr. Pursh, in his Flora, v. 1. 226; who nevertheless mentions an irregularity in the petals, that might possibly embarrass it as a new genus. See Phalangium.

This plant was observed by governor Lewis, about the upper part of the Missouri, near the Rocky-mountains, flowering in June. The bulb is roundish, tufted. Stem none. Leaves radical, few, long, and linear, half an inch broad, smooth; keeled underneath. Flowers flaky, naked, erect, round, smooth, unbranched, a foot or more in height, terminating in a spike, or rather cluster, of large, pale-blue flowers, each accompanied by a linear, membranous, withering bract, longer than the partial spike. Petals linear-lanceolate, nearly equal in length; five of them ascending, the fifth deflexed.

The bulbs are carefully collected by the natives, and cooked between heated stones, when they assume the appearance of baked pears, and have an agreeable sweet taste. They form a great part of the winter stores of these Indians. Though governor Lewis's party found them a pleasant sort of food, they could not be eaten, in any quantity, without causing bowel complaints.

QUAMOCLIT, an Indian name, retained by Plummer and Tournefort as generic; but by Linnaeus used only as the specific appellation of a beautiful species of Ipomoea; see that article.

QUAMPEAGAN FALLS, in Geography, falls in America at the head of the tide on Newichwanaock river, which joins Piscataqua river, 10 miles from the sea; so called by the natives, because falls were there taken with nets. At these falls are a few of saw-mills and others, and also a landing-place, where great quantities of lumber are rafted. Here the river has the English name of Salmon Falls river, from the number of salmon caught there. On many places from Quampeagan to the pond, from which it issues, there are mills for boards and corn.

QUAM-TOM, a town of China, of the third rank,
in the province of Yun-nan; 15 miles N.E. of Tchou-hiong.

QUAN, a town of China, of the third rank, in Chan-tong; 22 miles W. of Tong-tchang.

QUAN, or Guan, in Ornithology. See Penelope Grifisata.

QUANAMORA, in Geography, a town of Africa, in Upper Guinea, on the banks of the Scherbro', said to contain 5000 families. N. lat. 7° 45'. W. long. 10° 15'.

QUANDROS, a name given by writers of the middle ages to a fioned to which they attribute great virtues, and which, they fay, is found in the head of a vulture.

QUANG-LING, in Geography, a town of China, of the third rank, in Chan-fi; 15 miles W.S.W. of Ouei.

QUANG-NING, a town of China, of the third rank, in Quang-tong; 35 miles N. of Tchao-king.

QUANG-PING, a city of China, of the first rank, situated in the northern part of the province of Pe-tche-li, between the provinces of Chang-tong and Ho-nan, which has nine towns of the third class dependent upon it. All its plains are well watered by rivers. Among its temples, one is dedicated to thefe men, who, as the Chifene pretend, discovered the secret of rendering themselves immortal; 212 miles S.S.W. of Peking. N. lat. 56° 47'. E. long. 113° 29'.

QUANG-PUNG, a town of China, of the third rank, in Pe-tche-li; 17 miles N.W. of Tai-ning.

QUANG-SI, a province of China, situated between thefe of Quang-tong, Hoh-quang, Koei-tcheou, Yun-nan, and the kingdom of Tong-king; about 350 miles from E. to W., and 230 from N. to S. In commerce, as well as extent, it is not equal to that of the other provinces; and yet it fo abounds with rice, as to supply, for six months in the year, the province of Quang-tong, without which the inhabitants of this province could not subsist. The mountains with which it is covered, abound with mines of gold, silver, copper, and tin, and in this province is a fingular kind of tree, containing a soft pulp, which yields a fort of flour, and of this flour they make a very good bread. Besides parroquets, hedge-hogs, and the rhinoceros, wild animals, curious birds, and uncommon insects are found here in great number. This province contains twelve towns of the fift class, and eighty of the second and third. Its capital is Quei-ling. Grofler's China, vol. i.

The population of this province is estimated by Sir George Staunton at 10,000,000; its area comprehends 79,456 square miles, or 50,851,840 acres. The revenue remitted to the imperial treasury at Peking, comprising land, fall, and taxes, is rated at 500,000 taels, or ounces of silver. The military force is fixed to amount to 50,000 men. Its capital is Canton; which fec.

QUANG-YANG, a town of China, of the third rank, in the province of Quang-fi; 30 miles S. of Tien-nan.

QUANG-YUEN, a town of China, of the third rank, in the province of Se-tchen, seated on the Kialing; 50 miles N. of Pau-king.

QUANNEFIORD, a bay on the W. coast of West Greenland. N. lat. 62° 10'. W. long. 48° 5'.

QUANO, a town of Japan, on the island of Nipphon, on the S. coast, 70 miles E. of Hakone. N. lat. 35° 58'. E. long. 136° 14'.

QUANTALLA, an island of Africa, at the mouth of the Zaire, celebrated for a filver idol, to which the neighboring kings fend presents and offer sacrifices.

QUAN-TAO, a town of China, of the third rank, in Chan-tong; 25 miles W.N.W. of Tong-tchang.

QUAN-TCHANG, a town of China, in Chan-tong; 13 miles N. of Po.

QUANTITE, Fr. This word in music, like profody, does not fix the number of notes or of syllables, but their relative duration. Quantity produces the rhythm, as accent produces intonation. Rhythm and intonation generate melody. Rouleau. See MELODY.

QUANTITY, Quantitas, any thing capable of elimation or mensuration; or, which being compared with another
other thing of the same kind, may be said to be greater or
less than it; equal, or unequal, to it.
Mathematics is the science or doctrine of quantity.
Quantity is a general attribute, applied in a very different
manner to things of very different nature; whence it is im-
possible to give any universal definition of it.
Quantity is applied both to things and to modes; and
this either spirally to one; or plural, to several. In
the first case it is called magnitude, in the latter multitude.
Quantity may be reduced to four classes; viz.
Quantity, Moral, which depends on the manners of
men, and the free determination of their wills. As the
prices and value of things; degrees of dignity and power,
good and evil, merit and demerit, rewards and punish-
ments, &c.
Quantity, National, arising from the operation of the
understanding only. Such as the largeness or narrowness of
the capacity of the mind, and its conceptions. In Logic,
universals, predicaments, &c. In Grammar, the quantity
or measure of syllables, accents, tones, &c.
Quantity, Physical, or Natural, which is of two kinds:
I. That which nature furnishes us with in matter, and its
extension. And, 2. In the powers and properties of
natural bodies: as gravity, motion, light, heat, cold, rarity,
density, &c.
Quantity, Transcendental, or duration, the continuation
of any being, existence, time, &c.
Quantity is also popularly distinguished into continued
and discrete.
Quantity, Continued, or Continuous, is when the parts
are connected together, and is commonly called magnitude.
This, again, is of two kinds; either succedanea, or improper,
atime.
Quantity, Discrete, is when the parts of which it con-
stitutes exist different, and unconnected together; which makes
what we call number or multitude.

The notion of continued quantity, and its difference
from discrete, appears to some without foundation. Mr. Machin
considers all mathematical quantity, or that for which
any symbol is put, as nothing else but number, with regard to
some measure, which is considered as one; for that we can-
not know precisely how much any thing is, but by means of
number. The notion of continued quantity, without
regard to any measure, is inexact and confused; and
though some species of such quantity, considered physically,
may be described by motion, as lines by the motion of
points, and surfaces by the motion of lines; yet the magni-
tudes, or mathematical quantities, are not made by the
motion, but by numbering according to a measure. Vide Phil.
Traf. No. 447. p. 228.

Permanent quantity is farther distinguished into length,
breadth, and depth.

Wolfius seems to give us a more precise notion of mathe-
matical quantity, and its two species of discrete and con-
tinuous. Whatever is referred to unity in the same manner
as one right line to another, is what we call quantity; or
number in general.

If, now, the thing be referred to a given unit, as 3, it
is called a determinate number; if to unity in the general,
or at large, it is called a quantity; which, on this principle,
is the same with indeterminate number.

Thus, e. g. 3, the breadth of a river is accounted a quanti-
ty; if, then, it be enquired how great it is; to conceive
its quantity, we take some unit at pleasure, and see the rela-
tion of the breadth to it; and according to the different unit aforesaid, we express the breadth of the river in a dif-
f erent determinate number.

The breadth of the river, therefore, is quantity con-
ferred as referred to a vague unit, or to unity at large; but
the unit being determinate, the thing is understood by a de-
terminate number.

In this sense, algebra is the arithmetic of quantities. See
on the subject of quantity, Harris's Philosophical Arrange-
ments, chap. ix.

Quantity of Action. See Action.
Quantity, Impossible, and Imaginary. See Root.
Quantity of Curvature at any point of a curve is deter-
mined by the circle of curvature at that point, and is reci-
procal proportionally to its radius. Newton's Meth. of
flux. and Inf. Series, p. 60. Maclaurin's Fluxions, b. i.
See Curvature and Evolute.

Quantity of Motion, in Mechanics, is of two kinds; viz.
of momentary motion, and of entire motion.

Quantity of entire motion. The Cartesians define the
entire motion as the momentary one, by the factum of the
mass, or quantity of matter, into the velocity; but since
motion is a successive being, and has not parts co-existing
together, its quantity ought to be estimated by the aggregate
of the several parts existing successively; and is therefore equal
to the factum of the moment into the time.

Quantity of momentary motion is the factum of the
velocity into the mass; or it is a measure arising from the
aggregate of the quantity of matter, and the velocity
of the motion of the body; the motion of any whole
being the sum or aggregate of the motion in all its several
parts.

Hence, in a body twice as great as another, moved
with an equal velocity, the quantity of motion is double; if
the velocity be double also, the quantity of the motion will
be quadruple. Hence, the quantity of momentary motion
coincides with what we call the momentum, or impetus of a
moving body. See Force.

In the collision of bodies, the quantity of momentary
motion, which is found by taking the sum of motions tending
the same way, or their difference, if they tend towards con-
trary parts, is not at all changed by any actions of the
bodies on one another. See Percussion.

Quantity of Matter in any body, is the product of
the density into the bulk; or a quantity arising from the joint
consideration of its magnitude and density.

As, if a body be twice as dense, and take up twice as
much space as another, it will be four times as great.
This quantity of matter is the best discoverable by the
absolute weight of bodies. See Matter.

Quantity, Infinite. See Infinite Quantity.

Quantities, in Algebra, are indeterminate numbers, or
things referred to unity in general. See Number.

Quantities are properly the subject of algebra; which
is wholly conversant in the computation of such quantities.

Crown quantities are used to be noted by the first letters
of the alphabet, a, b, c, &c. the quantities sought by the
mathematics, d, e, f, g, &c. See Characters.

Algebraical quantities are chiefly of two kinds; positive,
and negative.

Quantities, Positive, or Affirmative, are those which
are greater than nothing, and which are affected with the sign +
 prefixed; or supposed to be fo.

Quantities, Negative, or Privative, are those less than
nothing; which are affected with the sign — prefixed.

Hence, i. Since + is the sign of addition, and —
the sign of subtraction; a positive quantity is produced
by adding any real quantity to nothing: e. g. 0 + 3 = 3;
and 0 — a = — a. And a privative quantity is produced

by

A a
QUA

by subtracting any real quantity out of nothing; e. gr. 
$0 - 3 = -3$; and $0 - a = -a$.

For an illustration. Suppose when you are quite deli-
tute of money, somebody gives you a hundred pieces; you
have then a hundred pieces more than nothing; which pieces
constitute a positive quantity.

On the contrary, suppose you have no money, yet owe a
hundred pieces; you have then a hundred less than nothing;
for you must pay a hundred pieces to have just nothing.
This debt is a negative quantity.

Thus in local motion, progress may be called a positive
quantity, and regresses a negative one; because the first in-
creases, and the second diminishes the space passed over.

And in geometry, if a line drawn towards any part be
accounted an affirmative quantity; another the contrary way
will be a negative one.

Privative or negative quantities, therefore, are equally
real with positive quantities, but opposite to each other, so
as to take away each other's effect, in any operation, when
they are equal as to quantity. Thus $3 - 3 = 0$, and
$a - a = 0$. However, though $a + b$, and $a - b$, are equal as
to quantity, we do not suppose in algebra, that $a + b = a - b$;
because to infer equality in this science, they must not only
be equal as to quantity, but of the same quality, that in
every operation the one may have the same effect as the other.
A negative quantity is said to be less than nothing, becaus
it is opposite to the positive, and diminifies when joined to it;
whereas the addition of $a$ has no effect. But a negative
is to be considered no less a real quantity than a
positive. Quantities that have no sign prefixed to them
are understood to be positive. See Negative Sign.

Quantities, commensurable, compound, exponential, heter-
genous, like, rational, simple, transfinite, and variable.
See the adjectives.

Quantities, Addition of. 1. If the quantities denoted
by the same letter be affected with the same sign, the
numbers prefixed to them are added as in common arithmetic.
2. If they be affected with different signs, the addition
is changed into subtraction; and to the remainder is prefixed
the sign of the greater.
3. Quantities denoted by different letters, are added by
means of the sign $+$; as in the following example:

$$
4a + 2b - 2c - 5d - g \quad a - b
$$

$$
5a - 2b + 6c + 2d - 3g \quad c
$$

$$
9a + 4c - 3d - 4g \quad a - b + c
$$

See Addition.

Quantities, Subtraction of. See Subtraction.

Quantities, Multiplication and Division of. See Multi-
plification, and Division.

Quantities, Combination of. See Combination.

1. If a positive quantity be multiplied or divided by an-
other positive quantity, the result is also a positive quantity.
2. If a negative quantity be multiplied or divided by a
positive, the result is a negative.
3. If a negative quantity be multiplied or divided by an-
other negative, the result is a positive.
4. If a positive quantity be multiplied or divided by a
negative, the result is a negative quantity. See Multiplica-
tion, in Algebra.

Quantity of a Degree. See Degree.

Quantity of an Eclipse. See Eclipse.

Quantities of Seeds, Sets, and Plants, in Agriculture,
the proportions of each, which are necessary for raising
good crops of the different kinds. The ascertaining of
the most useful and beneficial quantities, in the several cafes,
depends, in a material degree, upon a number of different
circumstances, such as those of the situation, the nature and
quality of the soil, the period of sowing, the state of the
feason, the manner of putting them into the earth, and fe-
veral others.

A great deal more feed, sets, and plants, are requisite
in late situations or backward seasons, heavy, wet, fluff
lands, and late sowings; than where they are more forward,
more light and dry, and put in early. And far less quanti-
ties made use of in the drill and dibble methods of put-
ing in the crops, than in that of the broadcast, or by the
hand.

In most sorts of white, or grain crops, the quantities are
from two to five bushels per acre, being more in barley and
oats, than in those of the other kinds, as from three to five
in general.

In those of the pulse kinds, usually from fix or seven
pecks, to two, three and a half, and four bushels, being
commonly the latter, or more, in some sorts of beans.

In those of the small feed description, as the buck-wheat
and turnip sorts, from one to two and three pounds; but in
the cabbage kind, only from six ounces to half a pound,
and a quarter or half a peck.

In the tap-rooted crops, as the carrot, parsnip, mangle-
wort, &c. from two to five pounds, and sometimes fix.

In lettuce crops, in the field, from three to four pounds
the acre.

In different sorts of plantation crops, as those of hemp,
flax, wool, fold, teaeful, &c. from two to three up to five
or six bushels, in the three first; but only from two to four
quarters, and from one to two pecks, in the two last.

The fets in the hop, madder, loquorice, and lavender kinds,
are from fix to seven hundred, and a thousand or more,
in the first, and two half; but in the madder from fifteen
or twenty thousand per acre. In the cabbage fort, from
eight hundred to a thousand and more plants or sets to the
acre. And in the potato the quantity of sets vary from eight
to twenty or more bushels to the acre, according to
the soil and manner of their being put into the ground.

The quantities of natural grains which are generally
employed upon the acre, are from two to four bushels and
upwards. And those of the artificial grains kinds, in the
clovers from ten to eighteen pounds; in fainfoin from three
to four bushels; in lucern from sixteen to eighteen pounds;
tares from two to three bushels; trefoil, three pottles of
cleaned feed, or two bushels of the uncleaned feed. And
in chicory from eight to twelve pounds. See Seed, Set,
Plant, and Sowing.

The subject is more fully explained in speaking of the
of the different sorts of crops, and the most suitable
quantities under different circumstances put down.

Quantity, in Grammar, denotes the measure and
magnitude of the syllables; or that which determines them
to be called long, or short; or, it is the measure of time
required for the distinct pronunciation of a syllable.

This quantity is the object of prosody; and it is the re-
gard to this that distinguishes verse from prose.

The economy and arrangement of the quantities, i.e. the
distribution of long and short syllables, make what we call
the number.

The quantities are used to be distinguished among gram-
arians by the characters short and long.

The proportion between the long and short syllables may
be generally fixed the same as that between the crotchet
and quaver in music; viz. as two to one. See Time.

Syllables are long or short, either by their nature, or by
accident; that is, on account of the place where they are
put
QUANTITY.

1. Except that a short vowel before two consonants, whereof the former is a mute and the latter a liquid, is common; as

\[ \text{'All' ἐπιλέξας τόν, ἀκούσας ἅλώματος κατακάθισε.} \] Hom. 

Σάραξ. v. 45.

2. A short vowel is sometimes made long before a single consonant, particularly before a liquid, as πωλάλα ἀντίπρομε, Hom.; παραγμοί, Hom.

Note.—1. In pastoral, elegiac, and epigrammatic verse, the syllable is more frequently short.

2. In dramatic poetry we may observe, 1st, that a short vowel before a short or aspirate mute followed by a liquid, and before a middle mute followed by a, remains short. In tragedy the syllable, if not final, is often long. 2dly. A short vowel before a middle mute followed by \( \lambda \), \( \nu \), or \( \kappa \), lengthens the syllable in all dramatic poetry.

3. When the syllable is lengthened before two consonants, the vowel in pronunciation affirms one of them; as θε-α-ζη, ἀπε-δεικνύς, κτά-πά-κοις, πέτροι, τε-τοις. Hom. When the syllable remains short the vowel concludes it; as πα-περις, πε-περις.

5. A vowel before another does not suffer elision, as in Latin, at the end of a word, unless an apophtegm is suffixed.

Note.—The elision of diphthongs takes place in verbs only; real inferences of this are to be found only in the fragments of the new comedy.

6. A long vowel, or a diphthong, is generally shortened at the end, and sometimes at the beginning, of a word, before a vowel; as οἷς ἤι, Hom.; ταῖς, Soph.; ι οἷς ἤι; Theoc.

Note.—A long vowel, or a diphthong, may be considered as consisting of two short vowels. If the latter is supposed to suffer elision, the former will of course remain short; as οἷς ἤι.

Composition and Derivation.

9. Compound and derivative words follow the quantity of their primitives; as \( \text{άστικος} \) from \( \text{τυγκύς}, \) \( \text{φως} \) from \( \text{φίων} \); \( \text{λοι} \) from \( \text{λίς} \).

Note.—Grammarians have sometimes complained that "non fanno regulae indicandum". But Dr. S. Clarke affirms, "Derivantes pro eo, a quo parte sunt penultimum timenter vel perpetuo corrupi, vel perpetuo producunt. Latin habet bene, logi, quasi contrarium ex lege. Similiter sedes, sed, indeque sedes, sedula. Cum fimili quidam ratione, apud Graecos sit. Verba minima numeros, sine quibus praebiscant et imperfecti omnibus et in soribus primis, activa et mediocribus, sperant producuntur: in futuris secundis et auribus secondis omnibus, sperant corripiunt; ut φως, ἠπόμ, ἄρω, ἄρως, ἀπεδεικνύς, indeque ως, ἀφρός, φθέργε, &c. Κρής, κρίνη, κρίνη; δέκα, indeque κρίτες, κρίτης, κρίτης, &c.

QUANTITY.

1. Except that αυ is long in circumflexed words, and in oxytons masculine; as σαυς, Τταυς.

2. These adverbs, ὃποιος, ἵνα διότι ομοίως: and the accusative of the first declension, whole nominative is long; as Ἀντίων, Ὀλυμπ.

3. It is long in words of two terminations; as ἀγαθός and ἀδίκος.

4. Μένων and μένων when circumflexed: τινι Dorian for σι. Πέπορ is sometimes long in Homer.

5. Nouns in αυ, αυς as ἀγαθός, lengthen w final.

6. Συνος is long in words of two terminations; as πρέσπη and πρεσπεία.

7. Accusatives from αυ long; as ἄρας, with ὃς; though ἀρας the enclitic is short; as τοι ἀρας.

8. The imperfect and second aorist of verbs in υψι; as ἰδεῖσθαι, ὕπερθεν.

9. Except that υ ψ υ ψ final is short; as ἡμείς, ἡμέρις, υπό, νός, βατάδις.

1. Except that αυ is long in the nominatives of participles; as τιλαί: in all cases of the first declension; as ἄνατος, ταμίας, μοῖρας, μοῖρας: except the Doric accusative; as ἄρας; in plural accusatives in αυ: from the long α in the accusative singular of nouns: in υυς; and in nouns in αυς: as Αιος; with ταιος.

2. Also υς is long in words of two terminations; as ἀνθρώπους and ἀνθρώπως in nouns in υς; increasing long; as ἀνθρώπης, ἀνθρώπες, &c.

3. And υς is long in words of two terminations; as ὅτιος and ὅτιοι: in monosyllables, as μός, μῶς: oxytons making the genitive in ας pure; as πλατός: ὡς is common. And in verbs in υμι; as ἢδεικνυς, &c.

On Quantity in the Latin Language.

As the proody of the Latin language is considered to form an essential part of a classical education, we shall, therefore, devote the more peculiar attention to this part of the subject. In the course of which some rules will be given on the quantity of syllables usually said to be long or short by authority; which, we believe, have never yet been collected by any writer, ancient or modern. Perhaps, therefore, in particular for this, and for such other reasons as the cœndour of impartial discernment shall discover, we shall not incur the cenure of having been too bigine, should we have indulged the hope of being enabled to offer the most complete system on Latin proody that has hitherto been presented to the public.

GENERAL RULES.

A Vowel before a Vowel.

1. One vowel preceding another, in the same word, is short; as puer, egregias.

O Melibaeus, Deus nobis haco offert. Virg.

2. The same happens, though an h intervene; as nihil, ãhenus, ãñhusco.

De nihiló nihil, in nihilum nihil posse reverti. Perfr.

Note.—H is generally considered only as a note of aspiration or breathing; though some ancient grammarians considered H as a continuant, and ranked it with the semi-vowels. See Terentianus Maurus, de syst. 511.

1. Except

31. As in, u, final are short; as α✈, ὡ 'Ανιδ, ταῦτα, εὐερα;
QUANTITY.

1. Except the i of fio is long, when it is not followed by a vowel and r; as fiam, fiam, fiam, fiat.

Omnis iam fiant, suntque poetae negebant. Ovid.

2. The e of the genitive and dative of the fifth declension, when it comes between double i, is long; as faciei; but it is short in spei, and long and short in rei et fidei.

Venenum erat ad Vestae quattuor jam parte deo. Hor.

Enhythum fractum; nee te diga fixt. Seneca.

Ipsi rei rationem redire possis. Lucret. &c.

Cursum nescio quis temer abest rei. Hor.

Ille vir haud magnus eum re, sed plenius fideli. Em.

Unum rectus habens, fideliqve immobile vinculum. Manil.

* Lucretius furnishes five examples of rei; Plautus two. These cases appear to have been anciently written both e-i and e-i, which accounts for the variation in quantity in Latin.

3. Genitives in ius have the i long in prose, though in poetry it is common: as unius or unius, illius or illius: except the i of aliue, which (formed by crasis from aliue) is always long, and the i of alterius, mostly short.

Navibus, infandum amissi, unius ob iram. Virg.

Parite mea paxem totius orbis erit. Claud.

Tu potes alterius studia habere Minerve. Claud.

Modum dum alterius * obligarius bona. Virg.

* Alterius is three times long in Terentianus; de syllab. 1372, de meir. 34; and 464.

4. The penultimate is long in auri, aulae, and other antique genitives of the first declension, and in such vocatives as Pompeii, Cai; because these were originally written with a double i; thus, Pompeii, Cai.

Ethereum femine, atque auri simplicis ignem. Virg.

Accipe Pompei, deductum carmen ab illo. Ovid.

5. In obo, in os (whether interjection or proper name), and in Diana, the first syllable is common.

Ohe! jam fatis ehi, oh, libelle! Mart.

Ruribus, is, magnus clamat toro triumphos. Mart.

Quaere ferebat duceor Sidonius, is.—Conslavum. Sil. Ital.

Io, verba caput, primus jugavit amnis. Propert.

Quis tois causas fugit? quid tos freta longas perpetras? Ovid.

Expert a eam mortem utrique Dianae. Mart.

Juno, Vesta, Ceres, Diana, Minerva, Venus, Mars. Em.

6. Acri, Dios, cheu, have the first long.

Prosinius ehat vire illi levitate, loco.</p>

Ovid.

Inalides: eum ipso deum est diis Camilla. Em.

7. In many Greek words a vowel is long, though immediately followed by another, as Achaea, Achelous, Laertes, Laocoe, and other words compounded with lae; Latius, Enyo, Panchaia, Thetis, Teygetus, Trias, Trius, Galatia, &c.

Erubuit Mavros, aver fires rifto Efesto. Claud.

8. Those adjectives which are written in Greek with the diphthong o, and in Latin with a single o or ae have that o long; as Aeneas, Museum, Darius, Thalia, Clio, Elefagia, Oracides, &c.

Et panacea potens, et Thesala centenaria. Lucan.

9. Most adjectives in eus, formed from Greek proper names, have the e long; and it continues so, when resolved into ei.

Oppida femoto Pelopony marta vigent. Claud.

Notes.—1. Those which contain a choric ("ue") in the two syllables immediately preceding the penultimate, were more frequently formed, for the convenience of furnishing a dactyl, with the penultimate short; as Hecateus, Nelloricus, Agrobus, Antenor, &c. 2. In imitation of the Greeks, we see in Statius, the adjective Tiberius.
6. If the former of two words end in a short vowel, and the next begin with two consonants or a double letter, the vowel often remains short.

Tu poteris viris pennis hebetari sinaragdosa. Ovid.

Note.—Virgil, however, who has adopted such licences as fulcis Hyacinth, and qui amant, has lengthened the short syllable but in one line; "Ferte eit ferrum, date telis, scandite murum." Many of these vowels, which at the end of a word are found long before two consonants beginning a following word, are lengthened by the context; as "Occulta epola, et pluris de pace triumphos." Juven.

Of a Vowel before a Mute and a Liquid.

7. A vowel naturally short, followed by a mute and a liquid, is common, though always pronounced short in prose: as aegris, pharetra.

Natum ante ora pateres, pateraque obruant se atras. Virg.

Note.—1. To produce this kind of position, three things are requisite.

1. That the mute precede the liquid. 2. That the mute and the liquid be both in the following syllable; or otherwise this rule cannot take place; as in ab-luo, where the two consonants cannot be founded in the latter syllable. 3. That the vowel preceding the mute and liquid be short by nature. Hence the a in aecris and matris is always long, because the a in iner and maters is always short.

2. In Latin words, l and r are the only liquids preceded by a vowel and a mute; in Greek words, l, r, and also m, n, have the same effect as Cyclopes, Tec-cneia, Da-phi-ne.

3. H is not, neither in this, nor the foregoing rule, to be deemed a consonant. Joined with any of the consonants, it has the power of lengthening a preceding short vowel; not even with two consonants (i. e. a mute and a liquid) in the next syllable; as His Pellaei proles xofam Philippi.

Cornitet egregius laps hic, cul nomen achates. Prisc.

Hic Paphisius myros, hic purpures amethystos. Ovid.

Arbor habet frondes, paulus femur humanus. Ovid.

Of Graff, or Contraction.

8. Every syllable formed by the contraction of two fyllables into one, is long; as cogeo for cogeo, the genitive afixus for afixus.

Titvre esque pecus, tu poll careeta lates. Virg.

Obscura fortis patres amethystos errant. Ovid.

Note.—This is a rule of very extensive application. We are told that the ancients expressed a long syllable by a reduplication of the vowel; thus vexit for the perfect vix. And it will be found that in many words the long syllable arises from the contraction of two vowels. Thus we write tibi tibi for tibi; ambages for ambages; his, his, for ilphis, trilips; iunior for junior; bosus for bosus; but for but; mi for mihi; and malo for magis volo.

Of Derivatives.

9. Derivatives usually follow the quantity of their primitives; as inimus, inima, anima, animales, animosus, animare; from lego; legemam, legeram, legam, &c.; but from legi; legeram, legeram, legero, &c. talius from totus, and tautos from tot.

Nec sita pari, homo terrae quot totius usus. Lucret.

1. Except defderative verbs in aris, which have the u short, although from the participle in urus, that has u long; as nuptium from nuptia.

2. Frequentative verbs, formed from the second supine of the first conjugation, by changing itus into itae, have the i short; as clamito, volito.

Portariam montes, nescit rudiculis mus. Hor.

Intermix tua teota super coluvero abis. Virg.

3. There are other long derivatives formed from short primitives, and short derivatives formed from long primitives.

Note.—1. Of the former, the following is nearly an accurate list: como from coma; forms and fomentum from favo; humus from homus; iunctus and jumentum from juro; mophia from morphia; regula from regul; regula from regula; regula from regula; regula from regula; regula from regula; regula from regula.

5. Some of these anomalies have, perhaps, arisen from the influence of crafts and syncope. Thus mollis from movae, may have been movibilis; momentum, momentum; motum, movitum; setum, setum; setum, setum; motum, movitum; jumentum, jumentum; from jovae. Sometimes the derivative becomes short by dropping one of the consonants which rendered the word whence it is formed to come, long by position; as differtus from differe; many from many; volutum from volvo; solutum from solven; tulfrum from tulfrum; pox from possum. When the primitive is necessarily short, by one vowel's preceding another, the derivative sometimes becomes long, by the addition of a consonant; as in hiberna, hiberna, hibernae. Liquidus is supposed to have its first common (as it may be derived from the deponent lieque, or from the neuter lieque), on the following authority.

Crafaic cannitium liquidus, et liquidus effrons. Lucrret.

Compound Words.

10. Compound words have the same quantity as the simple words from which they are formed; as perlageo from lego; perlagei from legi; improbus from probus; perjurus from per and jurs-juris.

11. The quantity of the primitive word is generally preserved in the compound, notwithstanding the alteration of a vowel in the latter; thus accido from accio, accido from celery, acquirro from querro, inquisus, oblquus, antiques from aquos.

Multa remissentur, quia jam cedentur, cedentur. Hor.

Except 1. The following are short compounds from long primitives; nihilum from nihil; dejero and pepjero from juro; caudificus, fatidicus, maledicus, veridicus, from dio; semispitus from sopitum; cognitum and agnatum from nontum; hosp from hosp de.

2. Imbecillus from bacillus has the second syllable long: cornu from cumbo has the u common.

Porto meo, nullo dextram subeunte bacculo. Virg.

Imbecillus, iners, fi quid vis addo prejino. Hor.

Cumulatio jugum flabii, propriamque diebo. Virg.

Hec tori Andromache 1 Pyrrhus connubia servas. Virg.

12. Prepositions, in composition, have generally the same quantity as out of it; thus amito and deducro have the first long, because a and de, as a final and monosyllabic e are long. Aboleo and pereimo have the first short, because ab and per, as e and r final, are short.

Expedium, primar repetens ab origine, famam. Virg.

Nec poteris ferrum, nec edas aboletra venus. Ovid.

Note.—1. A preposition ending in a vowel, although out of composition it may be long, becomes short by the first general rule; if followed by another vowel; as deceful, prohibeo. And if a short preposition end in a consonant, and be followed by another consonant it becomes long, by the second general rule; as adimito, percello.

2. Sometimes the preposition, instead of becoming long by position, leaves its final consonant, and remains short; as omino, inoepio.

Except 1. Di is short in dirimo and dijertus: as Hane Deus et melior item natura ducend. Ovid.

Caudas, iniquus, agam Cicero deletius ipdo. Virg.

Marti.
QUANTITY.

16. If the first member of a compound word terminate in \(i\), that vowel is short; as bivium, trivium, tripees, siccidentis, shitrocatra, agricultura, vaticinius, signifiéri, architectura, dimiter, trimitter, ichigenia, &c.

Jane. &c.

1. Except those compounds in which the \(i\) is changed in declination; as quidam, quiquis, quilibet, quattuor, quinque, quindecim, quatuordecim, quintum, quinti, quintus, siquis, or si quia.

2. The final \(i\) is long in those compounds which may be separated without destroying the sense; as ludi, magister, or ludus magister, parvipendio, or parvi penio, lucrificio, or lucrifico, signis, or si quis.

3. Those words which in joining undergo a change of sense, are long; as tibicen for tibicen, bigis, triges, &c. for bigiges, triges, &c.; ilicet for ile licet; felicit for feli licet; but tibicen, which has suffered neither, is short by the general rule.

Ite! ignis edax summa ad fæligna vertex.

4. Idem mafeline is long; but in the neuter it is short. Idemidem has the penultimate short.

Omnibus animo animus, ledetera excedere territ.

Instim qui scribat, idem factum occidit.

Qui fedens adversus idemdem te.

5. The final \(i\) of the former compound word, is long in nimimum, ubique, ubritique, ibidem.

Dixi equidem et dico. Captes altatus ubique.

6. As the \(i\) is common in ubi; so it is in ubique and ubivis.

Clausus: io matres audi nobis quesque. Latine.

Servor, ubique eis: uti mea grada ferio; Ovid.

The compounds of dies have the final \(i\) of the first word long; as biduum, triduum, meridies, pridie, posttridie.

Si solis tibi triduo legatur.

Note.—1. Pridie and postpridie are long by exception 3, being prior dies, and posterior dies.

2. Quotietae and quotidians are said to have the \(i\) sometimes short; but this is not satisfactorily ascertained, since the lines added in proof may, by the figure synizesis, be differently measured: thus

Conjunctus in culpa fragrantio quotidiana.

Catal.

Or quotidiana. It must be confessed, however, that thus read the line is harsh, and is unnecessarily rendered spondaic.

3. Triginta, trigintis, trigintis, triginti, are not considered as compound words, in which the \(i\) is short, as it is in all the real compounds of trid, etc. trigintes, sestina, stigmata, triginta, etc. &c. for triginta cannot with propriety be called a compound word, since sintas is only a termination. At all events the \(i\) of triginta, etc. is ever long.

17. If the first member of a compound word terminate in \(a\), it is short; as Argonna, aromphylax, arseopag, bibliotheca, philosophos, faceretanclus, duodecim, hodie.

Non natus putito, sed Argomnauta.

Mart.

Non dies hodie, quantum hic tam patris tandem — Hor.

1. Except words compounded with intro, retro, contra, and quando; as introducus, introdutio, retriciduo, controvercus, quandique, &c.; but quandocidem has the \(o\) short.

Isto retrovertitur equilines prataea ora.

Ovid.

2. Allo aliquus, utroque, exercet quius, utroque; and
and the compounds of quo; as quomodo, quocunque, quominus, quocirca, quovis, and quoque the adjective; but quoque, the particle, has the ο short.

Mendax est natura, ali·gui·que velatur. Hor.

3. Those words which in Greek are written with an ο-megas, have the ο long; as γεωμετρία, γεωγραφία, mìnōtaurus, lágopus.

Si nascentem gaudent lámpade Flaccus. Mart.

18. U and Y terminating the first member of a compound word, are short; as in Thrasýbulus, Eurýpylus, Polýpus, dúcēnti, dúpondium, quadrapés, centíplex, Trogýgena, cornúpeta, Polýdorus, Polýphemus, &c.

Nam qui dixit quæque cavō Polyphemum in antro. Virg.

Except jūdicē, which in its first syllable is, by syncope, long.

Et supras, et metum loci et Jove jādocat, quæ. Hor.

Of the first Syllable of Dīssyllabic Preterites.

19. Preterites of two syllables have the first long; as vēnī, vidi, vīcī.

Verī sunt duas dies, et ineluctable tempus. Virg.

Except bibi, tūli, dēdī, rēti, fīcti from scindo, (for abiciōd is long from abicendo, and abicēri short from abiscendo,) fidi from fīndo, (for fidi and confidi from fido are long.)

Aut fēcīt, et medias fecit ibi littora terras. Lucan.

Of the two first Syllables of Reduplicated Preterites.

20. Preterites doubling their first syllable, have that syllable and the following both short; as tētī, pēplū, pēpēri, dīdicī, tūticī, cēdīcī from cado.

Si mūnat fuerat tibi quattuor, ēllα, dēcēta. Mart.

Except cēdīcī from cado has the second syllable long; and likewise those preterites, in which that syllable is followed by two consonants; as fēfēlli, mōmōdī, ἕφσονδο.

Ebrīus et petulas, qui nullo forte cecidīt. Juven.

...... vatum fēpōndiā: nulla proper sero fiero. Senec.

Quæ Deum ipse virīa sinterna foribus fēpōndiā: Prud.

Note.—From the authorities here quoted, it is evident that fēpōndiā is the clasical orthography, not fēpōndiā, which would have the first syllable long by position, before syllables, as we may invariably observe in compound words; as rēfūn, rēplūcio, rēpons, rēfērō, rēspergo, &c.

Of the first Syllable of Dissyllabic Supines.

21. Supines of two syllables, and the perfect participle formed from them, have the first syllable long; as vītum, mōtum, ēłfum, rētum, vītus, mōtus, &c.

Terribiles si fīman formae, letumque, laborque. Virg.

Quos ego — fidēs mōs praetax componere fūcitus. Quīnt.

1. Except the first syllable is short in daētum, rātum, fātum, ēltum, lītum, quītum, sītum, rātum, and fūtum, from the obōfle fuō, whence we have futūrus.

Cui daētus hærebam caēlōs, curiaeque regēbam. Virg.

2. Cītum from cīeo of the second conjugation has the i short; but cītum from cīeo of the fourth conjugation has it long.

Corripit lēve, et teēcis cītus extulit aliis. Virg.

Unde rumpere concitā periculum mundo. Lucan.

3. Statum is common: hence we find fāturus, conflāturus, oblāturus, flāmen, rātus-s-um, rātus-ūs, Vol. XXIX.

praefītūm, fātio, fātuo, flābilis, flābulum, rātor, fātum, &c.: the former of which are said to come from òo, the latter from fōtō.

Hec fōtus in caldo multos permanit in annis. Ovid.

Damnāvit multō fātūrum fangeā Martem. Mart.

Suffītto imperi, cuius famōsitās honorum. Claud.

Non profectō sībi praefat naturā sed unus. Prop.

Confītūra fuit Megalēnē purpurea centum. Mart.

Of the first Syllable of Polyssyllabic Preterites and Supines.

22. Preterites and supines of more than two syllables have the same quantity in their first syllable as the present; thus vōcāvi and vocātum have the short, because the first of vōco is short: clāmāvi and clāmātum have the first long, because the first of clāmo is long.

Si vōcat officium turba cedente vestītur. Juven.

Indiūt, impluviaque mero, divoqve vōcāvit. Virg.

Except pōsui, pōsitum from pōno; gēnui, gēnītum from gigno; pōtui, pōsitum from politum, vōltum from volvo and volvō.

Of the Penultimate of Polyssyllabic Supines.

23. Supines of more than two syllables, in ētum, ētum, and ētum, lengthen the last syllable but one; as amātum, dēlētum, minūtum.

24. Supines in ētum, from preterites in ēvi, also have the penultimate long; as cupīvi, cupītum; petīvi, petītum; quēsvi, quēsvitum; polīvi, polītum; but the compounds of co, ambio excepted, have the penultimate short.

25. Supines in ētum, from any other preterites, shorten the penultimate; as cubīvi, cubītum; mōnīvi, mōnītum; abōvīi, abōvitum; agnīvi, agnītum; cōdīvi, cōdītum; recēsvitum of recōfleo is long, on account of its origin from the obfole cenīo, cenīvī.

Namque servavit luēν Cēsenam Phaethontis amāti. Virg.

Delēs Silvōrum acies, eccēsīs Canīlum. Virg.

Sātituēt erūtus vincīs ad sēdēs palmas. Virg.

Σαρκό εὐκατσίται prōbhs, gladiāque petītus. Claud.

Codōnem Phēnto, et nomēs multās equām. Virg.

Pētēs recēsvitēs evolviā equēs fallātūs. Claud.

Of the Penultimate of Participles in Rūs.

26. Participles in rūs always lengthen the last syllable but one; as amātūrus, habītūrus, lecītārus, auditūrus.

Tādēs verit, feris faētāra nepōtibus umbrae. Virg.

Increment of Nouns.

Note.—1. If the genitive case singular do not contains a greater number of syllables than the nominative, that noun has no increment, as pēnia, pēmav, carō, cārīs. But if the genitive contains more syllables than the nominative, the penultimate of the genitive is the increment; and whether that syllable be long or short, it preserves the same quantity in all the oblique cases singular and plural. If hēbus or hēbus be an exception, we should recollect, it is so by syncope and craits from hēbus. Aufonius, contrary to the practice of better authors, has an example of hēbus short, as if it had been formed by simple syncope without craits. See Aufon Epig. 62.

2. Nouns seldom have more than one increate in the singular, except, (when its genitive is jecimovair,) supellēx, and the compounds of captāt, ending in μα, have two increments. The dative and ablative of the third declension have two; of the aforementioned words, three increments. They are reckoned in the retrograde order, beginning with the penultimate, for the last syllable is never considered as an increment.

1. i-tn-e-ris, i-tn-e-r-bus.

2. jec-tn-o-nis, jec-tn-o-n-bus.

4. an-cal-tis, an-cal-t-li-bus.

5. B b
Of the Increments of the Singular Number.

Of the first, second, fourth, and fifth declensions.

27. In the first, fourth, and fifth declensions, there is no increment in the singular; except the antique increment of the first declension, by the resolution of the diphthongs in ai, in which the ai is long: as

Dives equum, dives pipelli vehis et aurum.

Verg.

28. The increments of the second declensions are short: as

pueri, viri, faciuli, teneri.

Verg. 

O pueri! ne tanas animis affligo bella.

Verg.

Except Iberi, Libræ, and its compounds Celtiber, Celtibéri, which lengthen the penultimate; as

Quaque fers movit, Ser-orius exit Iberos.

Lucan.

Vir Celtibéri nescit genitibus.

Mart.

. Increments of the third Declension.

29. Nouns in A shorten the genitive penultimate; as dogma-atis.

Non quiius videt immolatun poenætia judæus.

Hor.

30. Nouns in I, compounds of meli, shorten the genitive penultimate; as hydromel, hydromelitis.

31. Nouns in O, increasing in ïnis, shorten the genitive penultimate; as cardo, cardinis; imago, imaginis.

32. Enis and onis, from or, are long; as anio, anicius; fermo, fermö尼斯.

1. Except gentiles in generally shorten the increment; as Macedo, Macedonius; Saxo, Saxonianus. To add which Lingones, Scuones, Teutones, Vangiones, Vafiones. Some lengthen the penultimate; as Su- effiones, Vettiones, Burgundiones, Eburones. Juvenal shortens Britones; Martial lengthens it.

2. Nouns in er, from the Greek, or which sometimes drop the n, preserve in Latin the same quantity which they have in the original; as Agamemnon or Agamemno, Agamemnonis; Demipho or Demiphois.

Sanguine placátia ventos, et vingéna cafa.

Verg.

Hæc tum multiplex populus fœminæ replebat.

Verg.

Non longissimum deort domus quod Sævius Tethys. Claud.

Qua non tarthrels Cambri, nec Britonum unquam— Juven.

Quam veterebrae Britónum pauperis et quam— Mart.

Quo fero inquit poet Amagemono fero— Ovid.

33. Nouns in EC lengthen the genitive penultimate; as haelectis.

Hæc est sed quam protinus ipsa vore.

Mart.

34. Nouns in D shorten the genitive penultimate; as David, Davidis.

Ereco inductis Davidis origine lumen— Juven.

Note.—Ecclesiastical writers often lengthen the penultimate of David.

35. Masculines in AL shorten the genitive penultimate; as Hannibal-älis; fal-älis (masculine or neuter).

36. Neuters in AL lengthen älis; as animal-älis.

Verae sunt pereat, et luminis solis vere ventur.

Verg. 

Prenques cum spectant annuláta extre. terram. Ovid.

37. SOL lengthens solis: and also Hebrew nouns in EL lengthen the genitive penultimate; as Daniel-ëlis.

Regis solis est fulminis solis columnas.

Ovid.

38. All other nouns in L shorten the genitive increment; as vigil-ëlis, conflu-ëlis, exul-ëlis.

Aut urbem, aut pulchritud, ha main plebeocula pudet. Hor.

39. Nouns in EN shorten the genitive penultimate; as crimen-ënis, flumen-ënis.

Quoqua magis mirum est, audetem crinemis hujus— Mart.

40. No certain rule can be given for the quantity of the increment of nouns ending in UN. Many lengthen the genitive penultimate; as Chiron, Demiphon, Agon, Helicon, Lacon, Secyon, Solon, Simon; many shorten it; as Acteón, Agamemnon, Amazon, Iasion, Memnon, Philemon, Orion, Sidon, Sindon; and Ægeon has the penultimate common.

Credit, et excludit fanos Hecatæno poetas.

Hort.

Et vehit abuentem certamin Ammonis clamant.

Ovid.

Audaciter datas lavamns Ægina noua

Stat. 

Ægina inuia immanis erta lacertos.

Ovid.

41. All other nouns in N lengthen the genitive penultimate; thus Titan-ënis, Siren-ënis, delphin-ënis, Phorcyn-ënis.

Concitat iratus validos Titonos in arma.

Orphus in hybris, inter delphíno Asio.

Verg.

42. Neuter nouns in AR lengthen the genitive in ëris; as calcar-ëris.

Seu fumansæque equi ferceribus armos.

Verg.

But these neuters shorten ëris; bacchar, jubar, neactor-ëris. To which add par-ëris, and its compounds; as impar-ëris; dilpar-dilpars, &c.; also hepar-ëris.

Pugnavere pérœs; succubueru pérœs.

Mart.

43. But masculine nouns in AR shorten ëris; as Cæfar-ëris, Hamilton-ëris, lar-ëris.

Eccle Decius princeps Cæsaris alium.

Verg.

Except Car and Nar; as,

Laudibus immodicis Cæsars in alia ferunt.

Mart.

Sulphures posuit sparsim Néris ad undas.

Enn.

44. Greek nouns in TER lengthen the increment; as crater-ëris, character-ëris, spinhëris; except othér-ëris.

Indulgat vino, et vertunt craterës abhena.

Verg.

Quæcumque illa levan fugiunt facet æthera pennis.

45. Nouns in OR lengthen ëris; as amor-ëris; timor-ëris.

1. Except neuter nouns; as marmor, àquor-ëris.

2. Greek nouns in OR; as Héctor, rhetor-ëris.

3. Arbor-ëris, and membr-ëris.

46. The following nouns lengthen the increment; fur-furis, ver-veris, Recimer-Recimëris, Byzer-Byzëris, Ser-Sériis, Iber-Iberis, (as well as Iber of the second declension.)

Velenque ut solis delectant temnë Sôris.

Verg.

47. Other nouns in R, not mentioned; shorten the genitive penultimate; as aer, æris; mulier, ëris; cadaver-ëris; iter, itinis; verber, verberis; vultur, ëris; marmur, ëris; fermur, robor, jecurt, ebur-ëris; martyr-ëris.

Si nigro obstruto comprehenderit íera cornu.

Aphicæ, venetiæ occidentum marmístri auræ.

Verg.

48. Latin nouns in AS lengthen the increment; as pictas-ätis; Maccenas-ätis; vas, vatis, a vesel.

Insignem pictâtis virum tot adire Liberes.

Verg.

Except
49. Greek nouns in AS shorten ἄδις, ἄτις, and ἀνίς; as
Pallas, lampas, ἄδις; artocreas, ἄτις; Melas, ἀνίς.

50. Nouns in ES shorten the increment; as miles, milītis;
feges, fegetis; preces, praesidis; obses, obsidis; Ceres,
Cerēris; pes, pēdis.

51. Nouns in IS shorten the increment; as lapis, Phyllis,
īdis; cinis, ēris; sanguis, īnis.

52. Nouns in OS lengthen the increment; as nepos,
ōtis; flos, florīs; os, ōrīs; custos, cultōdis; rhinoceros, ōtis;
Tros, ōis; ēris, ēris.

53. Nouns in US shorten the increment; as lepus, corpus,
ōrīs; vellus, ēris; tripus, ōDIS.

54. Nouns in YS shorten the increment yīdis and yīdos,
and lengthens yīnis; as chlamys, yīdīs or yīdos; Trachys,
ynis.

55. Nouns in S, preceded by a consonant, shorten their
increment; as celebīs, ìtis; ìtīps, ìtīps; Lælaps, ìpis;
Cecrops, Dolops, òpis; auscepīs, ēpiis; hiemis, ēmis; also
ancepīs, biceps, cipitīs, and similar compounds of caput, in
which both increments are short.

56. Nouns in T shorten the penultimate of ītīs; as
caput, ītīs; fisciput, fiscipitīs; occiput, occipitīs.

57. A noun in X shortens the vowel before gīs; as
darbax, āgis; grex, grēgis; aquilex, lēgis; biturīx, īgis;
Styx, ygis; Allobroxx, ògis; conjux, ùgis; Phryx, ygis.

58. A noun in EX shortens īcis; as vertex, īcis;
ponifie, īcis; vīx (rather vībic), īcis excepted.

59. But EX having īcis, lengthens the increment; as
vervex, īcis.

60. And all other nouns in X generally lengthen the
increment; thus nouns in as; as pax, pācis; forna, ācis.

61. Thus words in IX; as radīx, felix, cicatrix, nutritx,
vīctrix, altrix, perdis, coturnix, pernīx, lodix, īcis.

1. Except appendix, chōnix, coxendix, cilix, calix,
forcīx, filix, hilīx, larīx, pīx, falīx; vārīx, īcis, and
ītrīx, ētrīgs.

2. Nix, nīvis; mačtīx, īchis, a gum.
62. And words in OX; as vox, vocis; velox, ócis. Except Cappadox; precóx, ócis.

Conditum et magna supremae nóce ciumus. Virg.
Mancipii locules, ergo φικρά Cappadociam réx. Hor.

63. In UX; as lux, lúcis; Pollux, lúcis. Except dux, crux, nux, trux-lúcis.

Refilis Ἀνέσσ, claraque in Uce refullit. Virg.
Confedere díces, et volgi flante corona. Ovid.

64. In YX; as bombyx, ycxis. Except onyx, ſyclis; Éryx, ycis; calyx, ycis; Narły, ycis. But Sandyx and Bebyx have the increment common.

Nec sēqua Arabio lucet bombycethe puella. Propert.
Illeque plecto, yel it fælicis amītis. Propert.
Interdum Libycon focantur fandīre piúm. Gratius.

Of the Increments of the Plural Number.

65. The plural increments, A, E, O, are long; as musárum, ambábias, animábias; rérum, rébus, hórum, quórūm, regnórūm.

Tuque, húrum interpres euráum, et concía, Juno. Virg.
Solicit in nobis rórum natura novata est. Ovid.
Róbus in angulis facile et commone veròm. Mart.

66. The plural increments I and U are short; as quibus, tribus, montibus, vertibus, lacibus.

Except bibus or bōbus, which, on account of its contraction from bōvibus, as already explained, is long.

Neêh tróbus nodis ternós, Amaryllis, colores. Virg.
Non ópulós mentes hóminem curaque levantur. Tibull.
Pars in frábibus teant, verolim菲ne temporīta fígunt. Virg.
Cum faver eduxit, lacitus demittit: at illud — Ovid.
Et totum huius cursus arcávis orbum. Virg.

 Increment of Verbs.

Note—1. When any part of a verb exceeds, in the number of syllables, the second periphras, the increafer regulus the indicative present, active, the excess is considered as the increment. As in nouns, the last syllable is never reckoned the increment; it is also in verbs; and, therefore, when there is only one increafer, it must be the pre- increment.

2. Thus amat, amant, ama, amem, amans, containing, like amas, only two syllables, have no increment. A-ma-mus, a-má-mis, dō-tis, dō-tes, dō-mus, have one increafer, because they exceed, by one syllable, amas, ãs, is, is, is, and das. A-ma-ba-mus, a-ma-bi-mus, have two increasements, because they exceed amas by two syllables. A-ma-vir-tis has three increasements. Au-
di-ese-ba-mi-ni has four, because it has four syllables more than audis. In determining the increasements of deponent verbs, an active voice may be supposed; thus, co-nas-tur has one increafer: co-nas-tur, two; co-nas-em-ni, three; because cons of the fictitious active voice has but two syllables. Or their increasements may also be regulated by other verbs of the same conjugation and number of syllables, which have an active voice.

67. A is long in the increments of verbs; as fláman, fláres, prope-rámus, doce-bárum, audíe-bámini.

Serius aut cílius sedem prope-rámus ad unam. Ovid.
Pannabam armis, qua aet fátricèrus alius. Hor.
Et canóre pares, et repindere portési. Virg.
Conséptilem ibam, cum e muo plurima flui. Virg.

Except that do, and its compounds of the first conjugation, have a short in their first increafer; as dámus, dábitur, däre; fo circundábamus, venundábo, &c. But in any other increment do, like its compounds of the third conjugation, is long; as débámus, dedicáti, circumdábamus, crebdiámus. Hor.

68. E is long in the increments of verbs; as débam, rébar, amérís, docérem, legérunt, amémus, amérarús, amáfíctis, régebat, audíebar, &c.

Sic aequidem duébam animo, rébarque futurum. Virg.
Ne juvenes célebret multo larinas, vrsó. Tibull.

Except 1. E before R is short in the first increafer of all the present and imperfect tenses of the third conjugation: as legérès or legere, the indicative present active, and imperative conjugation; legèrem and legèrér, the imperfect subjunctive active and passive. But réris and rére are long; as amarérís, amárécè; docérem, docére; re-

géreré, regéréré, audíreme, audíère.

Parère perfons, dicère de vitis. Mart.
Sic fensus Pelus, fi moréeretur, crat. Ovid.
Cum confirmatis dirécte rerum equi. Ovid.
Naltra, neque ad ides victor echeéré. Virg.

3. Béris and bérè are every where short; as ama-
béris, amabérís, monóbérís, monobebe; and among the ancient, largibérís, experibérís of the fourth. Ex-
cepting where the & belongs to the termination of the present; as scribérís and scribère of the future passive being long by the general rule.

Sanguine Trojano et Rutulo datáre, virgo. Virg.
Scribérís Varo f eros, et hostiam— Hor.

4. By syllóle, the poets sometimes shorten e before runt; as

Obánupe ferox runt per comás, et vox falcibus hæc. Virg.
Di ti bi divíxas ducérunt, arumeque frondes. Hor.

69. In every increafer, (whether the first, second, third, or fourth,) I is short; as amábimus, docebimini, regitérum, regísum, audíminum, audíebamini.

Mora tarda mente cedit: simul ite; sœcumímini. Catull.
Venímus; et lates indíce cumuis agros. Ovid.

Note.—In such verbs of the fourth conjugation as have in the first periphras plural of their present and perfect indicative, the same words, in regard to spelling, there is a distinction in the penultimate of the former being long, as venímus, repérimus; and that of the latter short, as venímus, repérimus.

Except 1. These have i long; simus, velimis, no-
limus, with the other perfons coming from them and their compounds; as sitis, velitis, nólis, nólice, nóli-
tote; malímus, malitis, polísimus, polísitum, &c.

Ne nimium simus, flítorum more, molesti. Mart.

2. I before ei in preterites is always long; as peti,

quisísti, audiisti, and in its derivative perfons; as peti-
virá, quasiísti, audívimus, &c.

Ceffi et sublato montem genitore petiél. Virg.

3. The first increafer of the fourth conjugation is long; as audímus, audíris, audíter, audiéto, audiéris, scimus, scire; and in auditum, as it is sometimes con-

tracted;
traced; and in ibam and ibo, from eo. But when a vowel follows, it is short by position, as audiebam.

Norinit teneris immutat ubera labris.

Lenibant tunc vulneris nostra finit.

Tu ne cede multa; sed contra audientior iae. [Virg.]

Jungimus hospitio dextris, et te felicem.

Qui non editas, futuri sibi falsabit.

Note.—Imus in every preterite, and in that of the fourth conjunction also, is short; as jumivis, vidimus, fectum, venimus, amavimus, adeoimus, percepimus, meminimus.

4. Rimus and ritis in the subjunctive preterite are short.

Egerimus noni; et nimium meminisse necesse est. [Virg.]

5. Rimus and ritis in the perfect future subjunctive are common.

Ous ob res, ubi viderimus nil paene creati.

Nec mi aurum pofo, nec mi prestum derelit us. [Lucet.]

Videritis illas ille, ubi circularus axem.

Deum cum millia multa facerimus. [Enn.]

Oderimus magis in culpis puno creatis. [Lucet.]

Cum mavis Jovis transcivit aquas. [Ovid.]

Note.—We have innumerable examples to prove that rimus and ritis in the perfect future subjunctive is common; but concerning the quantity of rimus and ritis in the preterite subjunctive, grammarians are not agreed. A difficulty in this investigation arises from the similarity of the two tenses; the latter having not uniformly been taken for the former, and vice versa; for "the perfect of the potential seems to be both past-perfect contingent, and future-perfect contingent. The perfect future has also to go a great affinity to the preterperfect potential, that on a word may, confidently with the feme, be supposed to belong to either. As these tenses are usually interpreted in English, there is a great resemblance in their structure, as well as in the ideas which they express. Both are composed of verbs in present time, the one a verb of present liberty, or the like, the other of present intention or obligation: of an infinitive denoting future or definite to be; and a participle signifying the perfect of the action denoted by the verb: thus, I may have written, I shall have written."

We find by A. Gallus, 18, 2, that it was a subject of dispute at Rome, whether the tenses in rim ought to be considered as past or future, or both. Such disputes may, perhaps, have arisen from the accidental circumstances which are involved, besides the immediate action of the verb; in the same manner as, in English, two forms, precisely the same in their structure and reference, are characterized by certain grammarians under different times, viz. I may write, and I shall write, the former being named, from the accented idea, a present, and the latter, from the deaccenting action, a future, while, in reality, if we apply the same criterion to them, they are both present, or both future. Indeed it has been contended that the future had the termination rim, as well as ro; so that it is reckoned not improbable that both may originally have been but one tense, which had both a past and future reference. It is evident that this is a confusion by no means irrelevant, but indispensably necessary, before we can, with certainty, determine the quantity of rimus and ritis in the subjunctive preterite. In addition to the authorities for reckoning rimus and ritis common, there is likewise sufficient example from Horace, Martial, Ovid, Seneca, Tibullus, and Plinius, to consider rits of the future, at least as common; and this is an argument founded on the analogy of other tenses between the quantity of the final syllable of the second person singular, and the penultimate of the first and second persons plural, for considering the following rimus and ritis also common.—Rimus, ritis, and ritis, are usually accounted short; but it is exceedingly probable that, whether referred to the preterite or perfect future, they fill might be used as common.

70. O, in the increment of verbs, is always long; as amatō, facitate, tōtē.

Cumque loci poterit, mater facitātī filiūtis. [Ovid.]

71. U, in the increment of verbs, is short; as sūmō, pofitūmus, volūmus.

Dicēte, Perides: non omissis p̄ıtum̄s omnes. [Virg.]

Note.—For U in the penultimate of the future in run, see the rule.

Section 11.—On the quantity of the penultimate and antepenultimate syllables, and on the quantity of such as are usually said to be long or short by authority.

Note.—It is very well known that the profodial rules, hitherto est, determine not the quantity of every syllable of the Latin language; but of such only as are more commonly ascertained from the circumstances of position, division, preteritis, subjunctivus, imperativus, and final. Therefore, if a number of inflections, the inquiries of the student are at a stand until he can appeal to that observation, which would be more happily employed in confirming his previous acquisitions. And thus with but partial instead of complete information, he arrives at the mere intimation, the first lines of his progress, at the time being when unquestionably might achieve the second, the satisfactory and practical illustration of his previous attainments. If we depend on practice for the first principles of our knowledge, we lose its best and happiest effect. Practice will always instance its most prevalent efficacy, when its office is alone to rear the superstructure on the basis of regular system and theory, and not to attempt the casual and fortuitous talk of laying a rudimentary foundation, and that too on a vacuum, the baseless texture of ignorance, not admitting that analogy and arrangement, that reciprocal and corroborative illustration, which so essentially aid the intellectual faculty with its decided and permanent improvement. The part which follows is an attempt to supply this deficiency. It was obtained by four consecutive analyses of the language, in which every word and syllable fell under minute and decisive consideration. This investigation was undertaken in consequence of its being suspected, since it is a general rule in the profody of the Latin language, that a vowel is either before two consonants, &c. is long, that a law exists, directly the reference of this, and of not let extensive influence; viz. that a vowel before a single consonant is short; though each of these general and very extensive rules, may have, in special cases, their exceptions.

The refuit justified the expectation peculiar to that, and principally with the addition of another general rule, the profodial system might become so comprehensive, as to include and provide for the whole language; and consequently, for all those syllables usually said to be long or short only by authority. The exceptions to this general principle are chiefly included in the rules for the penultimate and antepenultimate syllables. And though some of them have appeared in former treatises, yet from their enlargement, the addition of others, the general rule, and its more special exceptions, which have arisen from the repeated analysis we have undertaken, it will be easy to perceive, that we have in this part some claim to originality. In the preceding rules, and in such as shall follow on final syllables, in justice to the subject and our readers, we have felt it indispensably incumbent on us to avail ourselves of the valuable researches of preceding and contemporary profoundists. And the originality of this section places us under the obligation of devoting particular attention to the monosyllabic monosyllable, that is to say, of showing the comparative, that every rule and exception, which we now first offer, might not appear to rest on our bare assertion, but on the only legitimate warrant, poetic fiction. And thus, perhaps, we have now the opportunity, for the first time, of offering the only complete collection or system which determines the quantity of every syllable, at least of pure and Augustan Latin, that has hitherto been presented to the public.

1. Masculine patronymics in ades or ilder usually shorten the penultimate; as Priamides, Atlantiades.

Argu hic praeium temum coro tepo tecre. [Virg. Enn. 6. 494.]

1. Except those formed from nouns in ies as Pelides.

2. Amphiaraiides Naupactoo Acheo. [Ovid. Fab. 2. 43.]

3. Beldes nemen Ptmides et inclyta fem. [Ovid. Atn. 2. 82.]

5. Quique Lycurgides laevus, et areo naumae. [Ovid. ivn. 1. 505.]

2. Patronymics and similar words in ais, ies, and iiis, lengthen the penultimate; as Achais, Poletamis, Chrysies, Anthes, Minos, and Latois.

Pietas, epides, rapa Minoides, Dian. [Ovid. Met. 8. 174.]

Except 'Thebias and 'Phoecis: Niger is common.

1. The-
QUANTITY.

1. Thetætis jussis sua tempora frondibus ornatis. Ovid. Met. 6. 163.

5. Words ending in acus, icus, and idus, shorten the pen- nalitate; as 'Ægyptice, 'aromaticus, 'callidus.

1. Quos 'Ægypticos temper renullis ab eo— Call.

2. Idaeus locos, ubi mollis 'americus illum— Virg. Æn. 1. 693.

4. Urque fuam laiques, quos 'callidus addidit succep. Ovid.

5. Allo 'nīdus, 'sidus; 'fidus, infinis: but 'perfidis (from fer and fides) follows the general rule.

1. Ah! pereat quincunque meridius repertis uas. Prop. 2. 3. 7.

2. Continuus montes, nif doliocrurum opæa. Hor. Epist. 1. 16.

3. Efe tibi magnus, Thelêfene, videris amicus— Mart. 3. 40. 3.

8. Pretul poterit tam frugi tamque pudicus. Hor. b. 2. 5. 77.

4. Words ending in 'imus or 'ynus, shorten the pen- nalitate; as finitimus, maximus, thymus, fortissimus.

Thus animus, decimus, fluxus, oculus, anonymus, callionymus, and all adjectives and superlatives in imus shorten the penultimate.

1. Emelle heroum quandam fortissime fructa. Virg. Æn. 5. 389.

2. And two superlatives, imus and primus.

3. Scribere si fies est ir mentions turpis mimos— Ovid. Trist. 2. 515.

4. Aut fpidos ego jam rais apudob lodios. Hor. Æn. 10. 449.

5. Deplote quadrinum Sabini. Hor. b. 1. ed. 9. 7.

6. Quaerer attonata fructibus et virgultas capelle. Mart. 7. 73.

7. Que, velut latis qua fit primus campis— Hor. b. 3. od. 11. v. 9.

Note.—The quantity of the penultimate of patrimus and patrimus is undetermined: Facciolatus, the Italian lexicographer, says "lis est inter grammaticos de quantitate eorum penultima, quae abhinc est ub juicit, quia ehi certi forser adhuc paulatim." 1. Truditur s fico radis oolaggis ligne. Virg.

4. Ex descrip tum terris de eras sinis redit. Virg.

7. Adjectives in imus derived from nouns signifying 'trees, 'plants, and 'stones; also from 'adverbs of time, or from sublatives signifying the four seasons of the year, shorten the penultimate; as fugius, hyacinthinus, adamanthinus, eratlinus, diutinus, perennius, chimerinus, annutinus, hor- notinus; to which add bombycinus, elephantinus, which seem rather to refer to the fish and ivory, than to the animals themselves.

1. Suadets Assino fugere, ne potice carp. Phadr.

3. Tum caput ipsi sufer domino, truncumque relicquit. Virg.

6. Quicquiam mundi terminus obtulit. Hor.

2. 9. Other vowels before final 'is, 'ius, or 'us, is long; as mo- nile, annalis, mules.

So ancle, bovile, bülæ, caprile, cr. ile, fœcile, fœ- nile, ile, incile, mantile, mantile, ovile.

And âles, anilis, aprillis, civilis, carduellis, curulis, crudulis, confugalis, doxitis, exitis, fidelles, herilis, milles, patruelis, proles, quinitiis, subtulis, fetulis, etc. &c. with many others.

1. Et opportunum te botuli condit. Phadr.

2. At qui umbrae gerunt capilis tempora quercus. Virg.

6. A vowel before final 'es, 'els, or 'les, is long; as mo- nile, annalis, mules.

So ahénus, ãnum, prunus, prûnus, sèrènus, vêné- num,
;

2. And though of anthera, eatenothêra, flâterâ, there is no poetic function, they are long by derivation from *dêrher, *sêbris, and *patra, fo pantherâ (Virg. *Aen. 8. 460.) from *dyr.

10. Qui volet *agyrhos arte ferire viros.

13. And the following in rum; *fürum, *suppurârum, 25 gârum, 25 pârum.

14. Alfo the *comounds of vôre, as carnivôrus, omnivôrus; those ending in *phôrus and phôra, from *vôre, as amphôra, canephôra, eccphôra, phôphôrus, citôphôrus, &c.; and the derivatives of *agyrhos, as hydragyrôpus, lithagyrôpus.

15. Barbâtus hic ego sum, quis non intelliger uii.

17. Pes etiam et camriter hircus sub cornibus uersus.

18. Et gravia attrita penderat cessenus centralized.

20. Seillamque, helêbôrophorge graves, nigrumque bitumen.

22. Vino ornamentis coquifque opolvis, non.

23. Praepingis terâs, apophores cogitter alro.

25. Tartâra Panhroden hicem uro.

27. Anchôra jam molâram non tenet uti ratem.

29. Troja cadet; sed eum notari inae longa laboris.

30. Per hoc brane *purpûra decuss precuros.

31. Dísplicent nexe *philîrph corone.

32. Inanumque *sûrum, aut populi tabularia visid.

33. Suppûra quantas dingent antuus locertos.

34. Prettis cellis, vêro de locis ultâs illi.

35. Maturum *purpûra cautos jam sôrpràs mendât.

36. Phôphre reddre diem; quid gaudia nostra morât?

37. *Amphiôra non semum tant proîtis mori.

18. E before final ro or ro is short; as fêro, gêro, têro.

So tempêro, aspêro, latêro, cætiôro, capêro, celêro, confidîro, deîdêro, fecêro, propêro, sêro (to sow), quôcor, &c.

Vérâm, quid facias? ut homo esser, ita merec gêras. Ter.

Except *sphêro; *allevêro and *perlevêro from *veûreus, and the adverb *sêro from sêrus; for sêro, to fow, is short.

19. Other vowels before final ro or ro are long; as vêro, *spêro, ôro, uro.

So liro, tiro, inquirô, acquiro, conquirô, plôro, labôro, suîçêro, ignôro, crôro, figûro, liurô, dîuro, and many others.

Delicûs et paniculûs bombicynus ïrît.

2. Alfo the derivatives from genitives increasing short in õris or ïrîs; as decôro, murmûro, from decus-ôris, murmûr-ûris.

So memûro from memôr-ôris; corporûr from corpus-ôris; rohoûr from robus-ôris; exaugûrûs from augûrûs; fulgûro from fulgûr-ûris; expectôro from pec-ôris.

1. Littus ûrant, Rutulôque exercent vormere colles.

2. Sed malâ via ûcis est. Lambôndo mater in auros— Ovid.

3. Quid ûris? Fuit auct quam notri tibi cura recélle.

4. Hos ut facias voles xexilloravere arô.

5. Liceat insenîrare, si incemisici non licet.

6. Quid vitam mînor invâsât, Pallante permepto.

7. Umbra, et ceo diffundere ligna pharbat.

8. Quâ òndati Calhûris culta Galaês aquas?

10. Et validas auget vires, et robroât ïctum.

So grûtus, facûtus, bôlûtus, pûtus, agrôtus, argûtus, alûtus, brûtus, hîrsûtus, mûtûs, and many others; alto participles in ûris, ûtus, ûtus, and ûtus, as manûtus, deûrûs, nûtus, minûs, metûs, conûtûs, vôlitûs, &c.

1. O fortûmus nimium, tuis quod nomen!

3. Faciâ omen, cum valerem, rectâ consilia, aegrotis demus.

4. Tûta manem; medius Tanûs surnavit in undis.

2. *Venêtus is short by derivation from Venetiz; *quûtus from *quôt; *tôtus (fo great), from tôt, for tôtus is long; and *arûbûs from arbor-arûbûs.

3. Of dicôrum, and automâtus from automâtôm, there is no poetic authority.

4. Except alto the plural genitives of nouns ending in ma-ôtas; as poemâtum.

5. And the participles dûtus, rûtus, sûtus, ûtus; for which see the rule concerning diffyllabic supines.

1. Me ûsum fàper quân vos, dedûrim vobis confiûm cûtus. Plau.

3. Et enm verûbûmûm formam cepûimus in me et jûtum. Plau.

5. Nec hâm um èllo dolor, ûd omnes ûcubat amns. Lucan.

8. Sic Fêrûs ûbanæante ûde, ûbatique Britannis— Lucan.

10. Inferiûr vero ex ëfacio naciûs ârûbus horrida. Vârg.

21. Words ending in ûtus lengthen the penultimate; as aurûtus, crînûtus, invitûs, perûtus.

Fac jâm tu, praeco, nun omnem aurûtum popûlum. Plau.

1. Except
QUANTITY.

1. Except 'anheitus, 'ceritis, 'spiritus, and 'suppiritus.
2. Also all adverbs in itus; as humanitus, penitus.
3. 'Alitus is not derived from the termination itus, but from fiatus, and therefore shortens the penultimate.
4. Alfo polyyllabic participles in itus, not derived from preterites in tert; as habitus, crctitus-a-um, and nouns derived from them; as habitus-a, and exercitus-a.

5. And the participles from the verb eo, and its compounds; as transitius-a-um, and their derivatives; as transitivus-a; the participle ambitus is, however, long, and the noun ambitus-a short.

  2. Apul me jatu et cedens fuerit feretris.  Ter.
  3. Dum mmor irge mi, dom euniprurus hos regit arsus.  Virg.

For the 4th and 5th exceptions, see the rules for polyyllabic epitheta.

22. A vowel before final 'num, 'mens, 'mentum, is long; as levamen, clemens, amentum.

So acumen, crimen, flamen, flumen, gramen, jur- gamen, volumen, argumentum, jumentum, stratum, and many others; the nouns comprised by this rule being numerous.

1. Flaminicos, caceos, crathque paludibus alni.  Virg.
  2. Ergo lance clementum variant, urbano, atque octum.  Ter.

2. Alfo 'alimentum, 'documen or documenntum, 'emolumentum, 'monimentum or monumenntum, 'regimen, 'especimen, 'tagemen or tegumen and integumen.

3. And such verbs as frémo, gemo, &c. will naturally short the penultimate of frémens, gémens, &c.

Note.—The irregularity of such words as monimentum, documenntum, &c. has been considered as arising from the fiber of the feminine or third case: which, originally, before the effect of eneoce, is supposed to have generally been in itus; as monoem, monetum, monimentum; docemo, do docemo, doctum, and by eneoce dock-tum or doctum; whence dokimentum or docteamentum, &c. But if these verbal nouns were primitively deducible from their fibers, many of them must have subsequently affixed the characteristic of the infinite present, as the e of regimen and regimen will testify. See Salmon's Stemmata Latinitatis on the terminations men and menum.

  2. Bone cubo, falls; columen verb familiar.  Virg.
  3. Vulgus Hymen hymenae vocat, fugit ille vocantes.  Ter.
  5. Atque ipse vidit nutitum a vices.  Ovid.
  7. Nullus in urbe lucus, nulla emolumenta laborum.  Hor.
  8. Hie habet, heredes monimentum ne freatuerunt.  Hor.

23. A vowel before final 'mis, 'met, 'mis, is long; as háma, limes, sublimis.

So agena, dama, fama, flama, poema, rima, ruma, sima, lupa, flama, flama, fomes, trames, illisim, cómis, cemis, declimus, decrémis, quadrimenis, quintterëmis, infæmis, and many others in each of these terminations.

  2. Exspect inviudum admoem famiile humas.  Lucan.

Vol. XXIX.

1. Except 'cöma, 'cómë, 'cucumis, 'fämes, 'in
colimis, 'lacryma, 'nimis, 'pyrimis.
2. Alfo the 'derivatives' of animus and decimus; as anima, examinis, decima or decúma.
3. 'Déynâmis and 'endymonis have their penultimate regulated by the Greek short a and ã; as éuynámos, ëndynâmës.

  3. Curvarus cucumis, tumultuque curcius ventre.  Hor.
  4. Fecit; et incolumis lector quidvis cath in urb.  Hor.
  6. Fortuna multis du nimis, fatis salis.  Hor.
  7. Non mihi pyramidum tumulis eva Amo.  Lucan.
  11. 'Dynâmës domi habent maximum.  Plaut.

24. I or Y, or a vowel derived from the short increment of the genitive, before final nó or mor, is short; as animo, actimo, decimo, lactximo, and hiemo from hiëmës.

Quo redit ad falsos, et virtutem affectam amis.  Hor.

Except 'lismo and 'rimor.

1. Límot non ad obscuro morfique venenat.  Hor.

25. Other vowels before final nó or mor are long; as clámo, nómo, prómô, símô.

So fámo, fámo, têmo, dêmo, postrémô, fímo, írumô, fímø, rímor, &c.

Exspect et longe lapsum témone relicuit.  Virg.

1. Votum in ènumante novum; vellem, quadèmuesse sheflet.  Ovid.
  3. Atque omne ornamentum, fammæ crepitante, crémori.  Virg.
  4. Non annuam dincere decor, non mille carinae.  Hor.
  5. In quis: sint cibara, emptus comoritc in unum.  Hor.
  8. Hómo sum; humani nihil à me alienum putt.  Ter.
  9. Égnot; príte ille graves intertiss un,  Lucan.
  10. TEMPLUS CONSONTA TRINIT, 'frém textStyle noventur.  Lucret.

Note.—'Como-ère follows the general rule; but 'como-ère, a verb seldom used, shortens the penultimate: both are derived from cóma.

26. A vowel before final lo or lor is long; as cálo, célô, pilô, sölo.

So háló, málo, vélo, sólo, nólo, pálo, sólo, péculor, &c., and several others.

Excepta, ac fóluis opibus 6tacutus amicis.  Virg.

1. Except 'talo, 'tóló, 'tóló, 'ventilo, 'vóló, and 'cólo-ère, to cultivate, but 'cólo-ère, to filter, follows the general rule.

2. Alfo the penultimate of 'consulio is short, from consul-úlis; so 'géléo from gelu, and 'affiimo from fínilis.
3. Except alto "verbs in uto or ulor, which are generally derived from diminutives in ulus; as circulo, circulor, from circulus.

1. Tutus et geminos anxia mater ditt. 
   2. Et color extremus primo cum frigore mixtus. 
   3. Mille tremans varias adverso solis colors. 
   4. Pils usque, tardoque gerint in bella vindus. 
   5. Materiemque dlire, levare sae cladea. 
   7. Milendum utique in pitritim; vapsulandum; habendus compades. 

27. A vowel before final 'bes and 'ges is long; as nubes, ambages.

So labes, tabes, pudes, compages, impages, irages, fruges, &c.

1. Sub pedibus videt nubes et fides Daphnis. 
2. Jam dareturam dat plegem atque exigent ipsa. 

Except 'hebes, 'indiges, 'labes, 'seges, and 'tenes.

1. Uteque hecetpt peccus tantummodo contidit rinem. 
2. Fiat patris indiges et Romule Vestaque mater. 
3. Tertia domo geminos ex mel loebet. 
4. Illa fides demum votis respondet avari. 
5. Infltor hyberne tegitis, niveque cadere.

A vowel before final 'des and 'pes is short; as fides, tipes.

So analeides, anterides, hyades, pleades, swords, and all maculate patrilineous, according to the first rule; so alfo apes, dampes, tropes, and the following compounds of pes, bipes, tripes, quadrupes, centipes, antipodes, celeres, grapiapes, alipes, lepives, fo-nipes, cornipes, ignipes, longipes, loripes, palmipes, solipes, capipes, &c.

1. Mens bonis, fama, fides, hae clar, et ut audiet hapes. 
2. Infratrem alipes pitique 'tigetis.

2. And though we are without poetic authority for careinodes, caleodes, horminodes, yet their penultimate is evidently long from the Greek; so epodes; as 
   3. curpore, coquore, lymbribus.

1. Claritas irruimus nocturne prorida arma. 
2. Dutx et inferans permulta inerita sedes. 
3. Illa, velut pelagi ripes immo refintit. 
5. Spondeus datur subinde sudebatque praetis. 

Note.—The elided existence of triades seems not to be satisfactorily proved; Aldworth and Facitichian cite only one authority, Tert. Ann. 24, 4, where commentators propose voices, as a better reading.

29. A vowel before final 'dix, 'dix, 'lex, 'mex, 'nix, or 'rex, is long; as codex, radix, iles, cimex, imum, caxex, carex.

So judea, lodix, spadix, halex, pulex, pumez, remex, tomex, remex, muez, toxex, &c.

1. Inde porr sb putem, utque ad robudum sedicem. 
2. Prorint ab abreede eredire redditus. 
3. Prevenient preae, inter keta sequitur eix.
35. A vowel before final *sa* is long; as clāva, proclive, dives, civis, pāvo, rīvus.

So cāva, conviva, divā, ginīgā, pāva, praeogativa, ūva, xēlīva, olīva, conclāve, nēva, clāvis, fulāvīs, nāvis, rāvis, acclīvīs, declīvīs, procīlivīs, vívo, prāvo, rīvo, nīvo, prīvo, xēlīvo, ēxāvīs, ēxāvīs, divīvīs, ōvum, prévūs, and all adjectives ending in īvō, which are numerous.

1. Duceret apricis in collibus ëxīs colorem.
2. Turre crērē per totum pandit conélēre magιquē.
3. Dīves aget, dīves politos in ūnīs numerus.
5. Úberēs os, altum virtūs, sēculum virtūs.
6. Tam fēā prūνīque tenes, quān nuncia veri.

1. Except lāvis, lēbris, ērāvis, lēvis, ēvis, óvis.
2. Allo cāvo, grāvo, jūvo, lāvo, lēvo, nóvo, óvō.

3. I. Except *ās*, *ēs*, *ēvus*, *ēvīs*, *ēvum*.

1. Fiet aśer, modō āvīs, modō ūnām, et, cum volet, arbor.
2. Vīce summa būrīs spēm nos ventā inūnāre longīnum.
5. Íntūruit, Pan carūr ūves, ëxīmōque maγiōs.
6. Dura tamen mōllī ĥaex èxācēt quādū.
7. Unde grētēt perennes; ët celēr īgūs adārāt.
8. Temporēs celli, corpūsīque, animāque jōvītūat.
9. Ìnpes, pāta, cano, lūdo, lāvo, cano, quīscīo.
11. Nēc remorgūtūr iēs; ëxīs rēum ūmītāt quārtā.
12. Quo nūn Turnus évit, fōpolo guéterque potius.
15. Mēlā fēās, illī tūlaque ætūbe uērinās pīnas.

36. A vowel before final *ē* is long; as ēpica, formāca, seūtica.

So antica, apica, cloaca, carrūca, currūca, erica, mica, myrica, lactīcā, lectīcā, noctorīcā, ricā, ru- brīcā, lūcia, pātīncā, phōcā, famībīcā, sīcā, urtica, velīcā, &c.; and several ending in ēpha, from apōtica, bibliothēca, oropothēca, &c.

Parvula nam exemplō cf., magnī formācia laborīs.

Except *ālica*, *ēbraica*, *ēflīca*, *ēmanīca*, *ēper- tica*, *ētūnica*, *ēflarīca* or phalarīca*, *ēdica*.

1. Nos alecam, nullum poterit tibi mittere dīves.
3. In ūcō humātum sūlīs, notāque palude.
4. Manticō cum lumbūnerea uērēt, atque equēs ārōs.
5. Perīvōs dat plēnī inūmitāt ulnūre rāmīs.
7. Sed magnōm ūlīudent contorsa fēlāricā ventī.
8. Cēd dam, unīquām injūnārum ēudūlī mi scriptam ēdēm.

Note.—1. Alphabet is rather alphabetēs cf. απεικόνισθαι, and therefore does not relate to this rule.

2. And since adjectives in ēcus shorten the penultimātum; wherever the termination ĕcūs is derivable from an adjective in ēicus, though the adjective itself be not in ëve, the penultimātum is short by derivation; as,

Plutarchus from plātarchos; i.e. an oikōn πλαταρχος.

Fabrica from fabrica; i.e. oikōn oikē fabra.

Flaminia from flāminia; i.e. oikōn flāminus flāminia.

Manica from manus; i.e. vēlis manus manica.

Pedica from pedica; i.e. comē pedica pedica.

Lucania from Luκanciēs; i.e. oikē Lukanorum lucana.

Bucclia from buccclia; i.e. καρκίνων κουκκίνων bucclia.

Basilica from bāsília; i.e. καρκίνων βασιλική vel bāsilia.
37. Words ending in *aris or *are lengthen the penultimate; as alāris, altāre.
So agricola, peculiāris, nāris, alveāre, capillāre, plantāre, quīrē, and many others.
1. Suspicium, patulius captavit nābibus auris.
Virg.
2. Suspecti exigit lactum plantāribus hori.
Juv.

1. Oderant hālāre tribus, trātumque pessō. Hor.
2. Aut Ephestum bimariōs Corirhi. Hor.
6. See, ser dāre, the verbal increment in *āre.

So crūdēlis, carduelis, patricius, cædēla, loquēla, quercēla, corruptēla, cīciēla, clientēla, macliēla, si-tēla, Phīmēla, parālēlus, polymiēus, aerenōlis, forōmis, hērōitis, pernicīōsis, nīdus, crīdus, fūdus, and many others.
1. Nuncum est fidēlis cum potestate cīciēsis.
Phēdr.
2. Et circūm plius vehitur famīra Phīmēis.
Virg.
3. Quīs populās cæsāres Phīmēis fūt ubās.
Virg.
4 & 5. Cādeque fūsiōnem sēmum cēsis.
Juv.
6. Quōd Nero tā saevā, crūdelegu tyrannus fēcit?
Virg.
7. Hinc altūb tuēse cānet frontētār ad aurās.
Juv.
8. Nec fōcās fecit; sātor tamen eī fāpiam. Quī—Hēr.

39. Words ending in *uber, *ubār, or *ovār, lengthen the penultimate; as Octōber, faēbār, pāpāy, &c.
So fūber, tūber, ūber, hūber, pūber, cædāver, &c.
1. Te caepe, Octōber foretiae aetēs.
Aurōn.
2. Quīque frequentes hērībus et férībus ūber campus.
Virg.
3. Līlia parupres miēs popīvāriō sis.
Propus.

Except *coluber and *tubār.

1. Inque praimūne colōber dūnterīrīs aero.
Lucan.
2. Crīne rītōr, nigētore, brevi pēde, lūmine lēxus.
Mart.

40. Adverbs in *im lengthen the penultimate; as oppo-dim, virītim, tribūtim; except *Ramim.
1. Et velat abfemem certēmō Aētēsōn clamant.
Ovid.
2. Nec spērnat aurā, nec tamen cētātim fidēlātum.
Plurīd.

Nota.—" Nōria Lexēria, Graduātum ad Paras. Penultimam adverbii, effātim, longā spēcīs fīgunt. Nec eo inuis, quin poētae degeneris Latinītis eam producētur." Vide tamen Lexēria Faccīleī, ubi hanc observationem inveniēis. "Augustīnus poētā, suād Gel. l. 7. c. 7. suā dīgōtīa de quānta militēs, ut fā-
tūs eam εηεworth από την ρήματι: inuētum autem, cēm eam producēt succīs; qual et αρi矜e factum erit. 1. 2. in Ac. Apōsē. v. 616. Verum non est hoc fāsis, ut contra communem uēm patērī copiēt.

41. Words ending in final ques are compounded with aquae, and therefore lengthen the penultimate; as antiquae, inquae, oblōquae.
Terra antiqua, potens armis atque ubere glēbae.
Virg.

Except religius, which is not derived from aquae, and is therefore excepted.

Tercētīrī quies tēcēta paēde tībī.
Mart.

Nota.—"Though the real cause of the penultimāte of inquae, antiquae, &c. being long, is the contraction of the a. of quae, from which they are derived, into i, which is therefore long, according to the rubr we have given for contraction; yet since the above may be a more obvious definition than a Latin cause, we have not thought it improper to add it. And since this remark is applicable to some other terminations and examples, noticed in this analysis, it is sufficient here, once for all, to give this general answer."

42. Words ending in polu, or polium, being derived from polu, lengthen the vowel before l; as bibliopola, ceiopōlia.

So myropōlia, myropolium, propōlia, pharmacopōlia, &c.
1. Sed quia me vendit Bibliopola putat.
Plaut.
2. Nam omnibus plateas perpetuas, gymnasia et myropōlia. Plaut.

43. Words ending in arei, arius, erium, orius, lengthen the antepenultimate; as pāreco, cibārius, acro-
ērius, mefōrius.
So āreco, clāreco, hordērius, fēctārius, libārius, mercaenārius, herbaerius, capillērius, dictērius, cecel-
fidērius, nictēriūs, sphaerōrius, adulatorius, cenōrius, and many others.
1. Vīm germinam setit, pōrebque incerta duobus.
Ovid.
2. In hunc diem jam umns fūm mencherōrius.
Plaut.
3. Omnibus arīdes, dēxōria dicis in omēs.
Mar.
4. Quibus evrēos cum meō ferrō.
Mar.

1. Except *cīreco, *vārius, and *neētēreus, from nectārius.
2. Alfo *defidērium, from defidero; *maigērium, from magillērīum, and *minētriūm, from minētīlīrīum.
3. And the *derivatives of genitivus increasing in short āri; as aquēreus, arēreus, caēreus, corpōreus, ebūreus, marmoreus, ferrōreus, robōreus, from aquor-ōris, arbor-ōris, caelō-ōris, corpus-ōris, churōris, marmor-ōris, ferrōreus, robōreiūs.
4. Except alo some *derivatives from *omērōneus, as boreus, anthōboreus, hyperboreus, from *ēgéneo.

1. Siliciēt et mērinis et deśillatē cērēcis.
Juv.
2. Ex fērūrās aedificando exsūs tāria.
Virg.
3. Antē nērōnibus turbae medē fālēremon.
Mart.
4. Roma, dominique subit, defidēriiis locorum.
Ovid.
5. Vīnent, id factum, tu, et mēsēgēriu tuo.
Plaut.
6. Fēlīs mēnērēiis mulcas, parāpētis laborīs.
Ovid.
7. Arērobus būndās annus rasiātēs nuncē.
Virg.
8. Vīs poelo patriī pennūreis sāsī acē Rēcia.
Ovid.

So arēneaeus, hērēaeus, hordēaeus, refīnacēus, cretacēus, ariēnēus, condītēnius, rejectēnius, collectēnius, bipedēnius, and many others.
1. Herēbus nērōrius refīnacēus terra.
Var.
2. Prōneus et ingratae presentem effiūs urbi.
Virg.
3. Nec neulānicius nōvis, queru arēnōs terra fālē.
Lucrēt.
4. Si rectē facies, hēc manu aŭtōrus ēo.
Hor.
5. Oppositiono maētēs eōne saēcēs sēmēnēs aŭtōbarius.
Lucrēt.

1. Except cālēaeus, from cālēaeus.

Cālēaeasī quēs, maēs quēs Amārīlica amatē.

45. Words ending in icīus, icium, or iūtus, shorten the antepenultimate; as patriicus, xēdītius, cēdītius.

Patricius omēs ophōpōs cēm provocēt umās.
Juv.

So gentīcius, tribūniicus, adventītius, fācītius, auspūlicus, judicīcius, artificius, aruspilicus, malefic-
ius, beneficius, opificius, extipīcius, harrūpīcium, xacīcius, indicīcius, officiuis, macefīcius, and many others.
1. Except *novicius, or novitius; and those which come from long ūpiones; as efluitiūs, from eflitius, ire, iūtīmum.
2. Alfo *convicius, *licium, and *nutricium, from nutrixt-icis.

1. Jam fede in ipis tertiumque mācēus herret.
Juven.
2. Nēve in me frēude conquītum erē lingue.
Ovid.
3. Et prōfāne damāte bōves, et fēria tērē.
Virg.
4. Omēnis ināntum maxī nutrixtī tūba.
Marti. 
46. Words
QUANTITY.

55. Y before or after R, is long; as Butyrum, collyrium, papryrus.

1. Collirium facetiae ut madeant et collipa.
   Plaut.
2. Succinctius patruam Crispine papryrus.
   Juven.
2. And the derivatives of ージューパ; as hydrargryos, lithargryos.
3. See the 3d exception to the last rule.
   1. Et lacrymis fargunt ramulibus ora genaetique.
      Lucret.
   2. Sit tibi Mula lyrae folos, et cantor Apollo.
      Hor.
   3. Neve inter vitis corlyum fere; mere flagella.
      Verg.
   4. Ebphes inclinat philryra conviva capillus.
      Ovid.
   5. Infere nunc, Nobilibus, püryos poised online vites.
      Hor.
      Hor.
   7. At vert Zephyrum cum luta vacantibus sibi.
56. U before or after R, is long; as lúridus, uro, rúmor.

1. Neplethis Grenda filis infatuarique.
   Hor.
2. Quar vos ad celum effeas róneum secundo.
   Hor.
2. Except also ri in 3 genitives, increasing short in 3 is or Æriis, and their derivatives; as crux-cruciáus, truc- trucis, augur-úris, murmur-úris, fulpur-úris, which give crucio, trucido, murmúrio, augúris, fulpurís, and the like.
3. Alfo, 15 meditatives in Ærio and luxúrio; as estúrio, 17 other verbs in Ærio follow the general rule; as ligúrio, facetúrio.
4. U before final r, and ru followed by a vowel, are regulated by the rules for those circumstances; as augur, fatur, rúno.

1. Prae torqueat fìamus loco cëftra cërulius.
   Lucan.
   Virg.
3. Quod férius? Aut quonam nofitris tibi caereref? 
   Hor.
   Phaedr.
5. Nocturnos lemnere portantque Théfæla rides?
   Hor.
6. Cinéasteque ad vitam matrum immoquique easter.
   Ovid.
7. Et muneram querellae caucis doloris abepit.
   Ovid.
8. Quem dilcere Chasus; rúsibus indigenaete males.
   Ovid.
9. Infecit diversaque viribus, fulpurique rüdium.
   Virg.
10. Porríceus inceúa poíns Aurora rüdium.
   Hor.
11. Robor complexus réditius curvas metallo.
   Lucan.
   Plaut.
13. Pauperis et tugurii emendum cepite cadem.
   Plaut.
   Hor.
15. Vultus in unum me treceus.
   Hor.
   Hor.
17. Tractavit cædium manibus, dum furta ligíria.
   Hor.

57. 'O and 2 'U, before m are long; as vúmer, búmer.

1. Ingemere, et solen attritus flendendé ete vúmer.
   Virg.
2. Quæque fætus fríus trés marais fregere vicum.
   Virg.

1. Except, to o before m, 'cóméa, 'cómédo, 'ómítio, etc tómacum.
2. Alto atomus, domús, glómus, tómus (for which see feét. 2, rule 5); coma, cómes (for which see feét. 2, rule 23); domo, hómo, and vómo; (for which see feét. 2, rule 25.)

1. Non focus ac liquida & quando nolle cémétin.
   Virg.
2. Ut libet: hac porcio hodice cõmedendo tehunque.
   Hor.
   Hor.
4. Quo modasiam qui bránda rausus.
   Mart.
4. Alto, colímum, docúmentum, emolímentum, te-

 génem (for which see feét. 2, rule 22); húmus, polútumus (for which see feét. 2, rule 5); cebúmis (for which see feét. 2, rule 23); and autúmo; (for which see feét. 2, rule 25.)

5. For circuneco and circumago, see the rule for m.

1. Quod cum velit, homo, crimenam fili de collo detractit.
   Plaut.
2. Exhaustrum in cælem omnique in spectus suntema est.
   Lucan.
3. Ipse nihiló hómeros: see me l. bor ile gravat.
   Verg.
   Plaut.
5. Rari quippe levis, números vis sunt totem, quos.
   Mart.
6. Alìo fimul de lingue, confereos súmus.
   Phaedr.
7. Ignea monte ecalis, corpus et omne venene.
   Ovid.

58. U before e is long; as búcua, dúcio, caducus.

2. And in 4 genitives increasing short in 3 is or Æriis, and their derivatives; as dux-decis, crux-decis, trux-decis; hence crúcio, trucido, etc.

1. Quod puré tranquillus; homo, an dulce lucrículum.
   Hor.
2. Hec ego non credam Venefina digna iudicem.
   Juv.
3. Mals daria, nuciculeque jubet, dulceque placentas.
   Mart.
4. Interca volucere noics concernita penises.
   Petron.

59. Syllables indifferently spelled with one or two consonants are long; as literae or litterae, litus or litius, cúpa or cuppa, púpa or pulpia, flūpia or fluppha, fricoma or fricima, flúpia or fluppus or flupphos, clépium or clélium, which should invariably retain the double consonant, since it is by position alone that they are long, by the consonant, and not by the vowel, reduplication.

60. Syllables indifferently spelled with a single vowel, or a diphthong, are long; as teda or tæda, præhum or prælum, which latter orthography, the more expressive of the vowel quantity, it is better to retain.

61. Vowels derived from r, s, r, s, are long, as hirius, Sirius, músa, from μ, γ, γ, μ, μ.}

Note. — Many of these are already compiled under the preceding rules; the principal words referred to alone to this rule, are colón, crístern, hépar, hépòs, lepithus, lúchen, cede, rétrus, spézium, ðáerus, thórus, thorésis. To these we may add near 200 words of very rare occurrence, chiefly signifying plants, herbs, flowers, minerals, &c. &c. as ambelidus, ambelipa, ambelino, &c. Of these we would here insert our manuscript list, but since they are principally confined to such authors as Pliny, Celsus, Vitruvius, and Frontinus, they are matters rather of occasional reference, than of any grammatical rule.

62. Some words alike in orthography, differ in quantity only according to their signification; as

1. Póplus abó
2. Erit, nort et populus
3. Plebem, sic múlús est pro
4. Prævo; signt item malmum.
5. Návia mulus; nélina málus,
6. Strípe uno producit plúma. Múla genem vult;
7. Múla pona, Et plúus
8. Facciones pálidas; et feré
9. Stágnam lásueve, at non tamen sic
10. Pólus notans súdem. Nítor, nitentûque,
11. Nítentûque niter et nitentís sèchís,
12. Proténine solum; non ita solus aut
13. Ab eo sochú. Pía nótone
14. Rectis et eae corripit; licet
15. Verbitis aut vice vulneriis, tu
16. Exstihhitas plúgim. Pías de in globulo léco
17. Centralitupric: mole
18. Denutati, persegé pilum? notat atque pilus
19. Acei fóem mulique;
20. Et pilum quoque, maffarlare tejí.
21. Nítor, nómor, non Ére, Et notas cóndere
22. Cacériae gerere; sed cóndere orsre est comun.
23. Celláre aquas non dicimus; jí led colori orva, nóra.

Note.
QUANTITY.

Note.—The above verses not only furnish the words relating to rule 62, but all, to unite two objects in one; they at the same time afford a specimen of all the Horatian metres, which, to the classical student, may prove a useful compendium. The exposition of the second, probably, only the second production of the kind in print. The subject is spoken of by the two editors of Horace, Cracquius and Baxter, and, had it been more than a question of the subject, the present would have been impossible. In the Horatian metres comprising this specimen, the reader finds for the first time in Latin, the Horatian Primus, ed. [4th] page 246, or Versification, in the sequel of this work. The following, however, are the Horatian metres, as exemplified in the above lines: 1 An Adonic; 2. A dactylic pentameter; 3. A Pherecydian triad; 4. A Glycic choriambic; 5. Dactyl hexameter; 6. An hemistic aecopalous; 8. Iambic dimeter; 9. Iambic meter hypercaletic; 10. Iambic trimeter elastale; 11. Iambic trimeter; 12. An actepolad; 13. A Sapphic hendecasyllabic; 14. A great Alcece; 15. A small Alcece; 16. Alcece choriambic; 17. Choriambic dimeter; 18. Epichorichoric tetrameter; 19. Ionic metrierchimer; 20. Sapphie ionic; 21. Ionic meter trimeter; 22. Dactyl heptameter; 23. First elegiastic Archilochian; 24. Second elegiastic Archilochian. The remaining words alluded to by rule 62, are comprised by the following hexameters.

63. A vowel before a sungle consonant, not affected by any preceding or following rule, is short; as sapio, singula, gracilis.

Note. To confine the preceding rules to limits as short as possible, is, the preceding rules and their exceptions relate only to words of pure or Augustan Latin. Some terms of very rare occurrence, chiefly the names of plants, herbs, stones, fofli, &c. near 300 in number, are omitted, as matters of occasional reference, rather than of constant attention or grammatical rule.

We have now, after four consecutive analyses of the language, for the more complete information of the student, accomplished a task, perhaps never achieved before, nor so far as we are acquainted, offered to the public, in any profitable system. And we can venture to affirm, that any person was acquainted with common proedy, and the rules of this section, will not, within the precision of Augustan Latin, find a single word, except the few of rare and unrequent occurrence mentioned above, whose quantity is not regulated or accounted for by the rules now given. Thus, for the first time, we have endowed the majority of Latin quantity, by all preceding professors returned to a court of observation and practice alone, to a regular classification and system. Would our limits permit, we would here, for the sake of exemplification, take the words comprised by any letter of the alphabet, and account for the quantity of each by the principles and criteria we have here considered.

It is almost necessary here to add, that the quantities of syllables are marked with very frequent inaccuracy in most of our common dictionaries. The poets are the only satisfactory test.

SECTION III.—On final Syllables.

1. A final, in words declined by cafes, is short; as fama, regna, lampada.

Anchora de propria jactant: tant litore pappus. Virg.

1. Except the ablative singular of the first declension; as hae mufa, hoc AEneas.

2. The vocative singular from Greek nouns in ατ as O Palli, O Atil.

2. A final, in words not declined by cafes, is long; as amf, ultra, praeterea.

1. Lutus amf et levius Anagis fine palmis cutes. Virg.
2. Incredibili magister marmure pantum. Virg.

3. Except ita and ej short, and pollea common.

4. Quia is generally short, but since Phaedrus lengthens it, we may pronounce it to be common.

3. Some profoundis quote puta, with the a short, from Perihus, 4. 6. But the belt editions have puto, a reading evidently preferable, in point both of sense and grammar.

4. Though numerals in ginta are sometimes found short, approved authors lengths the a; yet it may be well to recollect, that the Greek termination KONTA, whence the Latin ginta is evidently borrowed, has the final vowel short; as

[glossary of frequent words and phrases in Latin]

(See many other instances in [B] B)

6. Tum ce accipiendum regem, acce et il se turbidus int. Virg.
7. Si auxilarum postulat degeat. La., ibam.
8. Postulat mirabil, cur non in fine itin his effet. Ovid.
10. Ego primam tello, nominem qui lex. Phaedr.
11. Sensum terna cum limina, name fenacer. Mart.
QUANTITY.

3. E final is short; as nate, patre, curre, nempe, ante.

Incept, parte, puere, ruis cognoscere matrem. Virg.

1. Except that final E in all cases of the 1st and 2nd declension, is long; as Callippe, Tydide, Anchis, idd; also fam¢, originally of the 5th. Thus also, rE, dE, and the 3 compounds quare, hodid, pri- dil, poltride, quotidid.

2. Alfo in all nouns wanting the singular; as cet, melk, temppe, pelage, Greek neuter plural.

3. The second perfon singular of the imperative of the 5 second conjugation, has the E long; as doce, mon; but cave, vale, vide, respone, and false, have e common.

4. Monofyllables ending in E are long; as me, te, ne (left or not) except 1 enclitics and syllabic adjectives; as quE, ne, te, te, te, te; as neque, quE, fuape, hujufe, tutE, &c.

5. Adverbs in E coming from nouns of the second declension are long; as placid, pulchre, valide or vali- de, &c. Except benE, melE, superne, inferne, mage.

6. Ferne, fere, and oh, have e long.

1. Hane tua Penelope lemo tibi mittit, Ulyxif.

2. Ec tuaquum fanc pervert rhodica, rhodica.

3. Hor. Quae mens ed hodie, cur eadem non puerum fuit?

4. At pelage multa, et late tibitrua videmus.

5. Vide, valE, carE ne tinhe, mainuque fragans.

6. Idqaque, quod ignoti factum, nati dicere falcem.

7. Responde, quibus-amisse reparare quam res.

8. Si quando veniet dicte; responde, poeta.

9. Quod dies nata vide, nisi te quoque decipis ipsem.

10. PuE, ne dolue column componam tibi.

[See alfo Perk. t. 108.]

13. Vera, quaesum; neqE me Argulke di gente negabo.

15. Nati bene cum facis, facia attem inomnia belle.

17. Mobius et vari et fernE natura mahrurn.

18. Jocunque ferrato, fabulacum laetere puppE.

19. Impurumus, cum arti ludefi donum ebe: jam.

Hor.

1. Final is long; as domin, clasii, fieri, doceii, audi, ili.

Old respondit rex Albus Longui.

1. Except the of Greek vocative; as Alexi, Amaralli, Theii, Paru, Daphni; but Simoi, or such as belong to nouns having entos in the genitive, are long.

2. Greek datives singular of the third declension, from nouns increasing, are varied. Minorind and Te- thy in Catullus, and Palladi in Statius, are short. * Thetidi in Catullus, and Paridi and Tyndaridi in Prop- ertius, are long; but Greek datives formed by con- traction are always long; as Demostheni, metamor- phosi; alfo those which come from the first declension in Greek; as Orelri, Euripid.

3. Neuters in i are also short; as gummy, mei, fnap.

4. Datives and ablatives plural of Greek nouns in 5 (in before a vowel) are short; as heroes, Peru.

5. Mii, tii, ri are common. Alfo ibi, nii, ubi and qual; but these lat are more frequently short.

* Note.—These may be long by poetic licence, or by position; for the i of Greek cafes is naturally short. Orph is may be considered as a dative in Virgil, Eel. 4. 573; and by genet is. It is a fuppose in the Georgics, 4. 535 and 555.

1. O crudelis Altei, nihil mea caritatis cura.

3. Troian invideo, quae baturin florum.

4. Non unquam gravis erat domum mihi dextra redit.

5. Extremum hunc, Arachne, mihi concedi laborem.

Virg.

5. O final is common; as quando, Cato, leo, abmo, octo, amo, doceto.

1. Armo annua venis, nos in locis in armis. Virg.

2. Non utcumque, faido; nec potion dicere parte. Mart.

1. Except monofyllables, which are long; as o, pru, du, fi, and pru, b not being accounted as a letter.

2. * Greek feminines ending in o are long; as Dode, Sappho, Chlor.

3. O final in datives and ablatives of the second declension, is long; as homno; to which add another ablative, as ergo, for the sake of, ergo therefore belonging to the rule.

4. Alfo * Greek cafes, written in the original with ome; as Androse, Atho.

5. Adverbs formed from nouns have the final o long; as hubito, merito, multo; and illo, quo, e¢, and their compounds. Alfo eir, intro, retr, ulprio. But the following are sometimes found short, denio, idec- o, fero, protefto, poftremo, the conjunction vero, po, to which fome add fedalio, crebro, and mutuo. * Modo (used adverbially,) and its compounds are short; as quomodo, dimmodo, poftmodo.

6. Though the final o of verbs, occasionally by writers of a secondary clafs, and more rarely by tho- es of the Augulian age, has been made sometimes short, yet its derivation from the Greek omea, and the more general practice of the principal ports, make it long: the 6 of feio, inefio, putio, cito, and of the imperative cedo, only, are generally short.

7. The gerund in do, in reality, being nothing else than the dative or ablative of the second declension, is, accordingly, by all authors of the Augulian age, made long; the 6 exceptions to this rule are very few, and only by writers of an inferior clafs.

8. * Ambo, duo, imo, illico, ego, generally shorten o final.

1. PrE meli viol, pru pargadtv aracico.

2. Citique, et Berio foror, oceandis ambo.

4. Addo, quod ute tus, nem præsa prænna.

5. Quoque alio titr, que tu faci igitur timean?

6. Hiero grammaticum ostium chorambon.

7. Hiero certis dimum pennis iberum.

8. Imperiali habero datu: viato velox.

11. Velit perro labor faccedore historiisam.

12. Hic inter dens corum mundi maxime genesices.

13. Floridae Komulae errantia pango duciam.

15. Duree quaque fortissima, ha mihi juris.

16. Se ubi nemes quis 4 sero de gente vimorum.

17. One nati, modi tihc velo mihi redeere.

18. Praterex duo atis tuu mihi valle repertii.

Virg.

1. Inde.
1. Indiē manu validas potēs ēt moderantem habebas. Lucr.  

Y final is short; as Moly, Tiphý, Chełý, Tetřý.  
Moly vocant supēri. Ovid.  

Except when y is a contraction, as in Tetřý, instead of Tethyn, the dative, it is long by the general rule for crāfs.  

8. Latin words ending in B shorten the preceding vowel; foreign words lengthen it, as ab, ob, Job, Jacob.  
Magnus ēō integro fec'lorum nācitur ordo. Virg.  

9. Final C lengthens the preceding vowel; as āc, sic, hic, (adverb), dāc, illic, &c.  
Sic ocūlos, sic ille manus, sic ora ferēbat. Virg.  

1. Except that nec and donec are short, as also the imperativē facē.  
2. Hic and hoc of the nominative and accusative, are common.  
* Two passagiæ quoted from incorrect copies of Ovid, to prove facē long, in better editions appear fācē and fāce; to that, according to the opinion of Alvarēs, it is safer to consider facē as short.  
1. Parē, nē invēdē, fine mēq, liber ībi in urbēm. Ovid.  
4. Hic vir, hīc ēst, tibi quem promittit faelect āudì. Ovid.  

10. Final D, in Latin words, shortens the preceding vowel; in foreign words it lengthens it; as quid, ād, apūd, illūd, sēd, David.  
Ipē docet quid āgām. Fās ēst et ēb hoste docerē. Ovid.  

11. Final L shortens the preceding vowel; as mēl, fel, pōl, fēmīl, fēmel, nihil, consûl.  
Innocē veniant: procul hinc, procul impius ēfō. Ovid.  

1. Except that Hebrew words are generally long; as Daniel, Nabāl, Saul.  
2. Sāl, fōl, and nil, are long.  

12. Final M was, ancīentē, short, and was not, as now, elided when followed by a vowel.  
Indignāta fērē tum millīs mīlitium ēō. Enn.  

It is short in circum, in composition with words beginning with a vowel, as circumcē, circumcauto.  
2. Quōs ca circumcētās fē quārisinga aut ultimās pōsās? Juven.  

13. Final N lengthens the preceding vowel; as ēn, plēn, quin, nōn, sīn, rūn, Pān, Salāmīn, Ōrōn, Titān.  
Mērēs et ardentēs Ōrōn auremignēs. Manil.  

Except nouns ending in 'en, which have īnīs, short, in the genitive; as carmen-īnīs, tegmen-īnīs.  
2. Āllo nouns in 'en of the singular number, from the Greek ο (omicron), and which, in Latin, are of the second declension; as Hōn, Pyōn.  
3. Nōs is short in the accussatives of Greek nouns, having the final syllable of their nominative short; as Mājān, Āgīmān, Orpēhōn, Alexīn, Ibīn, Chēlyn, Ityān.  
Vol. XXIX.  

4. Allo ān, ēn, forsan, forsitān, tamēn, attamēu, veruntamēu, vidēn, fatīn, have n short.  
1. Addūnt et titulī, titulus brevē etamēn habebat. Ovid.  
2. Laudābant alīs clarēs Doutōn, aut Mutēlēn. Hor.  
5. Forsētēn et, Prāmi fuerint que fāta, requīrās. Virg.  

14. Final R shortens the preceding vowel; as vīr, puēr, tēr, timōr, calcēr, Hamilcār, anāmār, audīuntār.  

Tum pōsēr omnīpotēns misīò perfērīt Olympum. Ovid.  

1. Except 'G Greek nouns, and 'fīnch as have ērīs, long, in the genitive; as crāter, Sätēr, vērē, Recīmer, 'Iber-ēris; but Cēlibēr, the compound of Iber, has the penultimate common.  
2. Allo 'ār et atherē, though they increace short in the genitive.  
3. And 'ārēr, 'ārē, 'ānēr, 'ānē, 'ārēn, 'ārēn, and with its 'compounds, compār, impār, dispār.  

2. Vēr erat aestētum, placidēque tepentūs aurīs. Ovid.  
3. Si tībi durus lērō, aut si tībi tērēs deśitēs. Lucan.  
5. Ducēt ad aurēris quēd nēs nālo Cēlibērīr ēras. Mart.  
10. Multā quidem dīxī, tērē cæstus abstēres. Hor.  
12. Ludērē pārērīr, impārēr, equīrēt in arundēne longē. Hor.  

Note.—Cor long is attributed to Ovid, but the line in which it is fādē to be found is thus found, is differently interpreted in editions; the same remark is applicable to virē as  
2. De grēge nunc tībi vērē, nunc de grēge natūs habēndās. Ovid.  
3. Thus corrected, virē is long merely by position.  

15. Words ending in AS, lengthen the final syllable; as mās, vōs, crās, fās, amās, farās, pītās, Thomās, Mūfās.  
Hās autem terrās, Italīque hanc litterās orān— Virg.  

1. Greek nouns in as are short, which make the genitive in adōr or adīs, as Arcēas, Pallas, Lampās, Ilās; to which add the noun Annēs, and Latin nouns in as, formed after the manner of Greek patronyms; as Appīs.  
2. Allo the final as of Greek accusatives plural of the third declension is short; as crāterēs, lamīpās, Troēs, Cyclopās, herōs, herōidēs, Hectorās, &c.  
2. Et piētēs anūs enovats pēnis. Petron.  
4. Nībēs his vēnōm, quam nōquēm arcerē tōfēt — Ovid.  

16. Words ending in ES lengthen that syllable; as rés, spēs, vulpēs, quīēs, herēs, eōsēs, Anchēsēs, totēs, loculpes.  
Velsē ad canān dictūr ciconiān. Phādrē  

1. 'The nouns and vocatives plural of Greek nouns increasing (not in es) short in the singular, are short; as Amazonēs, Arcēades, Delphēnēs, Nālādēs, Gryphēs, Phrygēs.  
2. To which may be added Greek vocatives singular in es, coming from nominatives in es, not formed from es of the Doric dialect, and having their genitive in es; as Demotēthēs, Socrates.
QUANTITY.

3. * Et, in the present tense of *cum, and its compounds, is short; as ades, abes, prodes, potes, &c.; and in the preposition penes.

4. Latin nouns of the third declension, in *et, increasing short in the genitive, are short in the final syllable; as hebès, alès, pedès, limès, obsés. But *et is long in the following; Cerès, paries, aries, abès, piès, and its compounds, as bipès, tripes, alipes, fiones; to which some add praepeto, a derivative of praepeto.

1. Treadès; et patrie fumantia tecta reliquent. Ovid.
2. Quisquis ex eo, millo hinc juxta obliviscere Græcis. Virg.
4. Vixi quos ex rapto, non heptis ab hostis tutus. Virg.
5. Flava Cerès ad neci quumque spectat Olympos. Virg.

*Note.—1. Though *et, in the present tense of *cum and its compounds is short, it is not in any other tense, nor in the final syllable of *cum, (as has been asserted), as

Poenès in tanto vite fia figiato? Propret.
Eftus loni fincta puella maris. Propret.

2. Whenever paries, aries, and abies are found long, there happens to be a cætura; and perhaps Cerès and pes are long by dialeque: Antonius shortens bipes and triges; and Probus observes that alipes and fonipes are likewise short; though the contrary appears in Virgil, Lucan, and Horace, yet some of the above-mentioned words could not be introduced into horæaque without the influence of a figure to lengthen their final syllable. Prapes, which comes not from pes, but from *peregrinis, is short in Virgil. (E. N. 5. 254.) Tiges, ascribed to Ovid, is, by the bell critics, rejected.

17. IS final is short; as bis, is, quis, cis, magis, turris, militis, creditis, Thetis.

Tum cés ad occasum, bis fe convertit at orum. Ovid.

1. Except *plural cafes in is; as nobis, vobis, (’quis for quibus), musis; the plural accusatives omnis, 4 urbis, &c.

2. The nominative in *is is long, when the genitive ends in *itis, *inis, or *entis long; as is, Samius, Salamis, Simois.

3. Is is long in the adverbs gratias and foris; in the noun gnis, and in vis, whether noun or verb.

4. All *second person singulars in *is are long; when the second persons plural have *ius long; as cis, fis, vis, is, *abuis, audis, velis, nolis, poësis, &c.

5. *Ri of the perfect is commonly considered short, of the "future", common; so are the penultimates of ausis and faxis; ris and ritis of *ero and potero are more frequently short.

1. Inducendus est et: das *uëst title munus. Martr.
2. Quid ante ora *patrum Trojæ fab minibus altis. Virg.
5. Sed is est nisi de tribus capellis. Virg.
7. Linea convexi viae et fine pondere cali. Hor.
9. Gratias anhelans, multa agendo, nil agens. Hor.
11. *Ego gentes ilium, aut quasi non aviro urbes. Hor.
14. OS final is long; as rōs, vōs, nōs, mōs, trōs, trōs, arbō, honōs, cufōs, nepōs.

6. Except *Greek genitives in *ar; as Arcades, Tethyinos, Terebos, Orphes.

2. Alto comos, impos, and *os-offis, with its compounds exós, have the final syllable short.

3. *Greek nominatives and vocatives of the second declension have or short; as Claros, Tenedos, Lebös, Atropos. But those nouns of the Attic dialect, having their genitives in *os, are long, as Androgeos, Athos: also nouns of the same dialect, which have changed *eros (λήθα) into lor (λήθα), as Penelos, Menelaos.

4. Greek neuters in *ar are short; as Argos, epós, cæs, melos.

2. Inesperet, & veni potius consueput eris. Ovid.
4. Tum cum tritis erat, deferit est Ilis ordin. Ovid.
5. Quantus Athen, aut quæ quœs, aut ipse caruus. Virg.

Incepit: pacefacentes servavit Tityros hædus. Virg.

1. Except *monosyllables in *us; as grus, plus, rüs, thun, jus.

2. Also the *genitives of feminine nouns in *a; as Clitis, Sapphus, Mantis.

3. Genitives singular, and nominatives, accusatives, and vocatives plural of the fourth declension, (all being contracted), have or long; as fractus, manus.

4. Also nouns increasing long in the genitive; as palus-ūdis, virtus-ūris, tellus-ūris, Opis-āntis.

5. Us is long in the contr. compounds of *saeus (forming the genitive in podis or podos,) as Tripüs, Melampüs, Odpipüs, Polyopus.

6. Also *those nouns which have *u in their vocative; as Panthüs, O Panthu.

7. Finally, *lae vocis has the final syllable long.

1. Romeis vīs opts, abuentem nutritum urbem. Hor.

20. YS final is short; as Capys, chelys, chamys.

At Capys, et quoniam melior fementia ment. Virg.

21. nominal and vocatives in *ya also; as Gortys, Phorcys. To these add contracted plurals; as Erynys, for Eryneys, or Erinys.

21. Final T shortens the preceding vowel; as caput, amät.

Venam hoc tantum alias inter: capit caudiur urb. Virg.

Except when final *t is long by craftis; as redit for reddi or reditiv.

Magus eliv est et corniculatus Othoni. Juven.

1. The last syllable of every verse is considered common; that is, if the syllable be naturally long, it may be accounted short; or, if it fuit the verse, voce verbis.

Gemināmica mīhi Tyrrenum navigat aquātur. Hor.

Cretic occulto ut illum aerē. Hor.

*Note.—1. In the first of the examples, *ar, naturally short, forms the second syllable of a spondee; in the last, a Suppuric verce, the word aerē, which is naturally a spondee, forms a trochee.

2. *The conscripts that diploede Dr. Clarke, (see Clarke’s Homer, Iliad A. v. 54,) by saying that the last syllable of a verse is common, only meant, that the local quantity of the syllable—'

For the last principal head of prosody; see Versification.

QUAN-TSOM, in Geography, a town of China, of the third rank, in Pe-chel-li; 32 miles S. of Chunte.
QUANTUM Meruit, called also an auff umpfs, in Law, an action upon the cafe, grounded upon a neceffity to pay a man for doing any thing so much as it deferves or merits.

This valuation of his trouble is submitted to the determination of a jury; who will affefs such a sum in damages as they think he really merited.

Qua tum Velebat, or an implied affumpft, is where goods and wares sold, are delivered by a traderman at no certain price, or to be paid for them as much as they are worth in general; then quantum velebat, or an action on the cafe, lies, and the plaintiff is to aver them to be worth so much; so where the law obliges one to furnish another with goods or provisions, as an inn-keeper his guests, &c.

Quanzt, John Joachim, in Biography, chamber musician to Frederic II, king of Prufia, to whom he had been flute-mifer before his acceffion to the crown. Quanzt was born at Oberfcheden, a village in the electorate of Hanover, in 1697. His father, who was a blacksmith, obliged him to work at the anvils before he was nine years old; which might have afforded him an early opportunity of making the famous Pythagorean experiment, mentioned by Jamblimus (de Vit. Pythag.), and by all the musical writers of antiquity. Indeed, the ear of our young Arbalus had been already formed, in his excursions with his brother, a village musician, who used to play about the country on holydays and festivals, whom he accompanied upon these occasions, on the base-viol, when but eight years old, and without knowing a note of music; but this performance, bad as it was, pleased him so much, that he determined to choose music for his profession; though his father, who died when he was only ten years of age, recommended to him, on his death-bed, to continue in the honourable profession of his ancestors.

Quanzt, after losing his father, had no other friends to depend upon for countenance and protection, than two uncles, who lived at Merfeb and Saxony; and these, sending for him, gave him the choice of their several professions, the one being a tailor, and the other a kunstpfiffer, or town-wait.

Upon this occasion, the passion for music in the young Quanzt overpowered all other considerations, and, preferring the fiddle-flight to the anvils or hearth, he bound himself apprentice to his uncle, the musician, for five years; but this uncle dying three months after, he was transferred to his son-in-law, Fleifchback, who was of the same profession; and it was under him that he first practifed the violin, an instrument to which his inclination at this time impelled him, preferably to any other.

Soon after this, however, he practifed the hautbois, and the trumpet, with which instruments, and the violin, he chiefly filled up the term of his apprenticeship; but as a true town musician, in Germany, is expected to play upon all kinds of instruments, he had been obliged, occasionally, to apply himself, during this period, to the fackon, cornet, base-viol, French horn, common flute, balifon, viol da gamba, and the lord knows how many more. These were in the way of business, but for pleasure, he now and then took lemons on the harpsichord, of the organif Kiewetter, who was likewise his relation; by which he laid the findentation of his knowledge in harmony, and love for composition.

Luckily for Quanzt, his master, Fleifchback, was not, like other country musicians, fond only of old, dry, stiff, and taffoif compositions, but had sufficient dexterity to choose his pieces out of the newest and beet productions of the times, by Telemann, Melchoir, Hofmann, and Heinechen, which were published at Leipfic; from the perusal, and practice of which, our young performer derived great advantage.

The duke of Merfeb’s band not being very numerous, the town-waits, at this time, were often called in, to affift at the musical performances, both of court and chapel. Here Quanzt frequently heard foreigners play and sing, in a manner far superior to any professors whom he had hitherto met with, which excited in him a strong defire to travel. Drefden and Berlin were at this time the most renowned cities in Germany, for the cultivation of music, and the number of able musicians. He eagerly wished to visit one of those cities, but was deficient of the means. However, he now began to feel his strength, and trusting to his feet and his fiddle, he boldly set off for Drefden.

It was in the year 1714 that he arrived in that city. His firft entrance was not auspicious, being wholly unable to procure employment: on this account, he made an excursion to Radeburg, where a journeyman fiddler being wanted, he entered into the service of the town musician, Knoll; but alas! he was soon driven from this poft, by the fatal accident of the town being burnt down by lightning. Again reduced to the state of a fugitive, and a wanderer, he levied contributions round the country by the power of his violin, which was now his principal instrument, till he reached Pirna.

Here, defigned still to be fervos fervorum, he could procure no other means of exercifing his profession, than by accepting the office of deputy to a fick journeyman musician of the town. It was during this time, that he firft saw Vivaldi’s concertos for the violin, which were fo congenial to his own feelings and ideas of perfection, that he made them his model as long as he continued to pracifie that instrument.

Still regarding Drefden as his centre, he eagerly accepted an offer that was made to him, of being temporary affiftant, to one of the town-waits, who was then ill; an employment which he preferred, for the opportunities it afforded him of hearing good music and good musicians, to the more honourable poft of being the bell of bad musicians at Berenburg, where he might have been appointed first violin, with a good salary.

His second arrival at Drefden was in the year 1716, where he soon discovered that it was not fufficient for a musician to be able to execute the mere notes which a composer had set on paper; and it was now that he firft began to be fensible of the exifence of fyle and expression.

Aurifius II. was at this time king of Poland, and elector of Saxony, and the orchestra of this prince at Drefden was in a flourishing condition; however, the fyle which had been introduced there, by the concert-mater Volmer, was French; but Pfendel, who succeeded him, introduced a mixed fyle, partly French, and partly Italian, which he afterwards brought to fuch perfection, that Quanzt declares, he never heard a better band in all his future travels.

No orchestra in Europe could now boast of fo many able profeflors, as that of the elector of Saxony, among whom, were Pfendel and Veracini, on the violin; Pantaleone Benvenite, on the pantalone; Weifs, on the lute; Richter, on the hautbois; and Buffardin, on the German flute; not to mention several excellent performers on the violoncello, balifon, French horn, and double-bafe.

Upon hearing these great performers, Quanzt was filled with fuch wonder, and posfessed of fuch a rage for improvement, that he laboured incessantly to render himself worthy of a place among fuch honourable associates.

For, however prejudiced he may have been in favour of his own reputable calling of kunstpfiffer, he began now just to think it fufficient for him to be prevailed upon, to relinquish that part of it, at leaft, which required him to play
country dances, though in itself so jovial, pleafant, and fatal an employment.

He continued, however, to be the kunftpfeifer's delegate in this city, till the death of Auguflus II.'s mother, in 1717, at which time, the general mourning procribing the use of every species of convivial mufic, he again, in his ufual manner, commenced traveller, and fiddled his way through Silefia, Moravia, and Austria, to Vienna; and in the month of October, of the fame year, returned through Prague to Drefden; which journey, he thinks, contributed more to his knowledge, in practical geography, than in any other art.

The jubilee of the reformation, brought about by Dr. Luther, happening to be celebrated soon after his return, he was called upon, among others, to perform a part upon the trumpet, at church, where the chapel-mafter Schmidt having heard him, offered to prevail on the king to have him regularly taught that instrument, in order to qualify him for the place of court trumpeter; but Quantz, however ardently he might have wished for an office at court, declined the acceptance of this, well knowing that the good taste to which he aspired, was not to be learned upon that instrument, at leaft as it was then played in Drefden.

In 1718, the Polish or royal chapel was intituted; it was to confift of twelve performers, eleven were already chosen, and a hautbois player, only, was now wanting, to complete the number. After undergoing the several trials, and giving the requisite proofs of his abilities, he had the happiness to be invested with that employment, by the director, baron Seyfertitz, with a salary of 150 dollars, and a lodging.

This was an important period in his life, and in the exercise of his profefion. The violin, which had hitherto been his principal instrument, was now laid aside for the hautbois, upon which, however, he was prevented from distinguing himfelf, by the feniiority of his brethren. Mortified at this circumstance, he applied himself feroiusly to the German flute, upon which he had formerly made some progresfes without a matter; but his motive now for refuming it, was the certainty of his having no rival, in the king's band, as M. Friepe, the firit flute, had no great paffion for mufic, and readily relinquifhed to him his place.

In order to work upon fure ground, Quantz took lessons at this time of the famous Buffardin, with whom, however, he only played quick movements, in which this celebrated flute-playerchiefly excelled. The fecracy of pieces, composed expressly for the German flute, was fuch, at this period, that the performers upon that instrument were obliged to adopt thofe of the hautbois, or violin, and by altering or tranfpoiting, accommodate them to their purpofe, as well as they could.

This stimulated Quantz to compose for himfelf; he had not as yet ever received any regular instructions in counterpoint, to that, after he had committed his thoughts to paper, he was obliged to have recourse to others to correct them. Schmidt, the chapel-mafter, had promised to teach him composition, but delayed keeping his word from time to time, and Quantz was afraid of applying to Heinichen, his colleague, for fear of offending Schmidt, as thofe matters were upon bad terms together. In the mean time, for want of other affifiance, he diligently studied the fores of great mifters, and without stealing from them, endeavoured to imitate their manner of putting parts together, in trios, and concertos.

About this time he had the good fortune to commence a friendhip with Pifendel, now appointed concert-mafter, in the room of Volumier. Quantz is very warm in his praise of Pifendel, whom he calls a profound theorifit, a great performer, and a truly honeft man. It was from this worthy concert-mafter that he learned to perform an adagio, and to compose in many parts. Pifendel had in his youth been taught to fing by the famous Pilucchi, and had received instructions, on the violin, from Torelli; however, having travelled through France and Italy, where he had acquired the peculiarities in the taste of both countries, he fo blended them together as to form a third genus, or mixed fyle of writing and playing, which was half French and half Italian. Influenced by his example, Quantz declares, that he always preferred this compound fyle, to that of Italy, France, or the national fyle of his own country.

At the marriage of the prince royal of Poland, in 1719, several Italian operas were performed at Drefden. Lotti, the famous Venetian mafter di capella, together with the moft celebrated fingers of Italy, male and female, were called thither upon this occafion; these were the firt Italian operas which Quantz had heard, and he confefles, that the performance of them gave him a very favourable idea of the genuine and fonnd Italian mufic, from which he thinks later times have too much deviated.

After describing the talents of the fingers who will have their place in our alphabet, he informs us that this famous opera at Drefden, was broken up by a quarrel between Heinichen, the king of Poland's chapel-mafter, and Senefino, who this fame year, 1719, went to England for the firt time.

Nothing very interesting occurs in the life of Quantz from this period, till 1723, when he took a journey with Weifs, the famous luteflit, and Graun, the compofitor, to Prague. Quantz, not long after the coronation of Charles VI. at Prague, went to Italy in the fuite of count Lagnasco, with the confent of his royal mafter, the king of Poland. He left Drefden in May 1724, and, when he arrived at Rome, he found that Vivoldi had fince introduced the Lombard fyle in that city, with which the citizens were fo captivated, that they would hear no other.

During his residence at Rome, he took lefions in compofition of the famous Gaffarini, who was at that time seventy-two years of age; and after studying counterpoint with him, which he calls mufic for the eye, he went to work for the ear, and composed foles, duets, trios, and concertos; however, he confefles, that counterpoint had its ufe in writing pieces of many parts; though he was obliged to unlearn many things, in practice, which theory had taught him, in order to avoid that dry, and stiff fyle, which too clofe an adherence to rules is apt to produce; upon this occafion, he very judiciously observes, that invention is the firit requisite in a compofitor, and that it behoves him to prefe a friendhip between harmony and melody.

In 1725 he went to Naples, where he met with his countryman Haffe, who then studied under Alex. Scarlatti. Haffe had not, as yet, diftinguifhed himfelf by any compofitions for the stage; however, it was at this time, that a confiderable Neapolitan banker employed him to fet a ferenata for two voices, which he did in the prefence of Quantz; the fingers who performed it, were Farinelli and Tafi. Haffe gained fo much reputation by this production, that it paved the way to his future fuccefs, and he was foon after appointed compofitor of the great opera at the theatre royal.

Quantz intreated Haffe to introduce him to his mafter, Scarlatti, to which he readily consented; but upon mentioning him to the old compofitor, he faid, "my fon, you know I hate wind instruments, they are never in tune." However, Haffe did not ceafe importuning him, till he had obtained the permission he required.

In
In the visit which he made to Scarlatti, M. Quantz says, that he had an opportunity of hearing him play on the harpsichord, which he did in a very learned manner; but observes, that his abilities on that instrument were not equal to those of his son.

Before his departure from Naples, M. Quantz frequently heard concerts at the duke of Lichtenstein's, in which Haffi, Farinelli, Tafi, and Francichello, were employed.

In 1726 he was at Venice, during the performance of two rival operas, "Siface," composed by Porpora, and "Siroe," by Vinci; the latter was most applauded. The Cav. Niculini, a contralto, La Romanina, a deep sopran, and the famous tenor, Paita, were the principal fingers in these dramas.

San Martini, the celebrated performer on the hautbois, who afterwards established himself in London, was now at Venice, as was Vivalli.

At Turin he met with Somis, under whom, Le Claire was at that time a scholar on the violin.

From Turin he went to Paris, which, with respect to music, was going from one extreme to another.

His character of French singing in the former part of the last century, is very just and characteristic.

"I was delighted with the French taste now," says M. Quantz, "though I had heard it formerly with patience. The old, worn-out, second-hand thoughts, and passages ill-expressed, disgusted me now, as much as a stale dish warmed again. The resemblance between recitative and air, with the affected and unnatural bowing of the fingers, particularly the women, shocked my ears."

M. Quantz was the first who applied an additional key to the German flute, in order to correct its imperfections; and it was in the course of this year, 1726, that he made the discovery.

In 1727 he arrived in London, where he found the opera in a very flourishing state, under the direction of Handel. The drama of "Admetus" was now in run, of which, he says, the music was grand and pompous. Senefino performed the first male part, and Cuzzoni and Faustina were the principal women.

He then gives a character of the fingers, flute of the opera, and of music in general in London, very correctly.

Upon his return to Dresden, he was established in the king's chapel, with an addition to his former salary of 250 dollars a-year. He now entirely quitted the hautbois, supposing it hurtful to the embouchure of the flute, which, from this time, he made his sole study.

In 1728 he went to Berlin, with baron Seyfertiz, in the suite of the king of Poland; where he was obliged, at the command of the queen of Prussia, but with the permission of his royal master, to remain for some months. Pifendel, Weits, and Buffardin, were, by the same order, called thither. After he had had the honour of playing before the queen two or three times, he was offered a place and pension of 800 dollars a-year. He was very willing to accept of them, but the king his master would not grant his consent: however, this prince gave him a general permission to go to Berlin as often as he was desired.

This year, 1728, the prince royal of Prussia determined to learn the German flute, and M. Quantz had the honour to teach him. On this account, he was obliged to go twice a year to Berlin, Ruppin, or Reinsberg, the several residences of his royal scholar.

After the death of the king of Poland, in 1732, his son, Augustus III. not choosing to dismiss M. Quantz, raised his appointment to 800 dollars, and confirmed the permission which had been granted by his royal father, for his going occasionally to Berlin.

In 1734 he published his first folio; but he does not acknowledge the sonatas, which were printed under his name, in Holland, about that time.

In 1739, M. Quantz finding a great scarcity of German flutes, undertook to bore them himself for the use of his pupils; an enterprise which, afterwards, he found to be very lucrative.

In 1741 he was again invited to Berlin, in order to enter into the service of his royal scholar, then king of Prussia, with offers of an annual pension of 2000 dollars for life; a separate payment for compositions; 100 ducats for every flute he should deliver; and an exemption from playing in the orchestra, or any where else, but in the king's chamber, as well as from dependence on any other commands than those of his majesty; which terms, as the king of Poland was too gracious longer to refuse his dismission, M. Quantz was unable to resist.

In 1752 he published his "Art of Playing the German Flute!" and it was this year that he invented the new joint for the upper-piece of the flute, by which means, without drawing out the middle piece, and without hurting the tone, the instrument may be raised or lowered half a note.

And now, having traced our industrus musician through the troublesome mazes by which he arrived at the temple of fortune, we had hopes that we should have left him to the enjoyment of that reputable cafe, that satisum cum dignitate, to which every artist in years aspires; but alas! this eminent musician and worthy man died at Potsdam in less than a year after we had seen, heard, and conversed with him in that summner reidence of his royal disciple and patron! A complete list of his works is given in Gerber.

QUANUSE, in Geography, a town of America, in the Tennessee government. N. lat. 35° 12'. W. long. 84° 28'.

QUAPA, a town of Louisiana, at the confluence of the Akanfis and the Mississippi. N. lat. 33° 48'. W. long. 91° 23'.

QUAPACTOTOTUL, in Ornithology, a name under which Niemering has described a bird, which, he says, imitates the human laugh. He says its body is eight inches long, and the tail as many; the beak of a blue-black, and bent and crooked; the breast grey, and the belly black; the tail of a brownish-black; and the wings, neck, and head, of a yellowish-brown.

This is the Cuculus ridibundus of Gmelin, the Cuculus Mexicanus of Buffon, and the Laughing cuckoo of Latham. It is found in New Spain.

QUAPIZOTUL, in Zoology, the name given by Hernandez to the Tajaçu of Maregrave, the Pecari of Buffon, and the Mexican hog of Pennant. See Sus Tajaçu.

QUAPOYA, in Botany, Abl. Guian. v. 2. 897. t. 343, 344, 345. a barbarous Caribbe name. See XANTHE.

QUAR in Agriculture, a term occasionally employed, in a provincial manner, to signify a small fort of quarry of any kind, but more especially of the lime-stone, free-stone, flag-stone, or slate-stone nature. It is much used in some of the more northern districts of the country. See QUARRY.

QUARANTAIN, in old Law Books, written Quarentaine, and Quarentenas, denotes the space of forty days.

"Quarentena in London, ponitur pro rectu habendi, 40 dies post funerem munimenon per breve regis, ut confuant, sc. &c. fit fibi viderint expedire." MS. de Temp. Ed. Ill.
The term is borrowed from the French quarantain; and is sometimes used for the time of Lent.

**Quarantain of the King**, in France, denotes a truce of forty days appointed by St. Louis, during which time it was expressly forbidden to take any revenge of the relations or friends of people who had fought, wounded, or affronted each other in words.

**Quarantain, or Quarantine**, is more particularly used for the term of forty days, which vessels, coming from places suspected of contagion, are obliged to wait in certain places appointed to air themselves before they come into port.

By the Stat. 26 Geo. II. cap. 6. explained and amended by 29 Geo. II. cap. 8. the method of performing quarantine, or forty days probation, by ships coming from foreign countries, is put in a much more regular and effectual order than formerly; and matters of ships coming from infected places, and disobeying the directions there given, or having the plague on board, and concealing it, are guilty of felony without benefit of clergy. The same penalty also attends persons escaping from the lazarettos, and officers and watermen neglecting their duty, and perpetrators conveying goods or letters from ships performing quarantine. *See Plague.*

In cafes of insurance, before the risk on a ship can be said to be completely ended, the mast not only has been 24 hours moored at anchor in her port of destination, but the mast has been during that time in good safety, in the fullest sense of those words. If, therefore, the ship is obliged to perform quarantine, this does not end the voyage. The voyage only ends when the ship is arrived at her port of destination, and is there moored 24 hours in good safety. Accordingly, if the ship, before the 24 hours are expired, be ordered to the proper place for performing quarantine, the risk continues, though she do not leave her moorings till long after the 24 hours are expired. See Risk.

**Quarantain also** denotes certain duties imposed upon ships, for the purposes of quarantine.

**Quarantine, Quarantine, or Quarantine, Quarantina, in Law**, denotes a benefit allowed by the laws of England to the widow of a man dying feised of land; by which the claimant may challenge to continue in his capital redemption, or chief manufactory (so it be not a cattle), for the space of 40 days after his decease; during which time her dower shall be affirmed. The particular lands to be held in dower must be aligned by the heir of the husband, or his guardian. *Co. Lit. 34, 35.*

If the heir, or any other person, attempt to eject her, she may have the writ of *quarantina habenda*; which lies for a widow to enjoy her quarantine.

**Quarantain also** is used for a measure or extent of land, containing 40 perches.

**Quarantaria, in Geography,** a high mountain between Jerusalem and Jericho; which, as tradition says, is the mountain to which our blessed Saviour was taken by the devil, when he tempted him with the visionary scene of all the kingdoms and glories of the world. This is, as St. Matthew styles it, an exceeding high mountain, and not only difficult, but dangerous, of ascent. It has a small chapel at the top, and another about halfway of its ascent, founded upon a prominent part of the rock. Near this latter are several caves and holes in the side of the mountain, made of anciently by hermits, and by some in later times, for places in which they kept their Lent; in imitation of that of our blessed Saviour. In most of these grots Maudrell found several Arabs quartered with fire-arms, who obstructed his ascent, demanding 200 dollars for leave to go up the mountain. He and his companions, says the traveller, departed without further trouble, not a little glad to have so good an excuse for not climbing so dangerous a precipice. Maudrell's Journey, &c. p. 80.

**Quarantia, in the Venetian Polity**, a court of judicature composed of forty judges.

The Venetians have an old civil quarantia, a new civil quarantia, and a criminal quarantia.

The criminal quarantia takes cognizance of all crimes except those against the state, which belongs to the council of ten. The new civil quarantia judges of appeals made from sentences made by judges out of the city; the old civil quarantia takes cognizance of appeals from sentences of feudal judges in that city.

**Quararibia, in Botany. See Myroda.**

**Quare clausum frigis, in Law. See Clausum frigis.**

**Quare ejusdem terminum,** a writ which lieth, by the ancient law, where the wrongdoer or ejector is not himself in possession of the lands, but another who claims under him. As where a man leaseeth lands to another for years, and, after, the lessor or reverfeioner entereth, and maketh a feufoin in fee, or for life, of the same lands to a stranger; now the lessor cannot bring a writ of *ejectione firme*, or ejectment, against the feufoin; because he did not eject him, but the reverfeioner: neither can he have any such action to recover his term against the reverfeioner, who did oul him; because he is not now in possession. And upon that account this writ was devised, upon the equity of the statute W. 2. c. 24. as in a case where no adequate remedy was already provided. And the action is brought against the feufoin for forcing, or keeping out, the original lessor during the continuance of his term; and herein, as in the ejectment, the plaintiff shall recover so much of the term as remains; and also shall have actual damages for that portion of it, whereof he has been unjustly deprived. But since the introduction of fictitious oulters, whereby the title may be tried against any tenant in possession, (by what meansforever he acquired it,) and the subsequent recovery of damages by action of trespass for mine profits, this action is fallen into disuse. See Ejectione Firme.

**Quare impeditis, a writ which lies for him who has purchased an advowson, against him who disturbs him in the right of it, by presenting a clerk to it when the church is void.**

It differs from the ailege of darrein presentment, ultima presentationis, which lies where a man, or his ancestors, formerly presented; this other lying for him who is the pur-chafer himself. Where a man may have the ailege, he may have this writ, but not contrariwise.

In contested presentations, upon the first delay or refusal of the bishop to admit his clerk, the patron usually brings his writ of quare impeditis against the bishop, for the temporal injury done to his property, in disturbing him in his presentation. And if the delay arises from the bishop alone, as upon pretence of incapacity, or the like, then he is only named in the writ; but if there be another pretention set up, then the pretended patron and his clerk are also joined in the action; or it may be brought against the patron and clerk, leaving out the bishop; or against the patron only. But it is most advisable to bring it against all three: for if the bishop be left out, and the suit be not determined till the six months are past, the bishop is entitled to present by lapse; for he is not party to the suit: but, if he be named, no lapse can possibly accrue till the right is determined. If the patron be left out, and the writ be brought only against the bishop and the clerk, the suit is of no effect, and the writ shall abate; for the right of the patron is the principal question in the cause. If the clerk be left out, and has re-
ceived institution before the action brought, (as is sometimes the case,) the patron by this suit may recover his right of patronage, but not the present turn; for he cannot have judgment to remove the clerk, unless he be made a defendant, and party to the suit, to hear what he can allege against it. For which reason it is the fader way to inflict all three in the writ.

The writ of quare impedit commands the disturbers, the bishop, the pseudo-patron, and his clerk, to permit the plaintiff to present a proper person (without specifying the particular clerk) to such a vacant church, which pertains to his patronage; and which the defendant, as he alleges, do obstruct; and unless they do so, then that they appear in court to shew the reason why they hinder him.

Immediately on the filing out of the quare impedit, if the plaintiff suspects that the bishop will admit the defendant's or any other clerk, pending the suit, he may have a prohibitory writ, called a ne admissitas; which recites the contention begun in the king's courts, and forbids the bishop to admit any clerk whatsoever till such contention be determined. And if the bishop doth, after the receipt of this writ, admit any person, even though the patron's right may have been found in a jure patronatus, then the plaintiff, after he has obtained judgment in the quare impedit, may remove the incumbent, if the clerk of a stranger, by writ of seire facias: and shall have a special action against the bishop, called a quare incumbavit; to recover the presentation, and also satisfaction in damages for the injury done him by inumbering the church with a clerk, pending the suit, and after the ne admissitas received. But if the bishop has inumbered the church by inluting the clerk, before the ne admissitas issued, no quare incumbavit lies; for the bishop hath no legal notice, till the writ of ne admissitas is served upon him. The patron is, therefore, left to his quare impedit merely; which now lies (since the statute of Welfm. 2.) as well upon a recent usurpation within six months past, as upon a disturbance without any usurpation had.

In the proceedings upon a quare impedit, the plaintiff must set out his title at length, and prove at least one presentation in himself, his ancestors, or those under whom he claims; for he must recover by the strength of his own right, and not by the weaknesses of the defendant's; and he must also shew a disturbance before the action brought. Upon this the bishop and the clerk usually disclaim all title: save only, the one as ordinary, to admit and inliture; and the other as presentee of the patron, who is left to defend his own right. And, upon failure of the plaintiff in making out his own title, the defendant is put upon the proof of his, in order to obtain judgment for himself, if needful. But if the right be found for the plaintiff, on the trial, three farther points are also to be inquired: 1. If the church be full; and, if full, then of what presentation; for if it be of the defendant's presentation, then the clerk is removable by writ brought in due time. 2. Of what value the living is: and this in order to affect the damages which are directed to be given by the statute of Welfm. 2. 3. In case of plenary upon an usurpation, whether six calendar months have passed between the avoidance and the time of bringing the action: for then it would not be within the statute, which permits an usurpation to be divested by a quare impedit brought infra tempus semelius. So that plenary is still a sufficient bar in an action of quare impedit, brought above six months after the vacancy happens; as it was universally by the common law, however early the action was commenced.

If it be found that the plaintiff hath the right, and hath commenced his action in due time, then he shall have judgment to recover the presentation; and, if the church be full by inlitation of any clerk, to remove him: unless it were filled pendente lite by lapse to the ordinary, he not being party to the suit; in which case the plaintiff loses his presentation pro hac vice, but shall recover two years' full value of the church from the defendant, the pretended patron, as satisfaction for the turn left by his disturbance: or, in case of incompetence, the defendant shall be imprisoned for two years. But if the church remains full void at the end of the suit, then whenever party the presentation is found to belong to, whether plaintiff or defendant, shall have a writ directed to the bishop ad admittendum clericum, reciting the judgment of the court, and ordering him to admit and institute the clerk of the prevailing party; and, if upon this order he doth not admit him, the patron may sue the bishop in a writ of quare non admittis, and recover ample satisfaction in damages.

Besides these possessory actions, there may be also had a writ of right of advowson, which resembles other writs of right: the only distinguishing advantage now attending it, being, that it is more conclusive than a quare impedit; since to an action of quare impedit a recovery had in a writ of right may be pleaded in bar.

There is no limitation with regard to the time within which any actions touching advowsons are to be brought; at least none later than the times of Richard I. and Henry III. for by statute 1 Mar. fl. c. 5. the statute of limitations, 32 Hen. VIII. c. 2. is declared not to extend to any writ of right of advowson, quare impedit, or ashe of darren prezentment, or jus patronatus.

In a writ of quare impedit, which is almost the only real action that remains in common use, and also in the ashe of darren prezentment, and writ of right, the patron only, and not the clerk, is allowed to sue the disturber. But, by virtue of several acts of parliament, there is one species of presentations, in which a remedy, to be sued in the temporal courts, is put into the hands of the clerks prented, as well as of the owners of the advowson. We mean the presentation to such benefices, as belong to Roman Catholic patrons; which, according to their several counties, are vested in and secured to the two universities of this kingdom. And particularly by the statute of 12 Ann. fl. 2. c. 14. § 4. a new method of proceeding is provided; viz. that, besides the writs of quare impedit, which the universities as patrons are entitled to bring, they, or their clerks, may be at liberty to file a bill in equity against any person prenting to such livings, and disturbing their right of patronage, or his ejusque vestris, or any other person whom they have cause to dilpet; in order to compel a discovery of any secret trusts, for the benefit of Papists, in evaion of those laws whereby this right of advowson is vested in those learned bodies: and also (by the statute 11 Geo. II. c. 17.) to compel a discovery whether any grant or conveyance, said to be made of such advowson, were made bona fide to a Proletant purchaser, for the benefit of Proletants, and for a full consideration; without which requisites, every such grant and conveyance of any advowson or avoidance is absolutely null and void. Blackst. Com. b. iii.

Quare incumbavit, a writ which lies against the bishop, who, within six months after the vacancy of a benefice, com- fers it on the clerk of any one, while two persons are con- tending at law for the right of prezentment. This writ lies always depending the plea. See the preceding article, Presentation, Assise of darren prezentment, &c.
QUA

Quare non admitit, a writ which lies against the bishop, for refusing to admit his clerk, who has recovered in a plea of advowson, on pretence of lapse, &c. See Quare impleads.

Quare non permitis, a writ that lies for one who has a right to present for a turn against the proprietary.

Quare obfruxi, a writ that lies for him, who, having right to paes through his neighbour's grounds, cannot enjoy the same, because the owner has fenced it up.

Quarentina. See Quarantain.

Quarera, or Quaratia. See Quary.

Quaritz, in Geogrophy, a town of Silelia, in the principality of Glogau; 5 miles W. of Gros-Glogau.

Quarken, or Quaren, a cluster of small islands, in the gulf of Bothnia, near the east coast. N. lat. 65°10'. E. long. 21°.

Quarles, Francis, in Biography, an English poet, born in 1592, near Rumford, in Essex, was son of James Quarles, esq. who held an office at the navy board in the reign of queen Elizabeth. The subject of this article was educated at Chrift's-college in Cambridge, and was afterwards entered a student in Lincoln's Inn. He obtained the place of cup-bearer to the queen of Bohemia, daughter to James I: and upon his return, he was appointed secretary to archbishop Usher in Ireland, from which country he made his escape, on the breaking out of the rebellion in 1641, after the los of his property. He had before distinguished himself by some works, chiefly on religious subjects, in consideration of which he had a pension from Charles I. About this time he had the post of chronologer to the city of London. On the commencement of the civil wars, he gave great offence to the parliament by a work, entitled "The Loyal Convert;" and when he actually joined the king at Oxford, he was plundered of his estates, his books, and manuscripts. Thefe lofes he did not long survive. He died at the age of 52, in 1644. Of his numerous writings, as well in prose as in verfe, the most celebrated, and indeed by which he is almost entirely known, is his "Emblems," a fet of defigns exhibited in prints, and elucidated by some lines attached to each. A confiderable part of the work is borrowed from the "Emblems" of Hermannus Hugo, but his verfes are his own. For a confiderable time they excited a large portion of public admiration in the religious world. They then fell into contempt; but we believe a new edition has of late years been given to the world. Quarles is thus characterized by an able critic: "He is by no means without his beauties; and his verfes, which are generally smooth, afford occasional bufts of fancy, and strokes of pathos, which are in real genius, though overrun with falses tastes. Mr. Jackfon of Exeter, in his "Letters on various Subjects," endeavoured to recall the public attention to this neglected poet, and pointed out with much feeling some of his brilliant passages; but though curiounfs may be amufed by hunting for his scattered beauties, he can never regain a place among the English classical poets."

Quarlesville, in Geography, a poft-town of America, in Brunswick county, Virginia; 204 miles from Washington.

Quarname, a town of Sweden, in the province of Smaland; 23 miles S. of Wexio.

Quarnero, or Cornnero, Gulf of, a part of the Adriatic, between Istria and Marlocha, anciently called "Sinus Platinicus." It is subject to sudden storms and hurricanes, which render its navigation dangerous.

Quarre, Fr. In old French muse, B quarre was the term for B. See Quadro.

Quarré les Tombes, in Geography, a town of France, in the department of the Yonne, and chief place of a canton, in the district of Avalon; 6 miles S. of Avalon. The place contains 2007, and the canton 7287 inhabitants, on a territory of 1924 kilometres, and 9 communes. Quarrée, in the old French time-table, implied a breve, or square note, equal to two semi-breves. See Time-table.

Quarrel, Querela, in Law. See Querela.

Quarrel feems properly to relate to personal actions, or at mолt to mixed ones, wherein the plaintiff is called quarras; and in all declarations of trepas, it is said, quarras.

Yet if a man release all quarrels or querelles, (a man's own deed being taken mолt strongly against himself,) quarrel includes all actions; and accordingly all actions, both real and personal, are hereby released.

Quarrels or affairs in a church or church-yard are esteemed very heinous offences, as being indignities to him whose service these places are consecrated; therefore mere quarrellome words, which are neither an affair nor an offence in any other place, are penal here. See AFFRAY.

Quarrel between the French and Italian singers at Rome, in the time of Charlemagne; for which we refer to our article CHARLEMAGNE. See also Rossinaud's Dictionary.

Quarrel, in Armory, a bolt, or square-headed arrow, to shoot out of an arbalist, or cors-bow.

Quarrel of Glofs. See Quary.

The word is formed, by diminution, from the Latin quadratum, or the French quarre, square; or, perhaps, immediately from the Italian quadrato, little square.

Quarry, in Agriculture, the common name of an opening, pit, drift, or shaft, which is dug into the earth or ground, and from which are to be raised ores of various kinds, different sorts of flones, flates, and other materials of similar natures. It is remarked by the writer of the work on "Landed Property," that the more useful and advantageous materials and substanccs that have at different times been dug and raised out of quarries in this country, are chiefly those of the iron ore kind, lime-flone, and other calcareous matters, materials for building, such as flates, flags, flones, and substanccs of other sorts, matters for the con structing and repairing of roads, as sand, gravel, and others of the same nature, earthy substanccs for the purposes of different manufactures, such as clays, &c. moulds and vegetable earthy matters, and coals, with other articles for use as fuel. There are, however, occasionally raised from openings of this nature, a few other kinds of substanccs, such as will be noticed below.

It has been farther supposcd by the above writer, that the substanccs which he has here mentioned, may with truth be said to be of more real use and value to mankind than all the mines of precious metals in the world; and that the eyes of the managers of landed estates shouid constantly be turned towards and fixed upon the discovery of the hidden valuable treasures and productions of this nature, wherever there is a probability or likelihood of their being to be met with. It is also suggested, that it would be highly beneficent and advantageous if mineralogists, and those who are acquainted with such substanccs, were to turn their attention towards the appearances or accompaniments which point out such useful concealed matters; as it might greatly facilitate the search for them, and frequently lead fortuitously to their discovery. The methods which are practised in searching for and ascertaining the presence of different sorts of materials...
The common methods of working and managing different forts of quarries, are in general, in most places, tolerably well understood and regulated, by such quarrymen as are constantly employed in the business; but a circumstance which they commonly neglect very much, or are in a great degree inattentive to, in many cases, is that of making good the ground below, by means of the turf or soil which is cast off from the top, or upper parts; and that of keeping the mouths of the openings sufficiently clear and free. Another common difficulty incident to them, is that of draining, and cleaning their bottom parts from injurious water. This may be effectet in various ways, as by the use of different forts of machinery worked by wind, water, and steam, and by some other means. See Quarrles, Pits, &c. Draining of.

In many of the more southern districts of the kingdom, and still more in those towards the north, and in Wales, there are quarries, from which substances of some of the following kinds are raised and used in their neighbourhoods, or sent away to a distance, in a very extensive manner; such, for instance, as those of the flinty kind, as iron-flone or ore, lime-flone, marble, chalk, granite, free-flone, grit-flone, flag-flone, white, grey, purple, and blue flate-flone, sand-flone, sand, gravel, clay-flone, sflythe-flones, tile-flones, &c.; different ooches, plumbago or black lead, calamine, gypsum, marle, pipe-clay, alum-earth, fuller’s-earth, peat-earth, culm, coal, cannel, salt-rock, &c. These flones and pits are wrought, and the materials got up from them, in several different ways, according to circumstances and convenience, as well as the particular nature, kinds, qualities, &c. of the different articles themselves; all of which are mostly well known, and capable of being performed by the workmen of their respective neighbourhoods, who are commonly employed in them, and very expert in their management.

Stony substances which bear a great variety of different names, and which possess equal variety in their qualities and useful properties, are met with, and dug up from quarries and pits, in many different districts and situations, in almost all parts of this island, in order to be converted to purposes of improvement and utility in a variety of different ways and intentions. Iron-flones and ores abound more in the northern parts, though they are occasionally found in some of the southern ones. A considerable quantity of highly rich iron-flone is got up and sent annually from the vicinity of Combemartin in Devonshire, to the iron-works of Mr. Raby at Llennyrth in South Wales. A large portion of it is also found on the borders of the Orkney river, and dispersed throughout the whole district, as well as in other parts of the same county.

Iron-flone is likewise met with in Suffolk in large quantities, imbedded with lime-flone and sand-flone, which rises near to the surface being the bile, the other having a coarser and more dull appearance, working heavier in the furnace. The very belt is frequently interferred with thin strips of soft marly matter. Iron-flone, to a great extent, exits on the cliffs of lord Dudley, and many others in Staffordshire, and contributes much to the employment and prosperity of the inhabitants. But, in the northern part of Lancashire, in the district of Low Furnes, flone and ore of this fort are perhaps found in the largest quantity, of the belt kind, and in the most general manner, of any where in the kingdom. There are numbers of shafts, quarries, and pits for working them, from, on Lindal Moor, Whittrig Moor, and Crofs Gate, in the vicinity of Dalton, as well as in some other places. In the former, the working is usually effected at the depth of from twenty to forty-five feet, but it has been done at leas as well as greater depths. The whole of their cavities are chambered with wood, and cell from a guinea to twenty-five shillings in sinking each fathom, without the wood. The ore runs in veins or seams between the rocks on the north and south part of the quarry, and it constantly dips towards the south-east at the rate of about a foot in five or six. The belt ore is that which has the most greasy appearance, and it is raised with less difficulty, working less hard, requiring less flux, and forming a more soft iron. It is raised from the shafts or pits by machinery of the gin or windlass kind, the men employing picks, picks, and hammers in digging it up. It was formerly got, in some places, by driving levels into the sides of the hills, and conveying it out on railways, in small wagons; but now the other way is mostly employed. Four men get about fourteen tons in the day, in some situations; but in others, double the number are required for getting the same quantity. It is wheeled to distant heaps, from which much of it is sent in small carts to the port of Old Barrow, from whence it is shipped to different parts of England, Wales, and Scotland, at the expense of from fourteen to thirty shillings in freight; and the rest converted into pig-iron by the furnaces in the neighbourhood. Iron-flones and ores are also met with in some other counties, and more to the north of the kingdom, where there are pits and quarries for raising them from.

Lime-flone is a very general sort of flone raised from quarries and pits in many different parts of this country, as in Devonshire, Suffolk, Kent, &c. towards the south, where it lies in vast beds, from which it is dug for use; in the more midland counties, as in Gloucestershire, Shropshire, Derbyshire, Staffordshire, and others, where it exits and is employed in a still greater extent; but by far the most extensively in those farther to the north, as Lancashire, Westmoreland, Yorkshire, Cumberland, and some districts of Scotland. In many parts of the county of Lancaster it is dug and raised from quarries, where it lies in a stratified manner at no great depth from the surface, being got up without much difficulty or trouble; while in other places it is forced from the solid rock, with great labour and expense. This is likewise the case in many other districts. Wherever it is met with, it is almost constantly a quarry material of great value, and which affords much employment to labourers.

In the county of Kent, the banks of some of the large rivers are scooped out into flone quarries in a remarkable manner, some of them worn out and diffused, others in the flate of being wrought. It has been observed, that this is the nearest flone country into which water-carriage can penetrate from the metropolis; and that the original London...
QUARRY.

was built, as well as the modern one chiefly paved, by materials from this district, such as the rag-flone, and the large pebbles gathered on the sea-shores, before the Scotch granite came into use. In the neighbourhood of Maidstone there are the appearances of many abandoned and neglected quarries of this nature; but the most considerable ones, which were lately wrought in that vicinity, are those of Farleigh and Pant. In each of these, blocks of flones, of different kinds, and of every form and size, are met with, being separated by seams, and large irregular masses of earth of various qualities; among the rest, brick-earth of the bell quality. In some places, the flones are buried several feet under these earthy materials; in others, the rock rises to the surface. After this, the quarrymen worm their way; following it, with irregular windings, leaving behind them refuse in greater quantity than the useful materials which they raise.

The flony subllances which are principally met with in them, are of two very different kinds: the one hard, and of a strong contexture, provincially denominated rag, or Kentish rag; the other of a soft crumbly nature, provincially termed baffle. The quarrymen are in the practice of dividing the first into two kinds; what they call the common rag, and the cork-flone, the latter being their principal object in these immense works. It has in its general appearance much resemblance to the strong grey lime-flones which are found in different parts of this country; but when minutely examined by means of a glafs, its fracture and contexture have the characters of the Devonshire marbles; except that the grain of this first of flones is somewhat coarser. In colour, too, it differs from these marbles, having a greater resemblance to the Yorkshire lime-flones. It is used for different purposes; much of it is sent to the neighbourhood of London, where it is burnt into lime, for the use of the sugar-bakers; who, for some reason or other, chiefly employ lime, burnt from this material, or flone, instead of that of chalk. It is likewise made use of as a building material; and, particularly in pedellars, for the posts of cattle-rids and other farm-offices. It is hewn with flone-mason's axes, working with tolerable freedom.

It is very durable, as some part of the basement of Wealdminister Abbey appears to have been built with the flone from these quarries. In this case, it seems to have been dressed smooth; and the surface still remains with little alteration; having withstand the attacks of time with great firmness; it being even now difficult to detect a loosened splinter in the work.

The common rag-flone comprehends all the different kinds which are met with in these quarries, except that of the above, and that which is of the haflocky nature; though the true unmixed rag is a different sort, having characters different from any of the others. In the colour, it inclines more to the red or liver colour, than that of the cork-flone, but otherwise resembles it considerably. Viewed with a glafs, its grain is finer, and the fracture flint-like.

Its uses are, however, but few. Some of the bell and most regularly-faced flones are sometimes laid aside for paving materials; but the large pieces are mostly reserved, in order to be sent by water to the district of Romney Marsh, for the purpose of forming the hard materials of the embankments and jetties, which are there made against the sea. The smaller sorts are, in general, converted to use as a road material.

The haflocky flone appears to the naked eye to be of a soft, white, sandy quality; and its fracture is the same but under the glafs, its grain is fine, its contexture uniform, and so thickly intertrefied with small feed-like granules, of a dark or black colour, as to give it a grey appearance. Sometimes bearing evident impressions of shells. Its text-

ure is loose and brittle; crumbling easily between the fingers into a coarse sand-like powder. It will not burn into good lime, although it is almost wholly calcareous.

Its principal use is that of forming a loose friable sort of roughly sub-foil, in some places, which is admirably suited to the growth of sainfoin, and some other crops of the plant as well as the fruit-tree kinds.

The quarries in several other counties contain flony materials of these different kinds, which are wrought and applied to a variety of different uses in these and other ways.

Quarries of marble are wrought in several districts in different parts of the country, and afford great advantages in various ways. In Suffex they have a marble, which, when cut into slabs, is used for ornamenting chimney-pieces, and many other purposes. It is equal in quality and beauty to most sorts when highly polished. For square building and paving it is also a material scarcely to be exceeded. By burning, it likewise affords a very valuable manure, equal, and by some thought superior, to chalk, being cheaper to those who are near the places from which it is dug. It is found the most perfect about Kirtford, at the depth of from ten to twenty feet underground, in flakes nine or ten inches in thicknes, and called the Petworth marble. It was much employed in building the cathedral at Canterbury, the pillars, monuments, vaults, pavement, &c. being formed of it. And the archbishop's chair is one entire piece of it. Marble is gotten in some of the counties in the middle of the island, as Derbyshire, Nottinghamshire, &c. At Beacon-hill, near Newark, a blue flone for hearths is got, which approaches to marble, and is capable of burning into lime. And in the county of Derby much good marble is raised in different places. In Lancashire there are quarries of fine black marble, and of flones, which approach to, and take on the polish of marbles. In many of the western and northern parts of Yorkshire, marble of various kinds is found, some much resemblimg, and others superior, in close-

ness of texture and dilithenches of colours, to the which it is wrought in Derbyshire. Also a flone, which greatly re-

sembles the marble of that county, and which is capable of receiving much such a polisb, and is nearly of the same colour, mixture, and appearance. On the side of the river Kent, near Kendall, a vein of beautiful marble has been lately disovered in the property of D. Wilfon, esq. of Dallam-Tower; and a main quarry opened upon it. Marble has also been met with on the oppostie bank.

In the county of Inverness, likewise, marble of the greatest variety of colours, and of the most beautiful kinds, has been met with in Benevis, on the property of Mr. Camerton; and inexhaustible quarries of it he untouched in the islands which belong to it.

Besides, this sort of material exisits in immense quantities, in quarries, in many other parts of the kingdom.

Chalk is a material which is raised from quarries and pits, mostly in the southern parts of the country, as in Suffex, Surrey, Kent, Effe, Berkshire, Hertfordshire, &c. It exisits in vast ranges and tracts in most of these districts, whence it is dug up from quarries, at different depths, ac-

cording to circumstances, exposed in shelves to dry, when wet, and then converted into lime for various uses, by means of fire, or employed in its broken and powdery state, with-

out undergoing the above processes, by merely digging it out of such places. In some parts, as in Kent, and the neighouring districts, it is often dug and raised from consider-

able depths, from beds of very great thicknes. And near Reading, in Berkshire, there is a stratum of this sub-

flance,
QUARRY.

flance, which is thirty feet in thickness. It is there used and dug out for manure, and occasionally as a building material, for the latter of which purposes it is very durable. The remains of the abbey of Hurley, and of the ancient chapel, now the parish church, built wholly of chalk, in the reign of William the Conqueror, are, it is remarked by the writer of the corrected Agricultural Survey of the district, still as fresh and found as if they had been the works of the last century. Chalk, when once indurated by the air, has a remarkable property in retarding the action of the weather.

Granite is a flony substance, which is found to exist in some of the southern parts of the country, as well as in the north, but it abounds more in the latter. In the western parts of Cornwall it is in great plenty in the districts of Penwith and Kirrier, presenting itself in large slabs on all the rocky hills or tors, as well as in the walled moors and valleys; and appearing in detached spots, even in the shelly flat tracts. It is of different colours and textures, being adapted to a great variety of uses and purposes, as those of building, and being wrought into columnar masses, eight or ten feet in length, for supporters to sheds, out-houses, &c.; and as gate-polls, and bridges over brooks, rivulets, &c.; as well as in the forming of rollers, rolling, fauting, and pig troughs. It is also an article of commerce to different parts. It is supposed to be exactly of the same nature with the original granite; and there are five sorts of it, which are distinguished by their colours, the white, the daly, or dove-coloured, the yellow, the red, and the black, most of which are charged with a brown and bright silver matter.

The county of Inverness has a great deal of this sort of stone, and there are numerous quarries in it for raising and working of it. The common granite abounds in all the different districts of it. In many places the whole rocks are composed of this kind, which is uncommonly useful for all ordinary purposes. By natural fissures, which run in straight lines, and generally at right angles, it is formed into all sized portions and shapes, having uniformly a plain surface.

And, by means of cutters or transverse lines, these stones are easily quarried, and found in the greatest plenty every where. They are remarkably beautiful, being almost as smooth and regular as hewn stone, and of course well suited for various sorts of building work. The bell buildings of the county-town are of a dark kind of granite, which is very hard and durable, but which has few or no fissures. It is generally found in large blocks, and in many of these parts, there is no other material for building or adding ornament with. The manner of giving it the polish it admits of at the quarries, is by means of small picks, or pick-axes, which are, in fact, hammers with sharp points at each end, in the manner of those employed by millers in preparing their grinding stones. It is a very heavy, compact stone. There is a mixed sort, denominated peasy granite, which consists of white, black, and grey spots, that sparkle beautifully in the sun, and is very ornamental, as well as much used for different purposes, as stairs, doors, and windows. Though this is very solid, and almost without natural fissures, it splits very straight, by means of iron wedges, let in a line, and struck alternately, with a hammer of great power.

A great deal of this kind of stone is imported into the metropolis and other large towns, for paving the streets, &c. It is on the whole a very advantageous sort of quarry material in various parts of the kingdom.

Quarries of free-stone are wrought in a great number of different places. In the more southern parts is found the Portland stone, which is so famous and useful in building. A fort of this kind of stone, which much approaches to it in quality, is also met with in Cornwall. Some like wise exits in Devonshire and Gloucestershire. The Cotswold quarries in the latter, afford free-stone of an excellent quality, particularly those at Painwick, Lodborough, Lockhampton-Hill, &c. It abounds more, however, in Cheam, Lancashire, Westmoreland, Cumberland, and some of the still more norther districts. Several excellent quarries of free-stone are carried on in the sir of these, as those at Runcorn, Manley, &c. where much valuable stone of this nature is raised. The second county also affords equally valuable quarries in many different places, from which vast quantities of the stone are raised, and employed, or sent away to a distance. Those about Ormskirk, Up-Holland, and Wigton, as well as those on all the eastern side, are in general of a very good quality. And in the vicinity of Lancaster there are some excellent ones; that on the moor or common, close to the town, is very extensive, and affords a free-stone that admits of a fine polish. In this district, this sort of stone is met with of a whitish-brown, yellowish, and reddish cast, but the finest is by much the most esteemed. In the eastern parts of Hereford and Shropshire, as at Shropshire, &c., which is raised from quarries, and used as a building material. And a fine-stone exits to considerable extent in others, as in Suffield, &c. that is sometimes dug up, and made use of for common buildings, &c. In Cheshire, on the hills near Macclesfield, about Knutsford, a sort of sandstone is met with, which is particularly well suited to the making of flags, and whetting tools, as well as sometimes to the forming of flates, for which it was formerly much employed. Near Pott-Shrigley, also, a fine sand-stone is found, that admits of a good polish. The quarry has not, however, been wrought for some late years, as from the extreme hardness of the stone, the expense of getting it is very considerable. There are several other quarries of excellent free-stone wrought in the same neighbourhood.

There has been great abundance of free-stone wrought, time immemorial, in the low parts of the county of Perth, and quarries of a greater or smaller sized stone of this sort appear almost in every place, with the exception of the caries. In the lowlands, and near to the eastern sea, the pores and grain of it are greater; but as the mountains are approached, the pores are less, and the grain finer, by which these stones admit a smoother polish. The quarry of Tulloch or parish, called Long-annat, affords a stone of a very excellent quality. It has a white colour, admits of a smooth polish, and refits the influence of the weather. Some of the principal houses in that part of the country, as well as some of the most magnificent public buildings in the capital of Edinburgh, as those of the Exchange, the Infirmary, and the Register-office, are of this stone, and those found at hand. And farther, in some instances it has been carried to the continent. But the quarry of Kingoodie, in the carie of Gowrie, belonging to Mr. Mylne, of Mylnfield, is unquestionably the finest of this kind of any in the county. Altonfiing blocks in great number are raised there, fifty feet in length, sixteen feet in breadth, and three feet in thickness. Such is the demand for this stone, both at home and abroad, that four vessels are employed in exporting it from this quarry. The work is, however, on the declive,
by blasting the flate-flone, and collecting and carrying it out of them on flating roads, in small carts or trucks constructed for the purpose, the levels being below the hills, but not nearly so low as the bottoms of the quarries. Others are wrought by draught roads from the bottoms of them. One man will raise eighteen or twenty hundred weight of flate in one day, where the metal rides well, but lefs in other cases. In some it is dug out by one set of men, split by another, and formed into flates by a third, for which purposes, flat crow-bars, flate-knives, and axes are employed. The flate is divided and distinguished into three sorts, as flirts, second, or third, or London, country, and towns. In the first, or Gofthwaite quarries, the flate has a darkith purple, or black caf, and is worth from forty to forty-four flillings the ton. In the Comilflone quarries it has a fine blue and green appearance, and is much thinner and lighter than the other fort. The Tilberthwaite flate, in fome inffances, splits very fine, thin, and light, but does not cover fo far as oflone of the Gofthwaite and Kirby quarries. This fort is worth from forty-eight to fifty flillings the ton. In fome quarries a fort of rent is paid per ton, on the flate which is raised, as ten flillings for the fift, eight flillings for the seconds, and fixpence for the thirds. In others a certain rent only is paid for the liberty of the royalty, and not a tonnage duty. These rents or duties on the workers of thefe quarries, are probably higher than they will bear, and have enabled the Welsh flate-dealers to underfell oflone of this county.

Weltmoreland and Cumberland, in fome inffances, afford good blue and green flates. In the latter, fome of an excellent quality are gotten in the quarries of Borrowdale, and inferior forts in fome of the neighbouring mountains.

The county of Argyle, in Scotland, in fome parts abounds with flate-quarries, as the tracts about Efdale, from which five millions of flates have for some time been annually collected at the rate of twenty-five flillings the thousand. Quarries of the fame kind are also wrought in many other parts, with great benefit to the inhabitants.

Slate-quarries are formed in many parts of the highlands of the county of Perth, but none in the low. The flates in fome are of a purple colour, in others of an azure blue, and in a few of a muddy, sandy, brown complexion along the cutters. It is well known where the different forts are quarried. The veins of flate-rock seem to run from Drumlanrig in the parish of Auchall, in a north-east direction to Dunkeld; and may be traced beyond the limits of the county both ways. The azure coloured are the bed metal, and rife of a greater size than any of the other kinds. Many of the buildings in different places are flated with this beautiful covering. Into the lower districts of the county, flates are imported from Efdale, and the other quarries on the west coast of the county of Argyle.

Quarries of grey flate exist in many different parts of the county of Inverness, in which the quality is very good, and well suited to the climate. In some places these flates are much preferred to blue ones, as the latter are more expensive in procuring, and though nailed on the roofs of buildings, are apt to be loosened by high winds, unless bedded in lime, which circumstance renders repairs difficult.

There are numerous quarries of sand and gravel to be met with in about every district of the kingdom, which are wrought either for the purpose of supplying domestic uses, or thole of repairing roads, &c. Those of the former fort, which contain the fine white, red, and yellow sands, are by far the most valuable, and wrought to the greatest extent, the materials being mostly dug out from the sides of banks and other places, and but rarely got by sinking the
Quarry.

The quarries into the more level parts of the ground, though this method is sometimes practised. The matters are commonly raised simply by digging and spades; and thrown into the carts, in many cases, from the quarries and pits themselves. Numerous quarries and pits of this nature exist and are wrought to a very great extent in the neighbourhoods of the metropolis, and with other large towns, all over the kingdom, for the purpose of sale for various domestic uses.

In the gravelly kind, those quarries which abound with the sharp, coarse, flinty, and pebbly kinds, are the most proper and beneficial for the making and repairing of all sorts of roads and carriage-ways. They are occasionally formed by working into banks and steep places, but more frequently by openings in the plain surface. Their depth is sometimes considerable, the materials being raised after being screened, the work, of course, very laborious and troublesome. In other cases, the carts are filled from the quarries or pits without much difficulty or trouble.

Quarries of clay-flint, flint-tiles, eyethe-flintes, and some other plasters, are found of good qualities in different districts. In Gloucestershire they have quarries of blue clay-flint at different depths, lying in beds of the same coloured clay, disposed in layers of from four to ten inches in thickness. The flint in new quarries is estimated by the effects which the atmosphere has upon it from some exposure. The best sort is a very useful material for several purposes. Quarries of flint-tiles principally exist, and those articles are raised from them, in different part of the Cotswolds. The best are prepared about Miserden, Beverstone, Charlton, and Hampton-field, the colour of which is yellow or grey; but another sort, which is red grit, is dug up about Iron Acton, and some other places, but which is less valuable.

There are quarries of eyethe-flintes in many parts of Lancashire, but the best are obtained from thence about Rainford, where they are well wrought and prepared for use. In several other districts, quarries of different kinds of whetting-flintes likewise exist, and are wrought to advantage.

Ochres of different kinds are met with in different places in quarries formed for the purpose of raising them. In the county of Devon, formerly large quantities of various shades between red and yellow, were raised and manufactured in thence about East-roll. Umber, in the parish of Combemartin, exists in a pretty large body. The working and preparation of these are, however, now much less attended to than heretofore.

In Suffolk there are quarries of red ochre about Graffham, and in various places contiguous to the sea, as near Childham, &c. where much is raised, prepared, and sent to London. Ochre quarries also exist in many counties more to the middle and north of the kingdom, from which great quantities of this substance are procured and prepared for sale in different parts from arts and manufactures.

Quarries of plumbago, or black lead, are likewise occasionally found and wrought, in different situations, in different districts of the country. This substance has been met with and raised near the borders of the Bovey river, in Devonshire, in some quantity, and prepared to be sent to Exeter for sale. Quarries of black lead are also found and wrought in Borrowdale, in Cumberland, near to the town of Keswick, to some advantage. And they exist in some of the middle tracts of the island, favouring great benefit to the proprietors of them. In the county of Inverness, there are some appearances of black or pencil lead about Glengary, but they have not yet been turned to any useful account.

In some districts, in the middle parts of the country, quarries of calamine, or lapis calaminaris, are met with, and much of this substance raised from them to great profit. It abounds in the Mendip-hills, in Somersetshire, about Rowbarow, Shipham, Winchcomb, and on Broadfield-down, &c. It is sometimes found within a yard of the surface, and seldom wrought deeper than thirty fathoms. In some places its quality is excellent. It is present in other neighbouring mountainous tracts, and raised with equal advantage.

Quarries of gypsum present themselves in many different parts, and are wrought in some with considerable benefit. In the county of Devon, it lies between the frata of red-flint, marle, and chalk rubbish, about Salcombe, Branscombe, and Beer, being useful for various purposes. Gloucestershire and Derbyshire have quarries of this nature, where there are fine beds of it. Tho' of Ault Cliff in the former, have it not so good, however, as that which is met with in the latter county. In Nottinghamshire it is of an excellent quality, especially that got near Newark and at Redhill. Cheshire has some, but not turned to much account. Westmoreland and Cumberland have good quarries of it, in some places, where a great deal is gotten up, and made use of. And it abounds in different parts of the county of York, where it is raised to advantage.

Marle is an article that is met with in pits and quarries in a variety of different situations, and of several different kinds and qualities. It is found and dug up for use in many places in Suffolk, and the counties more to the centre of the country; but it prevails in the greatest plenty in the county of Lancashire and some others, in which it is raised or worked out from large openings on the sides of hills, high banks, or in the plain surface, and set thickly upon the land. The getting or digging of the material out of such places, is usually performed by means of long iron mattocks, crows, spades, and wooden spiles; large pieces being in some cases forced down, not without danger to the workmen, by driving in the spiles or piles from above. This method is called falling. The work is extremely severe, and commonly done by the rod. The large cloths thus forced down, break into small pieces, and are then filled into carts for the purpose.

Shell-marle, though it is not much attended to in any part of England, is frequently met with and dug up from various parts of Scotland, and employed on the land in great quantities, with much success. The pits and quarries of this kind are commonly wrought with much more facility than those of the others.

Pipe, and other kinds of fine clays, are dug and raised from a fort of pits or quarries, in large quantities, in many different counties. Near Wear Giffard, in Devonshire, much of the first sort is dug and sent coastways, though not in such quantities as formerly. Brown potter's-clay is also raised and sent away in great abundance from the neighbourhood of Fremington. These sorts of clays are likewise found in much abundance in Berks, and still more fully in some of the midland districts, where the pits of them are wrought to a vast extent. They are articles of great importance and utility in several forts of manufactures, and for which there is great demand in many instances.

Alum earth is a kind of stratified matter, which is met with and raised from pits and quarries in a number of different situations, and various parts of the kingdom. In some they are wrought to very considerable extents and advantages, but in others in far less degrees, and with much less success.

The frata of this earth are dug and got up in different manners.
manner under different circumstances, but mostly by means of strong crowns, picks, and other tools of a similar kind, being wrought in somewhat the same method as in the cafes of marl. The buffmel is usually executed by common labourers.

Fuller's-earth is another material of this nature, which is dug out of the ground from pits and quarries at different depths in several parts of the country. In some it is very abundant, and of a rich good quality, as in those of the middle and more northern parts of the island, forming an article of great use and demand in several branches of buffmel. In others it is of a much less valuable nature, being far less in request. That which is found about Til-lington, in Sussex, is consumed in the neighbouring fulling mills. The mills of this fort in Yorkshire, and other parts also, consume immense quantities. The material is raised from the places in which it is found in much the same way as many other earthy substances, but it seldom requires so much digging, as it is a far less hard matter.

Fuller's-earth was formerly got up from pits and quarries in the neighbourhood of Maidstone, in Kent, and much ground wrought over; but the beds of sand by which it is covered are of such depths, as to render the works of little value or importance.

Quarries and pits of mineral peat-earth are found in some districts, and much of the material dug up from them, and made use of when prepared upon land. The vale of Kenten, in Berkshire, contains vast quantities of it, as well as some other parts. It is a stratified substance which is dug up from the surface at the depth of from one to six feet, lying below strata of small stones and calcareous matter. In raising it, a peculiar kind of spade is made use of, which cuts it in long rows, something like soap, which, when dry, are burnt into ashes and laid on the land. This substance is found to contain the oxys of iron, gypsum, and the muriates of sulphur and potash, in the proportions of forty-eight, thirty-two, and twenty parts to that of one hundred.

It is suggested by the writer of the work on "Landed Property," that in most mountainous districts, and many low Tenny counties, immense collections of vegetable mould or peat-earth lie in a state of neglect; even in places where they might be converted to valuable purposes; not only as sources of fuel merely, but as manure, either using the vegetable matter in its raw state, or after being reduced to ashes. In all these situations it might be readily dug up from different places, and applied to different uses in each of these ways, the pits or other spots containing it working in a very easy manner. The ashes of it are only employed on any large scale in the above county.

Culm, coal, and cannel, are articles of the fuel kind, which are found in a vast number of places, all over the kingdom in pits, mines, or quarries, and which are of the greatest importance in many of them. Speaking of coals, the author of the work on "Landed Property," considers them as rising in the minds of most men, far superior to most other productions and subterraneous matters, whether they are held in the light of agriculture, manufactures, or national defence. It is asked, if it were not for the colliers of this country, how many hundred thousand acres of its land, which are now appropriated to cultivation, would be required for the production of fuel? How many manufacturies, especially those of iron, which are so very valuable to civilized society, would be cramped, retarded, and stopped, in their progress and operations? And how many hardy seamen would be wanting to its navy? Surely, in his opinion, an indigenous production and material, on which the prosperity of the country so greatly depends, is entitled to the guardian care of its government; to ascertain the present expenditure, and the probable stock which is remaining. Let us not, it is remarked, play the spendthrift, and, by the follies of a day, entail centuries of want on generations to come, and the curses of millions on the memory of the present times.

In endeavouring to find these sorts of substances in parts where pits of them have not yet been wrought, the searching, it is supposed by the same writer, should, in general, be done by the land proprieters of the particular places, in a conjoint manner. There are, however, certain instances, in which individuals may prosecute the search with propriety, and in the most beneficial manner. In doing which, the principal things to be guarded against are those of misjudgment and imposition. Hence the necessary prudence of endeavouring to procure persons of skill and integrity for making such searches; which, are, in the first place, to be attempted by a close investigation of superficial appearances, and then where those are favourable in their nature, by the use of the boring rod or tool. It is supphsed that, at present, there are none who are equal to such undertakings, except those who have long conversant with the buffmels of coal works; men who have an interest in the existing colliers or works of that kind. On this account it is thought to become a matter of common prudence, in a given situation, to endeavour to procure an undertaker or overseer from a distant work; or such a one as can have no counter-interest to that of his employer; and then, closely to connect and bind them in one common interest. After having had different occasions for considering the subject, and for bellowing no small thought upon it, the writer is of opinion that the most eligible plan of proceeding, in such cases, is that of agreeing with an overseer, or undertaker, to pay him reasonably, but not extravagantly, for his time, and for his actual expenses in prosecuting the necessary searches; and, further, to agree to give him, in the event of success, a reward sufficient to call forth his best exertions; such reward to be payable, not on finding coal, but whenever the work, to be established in consequence of the discovery, shall have cleared the amount. In this way the proprietor will feel himself secure, while the person employed has the most powerful stimulus to industry, attention, and the accomplishment of the object of the undertaking.

Culm and coal have been met with and wrought in some degree, in Devonshire, Suffolk, and some other of the southern parts of the island; but they exist much more plentifully in the midland and more northern districts, as well as in some places in Wales and Scotland. In Gloucestershire, coal abounds in most parts of the forest of Dean, and its vicinities, and probably to within a small distance of the county-town, as at Newent and Painsley, where pits are established. Those of the forest tracts are very numerous, but not fully wrought for want of sufficient draining. Pits of this kind also exist in many places, in the lower vale part of the county. In this district, however, the coals are no where of the best quality.

In the counties of Salop and Somerset, coals also prevail very much, various pits of them in both, being wrought to considerable extent. Those in the northern part of the latter district, have strata of them which form an inclination of the plane of about nine inches in the yard; and are nineteen in number. They are seldom wrought where less than fifteen inches in thickness, but they vary from ten inches to upwards of three feet. The working is performed at considerable depths, especially since the establishment of improved machinery, and other means for raising them. The coal
coals is of the first quality, being pure and durable in burning, and from its firmness, largeness, and strength of grain, capable of being conveyed to any distance without injury. At present the quantity raised in these pits, is from fifteen hundred to two thousand tons weekly, but much greater supplies could be afforded, if they were wanted. The works are twenty-five in number, some of which afford a good profit.

The pits in the southern part are upon a more limited scale of work. In them the strata of coal form an inclination of the plane of from eighteen to thirty inches in the yard; but in some it is destroyed, and they descend in a perpendicular manner. There are, in number, twenty-five, which are in thickness from six inches to seven feet, being rarely worked under eighteen inches. The depth of working is middling, but will be increased. The quality of the coal is not the best, but tolerably good. The quantity now raised from these pits is from eight hundred to a thousand tons in the week, which might be easily extended. The working profits are by no means great. There are pits in other parts, but they are not many, or much worked.

Against the apprehension of pits of this nature being exhausted or worn out in these places, it is contended that more than treble the present quantity is capable of being raised from the works already carried on, and that this increased quantity might be supplied for several hundred years to come.

The works and quantities of coals contained in the counties of Stafford, Derby, and Nottingham, are likewise very great, and mostly of good kinds; pits of them being carried on in many places to vast extent.

Cheshire, too, is a coal district, in which a great variety of works for raising it are established in different parts, and much of it, which is of a very good quality, gotten up. The strata of coal here in many cases are several feet in thickness; at Wirral the seam is five or six feet thick, and the works extensive under the channel of the Dee. In some works the beds of coal lie at the depth of from seventy to one hundred yards below the surface of the ground, and are of different thicknesses to ten feet or more.

In Lancashire, coal of good sorts is most abundant. The beds of it run across the county in somewhat three different parts, as towards the south, nearly in the middle, and on the north-east part. Those in the two first are of considerable breadth and thickness in different parts, but the third is much less broad and very thin in many places. They all run, in some degree, from the north-east to the south-west, constantly keeping somewhat the same direction, though occasionally branching out in a lateral manner to some extent. The works on each of these different lines of coal strata, especially the two most towards the south, are very numerous, and, in different instants, of very considerable extent. There are some also established on the northern line, but they are of a far more limited nature. The layers or strata of the coals are of various widths, from a few yards to a very great distance, and their depths or thicknesses from a few inches to fix or seven feet. They lie at very different depths from the surface of the earth, according to circumstances and situation; on the eastern side of the county they sometimes nearly appear on the top of the ground, while, in the middle, and towards the south-west, they are often a considerable number of yards deep. All about most of the large towns in the southern parts of the district very extensive works are established, where immense quantities of coal are raised for home use, as well as being sent by canals, and, in some cases, for exportation. They are a sort of material which is of vast importance to the manufacturing state of the county, and which contributes greatly to its prosperity. The quantity is so great, when confederated as a whole, that they would seem to be almost inexhaustible.

The cannel coal, which is a sort that has some resemblance to fine black marble, is principally found and raised in the tract about Haigh, near Wigan, which is not more than a few miles square. It lies in pretty thick strata, at the depth of from five to seven or eight yards from the surface. It is of a very fine, hard, inflammable quality, being got up by sharp picks, often with considerable labour, and for which there is much demand, for domestic use, in the neighbourhood.

Coals also abound in the neighbouring counties of Cumberland and Northumberland, being found in many parts of the eastern mountains, and, with not many exceptions, all along the tract, which extends in different degrees of breadth from Sebergham to Whitley, and along the coast to Maryport, forming and comprehending a district of about one hundred square miles, in the former. And they are met with in great plenty throughout the greatest part of the latter county, particularly in the lower district of it; being of the best quality, and the most numerous, and thickest seams, in the south-east quarter; whence those vast quantities are exported which supply the great consumption of the London market, as well as the coaling and foreign trade. A trade which is the foundation of the commerce of the country, and the principal source of its wealth, as well as a never failing nursery for some of the best seamen of the British navy. The former county has likewise works which supply prodigious quantities, both for home consumption and the coalways and export trade. Cannel coal is also raised in this district in pretty large supplies in the neighbourhoods of Calbeck and Bolton.

Large portions of this article are likewise raised in the works in the county of Durham, which in some parts are carried on with much spirit and enterprise.

Coals are found, and raised in full supplies, in many places, in most of the counties of Scotland, to far as Perthshire; but they have not been met with any further towards the north in any sufficient quantities. Where they exist, to any extent, in these situations, they are generally of good kinds, and capable of being got up without any great difficulty, seldom lying at any very great depth below the surface.

It has been contended by some, that the coals in the pits and other places, in this country, are inexhaustible, while others maintain the contrary to be the case; as the matter relates to the county of Northumberland, we have the following calculations, on the authority of the writers of the Agricultural Report of that district. And they may perhaps equally apply to others. It is supposed, that towards elucidating this point, it may be of some use to estimate what number of acres are wrought yearly in the county to supply the necessary consumption. In order to accomplish this object, the thickness and number of workable seams of coal must be first ascertained; for which purpose they have been favoured with sections, exhibiting the thickness and depth of the various strata, in some of the deepest pits in the county, one of which has a depth of two hundred and seven yards, with fifteen seams of coal; the other a depth of two hundred and forty yards, with fifteen seams; consequently, if the medium be taken between the two, it will be nearly fixed yards thick of workable coal; from which may be formed, it is thought, a calculation of the quantity of coal in an acre of ground, supposing the aggregate thickness of the various seams amount to five yards.
An acre of ground contains 4840 square yards, which, multiplied by the thickness gives 29340 cubic yards in 6 yards, an acre.

From which deduct 3d for waste and the parts or pillars necessary to be left in working there remains 19360 cubic yards to be wrought.

And as three cubic yards of coal, when wrought, afford a Newcastle chaldron, therefore, 19360 = gives 6453 Newcastle chaldrons per acre, divided by 3.

The coals exported yearly from the rivers Tyne and Wear, with Hartley and Blyth, amount to about 825,000 chaldrons, which, with the home-consumption of the two counties of Northumberland and Durham, will make the quantity of coals raised yearly about 1,000,000 chaldrons.

And the chaldrons
raised yearly

1,000,000
= gives 155 acres nearly

divided by the chal-
drons per acre

6453
per year, cleared of coal 5x yards thick.

And by estimating the breadth occupied by the caking coals to be on the average eight miles broad, and twenty-five miles long in the two counties, it is found that there will be about two hundred square miles, or 128,000 acres of coal proper for exportation.

From Newcastle 510,000 chaldrons.
— Sunderland 315,000 ditto.

In all 825,000

Then the whole area 128,000 = 825 years. The time divided by the
yearly consumption

155
will be wrought out.

It is, however, suggested, that there are some reasons to suppose that a thickness of seam equal to six yards will not be obtained all over an extent of two hundred square miles, probably not more, on an average, than four yards; in which case the coal will be exhausted in five hundred and fifty years. And if the aggregate thickness of the seams to be obtained should prove only three yards, then little more than four hundred will be the term of continuance; but it is probable, it is thought, that before the half of that time be elapsed, the price to the consumer will be considerably increased from the increased expense of obtaining them, and the increased length of carriage from the pits to the rivers; this last, it is presumed, may be reduced in some situations, by adopting canals instead of waggon-ways, which, it has often been observed at, have never yet been attempted. From this investigation, it is suggested, that the apprehensions of exhaustion are not so chimerical as they have been supposed and represented to be by some persons. When, however, the vast extent of the working and unwrought tracts, in the different parts of the country, are considered, there cannot be any grounds for fear, in this respect, for a vast length of time yet to come.

Pits, some what of the quarry kind, are wrought in one district of this country, that of Cleebride, for the raising of coal, in some of which large quantities of this material are procured, from different depths, and different thicknesses of the strata of it. In the getting of it different means are employed, as those of blasting, picking with implements, for the purpose of roofing, the using of horses, and machinery wrought by steam, for forcing up the sub-

fiance, and some others. The digging, raising, and working of this article, employs a great number of labourers, and it is of much importance to the county in many points of view.

But though this sort of material is found in several different parts of the county, pits, or shafts of it, are at this time only wrought in the vicinity of the town of North-

wich. This arises from a great many different causes, but principally from that of the want of water-carriage for the conveyance of the material from them. The number of pits or shafts, which there are at this time in work, for the purpose of raising this article, are about a dozen. They are by much the most commonly made in something of the square form, being secured on the sides by means of strong timber, but they have occasionally a round form, and are walled on the sides with bricks.

The beds of this material, that are to be raised, are wrought at various depths, the deepest being in general the most pure, and they vary equally in their thicknesses and directions, as suggested above. In some cases the beds are of the greatest thickness, the more they approach the north-east, decreasing in a gradual manner, in their course to the south-west; and in some instances they incline from north-west to south-east, dipping at the rate of about three feet in twenty-seven or thirty.

The strata, which are passed through in getting at and working the rock-fall, lie in a very regular manner, and confide, in general, of a hard clayey substance and a sort of gypseous material in mixture in various ways and proportions, that of the latter kind being the most predominant as the pit or shaft approaches the rocky saline substance. In working, the clayey matter is designated by the name of metal of the several different colours belonging to that sort of substance, and the other material by that of plugger. These strata are mostly of a solid compact nature, but occasionally broken in particular places, when the metal is termed flaggy by the workmen.

In the business of working the pits, and raising the rock-fall, the rocky beds are reduced into pieces of proper sizes for the purpose, by means of blowing them with gun-powder, and those of splitting and dividing them with hammers and proper wedges for such uses; a good secure headway or roofing being constantly provided in the first place, to the opening from which the salt-rock is to be taken, which is effected by the use of small sharp picks, carrying on the work in a plain simple chambering manner.

The workings are sunk from these chambers to different depths, as the nature of the beds of rock, and the quantity of the purer kind of rock-fall, or Prussian rock, as the workmen term it, may direct; but commonly not above fifteen feet. Occasionally the roofs or headways of the pits or shafts are supported by considerable square pillars disposed in a somewhat regular manner, but in other cases they are wrought out in a sort of long openings, according as the workmen are inclined.

In getting the rock-fall, the workmen are paid by the ton at the rate usually of about twenty shillings, they finding the gunpowder and other tools.

In raising the salt from the pits or shafts, hores were formerly entirely made use of, but within these few years, recourse has been had to the improved steam-engine, as already noticed, though it is not yet generally employed at every pit. See Rock-Salt, Rock-Salt Pits, Salt, and Salt Brine Springs.

It is evident from the above account, that in whatever way they are considered, the quarries of different kinds in this country are of very material importance to its prosperity.
prosperity and convenience; contributing largely to the
carrying on of different sorts of works and improvements.
Without them much useful labour must be wholly at a stand;
a variety of necessary businesses be incapable of being car-
ried on; and the effects of it upon various arts and manufac-
tures, be much too serious to be thought upon. In
short, the numerous substanacies of different kinds, which are
taken from the bowels of the earth in this country,
constitute one great source of our national wealth and pro-
sperity.

Quarries, Pits, c. Draining of, the proper, most
convenient, and appropriate means of rendering all such forts
of works dry, free from water, and in a fit state to be
wrought with ease and advantage. In the effectual per-
formance of all kinds of undertakings of this nature, there
is occasion for the application of the same principles, which
are spoken of and explained in considering the nature of
draining land in general, and the particular manner which
is necessary to be pursued in the practice of spring drain-
ing. See Draining of Lands, and Spring-Draining.

There can be no doubt, indeed, but that the having re-
course to such principles, and the modes of practice result-
ing from them, will be equally expeditious, beneficial, and
successful, as well as in many situations of very material
importance, in the various cases of this fort, as in those which
have been mentioned; by leading to and introducing the
most ready and easy means of diminishing the quantities of
water, which are frequently met with in the course of
working them, and which not unfrequently obstruct and
hinder in a very high degree, but sometimes wholly put a
flop to the work which is carrying on in them. Such, at
least, is very often the case in quarries of the free-borne,
flint-borne, flag-borne, marle, and other kinds, as well as in
pits of the coal and other forts. The want of this fort of
knowledge, of course, is one great cause why such a number of quarries and works of that kind, in different
cases, often lie altogether, or for a great length of time, in
an unwrought state; which might otherwise be wrought to
very great advantage.

As it is now well understood, that most springs and sub-
terraneous collections of water are formed and supplied
from such grounds or lands as lie higher than that of the
places where they are found or met with, which, on ac-
count of their being of an open or porous nature, admit
that of rain and other sorts of moisture to filtrate and pass
freely through them, which hindering and deferring to very
great depths, through such open materials of the rocky,
flinty, gravelly, and other loose qualities, before it becomes
impeded and obstructed by some sort of impenetrable strata-
um or layer of an earthy or solid flinty nature, such for
instance as those of pure stiff clay or compact rock; it may
happen, that in many such cases, in sinking pits or shafts
for flint, coal, or any other kind of subterraneous material
near the bottoms of hills or high grounds, beds of quick-
sand will be met with, and dug into, which are so full of
water, that to pass through them becomes a most trouble-
some, difficult, and expensive piece of work, and some-
times impossible to be performed, but which, from knowing
that the water proceeds from the porous ground that lies
above, it may often be practicable to intercept and cut off
the greater part of the water, before it reaches such sand
beds in the quarries, pits, and shafts, by the means of
boring into and tapping the water at the tail of the banks
of this nature, provided that the ground naturally declines
lower than the place where the sand is found in the quar-
ries, pits, &c., and the whole or most of the water be
drawn off, and diverted from them at a comparatively
trifling expense to that which is employed as the common
remedy in such cases and circumstances.

In order to accomplish this intention, it will be necessary,
in afending from the quarry or pit, to carefully examine
and ascertain, if at any place higher on the declivity, any
porous stratum, bed of rock, sand, or gravel, tail out, which
may conduct and convey the water contained in it
to the sand bed, which is below in the works; and where
any such bed is found, to cut or bore into it in such a
manner as to form a drain, that is capable of carrying away
the whole or the greatest part of the water, and of
course to clear, or diminish the quantity contained in the
quarry or pit, which would otherwise have continued to
decend through such porous substrata or beds, and have
continued to fill the sands, or quarries and pits.

But although this part of the business may have been ac-
complished, and the supply of water from the higher ground
entirely cut off, a sufficient quantity to injure, hinder, and
inconvenience the working of the quarries or pits, may yet
continue to drain and ooze from the sides of the sand beds,
notwithstanding they should happen to dip towards the
lower ground, in which cases, however, that water may
readily and with great ease be commonly drawn off at some
particular point in it.

In order to effect this, and thereby remove the in-
convenience of this filtrating water, in descending from the
quarries or pits along the declivity, it should be endeavoured
to discover and ascertain, at what particular point or place
in the low ground, the sand terminates or tails out, which
is mostly best accomplished by means of proper levelling;
and if there should be there any appearance of the waters
having a natural outlet, it may, by means of making in it
a deep drain, be more readily and effectually drawn off and
removed; as springs, for the most part, naturally pass
and flow through narrow, winding, convoluted openings,
or perforations; of course, whenever the orifices or pendants
are opened, enlarged, or made lower than before, the dis-
charge of water becomes greater and more expeditious.
Where, however, there happens to be a deep imper-
vious layer or covering of clay, or other matter of a
similar nature, placed above or upon the termination or tail
of the sand, the drain need only be cut down to it or a
little way into it, as by means of boring through it, or the
remaining portion of it, a ready and easy outlet or pendant
may be given to the whole of the water, that may be con-
tained in the sand-bed or other porous stratum.

This mode of draining quarries and pits may often be of
great utility, advantage, and convenience, as it will also,
in a great degree, remove, or at any rate relieve, the
trouble and difficulty, that would afterwards have attended
the sinking the quarry, pit, or shaft; as the water thus
drawn or cut off, must of necessity diminish and reduce the
quantity, which would have been found at a greater depth,
the fame body of it probably passing downwards from one
stratum to another, as far as they continue to be porous, or
capable of admitting it. Therefore, it is of very material
importance to drain and lay dry all such ground as is situated
higher, but contiguous to quarries, pits, or other deep subter-
naneous works of the same kind, for the above stated reasons.

And it may, in general, be accomplished with but little
trouble, difficulty, or expense, by adopting the same prin-
ciples, and the same means.

But in regard to the removal of the water found and con-
tained in the bottoms of such quarries, pits, or deep works,
it must be drained off and got rid of in some different man-
ner, as the level of the ground may probably be, or decline,
nowhere lower than the mouths or openings of such quarries,

Vol. XXIX.
QUARRY.

pits, &c.; as it is solely and particularly on the supposition, and in such cafes as where the direction of the different strata and sand-beds have a dipping position with the natural inclination of the surface of the land, and not nearly horizontally, that the method of proceeding which is stated above is practicable, or capable of being employed with any fort of advantage. But should they, for instance, be in a reverse or contrary direction, there is but little possibility or chance of accomplishing the object, the removal of the water, unless by diffusing or hitting on their terminations, somewhere on the opposite sides of the hills or elevations, which in some cafes may very nearly or exactly be found out, by ascertaining the precise inclination or direction of the materials of the quarries, pits, &c. and by a careful and exact use of the level. But this will be much better comprehended, and a more clear, full, and perfect notion of its nature afforded, by the section figure in the plate on draining quarries, pits, &c. in agriculture, as given by Mr. Elkington, in his work on that subject.

This is the manner which is to be pursued in preventing the effects of water, or cutting off that which is met with in sinking the quarries, pits, shafts, or other similar works, before reaching or arriving at the stone, coal, or other fort of material that may be wanted; but that which is found in the bottoms of these different kinds of undertakings, or which proceeds from the rocks or their sides, or in other ways, in the course of working them, is commonly got quit by means of some fort of machinery, as that of the engine or other kind of pump, in order to affist in working of which, the water gained by cutting the drains already noticed may be particularly useful, especially where the usual stream for that purpose is insufficient in faving the great expense of working such machinery by the power of steam. But without the aid of a natural stream, which is capable of being converted to this purpose, it is rarely possible to find, by means of drains, or in any other way, a quantity of water sufficient to drive such weighty machinery, in a situation of proper height, to have the full and necessary command of it. However, in many cafes it may be an acquisition of great utility and value. It is explained at fig. 2, in the same plate.

In some situations, where a full and proper command of water can be had, and where the entrance to the quarry, pit, shaft, &c. is also suitable for the purpose, the use to which it may be converted and applied is still more important and advantageous, as the driving of machinery for bringing out the various kinds of materials, and at the same time working an engine-pump, in order to clear the works of the subterraneous water which flows from the cavities of the rocks, which are met with in working these forts of pits, &c.

It has been remarked in Mr. Elkington's work on drainings, in these cafes, that the duke of Buccleugh's coal-works, near Langholm, in the county of Dumfries, afford a striking example of this, as well as of the superior powers of water and machinery, when properly combined, and where a command of the water can be had, and when the latter is constructed on proper principles, and conducted with that care and ingenuity which are requisite in such difficult undertakings.

In working quarries of lime-stone, free-stone, and other forts of materials, it is not unfrequently happens, that, at a certain depth, part of the rock or other body, which contains the water, is hit upon, by which they are soon so filled with it, as completely to put a flop to the work proceeding any deeper, where the bell and often the greatest part of the stone is situated. In all such cafes, the most usual remedies have been, either the erection of a wind-mill pump, to draw out part of the water, as the whole cannot be taken away by such means, or the opening of a new quarry or pit contiguous to the other, which at the same depth mostly meets with a similar obstruction, or the bringing up of a very deep cut, often at great expense, under the level of the water, from the nearest declivity or hollow that can be met with. However, by the following method, all quarries of lime-stone, free-stone, marle, or other materials of the same nature, which are liable to such fort of obstruction, may be completed and effectively cleared of the water at but little expense; while, at the same time, the drain which is made may serve the double purpose of that, and the laying of the wet ground, caused by the spring contained in the rock, which is found contiguous to it, dry.

There commonly lies, immediately under the rock, a bed of strong, stiff, retentive clay, which absorbs all the water received and retained by that rocky stratum, and which being, at the same time, bound round on each side by a covering of the same fort of clayey material, or other stiff earthy substance, is not able to discharge itself, and of course constantly remains orstands full in the rock, so as to prevent the working or taking out the stone from the bottom.

In such cafes it is necessary, in the first place, to endeavour to find to what side the rock dips or inclines, which, in general, may easily be ascertained by the appearance of the surface, in examining the surrounding ground, and the aid of a proper level. When this has been discovered and fully ascertained, a suitable drain must be cut through the clayey covering to the rock, by which the water will be drawn off, which, for want of a proper outlet, formerly stood pent up in the hollows and cavities of the stone stratum or body. This is further and more fully explained by figs. 3 and 4, in the same plate.

But, in some cafes, this fort of evil or inconvenience may be removed and remedied in a different way. As it frequently happens that a bed or body of the same stone, which has a close, compact nature or solid, is found lying under one which has a more open porous texture, with hillocks and cranks in it, that are diffimible of water, which obstrufts and keeps up the water in the upper bed or layer, in such a manner, that not any of it can pass or filtrate through it to an inferior, or still deeper open stratum or bed; and on linking or cutting through this compact bed of stone, another layer is met with, which is of so open and porous a nature, as to admit the reception of any water from the above one, which may come upon it.

And sometimes a bed of gravel or sand is found under that of the close stone, which being still more capable of absorbing or taking up any water that may be let down to it, is far better and more properly suited for the purpose of clearing the upper bed of stone from water, than a stratum of open stone itself.

Therefore, when this is discovered and ascertained to be the case, and the water is kept up by the second bed of stone, so as to be injurious and hurtful to the working of the upper bed, and which will be equally so in working the second; the work may be greatly freed and relieved by boring through the close bed of stone, and letting down the water into the more porous one below, or into a stratum or body of dry sand or gravel, should there be such a one underneath it. But in place of boring, the sinking of small pits through the close stone is a more effectual method of letting down the water, though a much more difficult one in the execution.

The methods of digging and boring, even in the bottoms of quarries, pits, and shafts, where pumps and other machinery of the same nature are made use of, as has been noticed above, may, in some cafes, not only be practicable, but advantageous for letting down the water which they contain into an inferior open stratum.
That of boring has been practised with complete success in the case of a colliery in the county of York, which had been wrought many years, and in which the water was raised about sixty yards by a steam-engine; the proprietors of which, on boring down from the bottom of the pit next to the engine-pit, to the further depth of about ten yards, in order to ascertain the depth or thickness of a seam of coal, which was supposed to lie below those then wrought; the workmen, on taking out the boring rods, found that the water from the works, which usually ran across the bottom of this pit to the engine-pump, now ran down the holes they had made. And that the steam-engine, on being set to work, contained little or no water, it having escaped through these holes, and continued to run through the same ever afterwards, rendering the pump useless. It is remarked, that this instance of water at so great a depth from the surface, finding a passageway at a further depth of ten yards, or less, and immediately below, is extremely singular and striking in its nature. The situation was much higher than the nearest contiguous valleys, or the level of the sea. Trials of this sort can seldom be made, therefore the cases are rare, uncommon, and curious. But in extensive tracts of level land, where lakes or morasses have been formed, and which cannot be laid dry by cutting open drains, or driving levels through rocks, except at an expense for which the lands, when drained, would never compensate, the above instances warrant the trial of experiments with boring rods, which, if not attended with success, can be made at little expense.

In the county of Lancaster, as well as in some other parts, flint quarries are cleared of water exactly in the manner which has been already pointed out, but which fig. 5. in the plate will explain much better.

The success of the practice has likewise been farther shown by the late T. Ecclefeon, esq. of Scarifibrick-hall, an ingenious and extensive proprietor of land in the same neighbourhood, who remarks, that in flint quarries thereabouts, wells or pits are occasionally sunk to the open bed, which have proved serviceable. This mode was practised in a flint delf near the above town in a very beneficial manner. But in order to lay the delf more effectually dry to a greater depth, Mr. Elkington, on viewing the surrounding ground, marked out where he thought the rock terminated, or tailed out, and at the lowest level let out a drain to be cut and carried up to the rock, part of which work has been executed, and a very considerable flow of water comes from it; but on account of its great depth, sixteen feet, the whole will not be finished before he has seen the work again. The drain he has thus laid out is about ten feet lower than the bottom of the flint quarry, and when completed, will lay the head or body of flint dry lower than the present floor. All rocks, for the most part, where they terminate, are succeeded by broken loose flakes of the same nature as the rock, and they are frequently, nay almost always, succeeded by land, which, when in a thick bed, and of a running nature, such as quicksand, often cause great expense in cutting through to the tail end of any rock. This is more fully explained in speaking of the manner of draining in hilly lands, and where the soils are of a mixed nature. See Spring-Draining.

Therefore, in all such cafes as this, where there is any danger of meeting a quicksand, boring or flooding pits through the bed of close flint, is by much the most advisable, and at the same time the least expensive method that can be pursued.

The situations of marl pits are for the most part such, that they require very extensive cuts to be made through some parts of the surrounding banks or sides of them, in order to convey off the superabundant quantity of water which prevents their being dug or wrought to advantage. This business might frequently be effected in a much less troublesome and expensive manner, by the method of letting the water down by means of sinking pits or openings through the retaining and upholding stratum underneath the bed of marl, into some absorbent porous body of materials lying still deeper, which is capable of receiving it. Where the space of ground that is occupied by the marl is of considerable size, several pits will be required, in order to effectually carry off the water; and where it is necessary that they should be so deep as to be in danger of falling in, they ought to be wall ed round the sides, or filled up to near the top with loose stones, through which the water can seep and find its way. And any such holes or cuts as may be necessary for the purpose of collecting the water must be so formed and conducted as to lead into the pits. But in many cafes the water may be removed and got rid of in a still more easy manner, especially where the situation of the ground is favourable and suited to the purpose. In instances where the surrounding banks decline or fall on the opposite sides lower than the water, by cutting drainages into them, and boring with an horizontal auger into the tails of the strata containing the water, it may be drawn off and brought down to a level lower than that of the bed or body of marl. And as this water is not frequently supplied by a spring which rises in some part of the higher ground, and descends into the place where the marl is found, it will be necessary, in all such cafes, to cut off the source of it, and divert the flow of water into some other channel; as by that means the quantity of water below will be lessened, and more easily and readily carried off by the pits or drain which may have been formed.

Mines and shafts, for the purpose of raising different sorts of metals, are often much impeded, or wholly prevented from being wrought by the water which is brought into them from a distance, by various kinds of mineral strata. In many such cafes, the water flowing in this way may be intercepted, by making cuts up to the lowest banks of them, from some neighbouring water-courses, or other convenient outlet, and then boring or digging pits in the bottoms of such cuts, when the metals to such depths or levels will be rendered free from water, and capable of being wrought. This will, however, be more amply shown in considering the manner of draining, in some cafes of wetness, caused by springs arising in this way. See Spring-Draining.

In removing the water, or freeing the bottoms of quarries and pits from it, where machinery is required, the writer of the work on "Landed Property" has remarked, that in cafes where half-draws are found to be impracticable, well-draws and pumps become necessary, and are the most proper, as they may be wrought by water, where streams can be conducted to them; or by wind in high exposed situations; or in works of consequence, where fuel is moderately cheap, by small steam-engines. However, in instances where large bodies of water are required to be raised, and discharged at the height of a few feet only, marl-mills, such as are made use of in low marl-land districts, are found the readiest and most useful kind of machinery for the purpose.

In some cafes of this nature, the bottoms of quarries, pits, and mines, may be cleared from water, simply by forming openings into them from some parts of the neighbouring ground where it falls lower than the levels of them, at sufficiently short distances, without any other more expensive works being undertaken for the purpose. This should always be fully considered before any means are resorted to.
for laying them dry, as it may occasionally be the saving of much labour, trouble, and money.

Quarry, in Glazery, a pane, or piece of glass, cut in a lozenge, or diamond-form.

The word seems formed by corruption, from quadrat, (which see); unless we will suppose it to come immediately from the French quadrat.

Quarries, or quarrels of glass, are of two kinds; viz., square and long, each of which is of different sizes, expressed by the number of pieces which make a foot of glass; viz., 8ths, 10ths, 12ths, 15ths, 18ths, and 20ths; but all the sizes are cut to the same angle, the acute angle being 77° 19' in the square quarries, and 67° 22' in the long ones.

Quarry, in Falconry, is the game, or fowl, which the hawk is in pursuit of, or has killed.

Quarry, among Hunters, is sometimes used for part of the vicere of the beast taken; given by way of reward to the hounds.

Quarry-Cart, a name commonly given to that fort of cart which is principally employed in the work of quarries, and which is generally of a low, compact, strong kind, in its nature, form, and manner of construction, in order to furnish heavy weights, and receive them without difficulty, or the danger of being destroyed. Carts for this purpose should always be made of well-seasoned wood, be well put together, and have sufficient strength of timber in those parts where the main stress of the load is placed. See Cart.

Some quarry counties have well-formed carts of this nature, as many of those towards the northern boundaries of the kingdom.

Quarry-Waggon, or Truck, a small carriage of the low truck kind, which is much employed in the bourns of quarries, especially those of the slate kinds, for the purpose of holding and conveying the rough materials, which have been blown from the large mafly rocks, or separated in other ways, out of or from the quarries and pits in which they are situated and contained, to the places where they are to receive their different preparations and shapes.

It is formed and constructed on a frame somewhat similar to that of the common barrow, and mounted on two light iron wheels on the fore part, having two feet behind, projecting from the frame, bent something in the manner of the letter S, and of sufficient length to let it stand or rest in a horizontal position while it is in the act of being loaded. These feet are usually made of iron, but they may be formed of other materials. A fort of inclined plain is formed from the bottoms of the quarries or pits, up which it is forced, with great ease and facility, by the workmen, or small animals of the horse kind, after being filled with these forts of heavy materials. It is a very useful and convenient machine in this application, being met with in most of the slate quarries in the northern part of Lancashire, as well as in those of many other districts of the kingdom.

Quarrying, the business of directing and conducting the nature and management of splitting the different kinds of quarries, pits, and shafts, as well as of the different forts of work which are necessary to be undertaken, carried on, and performed, in the several different descriptions of them; such as those of separating, getting up, and preparing the various kinds of materials for use in the arts, or in other ways. It is a practice which requires considerable knowledge and experience, to be fully master of it in all its different bearings and intentions. See Quarry, and Quarrying Slates and Stones.

Almost every fort of quarrying-work requires a different kind of management, not only in the opening and working the quarries and pits in the grounds at first, but afterwards in the methods and practices of working them, and getting up the various sorts of materials from them, as well as in the modes of preparing, trimming, and arranging them, after they have been raised. They are, however, mostly well known and familiar to the quarry-men and pit-men who are usually engaged in works of the several different kinds.

Quarrying Slates and Stones, the methods of preparing and fitting them for their different uses and applications at the quarries and pits where they have been raised. The former of these articles, particularly those of the blue, green, and purple or blackish kinds, undergo several different sorts of preparation in the quarrying, according to the purposes to which they are to be afterwards applied. They are separated and divided into very thin pieces or slates, where light, neat coverings are required, or in much demand; but for more strong and heavy coverings, in exposed situations, or other places, they are split into much thicker sheets, layers, or slates, and are, of course, more clumsy in their appearance.

Each fort in the bourns of quarrying is wrought in a separate manner, and packed up by itself; the different sorts having appropriate names, as has been already seen.

The white or brown slates are never divided and prepared in fo thin a way as the other kinds, but separated into much thicker leaves or lamins, in this intention. The blue, green, and purple or darkish forts, are, for the most part, found capable of being split into very thin lamins or flockets; but those of the white, or brownish free-flone kinds, can seldom be separated or divided in any very thin manner, as the layers of the large leaves of the flones are of a much thicker nature, they consequently form heavy, strong, thick coverings, proper for buildings in exposed climates and situations, and of the more rough kinds, such as barns, flats, and other forts of out-houses.

In the different operations and proceedes of this fort of quarrying, slate knives, axes, bars, and wedges are chiefly made use of in the different intentions of splitting and cleaning the slates, they being separated into proper thicknesses by the axe, bar, and wedge, and afterwards chipped into their proper forms and shapes by the knife. All the different inequalities which may appear upon any part of them, are likewise removed by this last fort of implement.

In the quarrying of the latter sorts of materials, or of those of flones, the work is usually performed in such a manner as to suit the different uses for which they are intended. Where flags are to be formed, they are split or riven into suitable thicknesses, and squared to different sizes, so as to be adapted to different applications. These operations are executed in rather a rough way, as they are afterwards to be finished by the stone-mason. When for slabs, they have the proper breadth and depths given to them in a fort of squaring manner, being left to be completed as they may be wanted for particular uses and applications. Gate-posts, for the most part, quarried to as to have from about a foot to a foot and a half or more in the square. Trough-flones have the quarrying performed to as to be formed into various proper-sized slates or other forms, in a rough manner, being left in these slates to be afterwards hewn and hollowed out, in the intended parts, by the stone-masons.

Stones for building purposes are usually raised and quarried out roughly into something of the square shape, being left in that slate for the builders, who afterwards fit them so as to suit their own purposes and intentions.

In the quarrying of flones, the quarry-men commonly make use of large hammers, with cutting ends on one side, the other being formed in a plain manner; strong, sharp, crowbars,
bars, and broad, sharp, iron wedges; by which means these matters are, from the constant practice of the men, split and torn into such forms as are wanted with great ease and facility. See Quarried.

Quarring Tools, the different sorts of implements which are employed or made use of in the different works of this kind, as in the raising and preparing the various sorts of materials of this nature. They are principally such as those which have been noticed already, and different descriptions of picks, mattocks, and jammers, or boring implements, for the purpose of blasting the various kinds of stone, and other hard materials. These tools are individually described under their particular heads. See each of them.

Quarries, the small pieces which are broken or chipped off from the different sorts of materials which are found and wrought in quarries, while they are undergoing their different preparations for various uses. These substances, where they are of the hard kind, such as those of the blue and lime-flone, as well as some other sorts, are extremely well calculated for the purpose of forming and repairing roads, as they are nearly, if not quite, in a flate fit for immediate application in this way. Materials of these kinds ought, therefore, where they can be conveniently had, never to be neglected by those who have the care and management of roads, as they will save much expense and trouble, in a great number of instances. See Roads.

Quart, q. d. fourth, in Myths. See Quarte.
Quart is particularly used for a diminutive measure, containing one-fourth, or quarter, of some other measure; which fee.

The English quart is a fourth of a gallon, or two pints; the Roman quart, or quartarius, was the fourth part of their congnis.

The committee appointed for examining the standards of weights and measures, and ascertaining those that shall be used in this kingdom, delivered it as their opinion, in their report to the house of commons, A.D. 1814, that the gallon ought to contain 10 pounds of pure water, or 276.8 cubic inches; that the quart, or fourth part of the gallon, ought to contain 40 ounces of water, or 69.12 cubic inches; and that the pint, or half of the quart, ought to contain 20 ounces of water, or 34.56 cubic inches.

The French, from whom we borrow the word, besides their quart, or pot of two pints, have various other quarts, differing from the whole of which they are quarters; as quart de muid, and quart de bœuflet. See Muid, and Busheil.

Quart of Butter, in Rural Economy, a name given to a lump which contains the quantity of three pounds; and which is a mode of selling it that is peculiar to some districts, it being carried in this flate to the markets.

Quart de Soupir, in Fr., Myfie, is a rell equal to a semi-quarver. By a 4th part of a fourfur is meant an equivalent to a double croche, or two quavers in French; and one crotchet in English. See Time-table, and Value of Notes.

Quarte de Ton, Fr., a quarter of a tone, an interval introduced into the enharmonic genus by Arilloxenus. We have neither ear nor harmonic calculations that can furnish us with the exact interval or ratio of a quarter-tone; and when we consider what nice geometric operations are necessary to settle it on the monochord, we are very apt to suspect that this true quarter-tone never has been nor ever will be produced exactly in tune either vocally or instrumentally. Musicians, however, call the difference between A and B, a quarter-tone, an interval which, though in nature, is annihilated by temperament.

This quarter-tone is pretended to be of two kinds; the enharmonic major, in the ratio of 576 to 625, which is the complement of two minor femitones to a tone major; and the enharmonic minor, in the ratio of 125 to 128, which is the complement of the same two minor femitones to the minor tone. Rouleau.

Quaritan, in Medicine, an ague or intermittent fever, the paroxysms of which recur every third day, leaving two intervening days without fever. This is vulgarly called a third-day ague; but in medical language it is termed quartan, or fourth-day ague, because if we reckon the day on which the disease commences as one, then the second paroxysm is on the fourth day, which again becomes one in relation to the succeeding paroxysms. See Fever, Quartan, and Ague. See also Tertian.

Quartarius, a measure among the ancients, being the fourth part of a sextary, and nearly equal to a quarter of a pint of our wine-measure.

Quartaro, in Commerce, a liquid measure at Venice. The amphora, which is a wine-measure, contains 4 bigoncia; a bigoncia is 4 quartari, 16 fieche, or 256b. Pelo groffo; but a bigoncia of brandy is only 14 fieche, or 56b. Kelly's Un. Cambilt.

Quartation, in Metallurgy, is the separation of silver from gold by means of aqua fortis or nitric acid; which is an operation that has something singular in it.

If silver and gold are mixed together into a mafs, and the gold is not less than one-third part of the mafs in weight, the bell aqua fortis poured upon it is not at all capable of dissolving the silver; but if you add more silver to this mafs, by melting it again in the fire, with such a necessary addition of that metal alone as should bring the gold in the mafs to the proportion of less than one-third of the whole, and suffer it to cool, then aqua fortis poured on it will corrode the silver from it: this is also by so much the more strongly performed, as the quantity of gold is less than in the proportion of one-third of the whole mafs; but experience has taught us, that aqua fortis dissolves silver mixed with gold quickly enough when the gold confluences but one, and the silver three parts of a mixed mafs of them; and in this case, if the solution is not too impetuously performed, the gold usually remains in such a proportion, in the same figure that the whole mafs had before the separation of the silver by this method; so that, in this case, there is no reason to apprehend the gold's being torn into minute particles, and diffipated in some measure; though this can hardly be prevented when the silver exceeds the three-quarter proportion, in regard to the gold in the mafs. The artificers, therefore, always make it their study to observe very exactly this proportion of the gold being one-fourth part of the mixture; and thence it is that the operation itself has been called quartation.

In order to ascertain nearly the proportion of gold and silver in a mafs, the allayers rub this mafs upon a touchstone, so as to leave a mark upon it; and they then make marks upon the stone with some of those needles, called touch-needles, the colour of which they think comes nearest to that of the mafs; by comparing the marks of these needles with the mark of the mafs, they discover nearly the proportion of the gold and silver in the mafs. The mafs of gold and silver to be quartered ought previously to be granulated, by melting it in a crucible, and pouring it into a large vessel full of cold water, while at the same time a rapid circular motion is given to the water by quickly flirring it round with a stick or broom. The vessels generally used for this operation are called parting-glaflies. The aqua fortis must be purified for this purpose, and should be so strong as to be capable of acting sensibly on silver when cold, but not so strong as to act violently. If it be very strong, and the vessels
well cloved, a small quantity of the gold will be dissolved along with the silver, which is to be guarded against. Little heat ought to be applied at the beginning, the liquor being apt to swell and rise over the vessel; but when the acid is nearly saturated, the heat may be safely increased. When the solution ceases, which may be known by the discontinuance of the effervescence, or effusion of air-bubbles, the liquor is to be poured off. If any grains appear entire, more aqua fortis must be added, that all the silver may be dissolved. If the operation has been performed slowly, the remaining gold will have all the form of distinct masses, which are to receive solidity and colour by putting them into a taff under a muffle, and making them red-hot. If the operation has been performed hastily, the gold will have the appearance of a black mud or powder, which after five or six washings with pure water, must be melted. The silver is usually recovered by precipitating it from the aqua fortis by means of copper vessels, into which the liquor is poured, or of plates of copper, which are thrown along with the liquor into glafs vessels.

A considerable heat is required to accelerate this precipitation. Dr. Lewis observes, that when the aqua fortis has been perfectly saturated with silver, no precipitation is occasioned by plates of copper, till a drop or two of aqua fortis is added to the liquor, and then the precipitation begins, and continues as usual. The precipitated silver must be well washed in boiling water, and fused with some nitre, the use of which is to scoriify any cuprous particles which may adhere to the silver.

Here we may add, that silver and gold may be parted from one another by the vitriolic acid, as effectually, though not so commodiously, as by the nitrous. If the compound be reduced into grains or thin plates, and boiled in about twice its weight of oil of vitriol to dryness, the silver will be so far corroded, as to be eaily washed off by a little more of the acid; or if the mafs, after the corrosion, be melted in a crucible, the gold will separate and subside, the silver forming a scoria above it. Gold may be purified in the same manner from several other metallic bodies. M. Scheffer says, that this is the most direct way of separating tin from gold.

Lewis's Com. Phil. Techn. 95. 149, &c. See ALCHEMY, DEPART, and GOLD.

QUARTEAU, in Commerce, a wine measure in some parts of France: thus, at Blois, 3-74 quarteaus are equal to 100 English gallons, and each of them contains 6183 cubic inches; in Burgundy, 3-68 quarteaus are equal to 100 English gallons, and each contains 6275 cubic inches. Kelly's Un. Carn.

QUARTE, Fr., Quarta, Ital., the 4th in music, and the third consonance in point of perfection, according to the order in which concords are generated.

The 4th is a perfect concord; its ratio is 3 to 4. It is composed of three diatonic degrees, formed of four sounds; whence it has its name of fourth. Its interval is composed of two tones and a half: a tone major, a tone minor, and a major semitone.

The 4th may be altered two several ways: 1st, by diminishing its interval a semitone, and then it is called the diminished, or false 4th; 2dly, by augmenting it a semitone, and then it is called a tritonus, or superfluous 4th. (See Tritonus.) But the diminished 4th is never used in harmony, and only touched now and then in melody as an appoggiatura, or note of refinement.

The 4th in thorough-bass is accompanied by the 5, and called by some the chord of the 11th.

Another chord is called the superfluous 4th, or tritonus, by the French; which is what we call the chord of the 7, or the, in which the discord is in the base; but it is not the chord of the tritonus, unless the 4th is sharp. See CHORD, and ACCOMPANIMENT.

The succession of two perfect 4ths is allowed in composition, even in similiar manner, provided they are accompanied by the 6th; but these are passages that must not be abused, or pushed too far, as they are not authorized by the fundamental base. The Italians call a regular succession of chords of the 6th false bordons; for which see FOURTH.

QUARTEAU, in Commerce, a meausre for train-oil at Hamburgh: it contains 2 tonnes, or 64 fluggins, and is reckoned at 2 centners, or 224 lbs. net weight. Kelly.

QUARTELOIS, CARTELLOIS, or Cartelois, furtuits, or upper garments, with coats of arms quartered on them, worn by the ancient knights in their military expeditions.

QUARTER, the fourth part of a whole, or integer divided into four equal portions.

In working of fractions, the quarter is expressed by \( \frac{1}{4} \); three quarters by \( \frac{3}{4} \).

Quarter, as a Weight, is a quarter part of the quintal, or hundred-weight.

The quarter is 28 pounds avoirdupois.

Quarter is also a dry measure, containing of corn eight bushels flriked, or two sacks, being that by which corn is generally sold in the London market, and in large quantities in some districts of the country; and the quarter of coals is the fourth part of a chaldron, called a vat.

"Quartermium fraguient ex octo bifullis."

Fleta, lib. it. This seems to have signified originally the fourth part of a ton in weight, or capacity. See Weight.

Quarter, in Althenomy, the fourth part of the moon's period, or lunation, which is divided into four flages, or quarters; containing each from seven to eight days.

The first quarter is from the new moon to the quadrature; the second thence to the full moon. &c.

Quarter, in Heraldry, is sometimes used for an escutcheon, or coat of arms.

In this sense there are sixteen quarters required to prove nobility, in companies, or orders, where none but nobles are admitted.

The word quarters, required as a proof of nobility, is derived hence, that they used anciently to put the coats of arms of the father, mother, grandfather, and grandmother, on the four corners of the tomb of the deceased.

In Flanders and Germany we frequently see tombs that have eight, sixteen, and even thirty-two quarters.

Quarter is also applied to the parts or members of the first division of a coat that is quartered, or divided into four quarters. See Quartering.

The king of Great Britain, in the first quarter, bears gules three lions palleant or, &c. In the second quarter he bears azure three fleurs-de-lis, &c.

Quarter, French, is a quarter fingle, or alone; which is to poetise one-fourth part of the field.

This makes one of the honourable ordinaries of a coat. See Ordinary.

Quarter, in Lasso, Quarterium Anni, is the fourth part of a year.

Hence the days on which those quarters flatedly commence, are called quarter-days.

Quarter-days are the 25th of March, called Lady-day; the 24th of June, called Midsummer-day; the 29th of September, called Michaelmas-day; and the 25th of December, or Christmas-day. Quarter, Fr., in old counterpoint, was proceeding in diftance by a succession of 4ths; which was called, in bar-
barous Latin, *diaet [[]]aronare*; of which we have instances in the "Micrologus" of Guido.

**Quar['']t, in Navigation.** A quarter of a point, wind, or rhumb, is the fourth part of a cardinal point, wind, or rhumb; or of the distance between two cardinal points, winds, &c.

The quarter contains an arc of 11 degrees 15 minutes.

The quarter is what Wulfius, with regard to the other divisions, calls a secondary point of the second order.

**Quarters of a Ship** is that part of the ship's side which lies towards the stern; or which is comprehended between the aftmost end of the main chains and the sides of the stern, where it is terminated by the quarter-pieces. Although the lines by which the quarter and bow of a ship are determined, with respect to her length, are only imaginary, yet experience appears sufficiently to have ascertained their limits; so that if we were to divide the ship's sides into five equal portions, the names of each space would be readily enough expressed. Thus the first, from the stern, would be the quarter; the second, abaft the midships; the third, the midships; the fourth, before the midships; and the fifth, the bow. Falconer.

**Quar['']t, in the Sea Language, may be defined an** arc of the horizon, contained between the line prolonged from the ship's stern and any distant object, as land, ships, &c. Thus if the ship's keel lies on an east and west line, the stern being wellward, any distant object, perceived in the north-west or south-west, is said to be on the larboard or starboard quarter.

Quarter is also used for a canton, or division of a city; consisting of several ranges of buildings, &c., separated from some other quarter by a river, a great street, or by some other boundary.

Such are the twenty quarters of the city of Paris. Ancient Rome was divided several times, under its several augmentations, into quarters, which were called *regions*; as may be observed in the topographies of Aurelius Vitior, Onuphrius Pauvinus, Marliyan, Pyro Ligorio, Boffard, and other antiquaries.

In many cities there are commissaries of the quarter appointed to look to the policy of them. The prior of the Caporions accounts himself the chief and colonel of the fourteen regions, or quarters, of Rome. Mufcari, p. 134.

**Quarters, Franchise of.** See Franchise.

**Quarter, in War,** the place allotted to certain forces to live, lodge, and encamp upon, during a siege, or the like. See Camp.

The general's quarter, called the head-quarters of an army, is that where the general lodges and encamps in person. They used to make lines of communication, to join the several quarters together.

**Quarter at a Siege,** are the encampments on the principal passes about a place; serving to stop the avenues, and to prevent relief and convoy.

Quarter is also used for any lodging made in the field, or champaign, out of a siege. Thus they say, the general has extended his quarters a good way; the enemy coming by, made him contract his quarters.

**Quarters, Intrenched,** denote a place fortified with a ditch and parapet, to secure a body of troops.

**Quarters, Winter,** the place allotted to the troops to pass the winter season in. Wherein these differ from garrisons, see Garrison.

Winter-quarters, when cold or moist, are productive of inflammatory disorders, particularly hard coughs, with inflammations of the pleura or lungs. See Barracks.

**Quarters, Winter,** are also used for the time the troops continue in this lodging; and for the advantage the captains make of it.

In Spain they have also summer quarters.

**Quarter of Assembly,** is the place of rendezvous, where the troops are to meet and draw up, to march in a body.

**Quarters of Refreshment,** denote some well provided, fertile spots, to which troops, that have been much fatigued and harass'd, are sent to recover their strength, or health; even during the season of the campaign.

There are also quarters assigned for the bucklers, and their equipage.

**Quarter also denotes the safety and good treatment promised to persons or troops that surrender, and lay down their arms. Thus we say, the enemy begged quarter.** The phrase took its rise from an agreement anciently made between the Dutch and Spaniards, that the ransom of an officer, or soldier, should be a quarter of his pay. Hence, to beg quarter was to offer a quarter of their pay for their safety; and to refuse quarter was not to accept of that composition for their ransom.

On an enemy's submitting, and delivering up his arms, the victor cannot with justice take away his life. In a battle, quarter is to be given to those who lay down their arms; and at a siege, a garrison offering to capitulate are never to be refused their lives. If sometimes, however, in the heat of action, the soldier refuses to give quarter, it is always contrary to the inclination of the officers, who eagerly interpose for saving the lives of such enemies as have laid down their arms. Nevertheless, there is one case, in which life may be denied to an enemy who surrenders, and also capitulation refused to a place. This is when the enemy has been guilty of some enormous breach of the law of nations, and particularly if it be at the same time a violation of the laws of war. This denial of quarter is no natural consequence of the war, but the punishment of his crime; a punishment which the injured party has a right to inflict: but that the punishment may be just, it must fall on the guilty. When the war is with a savage nation, which observes no rules, and never gives quarter, it may be chastised in the persons of any that are feized or taken, among the guilty; so that by this rigour they may be brought to conform to the laws of humanity. But wherever severity is not absolutely necessary, clemency is to be used. Corinth was utterly destroyed, for having violated the law of nations towards the Roman ambassadors. However, that severity has been censured by Cicero, and other great men. He who has even the most just cause to punish a foreigner as his enemy, will always incur the reproach of cruelty, if he should cause the punishment to fall on the innocent people. There are other methodsable to the sovereign; as the depriving him of some of his rights, taking from him towns and provinces. The evil which a whole nation suffers is the participation inevitable to the members of a political society. The learned Vattel expresses this sentiment, that in a knowing age, it could be conceived that it is lawful to punish with death a governor who has defended his place to the last extremity; or who, in a weak place, has professed to make a stand against a royal army. Yet, even in the 17th century, this notion was so common as to make an article in the law of war; and, at a later period, it is not wholly exploded. What a thought! to punish a brave man for having performed his duty. Very different were the principles of Alexander the Great, when he gave orders for sparing some Mileans, "on account of their courage and fidelity." It is in vain to object, that an obsequious defence, especially in a weak place, against a royal army, only causes a great effusion of blood to no purpose; for this defence may save the state, by delaying the enemy some days longer; and
and, besides, courage supplies the want of fortifications. It is urged farther, that by threatening a commander with death, you may shorten the bloody siege, spare your troops, and gain a valuable opportunity. The answer is, says Vattel, that a brave man will defile your menace, or, provoked at such ignominious usage, will fell his life at a dear rate, make you pay for your injustice, and bury himself under the ruins of his fort. Besides, the menace of an unjust punishment is unjust in itself; it is an insult and an injury. But to execute it, would be barbarous and horrid; and if it is not to take effect, it must be allowed to be vain and ridiculous. Nevertheless, just and lawful means may be used for inducing a governor not obstinately to reduce himself to the last extremity; and this is at present done by all wise and humane generals. A governor is summoned to surrender, and in the progress of the siege an honourable and advantageous capitulation is offered him, with an intimation that if he stays too long, he will be admitted only to surrender as a prisioner of war, and at difcretion: if he perfils, and is at length forced to surrender at discretion, all the severity of the law of war may be used, both against him and his troops. But this right never extends so far as to deprive an enemy of life, who lays down his arms, unless he has been guilty of some proportionate crime towards the conqueror. See Capitulation, Prisoners of War, and Reprisals.

Quarters, in Building, those flight, upright pieces of timber, placed between the pannels and posts; used to last upon. They are of two kinds, single and double. The single quarters are fawn to two inches thick, and four inches broad; the double are four inches square.

Quarters in a clock, are little bells, which found the quarters of an hour.

Quarters, in Sea Language, the several stations of a ship's crew in the time of action. See Quartering the Men.

Quarters, in the Mange, to work from quarter to quarter, is to ride a horse three times upon the first of the four lines of a square; then changing your hand, to ride him three times upon the second; and so to the third and fourth, always changing hands and observing the same order.

Quarters of a Saddle, the parts or pieces of leather, or fluff, which are made fast to the lower part of the sides, and which hang down below the saddle.

Quarters of a Horse, and other Animals, the four principal parts of the animals; the fore-quarters confilt of the shoulders and the fore-legs; the hind-quarters, of the hips and the hind legs.

In the horse, the fore-quarters or shoulders should always fall in a neat manner backwards, where they join with the breast, and the hind-quarters be suitably long and well shaped towards the rump. Something of a similarity of shape should likewise prevail in the quarters of neat cattle, sheep, and swine, but they should be much more flexy downwards as they approach the thigh and leg parts. See Live-Stock, Horse, Sheep, and Swine.

Quarters of the Foot, in horses, are the sides of the coffin, comprehended between the toe and the heel on both sides; the inner quarters are those opposite to one another, facing from one foot to the other; they are always weaker than the outside quarters, which lie on the external sides of the coffin. A horse is said to have a false quarter, when the hoof has a kind of cleft occasioned by the cafting the quarter and getting a new one, for then the horn becomes uneven, and also lofter than the rest of the hoof; and the foot should be thod with some nicety. But if the cleft be considerable, and take up a fourth of the hoof, the horse is worth little afterwards for any purpose.

Quarter-Calf, among horses, is when for any difease in the coffin-bone or joint, one of the quarters of the hoof is call’d off, and when thus call’d, the reproduction of a new hoof or part takes place. It is a common occurrence among some horses.

Quarter-Evil, among domestic animals of the neat cattle kinds, is an affection which sometimes takes place in the glands of the udders, and sometimes in different parts of the feet.

Quarters, in Gardening, the large divisions of garden grounds, or those parts of them which are situated between the different walks, at a distance from the small, narrow portions on the sides usually termed borders, and which form or constitute the principal spaces or compartments for the cultivation and growth of the various sorts of the more useful culinary vegetables which are raised in large quantities; such as peas, beans, cabbages, cauliflowers, broccoli, early potatoes, and many others.

It is neccesary to have the quarters of garden grounds formed and laid out in such a manner as to favour the growth of early and late crops of the several different sorts, as much as possible; those for the former having a southern, or south-western exposure, and those for the latter, an eastern, or north-eastern aspect. By these means, early crops are, in some measure, rendered more forward and fine, and those of the more late kinds, in some degree, prevented from being injured or burnt up and destroyed by too full an exposure to the heat of the sun.

It is usual during the winter season to have the large quarters of garden grounds laid up in high ridges, in order to be exposed to the influence and effects of frosts, by which the earth may be rendered more light and mellow, and be in a more fit state for sowing or planting in the spring months, on throwing them down and rendering them level for the purpose.

The large quarters of gardens should likewise be kept as free and open as possible, not being inclosed and choked up, as is too frequently the case by planting fruit-trees and shrubs on their sides, either in the manner of edificers or otherways, as by such means the growths of the plants are much promoted, and they are prevented from being drawn up in a weak manner. See Garden.

All forms of garden grounds are found, except that of the square, to delange the regularity of the quarters, and, of course, to render them highly troublesome in digging and cropping. Where they are very large they may be subdivided into suitable sites, as one hundred feet in breadth, &c.; but the length being longer does not signify, as it may be varied in different ways, as by rows of trees, bushes, or which, in many cases, are preferable, by trodden walks and the modes of cropping.

Quarters of a Garden, the several divisions in which it is formed for the purpose of cultivating the different kinds of vegetables, fruits, &c. Thus, there are parts or quarters devoted to the growth of kitchen vegetables, fruit, and other trees, forcing, &c.

Quarters of a Field, or Farm, in Agriculture, are the particular parts of them, which are under, set apart, or intended for any fort of crops, or peculiar modes of cultivation and management. Farmers are frequently in the practice of dividing their lands or farms into different quarters or parts, according to the different sorts of husbandry which they are proper for, and the manner and succession in which the various kinds of crops are to be raised upon them, and the same is often the case with large fields; four, five, fix, and more divisions or quarters, being common in such

influences.
inferences. This plan of proceeding is supposed to give ease, facility, and dispatch, to the work which is afterwards carried on, as well as to have several other advantages and conveniences. See Farm.

Quarter-Bill, in Sea Language, a roll or list, containing the different stations, to which all the officers and crew of the ship are quartered, in the time of battle, and the names of all the persons appointed to those stations.

Quarter-Bullet, a bullet quartered into four, or eight parts.

Quarter-Chord, in Mining, seven yards and a quarter, which the miner hath crofs-ways of his vein on either side, for liberty to lay his earth, stones, and rubbish on, and to wash and drefs up his ore.

Quarters, Clof, in a Ship. See Close-Quarters.

Quarter-Clothes, are long pieces of painted canvas extended on the outside of the quarter-netting from the upper part of the gallery to the gang-way. They are generally decorated with martial instruments, or allegorical figures.

Quarter-Day. See Quarter.

Quarter-Deck of a ship, is that aloft the fleerage, reaching to the round-house; or that deck in ships of war which extends from the main-mast to the stern, next above the upper-deck.

Quarter, flat, in a Ship, denotes the fame with broad. Thus, if the truing in, or tack of a ship's quarter under water be deep, they lay, the hath a fat quarter.

Quarter-Gallery, a fort of small balcony, with or without ballustrades, on the quarter of a ship; which generally communicates with the gallery on the stern, by means of a door passing from one to the other.

Quarter-Guard. See Guard.

Quarter-Gunner, is an inferior officer under the direction of the gunner of a ship of war, whom he is to assist in every branch of his duty; as keeping the guns and their carriages in proper order, and duly furnished with whatever is necessary; filling the powder into cartridges; loading the guns, and keeping them always in a condition ready for service. The number of quarter-gunners in any ship is always in proportion to the number of her artillery; one quarter-gunner being allowed to every four cannon.

Quarter-Netting, is a fort of net-work, extended along the rails on the upper part of a ship's quarter. In a ship of war these are always double, being supported by iron cranes, placed at proper distances. The interval is sometimes filled with cork or old sails, but chiefly with the hammocks of the sailors, so as to form a parapet to prevent the execution of the enemy's small arms in an engagement.

Quarter-Pieces, subfiantial pieces of timber, mostly of fir, that form the outboard of the stern, and connect the quarter-gallery to the stern and tofhead.

Quarter-Point of the Compass. See Point.

Quarter-Rails, in a Ship, are narrow-moulded planks, generally of fir, reaching from the top of the stern to the gang-way. They are supported by f shakes, and serve as a fence to the quarter-deck, to prevent the men from tumbling into the sea by the rolling of the ship, particularly in small vessels.

Quarter-Round, in Architecture, is a term used by the workmen for any projecting moulding in general, whose contour is a perfect quadrant, or quarter of a circle; or which approaches near that figure. The architects usually call it ovolo; and Vitruvius, the echinus.

Quarter-Staff, a long staff, or pole, borne by forefathers, park-keepers, &c. as a badge of their office; and occasionally used as a weapon.

Quarter-Wheeling, or Quarter of Concentric, in the Military Art, is the motion by which the front of a body of men is turned round to where the flank was; this making the quarter of a circle.

If it be done to the right, the man in the right-hand angle keeps his ground, and faces about, while the left wheel; if to the left, the left-hand man keeps his place, &c.

Quarter-Wind, at Sea, is a lateral, or side-wind; or a wind which does not blow in stern, but a little aside of it.

Properly, the quarter-wind is that which comes in abash the main-mast throuds, even with the quarter of the ship.
The quarter-wind is the belt of all winds, as bearing into all the sails; whereas a wind blowing full in stern, is kept off by the fails of the mizen.

Quartermates, in Commerce, a corn-measure in Spain, containing 12 cartones; the falma contains 4 quarteras, or 48 cartones; the carga, 2½ quarteras, or 50 cartones; 78⅔ quarteras correspond to 100 Castilian faugas; and 100 quarteras Catalan to 128 Castilian faugas; 39 quarteras Catalan contain 10 English quarters. The cargo of wine and brandy is divided into 16 cartones, 32 quarteras, or 128 quartillos.

At Barcelona 39-08 quarteras are equal to 10 English quarters, and a single quenora contains 4401 cubic inches. Kelly's Un. Cambii.

QUARERED, Counter. See Counter-quartered.

QUARTERIDGE, money paid quarterly, or by the quarter.

QUARTERING of Soldiers, in Military Language, seems to have ancantly differed very little from that now in use, except that they were indiscriminately quartered upon all householders, as was practised in England to late as in the rebellion of the year 1745. Rapin says, that William the Conqueror quartered almost all his troops upon the monasteries, and obliged the monks to furnish them with necessaries; by which means he maintained his army without any charge, and had spies in all their religious houses, who watched the actions of the monks; these houses were long after charged with finding carts and horses for the carrying the baggage of the army; and there are full extant many of the original returns from different monasteries, stating the number of each they were able to furnish for that purpose. About the time of Henry VII. we meet with a regulation that bears some reference to quarters; this is a coat and conduct-money; the first was a species of clothing, probably, for recruits; the money for which was advanced by the county in which they were raised;—conduct-money was an allowance for subsistence, to and from the army, according to the number of days which the soldiers had to march; a day's march being estimated some times at 12 and sometimes at 15 miles. Both the coat and conduct-money were occasionally advanced by the different counties in which the troops were quartered, under the promise of being repaid by government. Towards the latter end of the reign of James II. and even after the accession of King William III. soldiers used to oblige the inhabitants of the towns in which they were quartered, not only to furnish them with diet and lodging, but also to advance them their daily subsistence. After the revolution, by the mutiny-act, passed the 23rd day of December, in the year 1689, other laws and regulations respecting quarters were enacted.

By the petition of right in the third of Charles I. it is enacted and declared, that the people of the land are not by the laws to be burdened with the fojournings of
of soldiers against their wills; it is also enacted by the 31 Car. II. c. 1. that no officer, military or civil, nor any other person whatsoever, shall presume to place, quarter, or billet any soldier on any subject or inhabitant of this realm, of any degree, quality, or profession whatsoever, without his consent; and every such subject or inhabitant may refuse to fowrump or quarter any soldier, notwithstanding any command, order, warrant, or billeting whatsoever. The present mode of quartering our troops is settled by the Mutiny Act, renewed annually, with little or no alteration. Accordingly by the mutiny act, 49 Geo. III. c. 12. §. 41. the constables and other chief officers and magistrates of cities, towns, villages, and other places, and in their default or absence, any one justice inhabiting in or near such place, and no other, shall and may, during the continuance of this act, quarter and billet officers and soldiers in inns, livery stables, alehouses, victualling houses, and the houses of fellers of wine by retail to be drank in their own houses or places thereunto belonging, (other than persons' cellars held under the authority of the commissioners for the affairs of barracks, and other than persons who keep taverns only, being free of the vintners' company in London,) and all houses of persons selling brandy, strong waters, cyder, or mead, by retail to be drank in houses, (other than the house of distillers who keep places of distilling brandy and strong waters, and of shopkeepers whose principal dealings shall be more in other goods than in brandy and strong waters, and who do not permit toelling in their houses,) and no other, and in no private houses whatsoever; nor shall any more billets be ordered than there are effective soldiers; which billets when made out shall be delivered to the commanding officer prefent: and if any constable, or such like officer or magistrate as aforesaid, shall presume to billet any such officer or soldier in any private house without the consent of the owner or occupier, such owner or occupier shall have his remedy at law against such magistrate or officer, for damages; and if any military officer shall take upon him to quarter soldiers otherwise than by this act, or shall offer any menace or compulsion to any mayor, or other civil officer before-mentioned, tending to discourage any of them from doing their duty, he shall on conviction before any two justices by the oath of two witnesses be ipso jure caffed: and if a civil officer, he shall forfeit to the party grieved 20s. on proof thereof to the next justice by ditrefs.

By f. 53. Officers and soldiers, billeted as aforesaid, shall be received and furnished with diet and small beer, paying for the same as hereafter mentioned, out of their subsistence-money.

By f. 54. If any person shall choose rather to furnish non-commissioned officers or private men, with candles, vinegar, and salt, greed, and allow them the use of fire and the necessary utensils for dressing and eating their meat, and shall give notice thereof to the commanding officer, and shall furnish the same accordingly; in such case they shall provide for their own victuals and small beer, and the officer who receives their pay shall pay the sums after mentioned out of the subsistence-money for diet and small beer to them, and not to the persons on whom they are quartered.

By f. 55. Every officer receiving the pay or subsistence-money, either for a regiment, or particular troops and companies, or otherwise, shall immediately, upon receipt of each sump, give public notice thereof to all on whom officers or soldiers are quartered; and shall also appoint such persons to repair to their quarters, at such times as they shall appoint, for the payment of the said pay or subsistence-money to the officers or soldiers, which shall be within four days at the farthest after the receipt of the same, as aforesaid; and such persons shall then and there acquaint such officer with the accounts or debts between them and the officers and soldiers quartered; which accounts the said officer is to accept of, and immediately pay the same, before any part of the pay or subsistence be distributed; provided the said accounts exceed not, for a commission officer of horse being under the degree of a captain, for such officer's diet and small beer, per diem, 2s.; nor for one commission officer of dragons, being under the degree of a captain, for such officer's diet and small beer, per diem, 1s.; nor for one commission officer of foot, under the degree of a captain, for such officer's diet and small beer, per diem, 6d.; nor for one light horseman's diet and small beer, per diem, 7d.; and hay and straw for his horse, per diem, 6d.; nor for one dragon's diet and small beer, per diem, 7d.; and hay and straw for his horse, per diem, 6d.; nor for one foot soldier's diet and small beer, per diem, 6d.; and if such officer shall not give notice and shall not immediately upon producing such account filet satisfice the same; upon complaint on oath by two witneses, at the next quarter sessions for the county or city where such quarters were, the paymaster of the guards, garrisons, and marines, are authorized (upon certificate of the said justices before whom such oath was made) to take up such accounts and the per-
fons to whom the fame is owing) to pay the said sums out of the arrears due to the said officer, upon pain of such paymaster forfeiting his place, and being incapacitated from holding it again. The act then states what course is to be pursued if there be no arrears due, or no subsistence-money remitted, and is directory of the course to be pursued by the paymaster.

By f. 49. The commanding officer may exchange any men or horses quartered in any place with another man or horse quartered in the same place, provided the number of men and horses do not exceed the number at that time billeted on such house.

By f. 47. And where any horse or dragoon shall be quartered upon any person who hath no stables, upon his complaint to two justices of the division, &c. and his making such allowance as such justices shall think reasonable, they may order the men and their horses, or the horses only, as the case may be, to be removed and quartered upon some other person who hath stables, and may order and settle a proper allowance to be made by the person having no stables, in lieu of his quartering such horse or dragoons, and order payment thereof to the person to whom the removal is made, for or to be applied for the furnishing of quarters for such men and their horses.

By 49 Geo. III. c. 37. It is enacted that every non-commisioned officer and private soldier who shall be furnished with diet and small beer by the perons on whom they are quartered, shall pay for the same 1s. 4d. per day, in like manner as the late act is enacted as to the 7d. per day.

By f. 2. Where the inholder, &c. furnishes certain articles in lieu of diet and small beer, as in the former act mentioned, he shall have one halfpenny per day for each non-commisioned officer, &c.

By f. 3. 1s. 3d. per day is to be paid for each horfe, instead of 6d. per day.

By f. 4. The provisions in the former act relating to the dieting on a march or recruiting are repealed.

By f. 5. All non-commisioned officers and soldiers shall receive their diet and small beer at the above rates while on the march and on the day of arrival at the place of their final destination, and on the two subsequent days, unless either of the two be a market day for the place where billeted, or within two miles thereof; in which case the innkeeper, &c. shall discontinue on and from such market-day the diet and small beer, and furnish in lieu thereof the articles in the said former act specified, and at the rate in this act prescribed.

By f. 6. If any person liable to have soldiers quartered on him shall pay any sum to any non-commisioned officer or soldier on the march in lieu of the diet and small beer, he may be proceeded against and fined as if he had refused to furnish according to the former act the things to be furnished to non-commisioned officers and soldiers so quartered as aforesaid.

By f. 7. The provisions of f. 5. are extended to halting on a march.

By f. 8. But if the halt be for longer than one day, and the day after the arrival be market-day as aforesaid, there is to be no discontiuance of diet and small beer.

By f. 9. Non-commisioned officers and private men employed in recruiting, and the recruits by them raised, shall, while on the march, and for two days after the day of their arrival at any recruiting station, be entitled to the same benefits as before provided for troops on the march; but no recruit enlisted after the two days subsequent to the arrival of the party at their recruiting station, shall be entitled to be supplied with diet and small beer at the rate herein-before preferred, except at the option of the party where quartered.

Provided that in case any recruiting party, with the recruits by them raised, shall remove from their station, and after a time shall return to the same place, they and the recruits shall not be again entitled to the diet and small beer for two days, unless the time of absence exceed 20 days. This act to continue to 25th March 1810.

By f. 52. Any justice within his county, &c. may command any constable or other officer who shall billet any soldiers, to give an account in writing to him of the number of officers and soldiers billeted by them, and the names of the persons on whom quartered, and an account of the place where they dwell, and of their signs, if any. See Martial Law, and Soldiers.

But by the 50 G. III. c. 96. f. 1. it is enacted, that after the 25th of June 1810, every non-commisioned officer and private soldier who shall be furnished with diet and small beer within the parts of the united kingdom mentioned in the 50 G. III. c. 28. by the inholders or other persons on whom such non-commisioned officers or private soldiers shall be quartered and billeted by virtue of the said act, shall pay and allow for the same, the sum of eight-pence per diem in the stead of one shilling and four-pence per diem, as in the said act specified; and that for such allowance of eight-pence, the innkeeper or other person shall furnish one meal; a dinner, &c. at any dinner if required in each day to each non-commisioned officer, trumpeter, drummer, and private soldier quartered and billeted on him, to consist of such quantities of diet and small beer as shall be specified and fixed in and by any regulations made or to be made from time to time by his majesty in that behalf, but not to exceed one pound and a quarter of meal previous to being dressed, one pound of bread, one pound of potatoes or other vegetables previous to being cooked, and two pints of small beer, and vinegar, salt, and pepper.

And by f. 2. of the same act, the mutiny act, and the said 50 G. III. c. 28. shall be applied for the enforcing such regulations as to the diet of soldiers and the payment of and accounting for the allowances for the same.

Quartering of Traitors, in Law. See Treason.

Quartering, in the Sea Language. When a ship under sail goes at large, neither by a wind nor before a wind, but, as it were, betwixt both, she is said to go quartering.

The term is also used when a ship fails with quarter-winds.

Quartering the Men, the disposing of the ship's company at the time of an engagement in such a manner, that each may readily know where his station is, and what he is to do: as, to come to the matter, for the management of the falls; to come to the gunners to traverse the ordnance; to come for providing the enemy with small shot; to come to fill powder in the powder-room; others to carry it from thence to the gunners in cartridggs, &c.

The number of men appointed to manage the ordnance is always in proportion to the nature of the guns, and the number and condition of the ship's crew. They are in general as follow, when the ship is well manned, so as to fight both sides at once occasionally:

<table>

The lieutenants are usually stationed to command the different batteries, and direct their efforts against the enemy.

The master superintends the movements of the ship, and whatever relates to the sails. The boatwain and a sufficient number of men are stationed to repair the damaged rigging; and the gunner and carpenter whatever may be found necessary, according to their respective offices. The marines are generally quartered on the poop and forecastle, or gangway, under the direction of their officers: although, on some occasions, they affilt at the great guns, particularly in distant cannonading. Falconer. See Engagement.

Quartering, in Gunnery, is when a piece of ordnance is so traversed, that it will shoot on the same line, or on the same point of the compass, as the ship's quarter bears.

Quartering, in Heraldry, the act of dividing a coat into four or more quarters, or quarterings, by parting, coupign, &c. i.e. by perpendicular and horizontal lines, &c. See Quarter and Quarterly.

The king of Great Britain quarters with Great Britain, France, Ireland, Brunswick, &c.

Colombiere reckons twelve forts of quartering; but other authors give us more—viz. party per pale, dividing the escutcheons from top to bottom. See Pale.—Party per cross, dividing it from side to side. See Cross.—Party of six pieces, when the escutcheon is divided into six parts, or quarters.—Party of ten; of twelve; of sixteen; of twenty; and of thirty-two; when there are so many partitions respectively.

Others give the divisions in another manner: as—Party per cross—per pale—per chief—per pale irclave—per bend dexter—per bend sinister—per chevron—barry bendy of eighty pieces—paleways of six pieces—barry of six pieces—barry of eight pieces—bendy of six pieces—chevy—fully, or lozenge—pale bendy, or bendy lozenge—barry bendy lozenge, or bendy lozenge—gyronny—barry lozenge counterchanged—waved of six pieces—barry nebule of six pieces—party per falkier—and party per pale in point. See farther under their respective articles.

Counter-quartering a coat, is when the quarters are quartered over again, or subdivided each into four. See Counter-quartered.

There are counter-quartered coats which have twenty or twenty-five quarters.

Quartering is also applied to the partitions or compartments themselves, that is, the several coats borne on an escutcheon, or the several divisions made in it, when the arms of several families are to be placed on the same shield, or account of intermarriages, or the like.

Colombiere observes, that thirty-two is the greatest number used in France; but that the English and Germans sometimes extend to forty: as a testimony of the truth of which, he says he saw an escutcheon of the earl of Leicesters, ambassador extraordinary in France in the year 1639, divided into the number of forty: and hence, he affirms, do go on to sixty-four several coats.

But a multitude of quarters make a confusion; and, accordingly, all the writers of armoury exclaim against it as an abuse. The first instance of quartering, of which we have any account, is said to be in the arms of Renatus, king of Sicily, &c. in the year 1435, who quartered the arms of Sicily, Arragon, Jerusalem, &c.

William Wickley observes, that such quarterings are much more proper for a pedegree, to be locked up in a chest, and occasionally produced as an evidence for the clearing or averting of alliances of families, and titles to lands, &c. than to be borne as a cognizance.

In blazoning, when the quartering is performed per cros, the two quarters a-top are numbered the first and second; and those at the bottom the third and fourth; beginning to tell on the right side. When the quartering is by a falkier, &c. the chief and point are the first and second quarters, the right side the third, the left the fourth.

Quartering is sometimes also used for the distinguishing of younger brothers from elder. See Difference.

Quarterization, Quartering, part of the punishment of a traitor, by dividing his body into four quarters.

"Wallingham, in Ric. II. Audittum et confessum turpifima secula tradactiuni, suspendo, decollationem, exenterationem, et quarterizationem adjudicavit."

Quarterly, in Heraldry, a person is said to bear quarterly, when he bears arms quartered.

The king of Great Britain bears quarterly of four; in the first quarter gules, &c. Great Britain; in the second, azure, &c. Ireland, &c.

Quarter-Master, an officer in the army, whose business it is to look after the quarters of the soldiers; their clothing, bread, ammunition, firing, &c. Every regiment of foot and artillery has a quarter-master, and every troop of horse one, who are only warrant-officers, except in the Blues. Whereof there are several kinds; viz. the Quarter-Master General, whose business is to provide good quarters for the whole army.

Quarter-Master of Foot, he who is to provide quarters for a regiment of foot.

Quarter-Master of Horse, he who is to provide quarters for a troop of horse.

Quarter-Master, in a Ship, is an inferior officer, appointed by the master of a ship of war to assist the mates in their several duties; as flowing the ballast and provisos in the hold, coiling the cables on their platforms, looking after the appearance of the ship, and keeping the time by the watch-glasses.

Quatern, Quarteron, a diminutive of quart, signifying a quarter of a pint, as a quart does a quarter of a gallon.

Quar-tier, in Commerce, a liquid measure in Germany, which, according to a regulation of 1713, made in Hanover, must hold 21h. of spring water, and the contents of which are 49 French, or 5¼ English cubic inches. A fuder of wine contains 4 exchefts, 6 ams, or 15 eimers; an aham, 4 ankers, 40 flbugens, 80 kannes, 160 quarters, or 320 nobles. Hence 36 flbugens, or 144 quarters, = 37 English wine gallons. A fas of beer at Lubeck contains 42 flbugens, or 168 quarters. Kelly's Un. Cambit.

Quartile, an aspect of the planets when they are three signs, or 90 degrees distant from each other.
The quartile aspect is marked thus □. See Aspect.
QUARTILLO, in Commerce, a liquid measure in Spain. At Barcelona, 128 quartillos are equal to 32 quarters. (See QUARTER.) A moido of wine contains 16 arrobas; an arroba 8 azumbres, or 2 quartillos. The arroba of wine contains 34 lb. of water (Cañillian weight), and measures 125½ Spanish, or 98 English cubic inches; hence four such arrobas are equal to 17 English wine gallons. The arroba of oil measures 966 Spanish, or 771 English cubic inches; so that these four arrobas correspond to 10 English gallons; this arroba is divided into 4 quartillos, or 100 quarterones, or pinallas. A Spanish bottle contains 30 arrobas of wine, or 38¾ of oil; a pipe is 27 arrobas of wine, or 34½ of oil; thus the bottle is 125½ English gallons, and the pipe = 114½. Kelly. See Tab. XXXII. of Measures.
QUARTO, or 4to, a book whose four leaves, or eight pages, make a sheet.
QUARTO, in Commerce, a money of account in Spain. See REAL.
QUARTO dell Torri, in Geography, a town of Naples, in Capitanata; 12 miles W. of Salpe.
QUARZO, or Quaz, in Law, denotes the fourth day inclusive beyond the return of a writ, in which those that are summoned are allowed to make their appearance. See Easter, day of term.
QUARTH-DECIMANS, QUARTH-DECIMANI, in Ecclesiastical History, an ancient sect in the church, who maintained that Easter was always to be celebrated, conformably to the custom of the Jews, on the fourteenth day of the moon in the month of March, whensoever that day fell out. And hence their name Quarto-decimani, q. d. Fourteen-teenthers.
The Atheists were mightily attached to this opinion, pretending that it was built on the authority of St. John, who was their apostle; and pope Victor could never bring them to obedience in this article, though he was upon the point of excommunicating them: but it is more probable he contended himself with menaces. See Easter.
QUAROVUM par constringens, in Anatomy, a name given by Spigelius and some others to the muscules called by Albinus and Riolanus orbicularis oris; and by Cowper and some others, contrilator labororum.
QUARTUS hyoidis mulfetus, a name given by Vefalius, Fabricius, and many other anatomists, to a muscle now generally called the coracoxyeides.
QUARTUS oculorum movens, a name given by Vefalius to one of the muscles of the eye, called by some rectus inferior, and by others humilis.
It is the depressor oculi of Albinus, being one of the quattuor recti oculi of that author.
QUARTZ, in Mineralogy. No substance in the mineral kingdom is more abundantly distributed than quartz. Grains of quartz generally compose a considerable part of the sands on the sea-shore, and of the sandstones of the secondary strata. Rolled pieces of quartz, or pebbles and boulders, are widely scattered over alluvial districts. Quartz is disseminated through granite, gneis, mica-flate, and other compound rocks which constitute the loftiest mountains on the globe; it also forms veins of vein extend intertinge these mountains, and sometimes entire simple rocks are composed of this mineral. Quartz has a confiderable degree of hardness, always striking fire with fleck, and the fragments have sufficient solidity to resist the blowpipe. Powdered quartz feels harsh, and, when rubbed on polished steel, or on glass, scratches the surface. Quartz is infusible by the common blowpipe. These two qualities, hardness and infusibility, are the essential characters of all the varieties of quartz, whatever forms or colours they may present, whether mafive or crystallized. Quartz has most commonly a conchoidal fracture, but sometimes the fracture is undulatus, foliated, or splinterly. The lustre is vitreous. Quartz has various degrees of transparency; from a perfectly pellucid colourless state, it passes by different gradations to opacity; but all the varieties, except the mafive, admit light through the very minute fragments. The colours are various, owing to the impregnation or intermixture with foreign subftances. The specific gravity of quartz is from 2.58 to 2.65. It yields a phosphor inferent light when rubbed, and is not soluble in any of the acids except the fluoric. According to Vauquelin, powdered quartz gives a green colour to tincture of violets.
Quartzifed quartz presents the phenomenon of double refraction, when an object is seen through one half of the pyramid that terminates the crystals, and the opposite side of the hexagonal prism on which it is placed, in the most common variety of the secondary forms of these crystals.
The substances found imbedded in quartz are, ores of tin, antimony, gold, silver, copper, and lead, arsenic, and micaeous iron ore, with chloride, hornblende, felspar, garnet, and float of lime. It is also penetrated by fibres of aiberius, and by minute laminae of mica and epidote; the latter substance is sometimes fo intimately diffused through quartz as to give it an homogeneous green colour. This variety of quartz is called prase.
Quartz crystallizes distinctly: some of the crystals are of considerable size.
In the imperial cabinet of Vienna, there is said to be a crystal of quartz seven feet in length. The forms of crystal-lline quartz are various; they have been reduced by modern mineralogists to fix or seven principal varieties. The most common is a fix-fid frim, terminated by a fix-fid pyramid, or two fix-fid pyramids joined at their bases. The sides of these pyramids are irregular, having the vertical angle 40°, and each of the angles at the base 70°. The sides of the upper and lower pyramids are inclined to each other at an angle of 104°. According to Haüy, the primitive form of the crystal is a rhomboide, varying little from the cube, the angles being 94° and 86°. The primitive rhomboide is rarely found in nature; it occurs sometimes in red hematite, coated with that mineral, and in chalcedony.
Bubbles containing air, water, and bitumen, are sometimes seen in quartz crystals, and have given rise to much speculation respecting their formation. Silices earth, of which these crystals are composed, is insoluble in water, by artificial means; but in the great laboratory of nature, its solution is effected probably by the effect of heat and compulsion, as ifex exist in the boiling fountains of Iceland and the Azores, and in the hot springs of Bath, Italy, and various parts of the world. It has been supposed that the silicious earth was held in solution by foda; but Klaproth, who analyzed the waters from the Reikum, in Iceland, thanks the quantity of alkali too small to have diffolved the fexe. One hundred cubic inches contained nine grains of fex, three of carbonat of foda, eight of common salt, and five of sulphate of foda. If rock crystals were formed in an aqueous solution greatly heated and compressed, it would not be difficult to conceive how volatile matter might be involved in the substance of the crystal during its formation; but our knowledge of the subterranean operations of nature is at present too limited to enable us to ascertain, or even to form any rational conjecture in what manner some of her more mysterilious processes are effected. Those who have frequent opportunities of exploring mines, will not be disposed to deny that silicious halantites, and crystals, are now forming at the common temperature of the earth, as they are observed.
QUARTZ.

served on the roofs and sides of artificial excavations, and
passages which have been undisturbed for some years. Ac-
cording to Chaptal, a quartzose or a siliceous paste is formed by
transfusion on ferruginous rocks at Chamillat, near Planches
les Mines, in Franche Comté, and where this is washed and
deposited by water, rock crystals are formed. Siliceous
flakes do not unfrequently been seen coating the wood
which has been left in mines.

Pleneigrunorphous crystals of quartz, or falso crystals of
this mineral, are frequently found in mines; they are tar-
nified and opaque, and their edges are blunted. They
assume the forms of cubic crystals of floor, and the pyra-
midal and other forms of calcareous and other crystals.
These false crystals are evidently moulded in the cavities
which the former have once occupied. Quartz also occurs
filling up the cavities of shells in a similar manner, and the
pores of wood and other organic substances.

Cellular quartz with polyhedral cavities, appears to have
been formed round crystals of other minerals which are sub-
sequently decomposed. The internal crystals are frequently
those of the metallic sulphurites. Brongniart fays
this conclusion is founded on direct observation, as the re-
 mains found in these cavities are sulphur, native gold, and
oxvd of iron, all sulphurites which originally formed part of
the decomposed sulphurites. Such is the cellular quartz at
Schemnitz in Hungary, and Joachimsthal in Bohemia. The
cellular quartz at Berezof, in Siberia, is fo porous that it is
lighter than pumice.

Rock crystal, or Mountain crystal, is the purest variety
of quartz, differing from common quartz by its transparency,
and the more regular form of its crystals; the fracture is
also more perfectly conchoideal. According to some analyses,
rock crystal contains 98 parts of silex, with 2 parts of
water. Bergman found in one specimen only

| Silex | 93 |
| Alumine | 6 |
| Lime | 1 |

Amethyst is a purple variety of rock crystal. See Am-
ethyst.

Caingeronum flones are rock crystals, from the mountains
of Caingeron, in Scotland. They are valued by jewellers
on account of their purity and colour. Close-brown quartz
are known by the name of the smoke topaz. Accord-
ning to Karlfen, the specific gravity of this variety is
2.88. Coloured rock crystals lose their colour, when care-
fully exposed to a gentle heat, but retain their transparency.
The yellow and orange-yellow varieties are the most
esteemed.

Milk quartz, called by some mineralogists roce quartz,
and by others the Bohemian ruby, as it is frequently of a
beautiful roce-red colour, which it derives from manganese.
By exposure to the light the intensity of its colour is dimi-
nished. It is used in jewellery, and takes a good polish; it
is sometimes sold for the ruby, but is less hard, nor has it
the transparency and brilliancy of that gem. Rose quartz
is found at Rabenflein, in Bavaria, in considerable masses,
and in a vein of manganese which traverses a coarse-grained
granite. It occurs also in Sweden, Greenland, Saxony, in
the island of Coll, one of the Hebrides, and in Ireland.
Some varieties are of a milky-white colour, others pearl-grey.

Iridescent quartz, Quarz byalin irifs, presents on its sur-
face, or in its interior, the various colours of the rainbow:
if sometimes derives this property from a thin pellicle of me-
tallie oxd which covers the surface, and sometimes from
minute fissures in the substance of the crystal. These colours
may be given to quartz by heating it and exposing it fud-
deny to a cold temperature.

Avanturine quartz (fee Avanturine) owes its brilliancy
to minute particles of mica diffeminated through it, and
sometimes to minute fractures. Avanturines may be formed
artificially, in some varieties of quartz, by heat.

Blue quartz, Quarz byalin saphirin, has been found in
Spain, Bohemia, and Bavaria.

Black quartz is found, mixed with carbonate of lime, in
the department of Ière in France, in Bohemia, and at
Coppé Nuova, on the road to Sienna. Brongniart Mi-
neralogy.

Cat's-eye, Quarz byalin chatoyant, so called because it re-
reflects a pretty variety of colours, according as the light falls
upon it in different directions; this property is owing to the
fibrous texture of this mineral, which may be observed in the
different characterised specimens. It contains 95 parts of
silex, and according to Brongniart is a variety of quartz,
and ought not to be classed with silex. The geologicalitu-
flon of this stone is not known. The cut and polished
specimens seen in cabinets come from Malabar and Ceylon.
It is said, also, to occur in Egypt and Arabia.

Green quartz, Prase, Quarz byalin wed obfeur. The colour
is a leek green; it is seldom crystalized; the form of the
crystals are those of common quartz. Prase has been said
to owe its colour to an intimate mixture with actyno-
lite, but Klaproth is of opinion that this is not well ac-
tained.

Simpie is classed, by some mineralogists, with quartz. It
is of a deep blood-red colour, and perfectly opaque, or
barely transmits light on the edges. It resembles red jasper,
but has a vitreous lustre, and conchoideal fracture, and is
sometimes crystalized.

Ferruginous quartz consists of small crystals, or of granu-
lar quartz, intimately mixed with oxd of iron, and has a
brown ochre-yellow, or red colour. From the iron which
it contains it becomes magnetic when heated. It is harder
than pure quartz.

Certain properties, beside colour, have given names to
some varieties of quartz.

Fat quartz is so called because it has a greasy appearance,
as if the surface had been rubbed with oil.

Feticl quartz differs from common quartz, by emitting an
odour, which rubbed, like that of sulphurised hydrogen
gas. When this fossil is heated below a red heat, it looses
its fetid odour on cooling, and when plunged into water be-
comes transparent. When feticl it is nearly opaque. It is
found in the vicinity of Nantes and Chantilly, in the de-
partment of Haute Vienne, forming a constituent part of
the granitic mountains of that district. It occurs also in
the island of Elba.

Elastic stone is a siliceous sandstone, found in the Bra-
zils, composed of oblong lamini of quartz, arranged in
one direction, and so interlocked together as to form a kind
of hinge with each other, from whence it poftesses a certain
degree of pliability, like that of a fliff piece of leather. In
appearance, elastic quartz resembles some of the flaty sand-
stones in the northern counties of England. According to
Klaproth its constituent parts are

| Silex | 96.50 |
| Alumine | 2.50 |
| Oxd of iron and tols | 1 |

The use of quartz in the arts is principally confined to
the manufactures of glafs, enamels, porcelain, and earthen-
ware. The finer crystalizations are employed by the jewell-
ers, and before the discovery of glafs, ornaments and veils
of great value were made by the ancients from rock crystal.
Stones in which quartz forms the principal ingredient, are
belter fitted for purposes of durable architecture, and in the

The princi
economy of nature this mineral gives liability to the folded fabric of the globe, enabling those rocks and mountains in which it abounds to resist the decomposing effects of air and moisture, and to vary for ages the impetuous fury of the ocean. For the properties of flaxes, of which quartz is composed, see Silex.

QUARTZ ROCK, in Geology. Entire rocks and even mountains are composed of quartz in various parts of the world, in the vicinity of granitic districts. The quartz is granular, and sometimes intermixed with a small portion of mica. Werner classes quartz rock as a distinct order of primary rocks, but it would be perhaps more consonant with a natural arrangement, to consider this rock as a constituent of granite on a large scale, certain causes having separated the quartz, mica, and felspar into distinct masses. Entire mountains of these three subfamilies are laid to occur in the Uralian chain, presenting the materials of granite on a large scale. Quartz rocks are met with in Scotland. In the highlands the summits of some of the mountains are formed of white quartz, and appear as if covered with snow. The two beautiful conical mountains, called the Sugar-loaves, in the vicinity of Dublin, are composed of granular quartz, of a similar kind to what forms veins in the gneiss and mica flate of the surrounding mountains nearer Dublin.

QUARTZOSÉ, in Mineralogy, a term applied to those rocks or minerals which are principally composed of quartz.

QUASHING, in Law, the overthrowing and annulling a thing. Thus, pleas in abatement (which see), when the suit is by original, conclude to the writ or declaration; by praying “judgment of the writ, or declaration, and that the same may be quashed,” causatur, made void or abated; but if the action be by bill, the plea may pray “judgment of the bill,” and not of the declaration; the bill being here the original, and the declaration only a copy of the bill. See Plea, Dilatory Pleas, and Certiorari.

QUASI-CONTRACT, in the Civil Law, an act which has not the strict form of a contract, but yet has the force of it.

In a contract there must be the mutual consent of both parties; whereas, in a quasi-contract, one party may be bound or obligated to the other, without having given his consent to the act by which he is obliged.

For an example: I have done your business in your absence, without your procuration; and it has succeeded to your advantage; I have then an action against you for the recovery of what I have disbursed; and you an action against me, to make me give you an account of my administration; which amounts to a quasi-contract. See Contract.

QUASI-CRIME, or QUASI-DELICT, the action of a person who does damage, or evil, involuntarily.

The repARATION of quasi-crimes consists in making good the damages, with interest.

QUASI-MODO SUNDAY, Law Easter-Sunday, or the next funday after Easter; thus called from the initial words of the introit of the mass for the day, Quasi modo geniti infantes.

In the ancient deeds these words are signified by g. m. g.

QUASS, the name of a liquor in Ruffia, which serves the natives not only for drink, but also for sauce to a number of dishes; and is the basis of the favourite cold soup of the North, which is made by adding cold meat cut in pieces, with cucumbers salted after a peculiar manner, or with onions, or garlic, to a bowl of this subacid liquor. The common Ruffian quass is prepared by putting into a large pot full of cold water as much rye-flower as will make a thin dough; this is then placed in an oven moderately heated, for three hours, and afterwards taken out and thrown into a tub of cold water; the mixture is worked with a machine like a chocolate mill till it froths. To this liquor are added two hafons of the grounds of old quafs, leaven, or a piece of their four bread; and the tub is covered with a cloth, and laid by till the liquor has acquired a fourth taste, which marks its being ready for use.

There is a better sort of quass, which is prepared as follows. Take a chetverik (about 35 pounds Ruff, or 30 pounds Engl.) of barley-malt, two or three handfuls of rye-malt, and a like quantity of unbolted rye-meal; mix them all together in earthen pots, then pour boiling water upon it, and stir the whole till it acquires the consistence of a thin pap. The pots must be full to within an inch of the brim. Upon this mixture must now be poured about an inch in height of the husks of oats, from which groats are made. Set the pots in a heated oven, in which some glowing coals are still remaining, which must be heaped about the pots. This done, clofe the oven, and leave the pots in it four-and-twenty hours. This time being chpped, take them out; again pour boiling water in till they be brimful, and stir all well together. Now pour it all into a wooden vessel or tub, provided with a spiggot and follet, first covering the bottom with a layer of straw, as is usually done in brewing beer; then add warm water, more or less, according to the quantity of quafs you want; let it stand an hour, and afterwards draw it off into vessels. In every vessel a flice of coarse rye bread must be put in, in order to make it ferment. Set the vessels in a cellar, and after four-and-twenty hours the quafs is fit for drinking.

In making quafs, barley-malt alone may be used. The rye-malt is added only from necessity, when the former, by itself, would be too poor, and not be sufficiently sweet. But the rye-meal is absolutely necessary.

From the quantity of malt and meal above stated, is obtained about six or seven kilderkins, or two ankers of quafs. The Ruffians in the summer feast on the vesfels of quafs immediately in the cellar, but in the winter they let them stand a whole night in a warm room, for the quafs to ferment.

QUASSE, in Geography, a town of Africa, in Benin. N. lat. 6° 20'. E. long. 3° 50'.

Qu. Ch. Cal. Perianth inferior, very short, of five ovate, permanent leaves. Cor. Petals five, seclle, equal, lanceolate, elongated, oblique, converging. Nectary of five ovate villous scales, attached to the inside of the filaments at the base. Stom. Filaments ten, thread-shaped, equal, the length of the corolla; anthers oblong, incumbent. Pfl. Receptacle fleshy, elevated, orbicular, broader than the corolla. Germin ovate, composed of five separate ones; style thread-shaped, with five furrows, the length of the filaments; stigma with five angles. Pfl. Drupas five, diffus, horizontal, ovate, obtuse, sifting into two parts, all blanding on a fleshy pentalgonal receptacle. Seed fustular, globule or oval.

Obl. Some flowers have abortive germs, others imperfect anthers.
QUASSIA.

This is the true original Quassia, whose wood is more powerful than that of other species; but being very rare, and of small bulk, its place is that of being supplied by Q. excelata hereafter described.

2. Q. Simaruba. Wing-leaved Quassia. Linn. Suppl. 234. Wildl. n. 2. Ait. n. 2. Woodv. Med. Bot. t. 76. (Simarouba amara : Aulb. Guian. v. 2. 859. t. 331. 332.)—Flowers monoeccious. Leaves pinnate; leaflets alternate, not quite sessile; common stalk naked. Clusters panicked. — Native of various parts of the West Indies, in a sandy soil, flowering in November and December. It was sent to Kew in 1797, by Mr. Alexander Anderson, but has not bloomed there. This is a tall and flowering tree, whose wood is hard, lasting, without any peculiar flavour. Leaves alternate, with six, seven, or eight alternate obovate, rather narrow, entire, flaked leaflets, two inches long, whitish beneath; their common stalk simple, roundish. Flowers yellowish-white, much smaller than the preceding, either monoeccious, or, as some say, dioecious, in branched or panicked clusters. The bark of the root is bitter, and much celebrated as a cure for the dysentery. Dr. Wright has given a full history of the plant, with a plate, in the Transactions of the Royal Society of Edinburgh, vol. ii. It is known in Jamaica by the name of Mountain Damfion, Bitter Damfion, and Stave-wood. In that island, according to Dr. Wright, the male flowers are never found on the same tree with the female.

3. Q. excelata. Lofty Quassia. Swartz in Stockh. Trans. for 1788. 302. t. 8. Ind. Occ. v. 2. 742. Wildl. n. 3.—Flowers polygamous. Stamens five. Leaves pinnate; leaflets opposite, flaked; common stalk naked. — Native of rather mountainous woods, in Jamaica and the Caribbean islands. The English commonly call it bitter wood, or bitter ahl. The tree is lofty, with a very straight trunk; the wood whitish, moderately close-grained, very bitter; frequently sold by the druggists for the true Quassia amara, and found useful in intermittent fevers, debility of the stomach, worms, dropsy, and chlorosis. It is also used for making cabinets, for preserving insects, or other natural curiosities; this wood being supponed inacessible to worms. The leaves are larger than the last, and composed of from four to five pair of opposite, elliptical, pointed, firm, entire, smooth leaflets, on short partial stalks. Clusters panicled, bearing very numerous, small pale flowers, solitary, male, the red hermaphrodite in the same cluster. Swartz describes the nectaries, of five minute villous scales, contrary to the remark of Willdenow, under his Zwinger, Sp. Pl. v. 2. 569, where it is said to be wanting in this species of Quassia. The flowers are mostly five, rarely four or fix. Germs from two to four.

QUASSIA Amara, bitter quassia, in the Materia Medica. The root, bark, and wood of this tree are all comprehended in the catalogues of the Materia Medica; and it is observed that the leaves, flowers, &c. possess similar qualities. The roots, being perfectly ligneous, may be medically considered in the same light with the wood, which is now more generally employed, and seems to differ from the bark in being less intensely bitter; so that the latter is thought to be a more powerful medicine. The wood is sent to this country from Jamaica and the Carribbean islands in billets, and is reduced to chips, or raised by the druggists. Quassia has no fenible odour; its taste is that of a pure bitter, more intense and durable than that of any other substance. It imparts its virtues more completely to watery than to spirituous menstrua, and its infusions are not blackened by the addition of martial vitriol. When the infusion is evaporated to dryness, it leaves a brownish-yellow, somewhat transparent, brittle extract, which has been regarded as a vegetable constituent, and named the bitter principle. (Edinb. Phil. Trans. t. 227.) The infusion is rendered muddily by nitrate of silver, and a soot, flaky, yellow precipitate is formed; acetate of lead occasions a copious white precipitate; and hence it has been inferred that these faults are incompatible in formula with it. The watery extract is from a fifteenth to a ninth of the weight of the wood; the spirituous about a twenty-fourth.

Quassia derived its name, as has already been observed, from a negro named Quassi (by Fermin written Coiffi, and by Rolander, Quassi), who employed it with uncom- mon success, as a secret remedy in the malignant, endemic fevers, which frequently prevailed at Surinam. In conformance of a valuable consideration, this secret was disclosed to Daniel Rolander, a Swede, who brought specimens of the quassia-wood to Stockholm in the year 1756; and since that time the effects of this drug have been very generally tried in Europe, and numerous testimonies of its efficacy published by many respectable authors. Its antifeptic powers have been submitted to various trials, from which it has been concluded, that it has considerable influence in retarding the tendency to putrefaction; which, in the eyes of Dr. Murray's opinion, cannot be attributed to its sensible qualities, as it possesses no astringency whatever, nor to its bitternes, as gentian is much more bitter, but lefs antifeptic. The medicinal virtues ascribed to quassia are those of a tonic, nutritious, antiseptic, and febrifuge: it has been found very effectual in relieving the tone of the stomach, producing appetite for food, affilling digestion, expelling flatuency, and removing habitual colic, produced from debility of the intestines, and common to a febrifuge life. Dr. Letfom observes, that in hysteric stomy, to which the female sex is more prone, the quassia affords more vigour and relief to the stomach than the Peruvian barks, especially when united with the vitriol album, and full more with the aid of some armbent. In dyspepsia, arising from hard drinking, and also in diarrhœa, he exhibited the quassia with great success. Although he does not concur in opinion with Linneaus, who says, "I am quidem judice chinhamum longé superatur;" yet he has met with several instances of low remittent and nervous fevers, the symptoms of which the bark uniformly aggravated, though administered in inter- mittent doses favorably to its succees, in which quassia, or make-root, was usefully substituted. In each case, he mostly observed that there was great cessation in the hepatic fevers, and the debility at the same time discouraged copious evacuations. And in many fevers, without evident remissions.
remissions to warrant the use of the bark, whilst, at the
same time, increasing debility began to threaten the life of
the patient; the doctor found that quassia, or snake-root,
finely or combined, upheld the vital powers, and promoted a
critical improvement of fever, by which an opportunity
was offered for the bark to effect a cure. Dr. Cullen says,
(Mat. Med. vol. ii. p. 174), ‘‘I believe quassia to be an ex-
cellent bitter, and that it will do all that any pure and simple
bitter can do; but our experience of it in this country does
not lead us to think it will do more; and the extraordinary,
condemnations given of it are to be ascribed to the par-
tiality so often shown to new medicines.’’ It is said to have
been given, combined with nitric acid, with evident benefit
in typhus, and also in flour albus. It may be given in in-
fusion, which is the best form of administering it; or in pills
made from the watery extract. It may also be given in
bubblace in doses of from grs. x to 3j three or four times a day.
The official preparations are the ‘‘infusum quassiae’’ of
the London Pharmacopoeia, and the ‘‘tinctura quassiae’’
of that of Dublin. The infusion is prepared by macerating
for two hours in a lightly covered vessel a scropful of quassia-
wood, chipped, in half a pint of boiling water, and straining.
In hyleria, this may be combined with purgatives and
tincture of valerian; in atomic gut, with aromatics; and in
dyspeptic affections, with chalybes, sulphate of zinc, or
mineral acids. The dose is from f3j to f3ij, given twice or
thrice a day. The tincture is prepared by digesting for
seven days an ounce of chips of quassia-wood in two pints
of proof spirit; and then straining. This may be used in
the famous cafes as the infusion.

It is asserted that the brewers have, of late years, used
quassia-wood instead of hops. Beer made with it certainly
does not keep, says Thomson, but soon becomes muddy and
flat, has a mawkish taste, and runs into the aceto fer-
mentation. It is consequently less nutritious and wholesome
than which is properly hopped. Wood. Mat. Med.
Thomson’s Lond. Diph.

QUASSIA Simaruba. See SIMARUBA.

QUATCHEOU, in Geography, a town of Asia, in
the country of Hami; 30 miles E. of Tche-tcheou. N. lat.
40° 28’. E. long. 94° 27’.

QUATER-COUSINS, QUATRE-COUSINS, fourth cou-
sins, or the 4th degree of kindred.

Hence, when parents are at variance, it is said they are
not quater, or cater-cousins.

QUATERNIA FOlia, among Botanists. See LEAF.

QUATO, in Zoology. See StOMA PeniSULa.

QUATORZIEME, Fr., the 14th, or double octave
of the 7th. It is called the 14th, because 14 sounds must
be formed to pass diatonically from one of its terms to the
other.

QUATOTOMOMI, in Ornithology, the name of an
American bird of the wood-pecker kind, having a red crest
on its head, and two white lines running down the sides of
the neck to the breast. It is called by Nieremberg Pfeif
imbrifetus; which fer.

QUATOZTL. See TANAGRA LecuSOPHalo.

QUATRE FACARDS, Les, in Geography, four small
islands in the South Pacific Ocean, so named by M. Bou-
gainville, in the year 1768. S. lat. 18° 40’. W. long.
140° 30’.

QUATREFOIL, a decoration resembling a rose with
four leaves, which constantly occurs in pointed architec-
ture.

QUATRE-NATIONS, q. d. Four Nations, the de-
nomination of a college founded in 1661, by cardinal Ma-
zarin, for the education and maintenance of sixty children,
Vol. XXIX.

natives of the four countries conquered by Lewis XIV.,
viz. fifteen for Fignerol and Italy, fifteen for Allfattia,
twenty for Flanders, and ten for Rouffillon.

QUATRICROMA, in the Italian Music, is what
we call a demi-femiquaver, thirty-two of which make a bar
in common time. See TUNE, and Triphe.

QUATRO CASE, in Geography, a town of Italy,
in the department of the Mincio; 17 miles S.E. of Mantua.

QUATROS, CORONADOS, Les, an island in the Pacific
ocean, discovered by Quiros in 1606. S. lat. 18° 40’.

QUATTROINO, in Commerce, a copper coin at Flo-
rence; also a money of account, 60 quattrini being equal
to 12 crasi, 1/4 paoli, or 2 lire. At Rome, the feso is
divided into 3/4 tettoni, 500 quattrini, or 1000 mezz quat-
trini; so that 5 quattrini make 1 paolo, and 3 paoli 1 tet-
tone. See SCudo.

QUATUOR, Lat., a name given to any musical com-
position, vocal or instrumental, in four parts, and in
dialogue, or a parte equale, when each have solo parts alter-
nately. The Italians sometime call a quattor quartello, but
more frequently quarto, and the English quarted.

A vocal quartet is a kind of song written for the four
voices; or for the composer to finish, as a trio or
chorus.

In the vocal quartet of a musical drama, four distinc-
characters should be supported both in the words and music,
according to the situation and state of mind of the several
personages who have petitions or complaints to make, or
answers to give.

The instrumental quartets of Haydn have been the de-
light of all that have performed, or heard them performed,
for full 30 years, and bid fair to continue to afford delight
for at least 50 years more.

QUATUOR Principalia Artis Musicæ, the title of a MS.
in the Bodleian library at Oxford (Digby 90.), which has
been ascribed to several authors. Anthony Wood gives it
to Tewkesbury, to whom it is likewise ascribed in the
Oxford Catalogue of MSS., with very little foundation.
Bishop Tanner has honoured Dr. John Hambois with this
production, a writer on music, who flourished more than a
century after this MS. was finished, as appears from the
teftimony of the writer himself.

There is, however, at Oxford, among the MSS. another
volume of Musical Tracts (Bodl. 515.), which had not
been sufficiently examined by any of the catalogographers
who have mentioned it; for, on a careful perusal and collation,
we found in it, besides the other tracts by Simon Tunfled,
or Tullede, a duplicate of the Quatuor Principia; and as
no doubt has been thrown upon Tunfled having been the
author of the two first tracts in the volume, it seems as if
we might venture, without doubt or hesitation, to assign to
him this amply, and, for the time when it was written, ex-
cellent treatise. That Simon Tunfled was a man of
sciences, and an able musician, as well as a doctor of divinity,
appears at the end of MS. Digby 90. After saying that
the book was finished in 1351, we have the following pas-
tage: ‘‘Ille autem anno regnis ear inter minores Oxoniæ
fratres, Simon de Tunfledo, doctor sacrae theologicae, qui in
musica pollebat, et eciam in septem liberalibus artibus.’’
Pits, Bale, Tanner, and all our biographical writers, speak
of him as a learned musician; and Pits enumerates the
Quatuor Principia among his writings. (De illult. Angl.
Script.) Simon Tunfledo, a Franciscan friar, born at Nor-
wich, was in such favour for his learning and piety, as to
be
be unanimously chosen provincial master of all England. He died at Bruzard, in Suffolk, in 1560.

The title of the tracts in the Oxford Catalogue of MSS. has occasioned the great diversity of opinions about the writer of the Quatour Principals; for No. 515 is entitled "De Musicæ continua et discreta, cum Diagramatisbus, per Simonem Tunstede, A.D. 1551." However, in the beginning of the volume, the author proposes to treat "De quatuor Principallis in quibus totius Musicæ radices con- sirunt," &c. which exactly agrees with the other MS.; and there is no difference from the beginning to the end, except in the omission of a kind of preface, or argument to the work, which appears in the tract ascribed to Tewkesbury (Digby 90.), beginning "Quaerammodum inter Tri- timum," and is omitted in that to which the name of Tun- stede is prefixed. Bodl. 515.

What the author calls the "Four Principals of Music," will be a forth from his own manner of dividing the work. In the first part or principal, containing nineteen chapters, he treats of music in general, its constituent parts and divi- sions. II. Of its invention, intervals, and proportions, twenty-four chapters. III. Of plain chant, and the eccle- siastical modes, fifty-eight chapters. IV. Of measured music, or time; of different, and their several divi- sions. This last principal is divided into two sections, of which the first contains forty-one chapters, and the second forty-nine.

The whole treatise fills a hundred and twenty-four folio pages; the diagrams, which are very numerous, are beautifully written, and illuminated with different coloured inks; and it seems to be in all respects the most ample and complete work of the kind which the fourteenth century can boast.

Quatuor Hominis Propositæ. See Propositi.

Quatuor-Vir, in Antiquity, frequently written III. Vir, is a Roman magistrate, who had three colleagues joined with him in the same administration.

To the quatuor-vir was committed the charge of con- ducting and setting the colonies fent into the provinces.

Upon unlucky accidents, and other dangerous affairs, it was usual to create quatuor-vir, with commissio to take care ne quid detrimenti reipublica caperet, that the republic were not prejudiced.

There were also quatuor-vir appointed to inspect and take care of repairs, &c.

Quauchochopitli, in Ornithology. See Picus Tricolor.

Quaver, in Muse, a measure of time, equal to one- half of the crotchet, or one-eighth of the semi-breve.

The quaver is marked by the character

The English quaver makes what the French call croche, crotchet, because of the hook at bottom. See Crotchet.

The quaver is divided into two semiquavers, noted and four demisemiquavers, marked See Characters.

Quavinging, the act of trilling, or shaking; or the running a division with the voice.

Quauhoyuatli, in Botany, a name by which some authors have called the tree, whole fruit is the calyx flutula of the shops. Hern. p. 87.

Quauhcuilui, in Ornithology. See Merops Gen- erus.

Quauhiyoamatli, in Zoology. See Sus Ta- jaffa.
flight walls are a sufficient defence; and in some places, where the rock is inaccessible, no walls are necessary. Here, however, are several redoubts and batteries. The principal battery, which points towards the basin, consists of twenty-two 24-pounders, two French 36-pounders, and two large iron mortars; this battery is flanked by another of fix guns, that commands the pales from the lower town. On the land side the fortifications are stupendous. When general Wolfe attacked this place, he thought it a vain attempt to make an assault on the side of the town which lies towards the water, where the rock is so steep, and so easily defended. In order to carry on the attack on the land side, he first attempted to land his troops some miles below the town, near the Falls of Montmorenci; but here he was repulsed by a large division of the French forces with loss. Foiled in his first attempt to get on shore, the brave Wolfe formed the bold design of ascending to the top of the banks above Quebec, commonly called the Heights of Abraham. After previous preparation, the soldiers clambered up the heights with great difficulty, and the guns were hauled up by means of ropes and pulleys fixed round the trees, with which the banks are covered from top to bottom. At the top the plain commences, and extends close under the walls of the city. Here the memorable battle was fought, in which the much lamented general fell, at the moment when all his noble exertions were about to be crowned with the successes which they so eminently merited. The spot where the illustrious hero breathed his last is marked with a large stone, on which a true meridional line is drawn. Although the great Wolfe found it so difficult a task to gain possession of Quebec, and it has been rendered much stronger since his time, the people of the United States imagine, that, in case of a rupture with Great Britain, it might be easily taken; and yet at the close of the year 1775, and the commencement of 1776, an attempt was made by American troops, under the command of Arnold and Montgomery, without success. On this occasion Montgomery fell, and Arnold's attempt, on the practicability and success of which he had previously boasted, proved fruitless. St. John's gate, which he endeavoured to force, and the adjoining walls, are stupendous; and the mere sight of them may convince any person, that an attempt to storm them must be altogether ineffectual, without the aid of heavy artillery, with which the Americans were not provided.

Independently of its fortifications, and situation on the summit of a rock, Quebec owes much of its strength and security to the long duration and extreme severity of the winter; as in that season it is wholly impracticable for a besieging army either to carry on any works, or to blockade the town. Mr. Weld says, that 5000 soldiers are necessary to man the works at Quebec completely. A large garrison is always kept in it, and abundance of stores of every description. The troops are lodged partly in barracks, partly in block-houses near Cape Diamond, which is the most elevated part of the point, and is reckoned to be upwards of 1000 feet above the level of the river. The Cape is strongly fortified, and may be considered as the citadel of Quebec; it commands the town in every direction, and also the plains on the outside of the walls. The evening and morning guns, and all falutes and signals, are fired from hence. Notwithstanding the great height of the rock above the river, water may be readily obtained even at the very top of it, by sinking wells of a moderate depth; and in some particular places, at the sides of the rock, it gushes out in large streams; and the water is of a very good quality. It is supposed, says Mr. Weld, that including the upper and lower towns and suburbs, there are at least 2000 dwellings; and the number of inhabitants, allowing six to a house, may be estimated at 12,000. Mr. Heriot says, that, in 1806, the number of inhabitants amounted to 15,000; and if this statement be correct, the increase must have been very rapid, for, in the year 1784, Quebec contained only 6472 inhabitants. About two-thirds of the inhabitants are of French extraction. The society is agreeable, and very extensive for a place of its size, which is owing to its being the capital of the lower province, and therefore the residence of the governor, different civil officers, principal lawyers, &c. The large garrison always maintained in it contributes to make it gay and lively.

The lower town is mostly inhabited by the traders who are concerned with the shipping, and it is a very disagreeable place. The streets are narrow and dirty, and, on account of the height of the houses in most of them, the air is much confined; and in the streets next the water, there is an intolerable stench from the shore when the tide is out. The upper town, on the contrary, is extremely agreeable; from its elevated situation, the air is very pure, and the inhabitants are never oppressed with heat in summer; it is, however, far from being laid out, the streets being narrow and very irregular. The houses are generally built of stone, and, except some few, built of late years, small and inconvenient. The chateau, in which the governor resides, is a plain building of common stone, situated in an open place, the houses round which form three sides of a oblong square. It consists of two parts. The old and the new are separated from each other by a spacious court. The former stands just on the verge of an inaccessible part of the rock; behind it, on the outside, there is a long gallery, from whence, if a pebble were let drop, it would fall at least sixty feet perpendicularly. This old part is chiefly taken up with the public offices, and all the apartments in it are small and ill contrived; but in the new part, which stands in front of the other, facing the square, they are spacious, and tolerably well finished, but none of them can be called elegant. This part is inhabited by the governor's family. The chateau is built without any regularity of design, neither the old nor the new part having even an uniform front. It is not a place of strength, as commonly represented. In the garden adjoining to it is merely a parapet wall along the edge of the rock, with embrasures, in which a few small guns are planted, commanding a part of the lower town. Every evening during summer, when the weather is fine, one of the regiments of the garrison parades in the open place before the chateau, and the band plays for an hour or two, at which time the place becomes the resort of numbers of the most genteel people of the town, and has a very gay appearance.

Opposite to the chateau there is a monastery belonging to the Recollets, or Franciscan friars; a very few only of the order are now left. Contiguous to this building is the college belonging to the Jesuits, whose numbers have diminished even still farther than that of the Recollets. The nunneries are three in number, and as there is no restriction upon the female religious orders, they are all well filled. The largest of them, called L'Hopital General, stands in the suburbs, outside of the walls; another, of the order of St. Ursule, is not far distant from the chateau.

The engineer's drawing-room, in which is kept a variety of models, together with plans of the fortifications of Quebec and other fortresses in Canada, is an old building, near the principal battery. Adjoining to it stands the
house where the legislative council and assembly of representatives meet, which is also an old building, that has been plainly fitted up to accommodate the legislature.

The armory is situated near the artillery barracks, in another part of the town. About ten thousand stand of arms are kept in it, arranged in a similar manner with the arms in the Tower of London, but, if possible, with greater neatness and more fancy.

The artillery barracks are capable of containing about five hundred men, but the principal barracks are calculated to contain a much larger number; they stand in the marketplace, not far distant from the square in which the chateau is situated, but more in the heart of the town.

The market of Quebec is extremely well supplied with provisions of every kind, which may be purchased at a much more moderate price than in any town visited by Mr. Weld in the United States. It is a matter of curiosity to a stranger to see the number of dogs yoked in little carts, that are brought into this market by the people who attend it. The Canadian dogs are found extremely useful in drawing burthens, and there is scarcely a family in Quebec or Montreal, that does not keep one or more of them for that purpose. They are somewhat similar to the Newfoundland breed, but broader across the loins, and have shorter and thicker legs; in general they are handsome, and wonderfull docile and fagacious; their strength is prodigious. A single dog will draw a man for a considerable distance, that could not weigh less than ten stone. People, during the winter season, frequently perform long journeys on the snow with half a dozen or more of these animals yoked in a cariole or sledge.

An attempt was made in 1711 by the English and Americans, under the command of brigadier Hill, to surprize Quebec; but it proved abortive. In 1759 it was taken by the English, under the command of the valiant Wolfe, who sacrificed his life in the engagement; and by the peace, in 1763, it was ceded, with the rest of Canada, to the conquerors, in whose possession it has since continued.

The scenery that is exhibited to the view from various parts of the upper town of Quebec, surpasses for grandeur, beauty, and fertility, any other, as Mr. Weld says, that he has seen, either in America, or in any other part of the globe. In the variegated expanses that is laid open before you, stupendous rocks, immense rivers, trackless forests, and cultivated plains, mountains, lakes, towns, and villages, in turn strike the attention, and the senses are almost bewildered in contemplating the vastness of the scene. Nature is here seen on the grandest scale; and it is scarcely possible for the imagination to paint to itself anything more sublime than are the several prospects presented to the sight of the delighted spectator. From Cape Diamond, situated one thousand feet above the level of the river, and the loftiest part of the rock on which the city is built, the prospect is considered by many as superior to that of any other spot. A greater extent of country opens upon you, and the eye is here enabled to take in more at once, than at any other place; but it appeared to Mr. Weld, that the view from the cape is by no means so fine as that, for instance, from the battery; for in surveying the different objects below you from such a stupendous height, their magnitude is in a great measure lost, and it seems as if you were looking at a draft of the country, more than at the country itself. It is the upper battery that Mr. Weld alludes to, facing the bafoon, and is about three hundred feet above the level of the water. Here, if you stand but a few yards from the edge of the precipice, you may look down at once upon the river, the vessels upon which, as they fall up to the wharfs before the lower town, appear as if they were coming under your very feet. The river itself, which is between five and six miles wide, and visible as far as the distant end of the island of Orleans, where it loses itself amidst the mountains that bound it on each side, is one of the most beautiful objects in nature, and on a fine still summer's evening it often wears the appearance of a vast mirror, where the varied rich tints of the sky, as well as the images of the different objects of the banks, are seen reflected with inconceivable lustre. The southern bank of the river, indented fancifully with bays and promontories, remains nearly in a state of nature, clothed with lofty trees; but the opposite shore is thickly covered with houfes, extending as along other parts of the river already mentioned, in one uninterrupted village, seemingly, as far as the eye can reach. On this side the prospect is terminated by an extensive range of mountains, the flat lands situated between and the villages on the banks not being visible to a spectator at Quebec, it seems as if the mountains rose directly out of the water, and the houfes were built on their steep and rugged sides.

Beautiful as the environs of the city appear when seen at a distance, they do not appear less on a more close inspection; and in passing through them the eye is entertained with a most pleasing variety of fine landscapes, whilst the mind is equally gratified with the appearance of content and happiness that reigns in the countenances of the inhabitants. Indeed, if a country as fruitful as it is picturesque, a genial and healthy climate, and a tolerable share of civil and religious liberty, can make people happy, none ought to appear less so than the Canadians. There are, however, in the vicinity of Canada two scenes, more particularly deserving of attention than any others: these are the falls or cataracts of the rivers Chaudiere and Montmorency; which see respectively. N. lat. 46° 48' 38", W. long. 71° 4' 29". Weld's Travels, vol. i.

QUEBITEA, in Botany, a name which seems to have been whimsically extracted by Aublet, from the Caribbean appellation of this plant, Dugueojabe. Aubl. Guian. v. 2. 838. t. 327. This has many creeping roots, and a twilled, decumbent, hairy stem, with alternate, elliptical, broad, entire, hairy leaves, three or four inches long, on hairy footstalks. Flowers minute, in short, dense, axillary, stalked filialae, with a small sepal at the base of the stalks. Aublet did not investigate the structure of these flowers, but he supposes the plant to be nearly akin to Dracemum, under which genus it is accordingly noticed by Jussieu. The roots, when chewed, are very acrid. The bruised herb is used externally, to cure the bite of serpents. It grows on the banks of rivulets in Guiana.

QUEBRANTAHUESOS, in Ornithology. See Proc.

QUECALA, in Geography, a town of Mexico, in the province of Mechoacan; 105 miles S.S.E. of St. Luis de Potosí.

QUECHUA, in Literary History. See Peru.

QUEDA, a sea-port city on the W. coast of the peninsula of Malacca, the capital of a kingdom, tributary to Siam, with a good harbour at the mouth of a river that will admit a vessel drawing 12 or 14 foot water on the spargle over the bar, which is gravel and mud. The town contains about 4000 houfes, inhabited by Chinese and Malays. The environs are agreeable and fertile; the woods abound in elephants and other animals, and in some places are mines of lead, which supply large quantities of these metals for exportation to Hindoostan, Arabia, and Perâ. The go
venom is monarchical, under a Malay Mahomedan prince, who, like many other Malay princes, engrosses almost the whole foreign trade of the port, excepting that of an annual Chinese junk, which pays a certain sum only as duty, and then has leave to trade freely with the inhabitants. This junk imports immense quantities of coarce China-ware, thin iron pipes, and many other articles from that country, and exports biche de mer, called swallow, sharks’ fins, edible bird’s nests, rattans, tin, rice, dammer, tortoise-shell, deer’s skins and finews, bullocks and buffalos’ hides and horns, jerked beef, and many other coarse articles. At Queda there is great plenty of rice, bullocks, buffalos, and poultry; but not such abundance of fruit and vegetables as at Acheen. The territory of Queda is a flat country, favourable for the cultivation of rice; a hill north of the town and inland, called the Elephant, favours the navigator’s approach; also the small islands called Peers, 20 miles west of the bar, covered with trees, and good regular mudfoundings, a great way off, even by night, indicate the distance to the mariner; 300 miles E.N.E. of Acheen. N. lat. 6° 20’. E. long. 100° 18’.

QUEDENAU, a town of Prussia, in Samland; three miles N. of Königsberg.

QUEDLINBURG, a town of Weiphalia, in the principality of Halberstadt, on the Boda, which divides it into the Old and New Towns. It has several churches, a hospital, and a college. Near this town is a princely abbey, situated on a hill: it was founded by King Henry I. between the years 932 and 936, and since enriched by various endowments. In 1539 it embraced Lutheranism, and obliged itself, by solemn oaths, to maintain that form of religion. It latterly confided of four dignitaries, viz. of the lady abbots and three others, distinguished by the titles of provost, dean, and canon. In 1802, the abbey and its revenues were voted to the king of Prussia, as an indemnity; and by the treaty of Tilsit, transferred to the kingdom of Weiphalia. The town of Quedlinburg is seven miles S.S.E. of Halberstadt. N. lat. 51° 48’. E. long. 11° 20’.

QUEDLITZ, a town of Prussia, in the province of Ermeland; four miles S. of Wartenburg.

QUECE, in Agriculture, a term sometimes provincially applied to the wood-pigeon, or birds of that kind.

QUEECHY, in Geography, a river of Vermont, which runs into the Connecticut at Hartford.

QUEEN, REGINA, a woman who holds the crown of a realm singly, and by right of blood.

The word queen is derived from the Saxon word, uxor, the wife of any one, but applied, by way of excellence, to the wife of the king only; whence she was anciently called the king’s queen; the West Saxons having no other name for a queen but the king’s wife. (Aélis Ælfréd, rebus, &c.) She was also called lady, in Saxon coelebys, just as madame, mademoiselle, were used in France, for the wife and daughter of the duke of Orleans.

The name queen is also given, by way of courtesy, to her that is married to the king; called, by way of distinction, queen consort. In respect of whom the former is called queen regnant, or regent.

The widow of a king is also called queen, but with the addition of dowager.

In the first sense, queen is, in all construction, the name with king; and has the same powers, prerogatives, rights, dignities, and duties that the king has. This is expressly declared by statute 1 Mar. I. r. 3. c. 1.

The queen consort is inferior, and a person distinct from, and a subject of, the king. In England, though she be a feme-covert, yet may she sue, and be sued, in her own name; and may make leaves, and grants, &c. as a femme.

She has several other prerogatives. Though an alien, she may purchase lands in fee-simple, without either naturalization, or denization; she may present to a benefice; nor is plenary a bar against her more than against the king. She is also capable of taking a grant from the king, which no other wife can do from her husband; and she may have a separate property in goods as well as lands, and has a right to dispose of them by will. She pays no toll, and shall not be amerced, if she be non-suited in any action; and may not be implored till first petitioned.

To confine her death, or violate her chastity, is high treason. She has an ancient pecuniary revenue, called queen-gold; besides a very large dower, with a royal court, and officers, distinct from the king’s; and her attorney and solicitor-general are entitled to a place within the bar of his majesty’s courts, together with the king’s counsel.

Another ancient perquisite belonging to the queen comfort, mentioned by all our old writers, and, on this account only, worthy of notice, is this, that on the taking of a whale on the coasts, which is a royal fish, it shall be divided between the king and queen; the head only being the king’s property, and the tail of it the queen’s. One reason of this whimsical division, as ascribed by our ancient records, was to furnish the queen’s wardrobe with whalebone.

The queen dowager, as the widow of the king, enjoys most of the privileges belonging to her as queen comfort. But it is not high treason to confine her death; or to violate her chastity, because the succession to the crown is not thereby endangered. Yet still, pro dignitate regali, no man can marry a queen dowager without special licence from the king, on pain of forfeiting his lands and goods. She has also this particular, that she loses not her dignity, though she marry a private gentleman; as peers and dowers do their peers, when they marry commoners. Thus queen Catherine, widow of Henry VII. being married to Owen ap Tudor, esq. maintained an action as queen of England. Much less does a queen regnant follow her husband’s condition, or is subject to other queens; but she is sovereign to her own husband, as queen Mary was to king Philip, and queen Anne to prince George of Denmark; unless it be otherwife appointed by parliament. The husband may be guilty of high treason against her; but in the instance of conjugal infidelity, he is not subject to the same penal restrictions. For which the reason seems to be, that if a queen comfort is unfaithful to the royal bed, this may debaue or bale around the heirs to the crown; but no such danger can be conphenent in the infidelity of a husband to a queen regnant.

QUEEN CAROLINE, in Biography, when princes of Wales, is told in the dedication of the opera of Julius Cesar to her royal highness, that the first musical sounds which her highness heard, were those produced by the voice of the celebrated Pitocci, the father of good taste, then in the service of his illustrious fire, at the court of Anpach.

Music doubtless was a ferious part of her majesty’s education, as it is, and has ever been, of all the princes and princesses of Germany; who have likewise frequent opportunities of hearing great performers and splendid performances; yet we do not recollect having heard that her majesty was a performer herself, or even an admirer or patron of the art. This princess died in November 1737.

QUEEN MARY. (See MARY.) During the short reign of this bigoted and intolerant princes, ecclesiastical music was again
QUE

again transferred to Latin words and the mafs, both of
which had been excommunicated during the reign of
her brother, Edward VI. But metrical psalmody had not yet
been generally received in our parochial churches. Mary
was herself a performer on the virginal and lute, as appears
by a letter sent to her by her mother, queen Katherine,
after her separation from the king, in which she encour-
ges her to fulfill cheerfully, to trutl to God, and keep her
heart clean. She charged her in all things to obey the
king's commands, except in matters of religion. She sent
her two Latin books, the one De Vita Chrifiit, and the
other the Epiftles of St. Jerome; in them, (fays the
queen,) I truft you shall fee good things. And sometimes,
for your recreation, ufe your virginals or lute, if you have
any."

Fuller tells us, that "eight weeks and upwards paffed
between the proclaiming of queen Mary and her anfembling
the parliament; during which time two religions were
of{er together yet on foot, Protestantifme and Poperie; the former
hoping to be continued, the latter labouring to be reformed;
—and during this interim the churches and chapels in Eng-
land had a mongrel celebration of their divine services be-
twixt reformation and fuperition. For the oleques for
king Edward were held by the queen in the Tower,
August 7th, 1553, with the dirige fong in Latin, and on
the morrow a maffe of requiem, and on the fame day his
(ores were buried at Westminifter with a femon fervice,
and communion in Englih."

In October following the laws of her predecessor, Ed-
ward, concerning religion, were all repealed. And in
November 1554, bishop Bonner "let up the old worship
at Paul's, on St. Katherine's day; and it being the fucum,
that on fome holydays, the queire went up to the fleeple to
fing the anthems, that fell on that night —and the next
day, being St. Andrew's, he did officiate himfelf, and had
(a folemn procefsion.)"

After this period, during the fubfequent years of Mary's
reign, the public fervice was every where performed in the
Roman Catholic manner, throughout the kingdom; and
we may imagine that the numerous comifions to Latin
words, which have been preferved of Dr. Tye, White, Tallif,
Bird, and the reft of our moft eminent harmoniifts, were
produced, and performed at that time, while the Romih
religion had the effeciant. And indeed it appears by a
record, now in the pofeifion of the Antiquarian Society,
that the lift of Mary's chapel efhablishment contains nearly
the fame names as that of her brother Edward.

QUEEN ELIZABETH. (See Elizabeth.) In speaking of
music during the long and prosperous reign of queen
Elizabeth, our nation's honour seems to require a more dif-
fufe detail than at any other time: for perhaps we never had
fo jufi a claim to equality with the reft of Europe, where
music was the moft successfully cultivated, as at this period;
when indeed there was but little melody anywhere. Yet,
with refpect to harmony, canon, fugue, and fuch laboured
and learned contrivances as were then chiefly studied and
admired, we can produce fuch proofs of great abilities in
the comifions of our countrymen, as candid judges of
their merit muft allow to abound in every kind of excel-
ience that was then known or expected.

Elizabeth, as well as the reft of Henry VIII.'s children,
and indeed all the princes of Europe at that time, had been
taught music early in life. For Camden, in giving an ac-
count of her fludies, says, that "she underftood well the
Latin, French, and Italian tongues, and (was) indifferently
well fen in the Greek. Neither did she neglect muftic,
so far forfcbe as might become a princefle, being able to fing
and play on the lute prettily and sweetly."

There is reafon to conclude, that she continued to amufe
herself with music many years after she acceded the throne.
Sir James Melvil gives an account of a curious converfation
which he had with this princes, to whom he was fent on
an embafly by Mary, queen of Scots, in 1564. After her
majefly had alked him how his queen dreffed? What was
the colour of her hair? Whether that or her's was bell? Of
which of them two was fairest? And which of them was
highcliff in figure? "Then she alked, what kind of ex-
erces the ufed?" I anfwered, fays Melvil, "that when
I received my dispatch, the queen was lately come from the
Highland hunting: that when her more ferior affairs per-
mitted, she was taken up with reading of histories; that
fometimes she recreated herfelf in playing upon the lute and
virginals. She alked if the played well? I faid, reafo-
nably for a queen."

"The fame day, after dinner, my lord of Hunfden drew
me up to a quiet gallery, that I might hear fome music,
(but he faid, that he durft not avow it,) where I might
hear the queen play upon her virginals. After I had
hearkened a while, I took by the taffet that hung before
the door of the chamber, and feeing her back was toward
the door, I entered within the chamber, and ftood in a pretty
fpace hearing her play exceflently well. But the left off
immediately, fo soon as she turned about and faw me. She
appeared to be burpried to fee me, and came forward,
feeming to strike me with her hand; alleging, the ufed
not to play before men, but when she was foltary, to fheen
melancholy. She alked how I came there? I anfwered,
as I was walking with my lord Hunfden, as we paffed
by the chamber door, I heard fuch a melody as ravifhed me,
whereby I was drawn in ere I knew how; excufing my
fault of homeliefs, as being brought up in the court of
France, where fuch freedom was allowed; declaring myfelf
willing to endure what kind of punishment her majefly
Should be pleafed to inflict upon me for fo great offence.
Then she fate down low upon a cufhion, and I upon
my knees by her; but with her own hand she gave me a cufhion,
to lay under my knee; which at fift I refufed, but the
compelled me to take it. She enquired whether my queen
or fhe played belt. In that I found myfelf obliged to
give her the prafe."

If her majefly was ever able to execute any of the pieces
that are preferved in a MS. which goes under the name of
"Queen Elizabeth's Virginal Book," the muft have been
a very great player: as fome of these pieces, which were
compofed by Tallis, Bird, Giles, Farnaby, Dr. Bull, and
others, are fo difticult, that it would be hardly poiffible to
find a master in Europe, who would undertake to play one
of them at the end of a month's practice.

Besides the lute and virginals, Elizabeth was a performer
on the viol and on an instrument something like a lute,
but stringed with wire, and called the palpham. A violin
of a fingular conftuction, with the arms of England, and
the crest of Dudley, earl of Leicelteer, this queen's favourite,
engraved upon it, was purchaffed at the fale of the late
duke of Dorfet's effects. The date of its make, 1578. It
is very curiously carved; but the leveral parts fere fo thick
and loaded with ornaments, that it has not more tone
than a mute, or viol in a fordine; and the neck, which is
too thick for the grip of the hand, has a hole cut in it
for the thumb of the player, by which the hand is fo con-
ined, as to be rendered incapable of shifting: fo that no-
thing can be performed upon this inftrument, but what lies
within the reach of the hand in its firft position. Playford
tells
tells us, that “Queen Elizabeth was not only a lover of this divine science (music), but a good proficient therein; and I have been informed, (says he;) by an ancient musician, and her servant, that she did often recreate herself on an excellent instrument, called the poliphant, not much unlike a lute, but flinging with wire.”

Among the Sloane MSS. in the British Museum, No 1520, there is a list of the officers of the court of revenue in this reign; in which is included the musical establishment of her majesty’s household, about the year 1587.

Her majesty’s chapel establishment was nearly the same, in number and salaries, as that of her brother and father, Edward and Mary. Indeed, it seems as if the religious scruples of musicians had been considerably diminished by the severity with which Tellwood had been treated in the time of Henry VIII., and the peril into which Marbeck’s zeal for reformation had involved him. For in comparing the chapel establishments of Edward, Mary, and Elizabeth, we find, that however the creeds of these monarchs differed, their musicians had constantly tuned their confidences to the court pitch: i.e. in perfect union with the orders of their sovereign, the supreme head of the church.

Cameron says, that “the Romish religion remained a full moneth and more after the death of queen Mary, in the same state as before.” For Elizabeth, who began her reign November 17th, 1558, had a solemn service performed for her lady Mary at Weftminder, December 5th, and another December 25th, for the emperor Charles V.; and thefe, as well as her own coronation, were celebrated in the Romish manner.

Burnet says, that “Elizabeth had been bred up from her infancy with a hatred of the Papacy, and a love to the Reformation; but yet as her first impressions in her father’s reign were in favour of such old rites as he had still retained; so in her own nature she loved flate, and some magnificence, in religion as well as in every thing else.”

We have no other music printed expressly for the cathedral service to English words during the reign of Edward VI. than that of Marbeck, which was mere canto fermo, without counterpoint; but the year after the publication of the English Liturgy, by queen Elizabeth, the following choral work appeared: “Erturne nos,” in two and three parts, to be sung at the Morning Communion, and Evening Prayer; very necessary for the Church of Christ to be frequented and used; and unto them be added divers Psalmes and Hymnes, in the like form, to the honour and praise of God. Printed at London, under Artillery-gate, beneath St. Dunstane, by John Day, 1566.” The authors of these compositions were Tallis, Cavilton, John- son, Oakland, Shepherd, and Taverner.

In 1565, our ecclesiastical composers, encouraged probably by the reception of the former publication, and favour of the queen, printed another collection of offices, with musical notes, under the following title: “Morning and Evening Prayer and Communion, set forth in four parts, to be sung in Churches, both for Men and Children, with hyms and other Holy Prayers and Antiphons, of sundry Modern Voyage.”

The musicians who contributed to this collection were Thomas Cavilton, Heath, Robert Hasleton Knight, John- son, Tallis, Oakland, and Shepherd.

Thefe two publications by John Day, fixed, for near a century, the style of our choral music; of which the movement was grave, the harmony grateful, and the contrivance frequently ingenious.

The great musicians of queen Elizabeth’s reign were Dr. Tye, John White, Thomas Tallis, William Bird, Dr. Bull, and Thomas Morley. And these, as ecclesiastical composers, were perhaps equal in learning and genius to the greatest contemporary contrapuntists on the continent of Europe.

We must not terminate our account of the cultivation and progress of music by queen Elizabeth and her subjects, without making honourable mention of her majesty’s “Virginal Book,” and referring for a summary account of its contents to Bird, William. In all our enquiries after musical curiosities throughout Europe, we have met with no pieces so elaborate and difficult for the harpsichord, as those by our ingenious countrymen.

This book, equally valuable for its antiquity and contents, was purchased at Brenner at Dr. Pepusch’s sale, 1762, whose property it was to the time of his death. After which it passed into the hands of vifcount Fitzwilliams, in whose possession, we believe, it still continues.

It is a magnificent folio MS. curiously bound in red Morocco, with gilt leaves. There are nearly 70 pieces by Dr. Bull in this volume. The writing is small, but uncommonly neat, upon fine lines. The compositions are in general extremely elaborate and difficult; particularly those by Bird, Dr. Bull, and Giles Farnabie, who have all contributed largely to the furnishing of this volume, which contains near three hundred pieces. The first movement in the book is an old English tune, called “Wallingham,” beginning in C natural, and ending in A major, which Dr. Bull has varied in a most full and complicated style, thirty different ways. Signora Margarita, the wife of Dr. Pe- pusch, when she quitted the Opera stage, applied closely to the practice of the harpsichord; upon which instrument she became a great proficient. However, with all her own diligence and talents, affified by the science and experience of
of her husband, she was never able to vanquish the difficulties of this piece, by Dr. Bull. And several of Dr. Pepusch's friends and pupils, who went frequently to his apartments at the Charter-house, have allied us, that though this manuscript was constantly open upon her harpichord desk, she never advanced to the end of the variations; as seems likewise manifest from the colour, as well as wear and tear, of the leaves, which are much more clean and entire in every other part of the book, than at the first strains of this composition.

Queen Mary II. joint sovereign with William III., seems to have done little more for music, than patronize Mrs. Arbabella Hunt, and the old Scots tune of "Cold and raw the wind doth blow." See Mary.

Queen Anne, in Geography, a poll-town of America, in Prince George county, Maryland, situated on the W. side of Patuxent river, across which is a wooden bridge. This small town is laid out on a regular plan, at the foot of a hill. It contains a few stores, and warehouses for the inspection of tobacco; 25 miles E.N.E. of Washington.

Queen Anne's, a county of Maryland, bounded W. by Cheapeake bay, and N. by Kent county; containing 16,648 inhabitants. Its chief town is Centerville. Belonging to this county is Kent island, 14 miles long from N. to S. and 5½ broad from E. to W. It is low, but the land is fertile, and its eastern side is bordered with salt marsh.

Queen Catherine's Foreland, the northernmost point of Terra del Fuego, at the east entrance into the straits of Magellan, discovered by Frobisher in 1576.

Queen Charlotte's Portland, the S.E. extremity of New Caledonia. N. lat. 22° 15'. E. long. 165° 14'.—Also, the S.W. point of New Hanover, in the East Indian sea, fo called in 1767 by Capt. Carteret. The land about it is remarkable for a number of little hummocks, or hills. S. lat. 2° 29'. E. long. 148° 27'.

Queen Charlotte's Island, an island in the Pacific ocean, about six miles long, and one broad, discovered in the year 1767, by Captain Wallis. It is described as sandy and level, full of trees, without underwood, and abounding with scurvy-grass. The coves of this island appeared to be about 30 feet long, 4 feet broad, and 3½ deep. The inhabitants were of a middle stature, and dark complexion, with long black hair, hanging loose over their shoulders. The men were well made, and the women handsome. Their garments were a kind of coarse matting, fastened about their middle, and capable of being brought round their shoulders. The men who landed saw no appearance of any kind of metal, but observed several tools made of shells and stones, sharpened and fitted into handles, like adzes, chisels, and awls. They had several repositories of the dead, in which bodies were left to putrefy, under canopies, and not deposited in the ground. The island was taken possession of by Captain Wallis and his crew, in the name of his Britannic majesty. They also left some hatchets, nails, glass bottles, beads, shellings, oxharness, and half-pence, as presents to the natives. S. lat. 19° 18'. W. long. 135° 4'.

Queen Charlotte's Islands, a group of islands, discovered in 1767 by Capt. Carteret, conflicting of Egeomt's island or New Guernfey, Lord Howe's island or New Jersey, and several others. A quarrel having occurred in consequence of the imprudent conduct of the master of Capt. Carteret's ship, between the crew and the natives, several of the latter were killed, and four of the former died in consequence of their wounds. This unfortunate event prevented any intercourse with the inhabitants of these islands. Egeomt island, says Capt. Carteret, who called it by this name in honour of the earl, is the same with the Santa Cruz of the Spaniards; and the place in which the ship had lain he called Swallow bay; about ten miles W. from this bay is a small island, near the coast, called Portland's island; and to the bay farther west, where the ship's cutter had been attacked by the Indians, he gave the name of Bloody bay. In this bay is a small rivulet of fresh water, and here were seen many hoves, and near the water-side, one much longer than any of the rest, which seemed to be of a kind of common hall, or council-house, and was neatly built and thatched. The hives and the floor of this edifice were covered with a kind of fine matting, and bundles of arrows were hung up in it ready for use. At this place there were also many fine gardens and plantations, included by a fence of stone, and planted with cocoa-nut trees, bananas, plantains, yams, and other vegetables. About three miles W. of this town was another of considerable extent, in the front of which, near the water, was a breast-work of stone, about four feet six inches high, angularly formed like a fortification; from which, and from other circumstances, there is reason to believe that the natives have frequent wars among themselves. At the distance of two or three miles farther westward was found a small bright, receiving a river, which was called Granville's river, and westward of it is a point, to which was given the name of Ferrar's point. From this point the land forms a large bay, near which is a town of great extent, and apparently very populous. About seven miles W. of Ferrar's point is another, that was called Carteret's point, from which a reef of rocks, that appears above water, runs out to the distance of about a cable's length. To the W. of this was another large town, fronted like the last, and the people who resided to the beach while the ship was passing, performed the same kind of circular dance with those of the former place. They were furnished with a number of canoes of different sizes. The inhabitants of Egeomt island are extremely nimble, vigorous, and active, and seem as well qualified to live on the water as on the land, for they were in and out of their canoes almost every minute. With their bows and arrows they do execution at an incredible distance. Their arrows were pointed with flint, nor was there seen among them any appearance of metal. The country, in general, is woody and mountainous, intersected with many valleys; several small rivers flow from the interior part of the country into the sea, and upon the coast there are many harbours. S. lat. 29° 30' to 11° 20'. E. long. 163° 30' to 165° 10'.

Hawkesworth's Voyages, vol. i. p. 349, &c.

Queen Charlotte's Islands, called by Capt. Gray, of the United States, who visited them in 1789, and by American navigators, "Washington islands," a group of islands on the N.W. coast of America. See Queen Charlotte's Island.

Queen Charlotte's Sound. See Queen Charlotte's Sound. Mr. Anderdon, who visited this island four times, has made the following remarks on the country near it. The land is every where uncommonly mountainous, rising immediately from the sea into large hills, with blunted tops. At considerable distances are valleys, or rather impoundments on the sides of the hills, which are not deep, each terminating towards the sea in a small cove, with a pebbly or sandy beach, behind which are small flats, where the natives generally build their huts, at the same time landing their canoes upon the beaches. The bases of these mountains, at least towards the shore, are constricted of a brittle, yellowish sandstone, which acquires a bluish cast, where the sea washes upon it. It runs, in some places, in horizontal, and, at other places, in oblique strata; being frequently divided, at small distances, by thin veins of coarse quartz. The mould, or foil, which covers this, is of a yellowish cast, not unlike marle, and is commonly
commonly from a foot to two or more in thickness. The quality of this soil is best indicated by the luxuriant growth of its productions: the hills being one continued forest of trees, owing the strength of their vegetation partly to the soil, and partly also to the agreeable temperature of the climate. In February, corresponding to our August, the thermometer was not higher than 66°; and in June, corresponding to our December, the mercury never fell lower than 48°. The weather is, in general, good; but sometimes windy, with heavy rain, which, however, never lasts above a day; nor is it ever excessive. Among the trees, which covered the hills, and which are of two sorts, one supplied the place of spruce in making beer, for which purpose a strong decoction of its leaves was fermented with treacle or sugar. The other fort of tree resembled a maple, and its wood served for fuel. On the small flat spots behind there is a great variety of trees. Among other plants that were useful, may be reckoned the wild celery, which grows plentifully almost in every cove, and one that was called icurry-grass, though very different from the plant to which we give that name. Both forts were boiled every morning, with wheat ground in a mill, and with portable foup for the people's breakfast, and amongst their peafl-foup for dinner. Sometimes they were used as fallad, or drefled as greens. There is another plant, which produces a fine flaky flux, of which the natives make their garments. A species of long pepper is also found in great plenty. The birds are almost entirely peculiar to the place. The principal fish caught with the feine were mullets and elephant-fish, with a few foles and flounders; but those which the natives mostly supplied were a fort of sea-bream, of a silver colour, with a black spot on the neck, large conger- eels, and a fih in shape like the bream, but so large as to weigh five, fix, or seven pounds, and called *Mogge* by the natives. Of all the forts of fish, which are here numerous, the mogge, small falamon, and colour fih, as the feamen called them, though different from ours, are superior to the rest. The rocks furnish a great variety of shell-fih. Infects are very rare. In this extensive land there are not even traces of any quadruped, excepting only a few rants, and a fort of fox-dog, which is a domestic animal with the natives. Neither is there any mineral worth notice, but a green jasper or ferpent-tone, of which the New Zealanders make their tools and ornaments.

The natives do not exceed the common stature of Europeans, and, in general, are not so well made. Their colour is of different calls, from a deep black to a yellowish or olive tinge; and their features are also various, some remem- bering Europeans. But in general their faces are round, with their lips full, and also their noses towards the point; though the firt are not uncommonly thick, nor the last flat. Their teeth are generally broad, white, and well set; and their eyes large, with a very free motion, which seems the effect of habit; their hair is black, ftrait, and frong; commonly cut short on the hind part, with the raft tied on the crown of the head; but some have it curling, and of a brown colour. In the young, the countenance is generally free or open; but in many of the men it has a serious ffair, and sometimes a fulleness or referve, especially if they are strangers. The women are in general smaller than the men; but have few peculiar graces. The drefs of both sexes is alike; and con- fifts of an oblong garment, about five feet long and four broad, and made of the flaky flax before mentioned. This seems to be their moft material and complex manufacture, and is executed by knotting; and their work is often orna- mented with pieces of dog-flax, or chequered at the corners. They bring two corners of this garment over their shoulders, and flant it on the back, with the other part which covers the body; and about the belly it is again tied with a girdle made of mat. Sometimes they cover it with large feathers of birds, (which seem to be wrought into the piece of cloth when it is made,) or with dog-flax; and that alone sometimes worn as a covering. Over this garment many of them wear mats, which reach from their flhoulers to their heels. But the most common outer covering is a quantity of fedge-plant, badly drefled, which they flant on a ftring to a considerable length, and throwing it about the shoudlers, let it fall down on all sides, as far as the middle of the thighs. By way of ornament, they fix in their heads feathers, or combs of bone or wood, adorned with pearl-fhell, or the thin inner fkin of some felf; and in the ears both of men and women, which are pierced, or rather flit, are hung small pieces of Jasper, bits of cloth, or beads, when they can get them. A few also have the ceptum of the nofe bored in the lower part. They wear long beards, but are fond of having them shaved. Some are punctured or flained in the face, with curious spiral and other figures, of a black or deep blue colour; but it is doubtful whether this be ornamental, or intended as a mark of peculiar distifion; and the women who are marked, have the puncture only on their lips, or a small spot on their chins. Both sexes, often fbein their faces and heads with a red paint, which seems to be a martial ochre, mixed with greafe; and the women sometimes wear necklaces of shark's teeth, or bunches of long beads, which fean to be made of the leg-bones of small birds, or a particular fhell. They live in small coves, in companies of forty or fifty, or more; and sometimes in single families, building their huts contigus to each other; which are in general miserable lodging places. The belt was about thirty feet long, sixteen broad, and fix high; built exactly in the manner of an English barn. They fean to have no other furnifhement than a few small fifeletts or bags, in which they put their fiping-hooks and other trifes. They live chiefly by fishing, making use either of nets of different kinds, or of wooden fifeletts, pointed with bone; but fo oddly made, that a stranger would be at a loss to know how they can answer such a purpofe. Their boats are well built of planks, raifed upon each other, and fastened with ftring withes, which also bind a long narrow piece on the outside of the fems, to prevent their leaking. Some are fifty feet long, and fo broad as to be able to fail without an outrigger, but the smaller fort commonly have one; and they often fallen two together by rafters, forming a double canoe. They carry from five to thirty men, or more; and often have a large head, ingeniously carved, and painted with a figure at the point, which fean intended to repreffent a man with his features deforted by rage. Their paddles are about four or five feet long, narrow, and pointed; with which, when they keep time, the boat is pushed along pretty swiftly. Their fail, which is seldom used, is made of a mat of a triangular fhape, leaving the broadeft part above. Their method of feeding corresponds with the naflines of their perfons, which often fmean disagreeably, from the quantity of greafe about them, and their clothes never being washed. We have seen them eat the vermin with which their heads are plentifully flocked. They also used to devour with the greatest eagerness large quantities of flinking train oil, and blubber of fads, which we were melting at the tent, and had kept near two months; and on board the fhips they were not fatisfied with emptying the lamps, but actually swallowed the cotton and fragrant wick with equal voracity. These people manifefl as much ingenuity, both in invention and execution, as any uncivilized nations under similar circumfances. For, without the ufe of any metal tools, they make every thing by which they procure their subsistence, clothing, and warlike weapons,
weapons, with a degree of neatness, strength, and convenience for accomplishing their several purposes. Their chief mechanical tool is formed exactly after the manner of our adzes, and is made, as are also the chisel and gouge, of the Jasper already mentioned, or of a black, smooth, and very fidiite. But their master-piece seems to be carving, which they use for various purposes, even the most trivial. Their substitute for a knife is a shell, a bit of flint or Jasper; and as an anger, they fix a shark's tooth in the end of a small piece of wood. They have also a small saw made of some jagged fishes' teeth, fixed on the convex edge of a piece of wood, nicely carved; but this, they say, is only used to cut up the bodies of their enemies whom they kill in battle. No people have a quicker sense of injury done to them, and none are more ready to refer it. Their temper is sanguinary and irritable; and they are so disinclined, that they steal everything upon which they can lay their hands. Such conduct may be expected, where little subordination exists, and where no man's authority seems to extend further than his own family. Their public contests are frequent, or rather perpetual, and it appears, from their number of weapons, and dexterity in using them, that war is their principal profession. These weapons are spears, patons, and halberts, or sometimes flones. The first are made of hard wood, pointed, from five to twenty, or even thirty feet in length. The short ones are used for throwing as darts. The "patoon," or "emette," is of an elliptical shape, about eighteen inches long, with a handle made of wood, flite, the bones of some fes animal, or green Jasper, and seems to be their principal dependence in battle. The halbert, or long club, is about five or six feet long, tapering at one end with a carved head, and at the other broad or flat, with sharp edges. Before they begin the onset, they join in a war-song, to which they all keep the exact time, and some raise their passion to a degree of frantic fury, attended with the most horrid distortion of their eyes, mouths, and tongues, to strike terror into their enemies: which, to those who have not been accustomed to such a practice, makes them appear more like demons than men, and would almost chill the boldest with fear. To this succeed circumstances, almost foretold in their fierce demeanour, horrid, cruel, and difgraceful to human nature; which is, cutting in pieces, even before they are perfectly dead, the bodies of their enemies, and, after dressing them on a fire, devouring the flesh, not only without reluctance, but with peculiar satisfaction. And yet these savages lament the loss of their friends; with a violence of expression, which indicates the most tender remembrance of them. The children are initiated, at a very early age, into all the practices, good and bad, of their fathers. They not only join in the war-song, but they likewise sing, with some degree of melody, the traditions of their forefathers, their actions in war, and other indifferent subjects; of all which they are immediately fond, and spend much of their time in these amusements, and in playing on a sort of flute. Their language is far from being harsh or disagreeable, though the pronunciation is frequently guttural, and whatever qualities are requisite in any other language to make it musical, certainly obtain to a considerable degree here, if we may judge from the melody of some of their songs. It is also sufficiently comprehensive, though, in many respects, deficient, if compared with our European languages, which owe their perfection to long improvement. Mr. Anderson has given a specimen of it. (Cook's Third Voyage, vol. i.) In the year 1770 Capt. Cook left among the inhabitants a boar and two fows, with some vegetables for cultivation. In 1773 he saw one of the fows, and found that the other and the boar were both living. The sheep and goats did not succeed; the latter having been killed by one of the natives, and the ram having run into the sea.

Queen's, the middle county of Long Island, New York, about 30 miles long, and 12 broad, containing six townships, and 19,236 inhabitants. Jamaica, Newtown, Hempstead, in which is a handsome court-house, and Oyster bay, are the principal towns in this county.

Queen's County, a county of Nova Scotia, comprising a part of the lands on the cape, on the S. side of the bay of Fundy. The settlements are as follow: viz. Argyle, on the S. side of the bay of Fundy, where a few Scots and Arcadians reside: next to this is Yarmouth, settled chiefly by emigrants from New England; Barrington, within the island, called Cape Sable, settled originally by Quakers from Nantucket. Besides these are Port Royal, so called by the French, and originally settled by the North Irish; Liverpool and Rofeway, settled and inhabited by emigrants from New England.

Queen's County, a county of Ireland, established in the reign of the first Mary, which comprehended the old district of Leix. Both the county and chief town, Maryborough, received their names in compliment to the sovereign. It is situated on the S.W. of Kildare, from which it is partly divided by the river Barrow, and is of a very compact form, being 25 Irish (nearly 32 English) miles in length, and as many in breadth. The superficial contents are about 235,300 acres, or 367 square miles, equal to 378,033 acres, or about 590 square miles English. There are 59 parishes, 96 only of which have churches, and a population of 82,000 according to Dr. Beaufort, and about 90,000 as the medium of various calculations. The high and steep mountains of Sliebhe-bloom (called also Ard-na-Erin, which in the Irish language signifies the height of Ireland) form so impracticable a barrier between the King's and Queen's counties, that in a range of fourteen miles they afford but one, and that a very difficult and narrow pass into the King's county, called the "Gap of Glandine." In this great ridge are the sources of the Barrow and the Nore; the Barrow running N.E. to Monalteeven, where it changes its direction to the S., and the Nore crossing the Queen's county by a southern course into Killkenny. The Dyfart hills in the eastern division are conspicuous and picturesque, standing rather singly than connected. From these eminences, through the vales formed by their particular situation, is commanded the view of a fine and beautiful country, highly adorned with rich plantations and magnificent demesnes. The rest of the county is rather flat, but lies high. The whole is watered with rivers and numerous mountain streams, and according to Sir Charles Coote, its superficial appropriations may be thus estimated.

The map belonging to the grand jury, reckons 244,938 acres, and of these 60,000 bog and mountain. Almost every description of soil is found in this county, and it varies from a very stiff clay to a sandy loam, which, though light, is yet fertile; a strong gravelly soil, very favourable to corn, is also prevalent. Lime-stone is so common, that there are rich quarries of it in almost every township. Thesoil
foil of the Sliabh-bloom mountains is variable, the surface inclining to a black and alternately yellow flint clay, of unequal depths, covering a loamy, rotten rock, or a gritty gravel, with occasionally a little appearance of lime-flint. The western side, more generally, inclines to a strong red clay, not unlike the nature of the soil in load of the northern counties in Ireland, where oats and potatoes only are grown; but it generally is, throughout, spoungy, wet, and boggy to the summit, and very rocky. Through the whole of the county, except in the south-eastern corner, near Carlow, where the colliers are extensive, bog is well intermixed, and is the general fuel. The depth of these bogs is various, and in some parts undifeovered, the bent fuel lying in lanes a few fapades depth below the surface, in others very deep. The mounds are a shallow bog, with a stratum of gravel or clay, under one or two fapades depth; this particular kind is easily reclaimed, and becomes the beet and furthest land in the county, and the coal is here but trifling, indeed often repaid in one year, having all the materials within themselves.

Amongst the mineral productions of this county, for Charles Coote, the author of the Statistical Survey, enumerates "coal, iron, copper, manganese, mica, lime-flint, marble, free-flint, ochre, marle, fuller's-earth, and a great variety of clays valuable in every branch of pottery." Such an enumeration is of little use; being recommended neither by detail of facts and places, nor by accuracy of information. The coal district is in another part of the same work more fully noticed; but the reader who wishes for information, is more likely to find it in the report of Mr. Griffith, mining engineer of the Dublin Society, which is shortly to be published. The coal is of that description called flint coal, the glance-coal of Jameson, and best known by the name of Kilkenny coal. The Queen's county colliers seem to have laboured under many disadvantages, from want of capital or of proper exertion; but a prospect is opening upon us of more attention to this source of wealth. There is a very small quantity of old timber in the Queen's county. There are, indeed, leaves still in existence, by which the tenant was obliged to cut, burn, or destroy so many acres of wood, to clear the land for the plough; a system which, if necessary to the establishment of order in the county, was the cause of reducing it to the bare flate with respect to timber, with which the English traveller is so often struck. The Barrow and the Nore are the principal rivers which water this county. The latter is not navigable, though, being a fine deep and spacious river, it might be easily rendered so, by levelling the numerous weirs, that are of great detriment to the adjoining lands, and throw up a considerable quantity of back water.

The Barrow is navigable throughout from Portarlington, near which it beautifully expands and winds through extensive and fertile banks. There are no lakes which defer notice. Maryborough is the county town, near which, as well as Mountmelich and Mountrath, there was a considerable woollen manufacture of stuffs, &c. which has declined. For any particulars respecting the towns, the reader is referred to the respective articles. Besides those mentioned, Portarlington is a place of some importance, and Stradbally a neat town. The county is represented in parliament by two knights of the shire, and by one member for the borough of Portarlington. Maryborough and Ballynekill were disfranchised at the union. Sir C. Coote's Statistical Survey. Beaufort's Memoir.

Queen's River, a river of the island of Dominica, which runs into the sea near Roseau.

Queen Bee, a term given by late writers to what used to be called the king-bee, or king of the bees; a large and long-bodied bee, of which kind there is only one found in every swarm, and which is always treated with the greatest respect by the rell.

It is well known that the generation and whole economy of bees principally depend upon this female sovereign, and that her presence is absolutely necessary to the prosperity and safety of the whole community; inasmuch that the loss of the queen proves the certain and total destruction of the swarm or hive, unless the owner supplies them in time with another ruler. Without her presence and direction, the other bees will do no manner of work; they will gather neither wax, nor honey, nor any other materials; nor can they breed and propagate their kind without her. A flock deprived of its queen, would yield to robbers, or fly languish and pine away, so that the whole society would perish.

But as soon as a languishing flock is supplied with a queen, pleasure and activity are apparent through the whole hive; the presence of the sovereign refines vigour and exertion, and her voice commands universal respect and obedience; of such importance is the queen to the existence and prosperity of the other members of this community. As the parent and sovereign of every swarm is a female, the whole government is vested in one; so that where there happen to be more, as there sometimes are, and especially in swarms that are united, confusion and discord prevail, until all, except one, are expelled and slain.

As in forming artificial swarms, and for other purposes, it will be necessary to distinguish the queen from the other bees, we shall observe, that she may be known by her size, which is much larger than that of the common working-bees, and longer than that of the drones; by the form and shape of her body, especially of the hinder part of it, which is more taper, and terminates in a much sharper point than the bodies of the other bees, in order the more readily to reach the bottom of the cells, where the eggs are deposited for the propagation of the species (see Generation of Bees); and also by her colour; her upper parts being scarlet at all different in this respect from the honey-bees, but her belly and legs are of a very deep yellow, resembling the purest and the richest gold. It is said that the may also be distinguished by the note of her voice, which is an octave; and by being one of the last which falls with her belly upwards, when the bees of a single flock are dropped into an empty hive, in order to be united with those of another flock.

Naturalists have observed, that the queen-bees are produced in a manner peculiar to themselves, and different from the drones and working-bees. Some have supposed that the eggs laid by the queen in a hive, and destined for the production of queen-bees, are of a peculiar kind; but though this is not the case, as M. Schirach has lately discovered, yet there are particular cells appropriated for this purpose. These cells are generally near the edges, and at the bottom of the combs, and sometimes on the sides of a honey-comb; they are of an oblong orbicular form, and very strong; and are more or less numerous in different hives, as occasion seems to require. It has been also supposed, that the matter with which they are nourished is of a different kind and quality from that employed for the nourishment of the other classes; that which has been collected out of the royal cells being of a gummy glutinous nature, of a deep transparent red, and dissolving in the fire rather than crumbling to powder.
It has been generally supposed, that the queen-bee is the only female contained in the hive; that the drones are the males by which she is fecundated; and that the working-bees are neutral, or of neither sex. But M. Schrach has lately established a different doctrine, which has been also confirmed by the later observations of Mr. Debrav. According to this writer, all the working or common bees are females in disguise; and the queen-bee lays only two kinds of eggs, viz. those which are to produce the drones, and those from which the working-bees are to proceed; and from any one or more of these, one or more queens may be produced; so that every worm of the latter or common kind, which has been hatched about three days, is capable, under certain circumstances, of becoming the queen, or mother of a hive. In proof of this doctrine, new and singular as it may seem, he alleges a number of satisfactory and decisive experiments, which have been since verified by those of Mr. Debrav. For the proof of this doctrine by Schrach and Debrav, and the objections of Mr. Hunter, we refer to the article Generation of Bees.

From this doctrine we may justly infer, that the kingdom of the bees is not, if the expression may be used, a pure divina, or hereditary monarchy, but an elective kingdom, in which the choice of their future ruler is made by the body of the people, while she is yet in the cradle, or in embryo; and who are determined by motives of preference which will perhaps for ever elude the penetration of the most sagacious naturalists.

The conclusions drawn by M. Schrach, from experiments of the preceding kind, very often repeated by himself and others with the same success, are, that all the common or working bees were originally of the female sex; but that when they have undergone their late metamorphosis, they are condemned to a state of perpetual virginity, and the organs of generation are obliterated; merely because they have not been fecundated, fed, and brought up in a particular manner, while they were in the worm state. He supposes, that the worm designated by the community to be a queen, or mother, owes its metamorphosis into a queen, partly to the extraordinary fize of its cell, and its peculiar position in it; but principally to a certain appropriate nourishment found there and carefully administered to it by the working bees, while it was in the worm state; by which, and possibly other means unknown, the development and extension of the germ of the female organs, previously existing in the embryo, is effected; and those differences in its form and fize are produced, which afterwards so remarkably distinguish it from the common working bees. Schrach's Histoire Nat. de la Reine des Abeilles, &c. 8vo. 1772. Or, for an abstract, Monthly Review, vol. xlviii. p. 564, &c. Phil. Trans. vol. lxvii. part i. p. 29, &c. See Generation and Sex of Bees.

This discovery is capable of being applied towards forming artificial fwarms, or new colonies of bees, by which means the number of these useful insects might be increased, and their produce in honey and wax proportionably augmented. M. Schrach, as well as M. Helforff, feem, however, to have been mistaken, when they affert, that the artificial queens, formed and reared in a community consisting only of working bees, proceed almost immediately to lay eggs, and to people the hive, without having had any communication with the drones, and at a time when, as they supposé, there were no drones in being. It is not necessary to admit the idea of the prolific quality of a virgin queen-bee; as nature has provided drones of different sizes, for the purpose of impregnating the eggs laid by the female, and continuing the species, adapted to different circumstances and situations. See Drone.

Queen's Bench. See King's Bench, &c.
Queen's Gilliflower, or Violet, in Botany. See Hemp.
Queen Gold. aurum regina, an ancient royal revenue, belonging to the queen of England, during her marriage to the king; and payable by divers persons (upon several grants of the kings) by way of oblation out of fines, amounting to ten marks, or upwards; viz. one full tenth part above the entire fine, or ten pounds for every hundred pounds fine, on pardons and contracts or agreements. This becomes a real debt to the queen, by the name of aurum regina, upon the party's bare agreement with the king for a fine, and recording it without any farther promise, or contract, for this tenth part extraordinary.
Queen of the Meadows, in Botany. See Spiraea.
Queen's Ware. See Pottery.
Queen's Theatre in the Haymarket, now the Opera-house, was built in queen Anne's time by sir John Vanburgh, and not finished till the summer of 1705, at which time there were only two theatres open; Drury Lane, and Lincoln's-Inn-Fields. Betterton, who was at the head of the Lincoln's-Inn-Fields company, removed to the new theatre in the Haymarket, April 9th, 1705; when it was opened with a new prologue, written by Sir Samuel Garth, and spoken by Mrs. Bracegirdle. The play was Dryden's " Indian Emperor," with singing by the Italian boy, April 23d, " The Merry Wives of Windsor," Falstaff by Betterton, with dancing by Mad. de la Val. And on the 24th, a new farce called "The Confutation;" after which was performed an Italian pageant, called the "Loves of Ergafo," set to music by Giacomo Greber, the German musician, who had brought over from Italy Margarita de l'Epine; the part of Licoria by the Italian boy. And this was the first attempt at dramatic music in the Opera-house. The company continued acting plays here till the end of June, when there were three representations of "Love for Love," acted all by women. July 20th, according to the Daily Courant, Betterton and his company returned to the theatre in Lincoln's-Inn-Fields, where they continued to act till the Queen's theatre was entirely finished. We are the more minute about the performances in this theatre, as Cibber's account, which has been generally followed by others, is very inaccurate. October 30th, Betterton and his company quitted Lincoln's-Inn-Fields a second time, and returning to the Haymarket, opened that theatre, which was now played in. This excellent comedy, though the parts were very strongly cast (Leigh, Dogget, and Booth, being among the men, and Mrs. Barry, Mrs. Porter, and Mrs. Bracegirdle, among the women,) ran but nine nights successively, though the performance of M. des Barques, a dancer just arrived from France, was added to the entertainment. It was, indeed, repeated once in November, and twice in December, this year; but it was generally found necessary, even in a new theatre, and with so strong a company, to fortify the bell plays with dances or music, and often with both. Sometimes there was singing in Italian and English, by signorina Maria, as lately taught by signor N. Haym; and sometimes music composed by signor Bonvicini, and songs by signorina Lovicini, &c. See Daily Courant.

QUEENBOROUGH, in Geography, a borough and market-town in the liberty of the isle of Shepey, late of Seray, and county of Kent, England, is situated about three miles south from Sheerness, and forty-five miles by south from London. It was anciently called Cyningburgh, from belonging
longing to the Saxon kings, who had a castle here, near the western entrance of the Swale, which, after the conquest, was denominated the castle of Sheep. This fortress being totally demolished in the reign of Edward III., that monarch commenced, in 1350, a more extensive and magnificent one, which was finished in the period of six years, under the superintendence of the celebrated William of Wykeham, afterwards bishop of Winchester. When the castle was completed, Edward came and resided in it several days, during which time he constituted the then village a free borough, and ordered it to be called Queenborough, in honour of his comfort Philippa of Hainault. By the charter of incorporation, which bears date in 1366, he conferred fundry privileges upon the burgesses, and empowered them to elect a mayor, two bailiffs, four jurors, a town fejeant, and a water bailiff, who were to take their oath of allegiance before the constable of the castle, and to act as justices of the peace within the liberty of the corporation. This charter was confirmed, with additional privileges, by king Charles I.

Queenborough consists chiefly of one street, which is very wide, and is formed mostly of modern buildings. According to the parliamentary returns of 1811, the borough, which coincides in extent with the parish, contains 163 houses and 805 inhabitants, who are principally fishermen and oyster dredgers. The market days are Monday and Thursday weekly, and there is a well-attended fair on the 5th of August. This town sends two members to parliament, who are elected by the mayor, jurors, bailiffs, and burgesses, about 150 in number, though by the last decision of the house of commons in 1725, the elective franchise was declared to reside only in the mayor, jurors, and common council. The mayor is the returning officer, and the patronage is in the admiralty and board of ordinance.

Of the castle built by king Edward, no traces remain except the moat by which it was surrounded, and a well, by which it was supplied with water, as the town still is. Though a large and massive structure, and erected, as the letters patent express it, "for the strength of the realm, and for the refuge of the inhabitants of this isle," it does not appear to have ever been of any particular use, at least it is never mentioned in history as having been belted, or occupied as an important military post. It was nevertheless several times repaired; first by Richard II., and again in the time of Henry VIII. Queen Elizabeth also seems to have contributed to its preservation and embellishment, as her arms were displayed on the ceiling of the great hall, surrounded by those of the nobility, and principal gentry of the county, with the date 1553, affixed to some panegyrical verses in honour of that princess. The church here was originally built as a chapel to Minster, a village situated about two miles from the town, and deriving its name from the minster, or nunnery founded there by St. Olave, abbot of Ercombert, king of Kent, about the year 693. That princess placed twenty-three nunns in her new establishment, and took upon herself the office of abbess; which the afterwards resided to her daughter Ermengild, and retired to Ely, where her sister Etheldreda prefided.

During the incursions of the Danes, this nunneri was deserted and nearly destroyed; but when their invasions ceased, it was again tenanted by a few nuns, and continued to exist, though in a very mean state, till the year 1130, when the buildings were re-edified by Corbel, archbishop of Canterbury, and filled with nuns of the order of St. Benedict. At the dissolution their number was limited to a prior and ten nunns, whose estates were estimated at 129l. 7s. 10d. annual rent. These, with the site of the suppressed monastery, were then granted to Sir Thomas Cheynell, lord warden and treasurer of the household to king Henry VIII. Of the buildings, a gate-house, and part of the church, are the only remains. The latter consists of two aisles, a chancel, and a nave chapel, with the lower division of a square tower at the west end. In conformity with the date of its erection, some of the arches are semicircular in form, but most of them are in the early pointed style. In the south wall of the chancel, under a range of cinquefoil arches, is the effigy of a knight templar, said to represent and commemorate Sir Robert de Shurland, lord of Shurland, who was created a knight bannerman by Edward I., for his gallant conduct at the siege of Carlaverock, in Scotland. Behind the figure, towards the back of the recess, is the representation of a horse's head in the act of swimming, which has given rise to much enquiry among antiquaries, and to many fabulous and superfluous stories among the vulgar. On the pavement are several brasses of knights and their ladies; and under the arch separating the chancel from the chapel, is a gorgeous altar-tomb in honour of Sir Thomas Cheynell, above-mentioned. Another altar-tomb, near it, bears the recumbent figure of a Spanish general, or admiral taken prisoner by Sir Francis Drake, on the defeat of the "Invincible Armada." From an entry in the parish register, it appears to have died on board a ship at the Nore in 1591. " Beauties of England and Wales, vol. vii. by E. W. Brayley.

QUEENSURY, a township of America, in Washington county, New York, bounded easterly by Westfield and Kingbury; 35 miles N.E. of Albany.

QUEENSFERRY, South, a royal burgh and sea-port town in the county of Linlithgow, Scotland, is situated on the southern shore of the Firth of Forth, at the distance of nine miles W.N.W. from Edinburgh, on the great road to the north. It is first mentioned in the charters of king Malcolm IV. by the designation of "Passagium Regis," as is generally supposed from the frequent use of the ferry here by his great-grandmother Margaret, queen to Malcolm Canmore, a princess highly celebrated in Scottish history for her charitable and benevolent qualities. At that period, however, it was only a village and port, endowed with some trifling privileges; indeed, its constitution as a royal burgh did not take place till about the year 1556, when its elevation to that rank was strenuously opposed by the corporation of Linlithgow. It is now governed by a provost, one land bailiff, two sea bailiffs, a dean of guild, and a town council, who, like most other townships in royal burghs, are self-elected. Formerly this port enjoyed a considerable trade, and even so late as the year 1640, it was frequented by above twenty ships belonging to resident owners; but its traffic is at present confined to the importation of coal, for the consumption of the inhabitants, and of the materials used in the manufacture of brown soap, which, with the fisheries and the business of the ferry, constitute the chief support of the town. The harbour is in good repair, and is frequently resorted to as a place of retreat in hard gales, by the smaller vessels navigating the Forth. The pabbage here does not exceed two miles in breadth; and, except in very boisterous weather, may be crossed at all times with safety and expedition. Much obscurity prevails relative to the founding of this ferry. The right of it is private property, and seems originally to have been attached to the lands of Murie Hall, which lie in the vicinity of the town, and are traditionally said to have been appropriated for "upholding the pabbage." The present proprietors are several gentlemen possessors of land on either side of the Forth, who let the pabbage yearly by public auction. As all the northern mails, and most carriage travellers, pass at this ferry, the intercourse between its shores is constant and regular. Cattle also are transported
ported over in great numbers, as well as carts and waggons; but the difficulty and danger of effecting these objects, have induced cattle-drivers and carriers to go round by the bridge at Stirling.

The parish of Queensferry is of small extent, being confined entirely to the royalty. In eccllesiastical matters it forms part of the provostry of Linlithgow, and synod of Lothian and Tweeddale; and, according to the population returns of 1811, contains 77 houses and 558 inhabitants.

On the summit of the ridge rising from the shore here, stands Hopetoun-house, the seat of the earl of Hopetoun, which is perhaps equal in magnificence of aspect to any palace or residence in Great Britain. The mansion is seated on a noble lawn, forming a kind of terrace along the Forth for more than a mile in front, and only terminated by the Frith, which winds round it, and appears like a wide and extensive lake, interpersed with islands and enlivened with a variety of shipping. Behind the house the ground is more various, breaking into hills, vallies, and promontories, which shoot into the Forth. All the grounds, to a considerable distance, are planted and adorned; and the house is judiciously flanked with a thick wood, to protect it against the violence of the northern winds. On this side the Forth assumes, at different points, different appearances, sometimes putting on the semblance of a lake, and sometimes that of a river. The house is a very noble display of architectural magnificence. It was begun by the celebrated architect Sir William Bruce, and finished by Mr. Adam, who is believed to have added the wings. It must be regretted, that the interior of this princely mansion does not correspond with the grand scale of the exterior, in the fize and decorations of the apartments. Beauties of Scotland by Robert Forsyth, vol. iii. Carlisle's Topographical Dictionary of Scotland, 4to. 1813.

QUEENSFERRY, North, a small sea-port town in the district and parish of Dunfermline, Scotland, is situated on the northern shore of the Frith of Forth, opposite to the royal burgh of South Queensferry, described in the preceding article. The principal export is whin-stone for paving, which is found in vast abundance in the extensive "whin-stone quarries" adjoining. Of that material a large proportion is conveyed to London, and many towns on the eastern coast of England. A hamlet, called St. Margaret, between this village and the headland, which forms the western boundary of Inverkithing bay, is noted as the landing place of prince Edgar Atheling, and his sister Margaret, afterwards queen of Scotland, when they fled from England to avoid the effects of the conqueror's jealousy of Edgar's claim to the English crown. By an act of parliament, lately passed, the ferry has been placed under excellent regulations; and the harbour on each side, but particularly on the north side, has been much enlarged and improved. A signal house here contains apartments for the accommodation of the travellers, the superintendant, and boatmen. Carlisle's Topographical Dictionary of Scotland, 4to. 1813.

QUEEN'S-HOPE, or EAST-HOPE, a town in the parish of Elyin, or Hope, county of Wigtown, Dumfries, and county of Flint, North Wales, is situated near the river Alun, at the distance of six miles N.W. from Wrexham. Together with the adjoining village and hamlet of Caer-Gwrle, it constitutes a burgh, both by prescription, and in virtue of a charter granted by Edward the Black Prince in 1351. That deed orders that the probable of the cattle shall be mayor, ex officio, and shall nominate two bailiffs, to govern under him, from among the burgesses. This place obtained the appellation of Queen's-Hope, after the year 1282, from the circumstance of its having been then bestowed by Edward I. on his beloved and heroic confessor Eleanor; or, as some affirm, from her majesty having lodged here, when on her way to Caernarvon to give the Welsh a ruler born within their own territories. The etymology of its ancient name, "Caer-gawer-le," (the camp of the gigantic legion,) seems to indicate that it was once occupied by the Romans; and in confirmation of this conjecture we may observe, that a Roman hypocaust has lately been discovered here, some of the tiles used in the construction of which were inscribed "Legio XX." Pennant supposes that it was an outpost to the grand station Deva, and notices the remains of two roads. The ruins of the castle of Caergwrle are feated on a lofty rock isolated from the surrounding land, and, on one side, extremely precipitous. At what time, or by whom it was originally built, is unknown; but in the reign of Owen Gwynedd, it formed part of the possessions of a chieftain named Gwyffyd Maclor. Edward I. made a grant of it to Prince David, and, afterwards, as above-mentioned, to queen Eleanor, at whose death both castle and manor were given to John de Cremwell, on condition that he repaired the former, which had been left to, and considerably damaged, as was supposed, by design, while the king and queen were resident in it. All that remains of this once magnificent fortress, is a circular tower, and a few fragments of walls, together with the deep fosse, by which it was defended. This fosse is excavated from the solid rock, which is composed of breccia, or an exceedingly coarse grit.

The conjoint borough of Queen's-Hope and Caergwrle, is contributory with the town of Flint in the election of a representative to the British parliament. It formerly had the privileges of a market and fairs, but these are now discontinued. The parish is divided into two districts, called Hope and Kinnerton, and contains, according to the parliamentary returns of 1811, 547 houses and 2617 inhabitants. Of these a large proportion reside in the town, which consists of three broad parallel streets, intersected at right angles by three others of less breadth, the whole placed on the side of a rising ground, gently sloping to the river. The principal building is the church, which contains two mural monuments, one decorated with kneeling figures, but without any inscription; and the other commemorating Sir John Trevor, knt. secretary to the earl of Nottingham, the conqueror of the boated invincible armada.

Some objects in the vicinity of the place claim notice. On a hill, opposite to that of Caergwrle, is the British encampment of Caer-Elyin, which is formed by a single ditch and rampart. The adjacent summits consist chiefly of limestone, and display on their surface numerous organic examples of the fossil remains called entrochi and aliroches. The uncommon species of the latter, usually denominated the arboreous fa-dlar, has been found here. At Rhuddlan are two springs strongly impregnated with muriate of soda, the waters of which are found highly serviceable in such chronic disorders as elephantiasis and scrofula. At this place is a fine old bridge over the river Alun. On the road to Mold, about two miles from Queen's-Hope, is Plas-Teg, the seat of the Trevor family. The house is a very noble building, and is generally believed to have been the work of Inigo Jones. Beyond this is Harts-Heath Hall, the property of Guillem Lloyd Wardle, esq. It is a large modern manor, forming a square, with three fronts, and is surrounded by fine plantations. Carlisle's Topographical Dictionary of Wales, 4to. 1812. Pennant's Tour in Wales.
QUEENSTADT, a town of Westphalia, in the principality of Halberstadt; three miles N.E. of Halberstadt.

QUEENSTOWN, a port-town of America, in Queen Anne's county, Maryland, on the E. side of Cheslet river; six miles S.W. of Centerville, and 65 from Washington.

QUEENSTOWN, a town or village of Upper Canada, which lies on the W. side of the straits of Niagara, near fort Niagara, and seven miles below the Falls. It is at the head of navigation for ships; and the portage occasioned by the Falls of Niagara commences here. From the sudden change in the face of the country in the neighbourhood of Queenstown, and the equally sudden change in the river with respect to its breadth, depth, and current, it has been conjectured, that the great falls of the river might originally have been situated at the spot where the waves are so abruptly contracted between the hills; and moreover it is a fact well ascertained, that the falls have receded very considerably since they were first visited by Europeans, and that they are still receding every year. See Weld's Travels, vol. ii. p. 130.

QUE.SAN ISLANDS. See Chusan.

QUE ESTATE, in Law, a place whereby a man entitling himself to land, &c. faith, that the same estate which another had, he now has from him. Thus, e. g. the plaintiff alleges that such four persons were feised of lands whereby to the adowfore in question belonged in fee, and who did present it; and that afterwards the church was vacant; que est estate, i. e. which est be now has; and, by virtue thereof, he presents, &c. See PRESCRIPTION.

QUE EST MEME, a term used in actions of trespass, &c. for a direct justification of the very act complained of by the plaintiff as a wrong.

Thus, in an action upon the case, the plaintiff laying the lord threatened his tenants at will in such fort, as he forced them to give up their lands; the lord in his defence pleads, that he paid to them if they would not depart, he would sue them at law. Que est meme, i. e. this being the same threatening that he used, the defence is good.

QUEGASCA HARBOUR, in Geography, a bay on the S. coast of Labrador. N. lat. 50° 9'. W. long. 61° 22'.

QUEL, in Natural History, a name given by the Chinese to a peculiar earth found in many parts of the East.

It is of the nature of an unburnt clay, and in some degree approaches to the talcs, as our flatites and the galates do. It is very white and abderive, used by the women of China, to take off spots from the skin, and render it soft and smooth, as the Italian ladies use the same. They sometimes use the fine powder of this stone dry, rubbing it on the hands and face after washing; sometimes they mix it with pomatum.

QUEICH, in Geography, a river of France, which passes by Landau, and runs into the Rhine, near Germerheim.

QUECHUN, a city of China, of the second rank, in the province of Quang-fi. N. lat. 23° 22'. E. long. 166° 44'.

QUEGE, a town of France, in the department of Mont Blanc; four miles N.E. of Conflans.

QUEIGNE, a town of Africa, in the kingdom of Bambouk.

QUELING, a city of China, and capital of the province of Quang-fi, derives its name from a flower called "quei," which grows on a tree resembling a laurel; it exhales a sweet and agreeable odour, that the whole country around is perfumed with it. This city is situated on the banks of a river, which throws itself into the Ta-ho; but it flows with such rapidity, and amidst narrow valleys, that it is neither navigable nor of any utility to commerce. Quei-ling is a large city, and the whole of it is built almost after the model of our ancient fortresses; but it is much inferior to most of the capitals of the other provinces. Birds are found in great numbers in the territories belonging to it, the colours of which are so bright and variegated, that the artificers of this country, in order to give additional luster to their silks, interweave with them none of their feathers, which have a splendour and beauty that cannot be imitated. Quei-ling has under its jurisdiction two cities of the second class, and seven of the third. N. lat. 25° 12'. E. long. 107° 51'.

QUEIOS, a river of Spain, in Navarre, which runs into the Ebro, near Tudella.

QUEIRA, a town of Africa, in Ludanam; eight miles S. of Benown.

QUEIS, a river of Silefia, which rises in the principality of Jauer, passes by Friedberg, Grieffenberg, &c. and joins the Bober, between Sprottau and Sagan.

QUEI-TE, a city of China, of the second rank, in Quang-fi. N. lat. 28° 18'. E. long. 107° 4'.

QUELAINES, a town of France, in the department of the Mayenne; eight miles S. of Laval.

QUELEA, in Ornithology, a species of Emberiza; which feeds on grass.

QUELINES, in Geography, mountains of Mexico, between the provinces of Guaxaca and Chiapa.

QUELLINUS, ERASMUS, in Biography, called the Old, born at Antwerp in 1607, was a pupil of Rubens, and became a painter of history of very considerable reputation. He lived to the age of 71, and left a son John Erasmus Quellinus, who also became a painter, but who left the Flemish for the Venetian style of art, which he practised at Antwerp, his native city, till he arrived at the advanced age of 85, having been born in 1630.

QUELPAERT, in Geography, an island in the sea of Corea, on which a Dutch vessel, called the Sparrow-hawk, was wrecked in the year 1635, then subject to the king of Corea. No island presents a finer aspect; the middle of the island is occupied by a peak of about 800 toises, visible at the distance of about 18 or 20 leagues, and the land gradually slopes towards the sea, so that the inhabitants resemble an amphitheatre. It bores a great height seems to well cultivated. It bores, however, to a people who are forbidden to hold any intercourse with strangers, and who detain in slavery unfortunate persons who are wrecked on the coasts. Some Dutchmen of the Sparrow-hawk, after a captivity of eighteen years, during which they received many bollinades, found means to take away a bark, and to croas to Japan, from which they arrived at Batavia. N. lat. of the south point 30° 14'. E. long. 126° 35'.

QUELUSIA, in Botany, a name given by Vandelli to the beautiful Fuchsia coccinea, now so common in gardens. The author supposed it a new genus, and meant thus to honour a royal villa near Lisbon, called Queius, where he first saw this plant in bloom.

QUEM doom, in Law, an old writ which lay where a rent-charge, or other rent, which was not rent-service, was granted by fine holding of the grantor. If the tenant would not attorn, then the grantee might have bad this writ.

QUEMARY, in Geography, a town of Bootan; 20 miles E. of Beyhar.

QUEMENNES, a small island in the English channel, near the coast of France. N. lat. 48° 22'. W. long. 4° 48'.

QUEMI,
QUEMI, in Botany, a name used by some authors for the nigella, or geth.

QUEMIGNY, in Geography, a town of France, in the department of the Côte d'Or; nine miles S.W. of Dijon.

QUENALBA, a bay at the S. extremity of the island of Shetland. N. lat. 59° 49'. W. long. 1° 40'.

QUENON WATER-BARROW, in Rural Economy, a contrivance of the barrow kind, much employed in the neighbourhood of the little village of Quendon, in Essex, and from which it takes its name, for the purpose of conveying water, wash, and other liquid matters, to live flock of different kinds, as fattening cattle, logs, hordes, and other animals, as well as for some other uses. It is a simple and excellent invention for all such intentions, as very great facility is given to its motion by means of the wheels, and it is, on the whole, very compact in its general formation, which gives it a superiority over many other coattirances of a similar nature, as being capable of being put in motion, when full, without any great difficulty, or the application of any extraordinary power or force.

It is represented at figs. 6 and 7, in Plate Agriculture, shewing the methods of clearing quarries, pits, &c. from water. Fig. 6. explains the plan, in which a, a b, are the wheels, that fall on to the side-beams c d, c d, which are about four feet in length, and have their ends c, c, formed in such a manner as to serve for handles. E is an oval tub about thirty inches in depth, twenty-four in length, and eighteen in breadth, which is supported on the beams by two gudgeons, which play in semicircular boxes fixed near the ends of the beams: a crofs piece connects the two beams at f f, as does another at g g, to which two little curved pieces come, parallel to the form of the tube. The wheels are about four feet in height, and carry the tub suspended between them; for the gudgeons play almost over the two short axles, which figure into the beams. Two flight legs are fixed underneath the barrow at i i, to keep it in an upright position, but they are not at all essential, for the tub would remain in a state of equipoise between the wheels even without such aid. It must be noticed, that the tub is funk rather more than one-half below the gudgeons. Fig. 7. displays the profile of the vehicle; the dotted line signifies the size and place of the tub, which is made oval, for the purpose of confining the breadth between the wheels, so as to pass in at narrow door-ways, &c.

It is probable that it might be somewhat improved by having the axles hooked within, so as to bear upon two loops in one of the iron hoops, and by this means render the use of gudgeons and boxes wholly unnecessary. The tub would lift off and on, as easily as at present, while it would hang in a more precise and perfectly central manner. And still further, it would be a great convenience, if the upper part of the tub were furnished with a proper spout in the front, in order to pour water or other liquid materials through between the pales, &c. for the supplying of cattle, &c. This would be more easily accomplished, if the tub were allowed to swing in a free manner, as it might in that case be tilted up with great facility, so as to favour its being done, as shewn by the dotted line in fig. 2. About the little town noticed above, it is a great deal employed in carrying water for house use as well as that of farms. It is described in the Agricultural Magazine. Many other forms of water-barrows are made use of in different places. See WATER-BARROW.

QUELOG, or QUELENA, in Geography, a district of Africa, in the country of Sugumella, near mount Atlas.

QUENOY, Le, a town of France, in the department of the North; five miles N.N.W. of Lille.

QUENTIN, in Commerce, a small weight used in Germany; the ounce contains two lochs, or eight quentin.

QUENTIN, St., in Geography. See St. Quentin.

QUÉPO, a town of Mexico, in the province of Costa Rica, on the Eftrella; 70 miles S.S.W. of Carthag.

QUERA, a town of Italy, in the Trefian; 15 miles W. of Ceneda.

QUERALOS, a town of Spain, in Catalonia; 24 miles E. of Urgel.

QUERCIA, in Medicines. See Epialos.

QUERCEO, in Geography, a town of Etruria; nine miles S.S.W. of Volterra.

QUERCUS, in Botany, the Oak, an ancient Latin name, whose etymology has been considered as very uncertain, if not quite inexplicable. So it will in feem to those who looked no further than the Greek or Latin languages, for though some have deduced the word from xerós, a pig, because pigs feed on acorns, this explanation has not proved satisfactory. De Theis, on the authority of Lepelletier, has found a much better etymology for Quercus, in the Celtic quer, fine, and cuez, a tree; and this appellation is supposed to have been appropriated to the oak, not only for the beauty of the tree, but because it bore the fared plant, mifletz. This tree was also called in the Celtic tongue derys, whence came the word druid, or prief of the oak, and even the Greek δρυς, an oak, vulgarly suppos'd the original of Druid. (See DRUIDS.)—Linn. Gen. 495. Schreb. 496. Wild. Sp. Pl. v. 4. 423. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 1025. Ait. Hort. Kew. v. 5. 287. Julfl. 410. Tourn. t. 349. Lamanck Illust. t. 779. Gaertn. t. 37. (Hex; Tourn. t. 350. Suber; ejfd.)—Clados and order, Monocca Polyandra. Nat. Ord. Amentacese. Linn. Julfl.

Gen. Ch. Male, in a loose catkin, Cal. Periandria of one leaf, bell-shaped, membraneous, with about five small, sharp, often eleven segments. Cor. none. Stam. Filaments from four to ten, capillary, short; anthers large, of two round lobes.

Female, from a bud usually on the same tree, Cal. Periandria of one leaf, inferior, coriaceous, hemispherical, rough, entire, very small in the flower, permanent. Cor. none. Pet. Germen superior, ovate, very small; style simple, divided above into two to five segments, longer than the calyx: stigma simple, permanent. Pet. none. Seed an oval or roundish coriaceous nut, of one valve, smooth, attached by its scarred base to the bottom of the shortish, hardened, permanent, cup-like calyx.

Female, Calyx bell-shaped, coriaceous, entire, rough. Corolla none. Style one. Stigmas from two to five. Nut coriaceous, embraced at the base by the hardened calyx.

This genus, so tillant in its botanical characters, and food valuable for its economical uses, confidts, in the Species Plan tarum of Linnaeus, of no more than thirteen species. The discoveries of Thunberg, but especially those of American travellers, aided by the more accurate enquires of botanists, have fo greatly enriched the subject, that Wahlenberg, who has studied it well, enumerates seventy-six kinds of Quercus, and even these are not all that we have to describe. The importance of many species requires that they should all be particularized. Two or three of the East Indian ones, now for the first time described, offer some exceptions to the generic character of the calyx.

Section 1.—Adult leaves undivided and entire

in Abbot's Insects of Georgia, v. 2. 181. t. 91. Michaux Querc. n. 7. t. 12. (Q. virginiana, Ilicis longiore folio, fructu misimo ; Pluk. Amath. 180. t. 441. f. 7.) —Leaves membranaceous, linear-lanceolate, tapering at each end, entire, smooth, with a small point. Nut roundish.—Native of North America; in low swampy forests, near the sea-coast, from New J. rel. to Florida, flowering in May. Pursh. It is said by Mr. Aiton, on the authority of Knowleton's M.S. S., to have been cultivated in England by Mr. Fairchild, before the year 1723; and indeed, by the collection of Bulstrode, this tree appears to have been planted there much earlier, among those introduced by the first earl of Portland. It rives in its native country, as well as in England, to the height of fifty or sixty feet. The bark is smooth; the wood is good, and much in use, but of slow growth. Leaves scattered, on short stalks, four or five inches long, and not an inch wide, smooth, thin and plant, of a fine green, with a willow-like aspect, deciduous, their edges slightly waved. Acorn in pairs, roundish, scarcely above half an inch long, with a thin, tuberculated, or flesseled cup. The leaves of the young plant are somewhat angular, or toothed at each side. There is said to be a dwarf spragge variety, with shorter leaves. Michaux has figured in his vol. 1. t. 22. Michaux has two supposéd varieties, which other botanists esteem distinct species; see the following. The specific name, chosen by Linnaeus, ist not a good one, Quercus being the cork-tree.

2. Q. maritima. Ever-green Willow-leaved Oak. Willd. n. 2. Pursh n. 2. (Q. Phellos maritima ; Michaux Querc. n. 7. var. 2. t. 13. f. 3.) —Leaves coriaceous, elliptic-lanceolate, entire, smooth, with a small point. Nut roundish.—Found on the sea-coast of Virginia and Carolina, flowering in May and June. This differs from the foregoing in its low shrubby habit, and firm evergreen leaves, which are more elliptical in shape, and not above two inches long. The whole plant is from three to eight feet only in height. It appears by the accounts of authors to be distinct from the above-mentioned variety of Phellos.

3. Q. fericea. Silky Willow-leaved Oak. Willd. n. 3. Pursh n. 3. (Q. Phellos ; Sm. in Abb. Inf. v. 2. 101. t. 51. Q. Phellos pumila ; Michaux Querc. n. 7. var. 3. t. 13. f. 1. 2.) —Leaves lanceolate-oblong, someway waving; obtuse at the base; rather dilated upwards; silky beneath. Nut almost glabrous.—Native of the sea-coast, from Carolina to Florida, flowering in May. It is perhaps the most humble of the whole genus, scarcely ever exceeding two feet in height, and throwing out creeping feysons, whence it has obtained the name of the Running Oak. The filikens of the leaves beneath gives them a glaucous appearance.

4. Q. myrtifolia. Myrtle-leaved Oak. Willd. n. 4. Pursh n. 4. —Leaves coriaceous, oblong, entire, smooth, acute at each end."—Native of Carolina, according to Willdenow, who alone has noticed this species, and from whom Pursh has admitted it into his work. The branches are round, brown. Leaves an inch, or rather more, in length, coriaceous, evergreen, oblong, somewhat acute at the base; entire and slightly revolute at the margin; shining above; opaque, but smooth beneath; on short footstalks. The form of the leaves is much like the common broad-leaved myrtle. The flowers and fruit are unknown. Willd.

foil of sand upon clay, from Virginia to Florida and Missouri, flowering in May. Miller cultivated it at Chelsea in 1739, but we know not that this species is still preferred, or, at least, distinguished from Q. ilex, in our gardens or plantations. It is one of the most valuable American trees, growing to the height of forty or fifty feet, and extending its branches, in open situations, to a great extent; whence it serves, by its dense evergreen leaves, to shelter cattle from the summer's heat and winter's cold. The wood is the finest and most durable ship timber. It is felled towards the end of autumn, and kept three months before it is used. Michaux recommends this tree to the notice of the French and Spaniards, as likely to thrive well on the sandy coasts of the Mediterranean, and of the western ocean. By his account it succeeds best where there is a basis of clay under the sand, to fix the larger roots. The aspect of the leaves is not unlike our European Q. ilex, but they are, except when very young, more uniformly entire, and more shining; their under leaf is less densely pubescent; and their short footstalks, as well as the mid-rib, reddish. The foliage of feeding plants, and of vigorous young shoots, is, indeed, strongly toothed. The adult leaves are scarcely more than two inches long, somewhat oval, or obovate and bluntish, without any terminal bristle; silky in the spring; subfuscibly of a dark but shining green, and downy, with flary pubescence, beneath. The flowers are but four or five. Stalks of the fruit an inch long. Acorn cylindrical, an inch long, with a flesseled, but not ruptured or flesseled, cap. The acorns are said to be greedily devored by hogs, and several wild animals; and to afford an oil, which the fagaxes of Florida mix with their food.

6. Q. cinerea. Ash-coloured Silky-leaved Oak. Willd. n. 6. Ait. n. 3. Pursh n. 6. Michaux Querc. n. 8. t. 14. (Q. humilia ; Walt. Carol. 234. Q. Phellos b ; fericas ; Ait. Hort. Kew. ed. 1. v. 3. 354. Q. Phellos ; Linn. Sp. Pl. 1412.)—Leaves coriaceous, elliptic-lanceolate, revolute, entire, bluntish with a small point; clothed with flary down beneath. Fruit fesile. Nut nearly globose.—Native of dry barren situations, and pine forests, from Virginia to Georgia, flowering in May. Michaux says it springs up chiefly on land that, after having been cultivated, becomes abandoned on account of the bad quality of the soil. The form of the tree is unfightly, and its fize very variable, from four to twenty feet in height. The wood is of no use but for firing. Leaves longer than in the preceding; the young ones dilated at the top, with three points. Fruit nearly or quite fesile, almost globular, and not much above half an inch long.

7. Q. microphylla. Small-leaved Dwarf Oak. Willd. n. 7. Nee in Annal. Scient. Nat. v. 3. 264. Fitch. Mifs. Hesp. v. 1. 99. Willd. —Leaves lanceolate, pointed, entire, villous; downy beneath. Calyx of the fruit villous. Nut roundish.—Found by Louis Nee, on the hills of Aramboro, in New Spain. A shrub, from three to five feet high, with a smooth ash-coloured bark. Leaves on short flanks, scattered, numerous, from four to six lines long, scarcely two lines broad, veiny, revolute, wavy, pointed, reddish-grey; villous above; densly downy beneath; those about the extremities of the branches opposite. Stipulas awl-like, falling off at the elope of summer. Acorns in axillary pairs, about the ends of the branches, ovo-late, the size of a large pea, half covered by the villous cup, which is invected with unequal scales. Nee.

long."—Found by Lewis Nee, in the kingdom of Mexico, near Acapulco. A tree twenty-eight feet high, with alternate branches; the young ones somewhat furrowed, and clothed with brownish-red hairs. Leaves from five to seven inches long, an inch wide, scattered, on short flanks, rather coriaceous, smooth, vein, entire, wavy, pointed; reticulated and green above; yellowish beneath, with tufts of hairs, as big as a pin's head, in the forks of the veins. Acorns nearly fleshy in axillary pairs, the size of a hazelnut, downy, half covered by the hemispherical, greyish, villous cup, befitting with very thin scales. 

9. Q. glabra. Smooth-leaved Japanese Oak. Thumb. Jap. 175. Willd. n. 9. "Leaves lanceolate-oblong, pointed, smooth, with parallel veins."—Gathered by Thunberg in Japan. A tree, whose branches grow two or three together, slightly spreading, rugged and knotty. Leaves alternate, flaked, lanceolate-oblong, entire, pointed, with parallel ribs (veins); tapering at the base; smooth on both sides; shining above, yellowish beneath. Spikes of flowers either solitary, or two or three together, downy. Thunberg.

10. Q. concentrica. Concentric-leaved Oak. Loureir. Cochinch. 572. Willd. n. 10. "Leaves lanceolate-obovate, pointed, incurved, entire. Calyx lax, very short, furrowed concentrically."—Native of the lofty forests of Cochinchina. A large tree, whose wood is serviceable for various uses. Branches ascending. Leaves scattered, flaked, smooth on both sides. Acorns flaked, oblong-ovate, smooth, red, pointed, their cups short and lax, externally marked with five parallel circular furrows; see n. 27.

11. Q. molucca. Molucca Oak. Linn. Sp. Pl. 1412. Willd. n. 11. Rumph. Amboin. v. 3. 85. t. 56. "Leaves elliptic-lanceolate, entire, acute at each end, smooth. Nut roundish, furrowed."—Native of the Moluccas islands. A large and lofty tree, whose wood is hard and heavy, lasting long under water. Leaves fix or eight inches long and three broad, on short flanks, with eight or ten irregular lateral veins. Acorns short and roundish, furrowed in their upper part; the cup short, warty. By Rumphius's account, there seem to be more species than one comprehended under the chapter above cited, but he does not give us sufficient marks to define them specifically.

12. Q. spicata. Cluster-fruited Oak.—Leaves ellipticle lanceolate, taper-pointed, entire, smooth. Spikes axillary, foliate, dioecious. Fruit spiked, aggregate, ovate. Gathered by Dr. Francis Buchanan, in woods at Snubb, in Upper Napa, flowering in May, 1802. This is a tree of vast dimensions, whose wood is useful, though inferior in quality to that of Q. annulata, n. 22. The younger branches are angular, clothed with very minute green pubescence. Leaves alternate, flaked, of a broad lanceolate, or elliptical figure, with a taper point, entire throughout, fix or seven inches long, and two and a half wide; bright green, smooth and shining above; paler, opaque, but scarcely pubescent, beneath; furnished with numerous, parallel, transverse veins. Footflakes not an inch long, deprecised. Stipulas deciduous. Flowers in long, linear, downy, pale, straight, foliate, axial spikes; the male with about eight stamens, much longer than the calyx, and a roundish rudiment of a germ in the centre; females on a separate tree, crowded three together in binate groups in each spike. Acorns edible, but not very good, the size and shape of a large filbert, even, pointed, dark brown; their cups short, feebly. The original names of Nepaul, or Nawars, know this tree by the name of Guly Sophia, or Pacyvinga; their Hindi conquerors, the Parbatties, call it Arculata.

13. Q. tribuloides. Caltrap-fruiting Oak.—Leaves ovate-lanceolate, taper-pointed, entire, smooth. Spikes aggregated. Calyx of the fruit spiny, covering the nut.—Diff. covered by the same leafy cohort as the preceding, in the forests of Upper Nepaul, flowering and fruiting at various seasons. A tree with smooth branches. Leaves on short flanks, lanceolate, more or less ovate, somewhat unequal at the base, about four inches long, and one and a half broad, rigid and rather coriaceous, with irregular, dilated, slightly curving veins; the upper surface polished; the under paler and opaque. Flowers monocious, in slender, downy, clustered, axillary or terminal, pendulous spikes, the male spikes most numerous. Stamens about eight, with a dotted central disk. Acorns spiked, scattered, ovate, smooth, obliquely pointed, about half an inch long, entirely concealed in the greatly enlarged calyx, which is downy, globose, and armed with very numerous, rigid, prominent, sharp thorns, a quarter of an inch, or more, in length, spreading in every direction. This species is called Cattum, or Catungu, in the Parbutty language; Shingali, or Cata Shingali, by the Nawars. Its great peculiarity consists in the acorns, which are capable, being entirely enclosed in a strongly muretated calyx, or globose cup, which approaches the nature of the chestnut, Fagus Caffiana, and in some of our specimens seems even to split into two or three valves. The flowers, however, agree with Quercus, to which genus Dr. Buchanan referred this remarkable plant. On one tree he observed the flowers to be all female.

14. Q. laurifolia. Laurel-leaved Oak. Willd. n. 12. Art. n. 4. Pursh n. 8. Michaux Querc. n. 10. t. 17, 18. —Leaves ovate, entire, smooth, nearly fleshy; tapering at the base. Nut roundish, even.—Native of shady forests, and the sea-coast, in Georgia and South Carolina, flowering in May. This is sometimes called the Swamp Willow, and was first brought alive to England, by the late Mr. Fraher, 1786. It rises to the height of fifty or sixty feet. Michaux speaks of the wood as of a good quality, but inferior on the whole to that of our fifth species, Q. virgata. The leaves are crowded about the ends of the branches, decussate, about four inches long, usually acute, but sometimes, as in Michaux's t. 18, remarkably obtuse. Acorns solitary, nearly fleshy, almost globose, with a fecal cup.

15. Q. imbricaria. Shingle Oak. Willd. n. 13. Art. n. 5. Pursh n. 7. Michaux Querc. n. 9. t. 15, 16.—Leaves elliptic-oblong, acute at each end, entire, almost fleshy; downy beneath. Nut nearly globose.—Native of the banks of rivers among the Alleghany mountains, and in the countries to the west, rarely to the east of those mountains, flowering in May and June. Brought to England in 1786, by Mr. Fraher. The leaves are twice the size of the lilac, acute, but not contracted, at their base, and downy on the under side. Acorns much like the last-described. This tree is forty or fifty feet high. Its wood is chiefly used by the French settlers in the Illinois country, for making boards to cover houses, whence the appellation of Q. imbricaria in Michaux, and of Shingle Oak among the English Americans. For although the scales of the cup are rather larger than those of Q. laurifolia, the specific name does not allude to that circumstance.

16. Q. ellipica. Oval-leaved Mexican Oak. Willd. n. 14. Nee in Annal. Scient. Nat. v. 3. 278. Fitch. Misc. Hftp. v. 1. 117. "Leaves elliptical, entire, coriaceous, nearly fleshy; rounded at each end; roughish beneath. Gathered by Lewis Nee, but without flowers or fruits, in the kingdom of Mexico, by the road from Ixmiuqilpan to Cimapan, as well as between Tixtala and the river Azul. The trunk is thick, twelve feet high, with a grey bark. Branches horizontal; the smaller shoots erect;
all very leafy. Leaves three inches long, and one and a
half broad, shortly ovate; smooth above; roughish and
veiny beneath, the veins forked. Footstalks thick and very
short. 

175. Banks le; Kämpf. t. 17. Wild. n. 11. (Kas no ki Kämpf. Amon. 816.)—Leaves obovate, pointed; serrated
towards the extremity; glaucous beneath. Nut roundish.
—Gathered near Nagasaki, in Japan, by professor Thunberg,
to whom we are obliged for a specimen. He describes it as
a very large tree, whose branches are somewhat umbelate,
erecet, round, purple, smooth, except some prominent
white points. The leaves are alternate, about three inches
long, and near two broad, with a blunt projecting point; their
upper surface smooth and polished; the under covered with
a fine glaucous mealy, and marked with prominent,
straight, parallel, but rather dilated, obliquely transverse
veins; the margin differently serrated upwards. Footstalks
about half an inch long, purple. Flowers axillary. Acorns,
by Kämpfer's figure, axillary, often in pairs, of a roundish
humid shape, pointed, not an inch long, their cups short,
seemingly marked with concentric lines; their flarks simple,
short and thick.

Hilp. v. i. 103.—Leaves obovate-oblong, coriaceous, entire;
flaking down; downy beneath; somewhat emarginate at the
base. Fruit racemosum. —Found by Louis Nee, in the kingdom
of Mexico, between Chilpancingo and Tixtala, and about
the river Azul. This is an elegant tree, twenty feet, or
more, in height. Trunk thick, with a dark-coloured bark
full of fissures. Branches horizontal; younger ones fur-
rowed, and dotted with white. Leaves fix or eight inches
long, and three broad, ovate, rigid; sometimes emarginate
at the base; green and shining above; downy beneath, with
the larger veins prominent, and the smaller reticulated.
Footstalks thick, a line in length. Stipulas crisped, downy,
deciduous. Female style large, axillary, two inches long;
the lower ones alternate, upper opposite. Acorns
ovate, half covered by their semilunar cup, which is the
size of the seed of Cicer aritinum, its scales scarcely at all
imbricated. Nee.

Hilp. v. i. 105.—Leaves obovate, entire, shining; some-
what heart-shaped at the base; downy and yellow beneath.
—Found in Mexico by the fame celebrated traveller and
botanist. This agrees with the preceding in its mode of
growth, and fruitification, intimating that it may be thought
a variety; yet the leaves are very different. They are of a
larger size, broader towards the end, and contracted to-
wards the footstalk, as well as more deeply emarginate at
the base; and their under side is clothed with ochre yellow
pubescence.

20. Q. semecarpifolia. Marking-nut-leaved Oak.—Leaves
obovate, obtuse, coriaceous, entire; heart-shaped at the
base; downy beneath; the young ones with spinous teeth.
—Gathered by Dr. F. Buchanan, on the banks of the torrents
in Upper Nepal, where its Parbutte appellation is Caffir,
and its Nawar name Ghiris. This is a middle-sized tree, with
angular branches, clothed when young with tawny down.
Leaves obovate, alternate, on short thick stalks, obovate-
oblung, four or five inches in length, and two in breadth;
more or less heart-shaped at the base; their upper surface
smooth and shining; the under opaque, clothed with rusty
down, and furnished with numerous, irregular, rather dif-
tant, transverse, prominent veins; their margin entire, finely
wavy. The extremity is usually rounded and obtuse, some-
times abrupt, sometimes tipped with a little spine. On young
branches the leaves are serrated with strong spines, or even
finnate, and clothed on both sides with rusty down. Stipulas
in pairs, awl-shaped, erect, permanent, as long as the foot-
stalks. Dr. Buchanan did not observe the flowers or fruit.
The aspect of the adult leaves is much like those of Semicarpus
Anacardium, or some of the entire-leaved species of Ficus.
Section 2. —Leaves more or less tomentose or serrated.

22. Q. annulata. Ring-cupped Oak.—Leaves obovate,
pointed; serrated in their upper half; somewhat glaucous
and downy beneath. Fruit spined. Nut oblong. Calyx fur-
rowed concentrically. —Gathered by Dr. Buchanan, at var-
ious places in Upper Nepal, bearing fruit, in December
1802. A very large tree, whose wood is excellent; the
branches two or three together, smooth. Leaves evergreen,
rigid, exactly like those of the last species, but somewhat
filky beneath, and less glaucous; the young ones very filky.
Stipulas linear, hairy, longer than the footstalks, deciduous.
Male flowers in pendulous, hairy, yellowish, shortish spikes,
springing from buds below the leaves, whose scales are
imbricated in five rows; female from three to six, in solitary,
axillary, upright, flaked, smooth spikes, about the length
of the footstalks. Calyx of the female flowers globose,
smaller than hemipede, composed of several concentric
imbricated layers, of which the outermost is smooth and
notched, the rest downy and entire. Germen globose. Style
very short and thick. Stigma three, obtuse. Acorns
quite suffil on the common flower-stalk. Cup rather smaller
than that of our British oaks, entire and even at the edge,
composed of seven or eight concentric, annular, imbricated,
crenate scales, externally filky. Nut ovate, acute, smooth
and even, twice as long as the cup. The Parbutties call this
tree Phullat; the Nawar Gifi, or Pas Iiringeli.

We find great reason to think that it may be, as Dr. Bu-
chanan first published, the same species with Thunberg's glauca
latt described. The leaves of his specimens flew a flight
degree of pubescence about the veins, but have not the
minute filikiness of ours. The greatest and most effential dif-
ference, if Kämpfer be as correct as usual, consists in the
female inflorescence. He delineates the acorns of glauca on
short, filike, axillary flaks, either solitary or in pairs; and
Thunberg describes the flowers as axillary. In our plant
the female flowers are indeed axillary, but they compose a
filked spike, and neither they nor the acorns have any par-
tial flaks. Such differences are found between other spe-
cies of Oaks, and prove effential and invariable. We there-
fore cannot but, for the present at least, rely on Kämpfer's
known fidelity, and propose our Q. annulata as a distinct
species.

23. Q. lamellosa. Many-cupped Oak.—Leaves elliptic-
oblung, pointed, serrated, many-veined; glaucous and fore-
most below. Nut roundish. Calyx of many concentric entire
layers, as long as the nut. —Discovered by Dr. Buchanan,
in the more remote woods of Nepal, bearing fruit in De-
cember 1802. In the Nawar language it is called Tuppsujha.
The tree is lofty, with smooth bluntly-angled branches.
Leaves alternate, six inches in length and two in breadth.
QUERCUS.

eelliptic-oblong, rigid, taper-pointed, sharply ferrated; smooth and green above; glaucous and often finely downy beneath, with innumerable, prominent, crowded, straight, parallel, mostly opposite, obliquely transverse veins; the apex and fize of the leaves much resembling Dillenia indica. 

Footstalks an inch and half long, tumid at the base. 

Stipulas deciduous. Female flowers in short axillary spikes. 

Acorns ovate, pointed, the fize of cheftsnuts, each completely enveloped and concealed by the large, globular, downy cup, which is as big as a small apple, and consists of eight or nine distinct, concentric, entire, imbricated layers, much more deeply separated than the rings of Q. annulata. An approach towards the genus Fagus, or Callaenas of sane authors, may be observed, as Dr. Buchanan figures, in this species, which is nevertheless a genuine Quercus, and far less doubtful than our tribuloides, n. 13. It proves however that the mere elongation of the acorn, beyond the cup, is not an indispensable character of the present genus. See also tomentosa, n. 42.

28. Q. diversifolia. Various-leaved Mexican Oak. Willd. n. 21. Nee in Annal. Scient. n. 3. 270. Fifth. Mfie. Hisp. v. 1. 107. Willd.—Leaves ovate, undivided or deeply toothed; yellow and downy beneath. Fruit spikcd, globule.—Found by Louis Nee, between the villages of Chalma and Santa Rofa in New Spain. A forest, from ten to fourteen feet high; its trunk seldorn straight; the bark cracked, dark-coloured; the branches alternate. Leaves either an inch and half long, and undivided, or two inches and a half, and deeply toothed; smooth and shining above; downy, and dull yellow, beneath. Footstalks hardly a line in length. Stipulas oblong, reddish, membranous, contracted at the base, deciduous. Acorns four or five, fesile, on a thread-shaped axillary flalk, two inches long. Cup the size and fhape of a pea, covered with scales. Nuts scarcely projecting above a line beyond the cup. Nee. The fruit, being fesile, is evidently spikcd, not, as the authors quoted term it, racemose.

Pikenet’s t. 196. f. 5. cited with doubt by Willdenow and Purh, appears to belong, as Linnens thought, to his own Hippomane fiponif. The fhape of the leaves cefainly does not agree with the above description, though perfectly answerable to Plumer’s figure of this Hippomane, which is Sapum ilicifolium of Willdenow, Sp. Pl. v. 4. 573, who there copies the fame fonym from Linnens, without any mark of uncertainty.

30. Q. gramunifia. Holly-leaved Montpellier Oak. Linn. Sp. Pl. 1415. Willd. n. 23. Ait. n. 6. (He foniis rotundifolius et pinpointis, e luco gramunio; Magn. Monsp. 140.)—Leaves roundish-elliptical, nearly fesile, undulate, with deep fimpan divaricate teeth; densely downy beneath; somewhat heart-shaped at the base.—Native of the wood of Gramont, near Montpellier, and of Spain. Cultivated in England in 1730. It blossoms in June. This is rather a small fragging tree, with numerous round grey branches, downy when young. Leaves evergreen, scarcely an inch long.
QUERCUS.

long, rigid, broadly elliptical, often nearly orbicular, very much undulated at the margin, their deep brown spinosous teeth pointing every way; the upper surface dark green, rather glaucous, besprinkled with minute hairy hairs; the under densely clothed with white entangled down. We have seen neither flowers nor fruit. Willdenow appears mistaken in discarding the synonymy of Magnol, which answers extremely well to the Linnean specimes; though indeed the author speaks of his plant as a variety of \textit{Q. Ilex}. It is, nevertheless, true that Linnæus confounded herewith a plant from Magnol's herbarium, which is not distinct from \textit{Q. Ilex}.

Native of several places in the neighbourhood of Mount Athos, according to professor Desfontaines, from whom we have a wild specimen. It flowers in May. This is a large and handsome evergreen tree, whose trunk is from twenty to thirty feet high; the wood hard, compact, and very useful; the bark even, not corky, though full of fissures; branches downy. Footstalks a quarter of an inch long, downy. Leaves various in shape, but more or less elliptical, an inch or half an inch long; either quite entire, or serrated with small spiny teeth; their upper surface, at least when young, besprinkled with minute hairy hairs; the under always very white and denely downy. Male flowers in copious, long, lax, pendulous spikes, with usually seven filaments; female on the same tree, axillary, solitary or aggregate. \textit{Acorus} cylindrical, an inch and half or two inches long, half an inch in diameter, caved and very palpable, either raw or roasted. Cup hemispherical, covered with numerous, obtuse, downy, closely imbricated scales.

32. \textit{Q. Ilex}. Common Evergreen Oak, or Holm Oak. Linn. Sp. Pl. 1412. Willd. n. 25. Ait. n. 7.—Leaves ovate-oblong, acute, coriaceous; entire or serrated; hoary beneath. Bark even. Nut ovate. The varieties are: \textit{s}, with lanceolate entire leaves; \textit{Smilax} Dalech; Bauch. Hill. v. 1. part 2. 101. Suber fecundus; Matth. Valgr. v. 1. 188, as to the figure; \beta, with lanceolate ferrated leaves; \iota; Matth. Valgr. v. 1. 186. Duham. Arb. v. 1. t. 123: \gamma, with rounder, less rigid, and more or less ferrated leaves; Phenodryus; Matth. Valgr. v. 1. 189, as to the figure. Ilex n. 3; Duham. Arb. v. 1. t. 124. This species occurs in various parts of the south of Europe, and north of Africa, and is hard, as well as evergreen, with us, thriving particularly near the sea, though of slow growth, flowering in May and June. It usually forms a large bushy tree, but occasionally rises with a straight naked trunk, and round head, to a great height. The wood is hard and heavy, valuable for many purposes. The French use it for pulleys in the navy. The bark is hard and even, not corky. Leaves various in shape and size; dark green, convex, and quite smooth above; hoary or downy beneath; their edges either revolute and entire, or irregularly notched and serrated. Footstalks half an inch long, downy. Acorns usually two, on an axillary downy stalk which is longer than the footstalk, ovate, hardly an inch long, with a scaly downy cup. They are eaten by hogs, but are very different in shape and quality from those of the leaf-deprived species. So many varieties, or species, nearly corresponding with these two, are mentioned by authors, that it is difficult to understand them. The subject requires, and well deserves, a practical investigation. Lamarck, under the article Chêne, in his dictionary, mentions several kinds, which he knew but imperfectly, and which we have no means of elucidating further,

so that we dare not adopt, or attempt to reduce them to order.

33. \textit{Q. Suber}. Cork Tree. Linn. Sp. Pl. 1413. Willd. n. 26. Ait. n. 8. Hunter's Eucl. Sylv. 362, with a plate; Suber; Camar. Epit. 115. S. primus; Matth. Valgr. v. 1. 187. S. latifolium, perpetuò virens: Duham. Arb. v. 2. 291. t. 80. S. latifolium; Ger. Em. 1547, the middle figure only. —Leaves ovate-oblong, blunt, coriaceous; entire or sharply serrated; downy beneath. Bark cracked, fuscous. Native of the south of Europe, and north of Africa. Duhamel says it can hardly bear the climate of the north of France. It lives however in our English gardens, where it has been kept more than a century. The bark is remarkable for a thick fyspous cortex, yielding the well-known substance cork. The leaves much resemble the broad variety of \textit{Q. Ilex}, nor do the acorns greatly differ from those of that tree. We have not been able to ascertain what authors mean by the \textit{Suber} angustifolium non ferratum, the figure of which, Matth. Valgr. v. 1. 188. Duham. Arb. v. 2. t. 81, we have cited as our first variety of \textit{Ilex}. We should suspect the \textit{Suber} itself to be altogether a variety of \textit{Ilex}, differing only in the bark; and that there might be a broad and a narrow-leaved variety of each; were not the dwarf tufted fuscous habit of the Cork Tree, on the sandy plains of Italy, Spain, &c. fo peculiar. Yet this possibly may, as well as the nature of the bark, be owing to the soil, for in strong ground the cork, according to Duhamel, degenerates. Willdenow says "the leaves of \textit{Q. Suber} are a little elongated at the base, running down into the footstalk, which is not the case with \textit{Ilex}!" but this character seems feebly permanent.

34. \textit{Q. coccifera}. Kermes Oak. Linn. Sp. Pl. 1413. Willd. n. 27. Ait. n. 9. (\textit{Ilex coccifera}; Camar. Epit. 774. I. aculeata coccediandifera; Garid. Aix. 245. t. 53. Niefoile in Mem. de l'Acad. des Sciences for 1714. 435. t. 17. 18. I. coccigera; Ger. Em. 1542.)—Leaves elliptic-oblong, rigid, smooth on both sides, with spreading, brylly, spinous teeth. Nut ovate. Calyx with spreading pointed scales. Native of the south of Europe, and the Levant, flowering in the spring. This is a bushy evergreen shrub, celebrated for producing the kermes, a valuable article of dyeing, before the introduction of cochineal, and which afforded the color kermesinus, or crimson. The kermes is an insect, of the genus \textit{Coccus}, which sticks to the branches, in the form of a red ball, the size of a pea. It is now out of use among dyers, and is only used by French apothecaries. The leaves of this shrub are, at most, but half the size of the leaf, though they vary much in magnitude as well as figure. They are diffuselyth with their rigidity, smoothness on both sides, and their prominent needle-like marginal prickles. The scales of the mature calyx are also much more elongated and prominent than in \textit{Ilex} or \textit{Suber}, and of an angular awl-shaped figure.

35. \textit{Q. Pseudo-coccifera}. Ballard Kermes Oak. Desfont. Atlant. v. 2. 34. Willd. n. 28.—Leaves elliptic-oblong, rigid, smooth on both sides, with spinous ferratures. Nut ovate. Calyx with flat, slightly spreading, scales. Observed by Desfontaines at Algiers and about Mount Athos. At Tunis it is called the "meal-bearing oak," probably from the use of the acorns as food. This is a tree, from fifteen to twenty feet high, with round branches, clothed with woolly down when young. The leaves are twice or thrice as large as those of \textit{Q. coccifera}, thicker and less wavy, with much smaller and shorter spinous ferratures, rather than teeth. Calyx clothed with numerous, flat, short, slightly spreading scales. Nut ovate, pointed. Willdenow, not having seen a specimen, has misunderstood the
the nature of the calyx, and has in other respects altered Desfontaines' specific character for the wood.

36. Q. rigidia. Rigid-leaved Oak. Willd. n. 29.—(Leaves coarsely glandulose, nucem cylindracea, nunc subrotundata, cupulata echinata; Tourn. Cor. 49.)—“Leaves oblong, undivided, with spiny ferratures, smooth; glaucous beneath; heart-shaped at the base. Footstalks bearded at the summit. Scales of the calyx of the fruit rigid, spreading.”—Native of the coast of Caramania. Willdenow.

A pretty species, sufficiently distinct from its allies. Branches pale brown, dotted. Leaves oblong, an inch or rather more in length, rigid, with spiny ferratures; deep green and shining above; glaucous beneath; cordate at the base. Footstalks very short, smooth, except at the top, where a line of brownish hairs, on each side, runs up the midrib. Calyx of the fruit feathery, becket with rigid, woody, lanceolate, spreading scales. Willd.

A specimen before us, gathered by the late Dr. Broussonet at Algiers, answers precisely to this description, especially in the curious character of the hairy lines, running a little way up the midrib of the leaf; but the foliage is equally green and shining on both sides. The calyx resembles that of coccorea, but its inner scales are longer, and more spreading.

37. Q. rotundifolia. Round-leaved Spanish Oak. Lamarck Dict. v. t. 723. Willd. n. 30.—“Leaves obovate-oblong, abrupt, with spiny teeth; heart-shaped at the base; smoothish above; downy beneath.”—Native of Spain. Seen by Lamarck, in a young state, in the gardens of Madrid. The branches are round and downy. Leaves stalked, an inch or more in length; glaucous-grey, and not quite smooth, above; white and cottony beneath. The acorns are said to be large and long, edible like chestnuts. This description is not applicable, on the whole, to our n. 31, Q. Ballota.

38. Q. humilis. Dwarf Portuguese Oak. Lamarck Dict. v. t. 719. Willd. n. 31. Ger. Em. 1340. (Q. pedem vix superans; Bauh. Pin. 420. Robur 7; Chf. Hift. v. t. 19.)—Leaves obovate, with spiny ferratures; heart-shaped at the base; downy beneath. Calyx of the fruit flattened. Nut oblong.—Found by Cluibus in barren sandy ground near Lisbon, very abundantly. The whole plant is rarely more than a foot high when wild; though Lamarck says it becomes twice or thrice as tall by culture. The young branches are downy. Leaves an inch, or inch and half long, on short footstalks; smooth and shining above; downy and hoary beneath; their larger veins straight and parallel. The acorns are described as more bitter than our common oak, their form oblong, their cups remarkably short and flattened.

39. Q. luftanica. Portuguese Gall Oak. Lamarck Dict. v. t. 719. Willd. n. 32. (Q. valentina; Cavani. Ic. v. 2. 25. t. 129? Robur 4; Chf. Hift. v. t. 18, and R. 5; ibid. 19. Gallina five Robur majus; Ger. Em. 1348, and G. minor; ibid. 1349.)—“Leaves elliptical, with deep pointed ferratures; downy beneath. Fruit racemose. Calyx hemispherical. Nut oblong.”—Native of Portugal, and perhaps Spain. Lamarck says this species confounds several varieties, all very low thorns, subject to bear gall; their branches copious and slender, they leaves small, intermediate in form between the evergreen and the ordinary oaks of Europe. Willdenow describes the leaves an inch in length, oblong, obtuse, rigid; their ferratures somewhat pointed; the upper surface polished and smooth; the under hoary with flender, tawny, crowded hairs. Footstalks short. Fruit racemose, or rather, as we should imagine, spiket. He adds that the figure of Cavanilles fearfully answers to the plant in question; and indeed that author describes his as a lofty tree, taller than Q. fies, with deciduous leaves, and large, solitary acorns. We have seen no specimen.

40. Q. infulata. Oriental Gall Oak. Olivier’s Travels, English edition, v. 2. 42. t. 1. 145. Willd. n. 33.—Leaves ovate-oblong, very smooth on both sides, deeply toothed, somewhat minutated, deciduous. Fruit feathery. Calyx telfilled. Nut elongated, nearly cylindrical.—This oak, according to Olivier, is scattered throughout all Asia Minor, from the Bosphorus as far as Syria, and from the coasts of the Archipelago, as far as the frontiers of Persia. It seldom attains the height of six feet, and the stem is crooked, with the habit of a thorn rather than a tree. The leaves are an inch or inch and half long, deciduous, bright green, smooth on both sides, but paler beneath; their ferratures deep and broad, not acutely pointed. Fruit solitary, nearly feathery. Cup slightly downy, its scales not very distinct. Acorns two or three times longer than the cup, smooth, nearly cylindrical. The galls produced on the young branches of this oak, from the puncture of a species of Diplopterys, are preferred to all others for dying, and are a great article of the Levant trade. (See Galls.) Olivier observes that the plant bears a number of different galls, besides the above, which are neglected, as useless.

41. Q. muraonata. Pointed-toothed Mexican Oak. Willd. n. 34. (Q. caltanea; Nee in Annal. Scient. Nat. v. 3. 270. Fitch. Mfle. Hift. v. t. 114. Willd.)—“Leaves obovate-ovate, with tooth-like notches; densely downy beneath. Fruit racemose. Nut globose, nearly covered by the calyx.”—Native of New Spain, in the road from Mexico to Acapulco, beyond the river Mecacla. A tree, twenty feet high, with a straight trunk, covered with a brittle dark-coloured bark. Branches erect, alternate, smooth, much sub-divided. Leaves three inches long, and one broad, acute; abrupt and heart-shaped at the base, their ferratures awned; the upper surface green and smooth; the under clothed with fine yellow down. Footstalks two lines long. Stipula none. Nee.

42. Q. tomentosa. Downy Mexican Oak. Willd. n. 35. (Q. peduncularis; Nee in Annal. Scient. Nat. v. 3. 270. Fitch. Mfle. Hift. v. t. 106. Willd.)—“Leaves obovate-ovate, with tooth-like notches; densely downy beneath. Fruit racemose. Nut globose, nearly covered by the calyx.”—Native of New Spain, in the road from Mexico to Acapulco, beyond the river Mecacla. A tree, twenty feet high, with an upright trunk, and grey brittle bark. Branches numerous, alternate, clothed with dense reddish wool. Leaves five inches long, hardly two wide, crowded, obtuse at the base; pointed at the end; bordered with tooth-like notches; green and smoothish above; downy; with prominent veins, beneath. Footstalks downy, very short. Female flowers on an axillary solitary stalk, three or four inches long. Acorns but little bigger than pepper-corons, each almost entirely concealed in its scaly, downy, reddish cup. Nee. This species agrees with ours thirteenth, tribuloides, in having its acorn concealed by the cup. The fruit is described, by the authors we are obliged to copy, as race-mose. We have seen no specimens, but analogy would induce us to suppose it rather spiket.

rowed, villous. *Leaves* alternate, from five to seven inches long, and three broad; green and shining above; more or less downy, and flesh-coloured, or reddish-brown, beneath; the margin undulated and crenate, the notches rounded; their edges turned towards the point of the leaf. Fruit supported by a very short common stalk. *Calyx* hemispherical, the size of Chick peas. *Cicer aritinum*; its scales acute at the point. Nut but little larger than the calyx. Plukenet's t. 54. f. 53, in some measure resembles the species before us, but is said to have a large fruit, and is cited by authors as *Q. Primus* Nee.

45. *Q. rugosa*. Rugged Mexican Oak. Willd. n. 38. Nee in Annal. Scient. Nat. v. 3. 275. Fitch. Misc. Hilp. v. 1. 112. Willd. "Leaves obvate-oblong, coriaceous, rugose; toothed towards the end; heart-shaped at the base; downy and rufy beneath."—Native of the woods of Huitzilqualla and Ocuila, in the way from Mexico to Santo Cristo de Chalma. A middle-sized tree, having numerous, alternate, round, grey branches, rough with minute prominent points. *Leaves* three inches in length, hardly two in breadth, thick and coriaceous; rugged, green and shining on the upper side; brown and downy at the back; heart-shaped at the base; the margin toothed from the middle to the extreme. *Footstalks* two lines long, thickened at their base. *Female flowers* in scaly axillary culls. Nee.

46. *Q. macrophylla*. Large-leaved Mexican Oak. Willd. n. 39. Nee in Annal. Scient. Nat. v. 3. 274. Fitch. Misc. Hilp. v. 1. 111. Willd. "Leaves obovate-oblong, coriaceous, rugose; toothed towards the end; heart-shaped at the base; downy beneath. Fruit spiky."—Found by Louis Nee, the discoverer likewise of the five preceding species, in the districts of Chilpanic and La Curva, and on the mountains of Quirapu, in New Spain. This is a tree, thirty feet high, with a stout upright *trunk*, and dense *bark*. The principal *branches* are horizontal; the *ruff* upright, furrowed when young. *Leaves* a foot long, and seven or eight inches broad; rounded at the end; gradually tapering down to the emarginate, or heart-shaped, base, where they measure only four lines across; their upper surface green and shining; the under yellowish, clothed with very minute down; the margin *crenate* and wavy. *Footstalks* very short and thick. *Female flowers* feathery on a common *stalk*, and encompassed with downy *bracteae*. Nee.

This is one of the tallest trees produced in the southern parts of the United States, and remarkable for the beauty of its form, as well as the large size of its *acorns*, which are plentiful and sweet, a delicious and beneficial food for hogs and other wild animals. The *wood* is excellent, much used for making wheel-carriages, and yet so readily split as to serve for balk-work and brooms. The *leaves* are fixed inches, or more, in length, and three broad; silky in the spring; smooth and glaucous in summer; sometimes very downy on old trees. *Footstalks* an inch long. *Stamens* five to ten. *Acorns* in inch and half long; ovate; their cups shallow, covered with numerous closely-imbricated scales. Michaux says the *bark* is whitish, peeling off in long strips.

48. "*Q. Chinquipuin*. Chinquipuin, or Dwarf Chefuneat Oak. Pursh n. 34. (Q. primoides; Willd. n. 41. *Q. Primus*, var. 4. pululちは; Michaux Querc. n. 5. t. 9. f. 1. *Q. Primus* Chinquipuin; Michaux Arb. v. 2. 65. t. 10. good. Pursh.)—Leaves on short stalks, obovate, smooth; glaucous beneath; tapering at the base; with nearly equal, dilated, acute, callous-tipped, tooth-like *ferrugineae*. *Calyx* of the fruit hemispherical. Nut ovate.—Found on dry mountainous lands, from Pennsylvania to Carolina, flowering in May, when, according to Mr. Pursh, it is highly ornamental. This is a humble *florib*, not above three or four feet high. The young leaves are whitish and downy beneath; the adult ones smooth and glaucous, scarcely above one-third the size of the preceding. *Female flowers*, according to Michaux, small, two or three together, on a short, solitary, axillary *flattt*. *Acorns* of a middling size, with a thin, nearly hemispherical, cup.

49. *Q. montana*. Rock Chefueat Oak. Willd. n. 42. Pursh n. 32. (Q. Primus; Sm. in Abbt's Inf. v. 2. 163. t. 82. *Q. Primus*, var. 2. monticola; Michaux Querc. n. 5. t. 7.)—Leaves on shortish stalks, obovate, acute; downy and white beneath; with nearly equal, dilated, short, blunt, callous-tipped tooth-like *ferrugineae*. Fruit in pairs, on short stalks. *Calyx* hemispherical, with rugged scales. Nut oblong-ovate.—Found abundantly, in rocky situations, on the mountains of North America, from New England to Carolina, flowering in May. Michaux tugs that this species would be well worth cultivating in Europe. The tree rises to the height of sixty feet; the *wood* is tough and very useful, the *bark* excellent for tanning. It differs from *Q. Primus*, n. 47, with which it has been confounded, in the confluent white downiness of the under side of the *leaves*, which are much smaller and less dilated upward. The *acorns* moreover are but half the size of that species, and more oblong, two together on a very short stalk.

50. *Q. bicolor*. Swamp White Oak. Willd. n. 43. Pursh n. 31. (Q. Primus, var. 5. tomentosa; Michaux Querc. n. 5. t. 9. f. 2. *Q. Primus* dicolor; Michaux Arb. v. 2. 46. t. 6. Pursh.)—Leaves nearly obovate, obovate; downy and white beneath; with very broad, unequal, obtuse, callous-tipped, lobe-like teeth. Fruit in pairs, on long bristle-pointed stalks. *Calyx* hemispherical. Nut oblong-ovate.—Native of low wet woods, from Pennsylvania to Carolina, flowering in May. Pursh. It grows to a very large tree. The *leaves* have extremely broad shallow teeth, or, as they might be called, lobes, approaching to the figure of our common English Oak leaves; their under side white and very downy. The *acorns* are sweet and edible, like most of the *Primus* tribe. Willdenow says the teeth are occasionally variable in size, one or two of them being sometimes remarkably elongated; and that the base of the *leaf* is more entire than in the foregoing.

51. *Q. Calflarea*. Yellow Oak. Willd. n. 44. Pursh n. 33. (Q. Primus, var. 5. escunina; Michaux Querc. n. 5. t. 8.)
t. 8.)—Leaves on long footstalks, oblong-lanceolate, pointed; somewhat downy beneath; with numerous, nearly equal, dilated, acute, callous-tipped, tooth-like serratures. Calyx hemispherical. Nut roundish-ovate.—Found in the Alleghany mountains, and on the banks of the Delaware, flowering in May. Pursh. Michaux says it occurs in all the fertile countries to the west of those mountains; and as the temperature of that climate agrees with the north of Europe, the tree in question would be well worth trying here. The wood is excellent; bark very serviceable in tanning; and the acorns sweet. The tree is large and handsome, of seventy or eighty feet high. Leaves much like those of our Sweet Chestnut in form, but glaucous and often downy beneath. Acorns much rounder than in any of the four preceding, and shorter in proportion to the cup. These Chestnut Oaks, Primus and its allies, seem not to have as yet attracted the notice of European cultivators, perhaps from their having been improperly confounded by botanists. The above accounts of their distinctions, and their valuable qualities, it is hoped, may cause them to be fought out, and introduced into this country. Their different acorns might surely be easily imported.

Section 3.—Leaves lobed at the extremity.

52. Q. aquatica. Water Oak. Soland. in Ait. Hort. Kew. ed. 1. v. 3. 357. ed. 2. n. 111. Willd. n. 45. Pursh n. 11. Michaux Querc. n. 11. t. 19. t. 20. f. 1. 4. 5. and t. 21. (Q. foliis cuneiformibus, obfoletæ trilobis, intermedio produciōne; Gron. Virg. 149. Q. folio non ferrato, in fummate quasi triangulato; Catecb. Carol. v. 1. t. 20. Herb. Linn.)—Leaves wedge-shaped, smooth; tapering at the base; dilated and obscurely three-lobed at the end, the middle lobe largest. Calyx nearly hemispherical. Nut roundish.—Native of swamps in North America, from Maryland to Florida, blooming in May. Miller is said to have cultivated this species in 1748, but it is little known in England. The tree is forty feet high; its wood, according to Pursh and Michaux, is little esteemed; but the latter is of opinion that it might prove more valuable if felled in winter; he mentions also that the tree is not peculiar to swamps, or inundated meadows, but occurs sometimes in dry sandy ground, as on plains near the sea-coast of Florida. Few trees vary so much in the shape of their leaves, according to age or situation, as this. The proper form of its foliage is wedge-shaped, much elongated and tapering at the base; dilated, rhomboid, or very slightly and bluntly three-lobed at the extremity; the edges entire; both sides usually smooth. Footstalks variable in length, but rather short; clothed, when young, with flary hairs, which are sometimes scattered over the back of the young leaf. Some of its leaves, however, even on the same tree, are deeply three-lobed; and those of young plants are, the first year, oblong and quite entire; the next two or three seasons, variously toothed and fruticate; infusorial that botanists know not how well to distinguish its varieties from some of the following species. The acorns are short and roundish, with a shallow cup, and hand generally in pairs, on short stalks.

53. Q. nigra. Barren Oak, or Black Jack. Linn. Sp. Pl. 141. Willd. n. 46. Ait. n. 12. Pursh n. 15. Sm. in Abbots's Inf. v. 2. 115. t. 58. Michaux Querc. n. 12. t. 22. 23. (Q. marylandica, folio trifido, ad fllasfas accedente; Catecb. Carol. v. 1. t. 19.)—Leaves wedge-shaped; somewhat heart-shaped at the base; dilated, abrupt, and very slightly three-lobed at the end; the middle lobe hortèct; smooth above; ruly beneath. Calyx hemispherical, with membranous scales. Nut roundish-ovate.—In barren sandy or gravelly woods, from New Jersey to Florida, flowering in May. This tree is of low growth, especially in the more northern states. It bears abundance of acorns, very good food for hogs. The wood is small, but excellent for fuel. Pursh. The leaves are twice or thrice the size of the leaf, singularly dilated, and abrupt, at the end; their lobes, when young, more evident, and each tipped with a bristle, which soon falls off. Acorns mostly in pairs, nearly felled, with very few acorns.

54. Q. triloba. Downy Black Oak. Willd. n. 47. Ait. n. 13. Pursh n. 14. Michaux Querc. n. 14. t. 16. (Q. rubra; Abbots's Inf. v. 1. 99. t. 50.)—Leaves wedge-shaped, with three terminal, brilly-pointed lobes; the middle one longest; downy beneath. Calyx of the fruit flatish. Nut nearly round.—Native of barren tracts, near the sea-coast, from New Jersey to Georgia, flowering in May. It was brought to England in 1800, by Meffra. Frazer. The tree is fifty or sixty feet high, of rapid growth, even in a poor Soil. Michaux describes it as very fit for making live fences; though the wood is most generally used in America for paling. The leaves are much smaller than those of Q. nigra, rounded, not heart-shaped, at the base, and with longer footstalks. Their lobes are direct, not laterally dilated, each tipped with one or more small bristles, and the under face is covered with dense white down. The foliage of young shoots, that spring up where forests of this tree have been burned, are often near a foot long, deeply pinnatifid, and sharply lobed; as represented in Michaux, t. 26. f. 2.

55. Q. nova. Dwarf Jagged Oak. Willd. n. 48. Pursh n. 13. (Q. aquatica; Sm. in Abbots's Inf. v. 2. 117. t. 59. Q. aquatica elongata; Ait. n. 111. Q. elongata oblong-wedge-shaped, smooth, somewhat fruticate; three-lobed at the extremity; lobes divaricated, pointed, the middle one largest; forks of the vein downy beneath.—In barren lands, called pine-barrens, of South Carolina, flowering in May. Pursh describes it as "a low-growing species, always keeping distinct from Q. aquatica." The leaves are almost felled, two or three inches long, much more diligently lobed than in aquatica or nigra, and more fruticate or angular beside, than in any of the three last described. The acorns are almost globular, with a very shallow cup.

Section 4.—Leaves fruticate, with pointed lobes.

56. Q. hemisphærica. Hemispherical Oak. "Bartram's Travels 320." Willd. n. 49. Pursh n. 12. (Q. aquatica maritima; Michaux Querc. n. 11. t. 20. f. 2.)—Leaves oblong-wedge-shaped, smooth, somewhat fruticate; three-lobed at the extremity; lobes divaricated, pointed, the middle one largest; forks of the vein downy beneath.—In barren lands, called pine-barrens, of South Carolina, flowering in May. Pursh describes it as "a low-growing species, always keeping distinct from Q. aquatica."" The leaves are almost felled, two or three inches long, much more diligently lobed than in aquatica or nigra, and more fruticate or angular beside, than in any of the three last described. Willdenow says they are evergreen, and that the foliage of the young plant is fo like Q. phellos, our first species, as to be hardly distinguishable. Michaux, however, affirms this supposèd species to be but a maritime variety of aquatica, and Pursh thinks it a young plant of that kind.

57. Q. elongata. Downy-leaved Oak. Willd. n. 50. Ait. n. 14. (Q. falcata; Michaux Querc. n. 16. t. 28. Pursh n. 22. Q. difcolor; Ait. ed. 1. v. 3. 358.)—Leaves downy beneath, fruticate, with three or more somewhat falcate, brilly-pointed lobes; the terminal one elongated, jagged. Calyx hemispherical.—In sandy soil, near the sea-coast; from New Jersey to Georgia, flowering in May. A very large tree, commonly called Spanish Oak; in the southern states, Red Oak. Pursh. The height of the tree is fifty or sixty feet. Leaves on long stalks; obtuse or rounded at the base; deeply lobed, or in form measure palmate; the lobes often recurved, or fickle-shaped; taper-pointed, and more or less notched at the end, each segment tipped with a long bristle. Acorns small, roundish; its cup hemispherical, with lax
QUERCUS.

58. Q. tinctoria. Dyers Oak, Black Oak, or Quercitron. Willd. n. 51. Ait. n. 15. Pursh n. 16. (Q. tinctoria angustifolia; Michaux Querc. n. 13. t. 24). Q. discoolor; Willd. Arb. 274.)—Leaves downy beneath, obtuse-oblong, dilated, widely finnate; lobes short, obtuse, slightly toothed, bristle-pointed. Calyx of the fruit flat underneath. Nut globose.—In all large woods, particularly in the mountainous parts, from New England to Georgia, flowering in May. It is one of the largest trees of the American forest, highly valuable for its timber, as well as bark, which last is so very superior in tanning to any other species of Oak. Pursh says, this Oak is found only in a good soil, always at a distance from the sea; attaining its greatest size, which is eighty feet in height, and eight in diameter, in the valleys between the high mountains of North Carolina. The bark is used by tamers, throughout the north and west parts of the United States. It gives a yellowish colour, whence the name of Quercitron, and which enhances the value of the leather. The bark, bruised and powdered, was in great request among dyers in France, before the war interrupted this branch of commerce. The leaves are conspicuous for their broad, angular, abrupt figure, a span long, and nearly as wide, with shallow finnate, and bristle-tipped angles. Acorns almost fleshy, globular, with a feysy, hollow, flat-tip cup.

59. Q. discoolor. Sinuous Dyers' Oak. Willd. n. 52. Pursh n. 17. Sm. in Abbots's Inf. v. 2. 111. t. 56. (Q. tinctoria finnata; Michaux Querc. n. 13. t. 25). Q. virginiana, venis rubris muriis; Pluk. Phyt. t. 54. f. 5.)—Leaves downy beneath, oblong, pinnatifid; leaves oblong, toothed, bristle-pointed. Calyx turbinate. Nut ovate.—In large forests, from Pennslyvania to Carolina, flowering in May. This resembles the preceding and Q. coccinea, n. 61. The young expanding leaves are covered with white down on both sides, which is not the case with either rubra or cocinea. Pursh says, this differs from the last in having much more finnate, or pinnatifid leaves, and larger, more ovate, acorns, whose cups are turbinate, or tapering at the base. The qualities of the wood and bark probably agree with the tinctoria, or Michaux, who considers the present plant as but a variety, would have mentioned the contrary.

60. Q. rubra. Mountain Red Oak. Linn. Sp. Pl. 1413. Willd. n. 53. Ait. n. 16. Pursh n. 20. Michaux Querc. n. 20. t. 35. 36. Abbots's Inf. v. 2. 205. t. 103. (Q. eucalypti divaricata, foliis amplexibus acutatis; Pluk. Phyt. t. 54. f. 4.)—Leaves smooth, oblong, finnate, on long stalks; lobes acute, sharply toothed, bristle-pointed. Calyx of the fruit flat underneath. Nut ovate.—Native of forests on a fertile soil, from Canada to Pennslyvania, and in all the country west of the Allegheny mountains, blooming in May. It was cultivated by Miller before 1739, and is to be found in several plantations. A large and handsome timber tree, of rapid growth; its wood highly useful for building and for carriages; and the bark is said by Michaux to be the very best known for tanning, the European tanners, settled in America, having found it, by experiment, more efficacious than any of the oak barks of Europe. The tree is ninety or one hundred feet high. Leaves four or five inches long, on footstalks about half that length; unequally finnate or pinnatifid, with rather spreading, but not remote, lobes, whose ends are very acute, as well as here and there, sharply toothed, each tooth and point tipped with a long bristle. Acorns rather large, ovate, with a short flat-bottomed cup. The leaves turn of a deep red in autumn, which hue is common to most American trees and shrubs, in a greater or less degree. Pursh says, this is exclusively known by the name of Red Oak, though various others are so denominated in several parts of America.

61. Q. coccinea. Scarlet Oak. Willd. n. 54. Ait. n. 17. Pursh n. 18. Michaux Querc. n. 18. t. 21. (Q. rubra Ait.; Ait. ed. 1. t. 3. 357.)—Leaves smooth, oblong, deeply and widely finnate, on long stalks; lobes diversified, acute, sharply toothed, bristle-pointed. Calyx of the fruit turbinate, half as long as the nut.—Native of woods, on a fertile soil, from New England to Georgia, blooming in May. This was one of the first American trees brought to Europe, having been cultivated before the end of the 17th century, by bishop Compton, as well as by the first earl of Portland. The bright red foliage in autumn gives the tree a beautiful and striking appearance, both in its native forests and our European plantations. It nearly equals the preceding in fine; the wood, according to Michaux, is better, but the bark less valuable. The leaves are larger, with deeper, more rounded, stiufes, and more dilatant lobes. Acorns half covered by the deeper, more turbinate, cup.

62. Q. Catechus. Barren Scrub Oak. Willd. n. 55. Pursh n. 21. Michaux Querc. n. 17. t. 29. 30. (Q. rubra Ait.; Sm. in Abbots's Inf. v. 1. 27. t. 14. Q. eucalypti divaricata, foliis amplexibus acutatis; Catech. Carol. t. 1. t. 23.)—Leaves smooth, oblong; wedge-shaped at the base; deeply and widely finnate, on short stalks; lobes three or five, diversified, acute, two or three-cleft, bristle-pointed. Calyx of the fruit turbinate, half as long as the nut.—Native of dry barren ground in Maryland, Virginia, Carolina, and Georgia, abundantly, flowering in May. This species is shrubby, not above fifteen feet high; its wood of a bad quality, used only for firing. The shortness of the footstalks, and the fewness of the lobes of the leaves, added to their acute base, are sufficient botanical disjunctions between the present and the two last, especially as the size and quality of the tree are so unlike those species.

63. Q. palustris. Marsh, or Pin Oak. Willd. n. 56. Ait. n. 18. Pursh n. 23. Michaux Querc. n. 19. t. 33. 64.—Leaves smooth, oblong, deeply and widely finnate, on long stalks; lobes distant, parallel, acute, sharply toothed, bristle-pointed; forks of the veins densely woolly beneath. Calyx of the fruit flattened. Nut nearly globose.—Native of low swampy woods, from New England to Pennslyvania, and in the Illinois county, flowering in May. Mesfer. Frazer are recorded as having brought this species to England in 1805, but it was previously cultivated in Holland and France. This is a large tree, whose wood is tough, used for making spoks of wheels. The leaves are smaller than those of rubra or coccinea, and with more numerous lobes than Catechus; their finnate rounded and very wide, and the forks of the veins marked by a tuft of glandular hairs. The acorns are small, globular, with shallow cups, and generally very abundant.

64. Q. acutifolia. Pointed-leaved Mexican Oak. Willd. n. 57. Nee in Annal. Scienc. Nat. v. 3. 267. Eich. Mittl. Hft. 11. 122. Britton.—Leaves four to six inches long, on footstalks about half that length; unequally finnate or pinnatifid, with rather spreading, but not remote, lobes, whose ends are very acute, as well as here and there, sharply toothed, each tooth and point tipped with a long bristle. Acorns rather large, ovate, with a short flat-bottomed cup. The leaves turn of a deep red in autumn, which hue is common to most American trees and shrubs, in a greater or less degree.
QUERCUS.

inches broad, their footstalks an inch in length; ovate and unequal at the base, gradually contracting upwards to a sharp point, finuated, beset with awl-shaped teeth; green and thinning above; reddish and vein beneath, the forks of the veins villous. Female flowers in axillary four-flowered clusters, (or rather, we prefer, spikes.) Germs ovate. Acorns small, scarcely as big as a pea, nearly covered by the cup, which is clothed with blackish scales. Nee.

65. Q. candidissima. Hoary Mexican Oak. Willd. n. 58. Nee in Annal. Scient. Nat. v. 3. 277. Fitch, Mifc. Hilp. v. 1. 115. Willd.—"Leaves ovate, finuated; white and downy beneath; lobes toothed, bristle-pointed."—Native of New Spain, in sandy ground near Tixtala. A tree of a middling size, with a dense head of upright branches. Leaves nine inches long, four wide, tapering at each end, finuated, with bristled-pointed teeth; green and smooth above; white and downy underneath. Footstalks four lines in length. Flowers and fruit not observed. Nee.

66. Q. illisatia. Holly-leaved, or Bear Oak. "Wangen. Amer. 79. t. 6. f. 174." Willd. n. 59. Alt. n. 19. (Q. Banierti; Michaux Querc. n. 15. t. 27. Pursh n. 23. Q. aquatica? Sm. in Abbot's Inf. v. 2. 157. t. 79?)—Leaves obovate-wedge-shaped, with three or five deep bristled-pointed lobes, entire; downy beneath. Fruit stalked, in pairs.—Found in dry barren fields, and on mountains, from New Jersey to Virginia, flowering in May; covering, wherever it occurs, large tracts of ground, thence termed Oak-barrens. It is known by the name of Bear Oak, Black Scrub Oak, and Dwarf Red Oak. Pursh. A small four to six feet, occasionally more, in height, with downy branches. Footstalks downy, near an inch long. Leaves two inches, or two inches and a half long, and near two wide, tolerably uniform, acute at the base, cut into five, rarely but three, deep divericated, broad, acute lobes, entire at the margin, and scarcely toothed at the summit, though tipped with one or two bristles; the upper side green, veiny, and smooth; the under pale, and finely downy. Female flowers in pairs, on thick, solitary, axillary, downy stalks, much shorter than the footstalks. Acorns about half an inch long, nearly globular, half covered by their fealy hemispherical cups. Michaux thinks this species would serve well for making quick hedges. A specimen from Kalm, unnamed, is in the Linnaean herbarium.

67. Q. Pseudo-fiber. Baftard Cork Oak. "Santi Viagg. 156. t. 4." Spreng. Antiq. Bot. 16. t. 1. Willd. n. 63. Desfont. Atlant. v. 2. 348.—Leaves ovate-oblong, finuated, hoary beneath; lobes numerous, pointed, entire. Bark fleshy, cracked. Nut ovate. Calyx muricate, with lax, recurved, linear scales.—Native of the mountains of Tucanu, Spain, and Barbary. Desfontaines gathered it on mount Atlas, and the abbe Durand near Tangier. A tree fifty or sixty feet high, whose bark is corky, though less so than in Q. Suber, n. 32. Young branches downy or hoary, sometimes smooth, fringed. Leaves deciduous, an inch and a half to three inches long, an inch or an inch and a half wide, acute; entire and slightly heart-shaped at the base; somewhat dilated upwards, and bordered with numerous, uniform, small, broad, acute, lobes or serratures, separated by roundish sinuæ; upper surface green and smooth; under glaucous, hoary, or somewhat downy. Acorns on short stalks, ovate, above an inch long, half covered by the cup, which is downy, and clothed with lax bluish scales, recurved at their tips. Desfontaines says the leaves of young trees are deeply finuated and serrated; those of old ones more slightly so. In our specimens from Durand and Broulonet, the under side is scarcely downy, except a dense fringie to the mid-rib. The transverse veins are more numerous, straight, and parallel, than in Sprengel's plate. Footstalks rather above half an inch long, smooth or downy. Acorns nearly fleshy, crowded about the ends of the branches. Yet we think it must be, at least, the plant of Desfontaines.

68. Q. Europea. Great-branchly-cupped Oak, or Velanida. Linn. Sp. Pl. 1414. Willd. n. 61. Alt. n. 20. Mill. lc. t. 215. Olivier's Travels, English edition, v. 2. 44. t. 13. (Q. orientalis, calafane folio, glunde recondita in cupula cafjia et quafomuq; Tourn. Cor. 40. Velani; Tour Noy. v. 1. 128. Glans Cerri; Dallech. Hilu. v. 1. 7.)—Leaves ovate-oblong, with bristle-pointed tooth-like lobes; hoary beneath. Calyx of the fruit very large, hemispherical, with lanceolate, elongated, spreading scales. —Native of the Levant. Miller cultivated this Oak in 1731. The tree is not so lofty as some other species, nor is the wood much esteemed, or used, but in cabinet work. Leaves stalked, about three inches long, bright green; a little downy at the back; their edges, as in the last, very coarsely and acutely serrated, rather than lobed, each tooth tipped with a brily point. Acorn large, short, a little hollow at the top. Cup fesile, woody, two or three inches in diameter, from the projection of its numerous, oblong, thick scales. These cups are used, as well as the gall-nut, (see n. 46.) by the Orientals, Italians, and English, in dyeing, and are a considerable article of commerce. Tournefort says the modern Greeks call these acorns Velanida, a corruption of Palma, and the true Velanida. The young acorns and cups, gathered from the tree, are much more esteemed than such as fall of themselves, when fully grown, and fell for twice the price of the latter. Dalechamp, Lobel, and Bautin, mistake the urine cup and acorn of this species, as belonging to Q. Ceris, n. 83.

Sect. 5.—Leaves finuated, with blunt or pointlefs lobes.

69. Q. alba. White Oak. Linn. Sp. Pl. 1414. Willd. n. 62. Alt. n. 21. Pursh n. 29. Michaux Querc. n. 4. t. 5. (Q. alba virginiana; Cateb. Carol. v. 1. t. 21. f. 2.)—Leaves oblong, deeply pinnatifid; glaucous beneath; lobes linear-oblong, obtuse, entire, dilated upwards. Fruit stalked. Calyx depressed, warty. —Native of woods, on a fertile soil, from New England to Carolinas, flowering in May; cultivated here in 1724, by Mr. Purcell. Pursh says it is one of the most abundant and useful of its genus, in America, and grows in the middle States to an immense size. The adult leaves are nearly a fipan long, deeply and elegantly pinnatifid; tapering and acute at the base; gradually dilated upward; somewhat abrupt, though three-lobed, at the end; their lobes all entire, blunt, pointlefs, veiny; the upper surface green and thinning; the under opaque and glaucous; not downy, as Linnaeus and Willdenow define them, except perhaps when young. Footstalks short, angular, half an inch, or more, in length. Fruitchalks twice as long, each bearing one or two, lateraly sessile, ovate acorns. Full an inch in length, with a short tuberculated cup. Michaux observes, that this Oak is preferred to all others in America, for building houses and ships; as well as for cafsks. The wood is so tough and pliable, as to serve for making bafkets and brooms. The acorns are sweet, and Parkinon records that, in his time, the Indians were said to obtain from them, by boiling, an oil which they used in cookery. A supposed variety, called repandus, is figured by Michaux, in which the leaves are merely waved, not lobed; and green on both sides, though downy beneath. With this we are unacquainted, as also with Willdenow's intermediate variety, called pubescens. 

70. Q. Fagus. Italian, or Small-branchly-cupped Oak. Linn.
is more general in the woods and hedges of Britain, nor more important as an object of national culture. The tree is the most ornamental to our plantations and landscapes; the wood more useful than any other, for its hardnèfes, toughness, and durability; the bark peculiarly valuable for tanning. The leaves are alternate, with short, or scarcely any, footstalks, obovate-oblong, smooth, irregularly incised, with obtuse, rounded, pointèfs, entire leaves; their upper side of a rich shining green; the under pale, slightly glaucous; the base somewhat heart-shaped, or auricled. 

Chiffers, or rather spikes, axillary; the male ones lax, pedunculose, many-flowered, yellow; female on footstalks an inch and a half or two inches long, composed of about three, laterally sessile, green flowers, surrounded by a naked elongation of the common flalk. 

Calyx of the male branny, bell-shaped, mostly five-cleft, with about ten flòres; of the female carnaceous, scaly, downv, globose, at length hemispherical, woody, entire. 

Germn ovate. 

Style short, cylindrical. 

Stigmas three. 

Acorn elliptic-oblong, thrice the length of the cup. This being what Linnaeus, as well as British botanists, always considered as Quercus Robur, the superior quality of its wood, no where better understood than here, entitling it, above all others, to that appellation, we cannot, on any account, submit to the errors of Willdenow, or any other writer, who has been pleased to change the name; and we feel equal forprize and regret that the excellent editors of the new Hort. Kew. should, in this case at least, have carried their implicit conformity so far. We trust they will hereafter correct themselves in this point, as well as in the barbarous name Araucaria, retained by Willdenow, contrary to all propriety, for Dombeya. See that article.

72. Q. sessiliflora. Selfile-fruited Oak. 

Engl. Bot. t. 1845. (Q. Robur; Wild. n. 64. 

Ait. n. 23. Lamark Dict. v. 1. 717. 

Mart. Ruth. t. 11, var. sessilis. Q. sessilis; Ehrh. Arb. 87. Q. platyphyllus mas et femina; 

Dalech. Arb. 1342. 2. Q. sessiliflora var. sessilis. 

Bauh. Pin. 419. Raull Syn. 440, 

Leaves on longish footstalks, deciduous, oblong, smooth; 

finules opposite, rather acute; 

Native of woods and hedges, in the temperate parts of Europe; rather less common in England than the preceding, flowering in April or May. Professor Martyn has rightly corrected Miller, who mentions the present as the common Oak of this country, and the former as rare. Why the German botanists, like Lamark, take this for Robur, is difficult to understand, unless the mistake originated in inattention to the qualities, as well as history, of the trees. 

The wood of our sessiliflora, in which name we gladly follow Mr. Salisbury, is of far less value than the true British Oak, and the importance of distinguishing the two species becomes, therefore, the more obvious. The leaves grow on longer footstalks, and are generally more equally and regularly pinnatifid. The female flowers, and the acorns, are almost perfectly sessile. In English Botany four stigmas are delineated; but we know not how far that character, which would be an excellent one, is constant.

73. Q. pubescens. Downy-waved-leaved Oak. 

Wild. n. 66, excluding the reference to Fl. Brit. (Q. Robur lanuginosa; Lamark Dict. v. 1. 717. 

Robur prima; 

Clus. Dict. v. 1. 18.)—Leaves obovate, flaked, 

finulate; 

downy beneath; 

lobes obtuse, angular, wavy; 

somewhat heart-shaped and unequal at the base. 

Fruit nearly sessile—Native of France, Austria, Hungary, Tartary, and of the Val d’Aosta, Piedmont, in which last place it was gathered by Mr. Davall. We have seen a tree of
QURCII.

this species, growing on the north lawn at Holkham, Norfolk, the seat of Mr. Coke, where it was planted by his an
celor, the earl of Leicester; but no British writer seems
acquainted with the species in question, though unques
tionably distinct. Willdenow justly says it is like his 
lobes, but the foliage is different, being of more
Ait. 1797. P. pubescens; 
Ait. n. 25, but not of Wildenow. Q. Robur nigra; Lamarche Dict. v. 1. 717. Chêne noir; Secondat du chêne. 3. t. 57.—Leaves elliptic-oblong, falked, finuated; downy and hoary beneath; lobes numerous, obtuse, even, and en-
tire; base equal. Fruit Cicell. Native of France and the
south of England, flowering in April and May. Professor
Martyn had its specimens from the New Forest, Hampshire, in which it is known by the name of the Durmalt Oak. The
whole tree is well described by him as having much the air
of a chef-ten, and being of freer growth than the true Robur;
the bark lighter coloured and smoother; the wood not so
strong, nor of so firm a texture. The leaves are less deeply,
but more copiously, finuated, with five, six, or seven short
lobes at each side; the under surface downy, and of a hoary
grey, with purplish ribs. The foliage appears later than in
either of our common Oaks, and lasts longer, sometimes
the whole winter. Acorns Cicell, rather large. Lamarche's
description, indicated above, accords exactly with our
Oaks, but is Examined with our departed friend Willdenow, in dis
inguishing the Durmalt Oak from our felfiflora, but he errs in referring to it as pubescens, and has led 
Mr. Aiten into the same mistake. Its leaves are more oblong, less deeply
finuated, flatter, not undulated; the under side whiter, with
coloured veins. The fruit larger, and more decidedly Cicell.

Q. pyrenaica. Pyrenean Oak. Wild. n. 67.—
"Leaves oblong, pinatifid, falked; downy beneath;

somewhat heart-shaped and unequal at the base; lobes ob-
tufe, slightly toothed. Fruit Cicell."—Native of the Pyrenees.
The leaves are larger than in felfiflora, falked, deeply finuated; 
denly downy underneath. Fruit Cicell downy. Acorns four, Cicell on one common elongated falk.
It differs abundantly from pubescens, in having much
larger leaves, finuated in a pinatifid manner, very downy
beneath; and falked fruit. Such is Willdenow's account.
We have seen no specimen. Can this be our above-men
tioned variety of pubescens?

Wild. n. 68. (Thehodrys alba augufiifolia, fioio
ferrato; Dalech. Hift. 25.) Leaves on short downy
falkes, ovate, with numerous, uniform, shallow lobes;
downy beneath; somewhat heart-shaped and unequal at
the base. Fruit Cicell.—Native of Spain and the south of
France. Leaves small, an inch and half long, deciduous,
Falked, very slightly finuated, or, more properly speak-
ing, coarsely toothed, the lobes being very short, equal,
and obtuse; the upper side polished and smooth, the under
white and downy. Footfalks downy. Fruit Cicell. Will
denow. In the Limnanth earbarium are species, gathered
by Baron Alltienroer in Spain, which answer extremely
well to the above description, and not amiss to the figure
of Dalechamp, which Lamarche cites with hesitation. In the
free however, the lobes, or teeth, are acute, and the upper
surface covered with minute hairy hairs. There are also long,
linear, recurved, ramentaceous ftipulae, that are soon
deciduous. We do not scruple to consider this as Lamarche's
plant at least, and probably Willdenow's.

Mie. Hifp. v. 1. 116. Willd.—Leaves ovate-vedge-
shaped, finuated, smooth; lobes toothed."—Native of New
Spain. Branches furrowed, alternate. Leaves four inches
long, two inches, and half wide, smooth, alternate, orbi-
cular towards the extremity; wedge-shaped at the lower
part; finuated; the lobes rounded, obtuse, toothed. Foot-
flakes slender, three or four lines in length. Nee.

78. Q. obfulfoba. Blunt-lobed Iron Oak. Michaux
Querc. n. 1. t. 1. Purf. n. 25. (Q. ftellata; Wild.
n. 71. Ait. n. 26. Wengenh. Amer. 78. 6. t. 15.)—
Leaves oblong, finuated, roughish on both sides; lobes ob-
tufe; the upper ones dilated, abrupt, slightly divided.
Calyx of the fruit hemispherical.—Found in mound of the up-
land forests, from Canada to Florida, blooming in May. 
The tree is fifty or sixty feet high, spreading, its timber of
great value for ship-building. The whitenefs of the bark,
as in Q. alba, causes both these species to be called White
Oak by the Americans, who nevertheless know how to dif-
tinguish their timber. The leaves of the pretant are roughly
beneath, with minute rusty hairs, not hoary; and their
upper surface appears to partake occasionally, if not always,
of the same fort of pubefcence. Their length is from three
to five inches; the base wedge-shaped, spreading upwards
into two smaller, opposite, rounded lobes, beyond which the
fog' dilates, suddenly and widely, into a pair of broad,
flattly cloven, or emancipate, lobes; and, after another
sudden contraction, ends in a terminal three-cleft one. 
The margin is entire throughout. Footfalks short, downy.
Acorns three or four on a short falk, of a middling fize,
scarcely exceeding our British Oaks, elliptical, about half
enfolved in the fcaly cup.

79. Q. lyrata. Over-cup Lyrate Oak, Swamp-poif, or
Ait. n. 27. Purf. n. 28. Michaux Querc. n. 3. t. 4.—
Leaves oblong, deeply finuated, smooth; much contracted
in the middle; lobes acute; the upper ones dilated, an-
gular, and abrupt. Calyx of the fruit glofbo, mucrinated,
nealy covering the nut.—Native of swamps, from Carolina
to Florida, and on the Missifipi; flowering in May. Purf.
Michaux says, that though he always found these species in
waterly places, its growth, in a dry surfly-ground, ex-
ceeded that of all other species planted with it. He gives
fifty or sixty feet as the height of the tree; Purf from eight
to fifteen only. The smooth fine-green leaves have more
acutely-angular lobes than the foregoing, and are remark-
ably contracted about the middle. Acorn glofbo, nearly
covered by the globular prickly cup.

80. Q.
80. Q. macrocarpa. Large-fruited Oak, or Over-cup White Oak. Wild. n. 73. Pursh n. 26. Michaux Querc. n. 2. t. 2. 3.—Leaves oblong, lyrate; downy beneath; terminal lobe very large, three-clit, finnatin. Calyx of the fruit hemispherical, scaly, fringed with bristles.—Found on dry flat or limehony hills, in all the countries to the west of the Alleghany mountains, flowering in May. A large tree, with a whole wood, according to Pursh and Michaux, is very excellent. The bark of the young branches is corky. In wet situations the whole plant languishes, and becomes covered with lichens. The leaves are a foot long, more truly and precisely lyrate than those of the last; but the specific name of the prefont is excellent, the acorns being larger than those of any other known American species. Their form is oval, their length two inches, and they are half covered by the cup, several rows of whose broad scales end in long bristles, making a rigid fringe.

81. Q. oliveformis. Olive-shaped Mycty-cup Oak. "Michaux Arb. v. 2. 32. t. 27." Pursh n. 27.—Leaves oblong, smooth, glaucous beneath; deeply and unequally pinnatifid. Fruit elliptic-ovate. Calyx cup-shaped, fringed."—Observed by Michaux on the banks of Hudson's river, and in the western parts of New York; by Pursh in Pennsylvania and Virginia, on iron-ore hills; flowering in May. This is described as a large tree; the foliage handsome, somewhat resembbing that of the last. We have not examined either a specimen or figure. Willdenow does not mention this species.

82. Q. cirtina. Hairy-cupped Oak. Lamarrck Dict. v. 1. 718. Olivier's Travels, English edition, v. 2. 5. t. 12. (Q. Tournefortii; Wild. n. 74. Q. orientalis latifolia, foliis ad collam pulchrre incisis, glade maximâ, cupulâ cuntis; Tourn. Cor. 40. Voy. v. 2. 172.)—Leaves on long stalks, oblong, deeply pinnatifid; downy beneath; lobes lanceolate, blunt, nearly entire. Calyx of the fruit hemispherical, downy, bristly.—Gathered by Tournefort in vallies and plains near Tocat, in Armenia. Olivier says it is met with throughout great part of Asia Minor and Syria. The timber is brought to the arsenal of Constantinople, from the southern shores of the Black Sea, and is also most commonly employed for the frame-work of houses. The tree grows to a considerahle height, and furnishes excellent wood. He, who takes the tree in question for Q. Cerris of Linnaeus, may, possibly, confound the real Cerris along with it, as Lamarrck, though not without error, has combined them. Olivier's plate, however, very clearly represents the above plant of Tournefort; and Lamarrck's excellent definition of the same, a variety of his cirtina, is abundantly sufficient to flarip it a species.

"Leaves very softly villous, deeply pinnatifid; their segments oblong, nearly simple, obtuse, somewhat peltate, (or parallel.) He says it is reported to grow wild in the province of Angoumois, and is a tree of handsome aspect, remarkable for its soft, downy, broad leaves, cut very deeply into large segments, blunt at their extremity, often simple, sometimes furnished with a few angles, or short lobes, at their posterior margin. Acorns fehle, their cup bristly, as in the Burgundy Oak (Cerris). Tournefort's specimens agree with the Angoumois Oak, and is called, seen by Lamarrck in a cultivated plantation, at Genoanville. We have seen no specimen, but the above accounts are sufficiently clear to admit of no doubt. Olivier's plate represents the leaves three or four inches in length, their segments about an inch long, almost all simple and undivided, bluntish, entire, more or less divaricate, each making an angle with the narrow linear border of the main rib. Footstalk slender, an inch, more or less, in length, apparently smooth. Acorns lateral, about an inch long, elliptical, obtuse, solitary, on short simple stalks; the cup beft with numerous soft taper bristles, divericated upwards and downwards, near half an inch long. Nothing is exhibited, or described, concerning the species, which are very remarkable in the two following species.

83. Q. Cerris. Turkey Oak. Linn. Sp. Pl. 1415. Wild. n. 75. Alt. n. 28. (Q. cirtina x c. ; Lamarrck Dict. v. 1. 718. Q. halipheus; Jull. in Hort. Paris. Q. burgundica, calyce hispido; Bauh. Pin. 420. Cerris Pinn. majore gladio; Lob. l. c. v. 2. 156. Dod. Pempt. 834. Ger. Em. 1345. Cerris; Dalech. Hift. v. 1. 6. 50.)—Leaves coarsely serrate, oblong, deeply and unequally pinnatifid; hairy beneath; the lobes lanceolate, acute, somewhat angular. Stipulas longer than the footstalks. Calyx of the fruit hemispherical, bristly.—Native of France, Italy, and the Levant. Sometimes cultivated in England, but not commonly. This is a tall handsome tree, whose synonyms are much confused by old writers with Q. Aegilops, n. 68, and by more recent botanists with the following. Its leaves are deeply pinnatifid in the manner of the foregoing; or more or less unequally; but the lobes are more acute, pointed, and most generally angular, sometimes remarkably lobed or compound. The under side differs essentially, in being neither downy nor hoary, but rough with minute, scattered, tawny, bristly hairs; the upper, which is of a darker green, and rather shining, is also occasionally roughish to the touch. Footstalks rough, thick, hardly a quarter of an inch, sometimes not a line, in length. Stipulas linear, acute, downy, from half an inch to an inch long, permanent, accompanied by an axillary tuft of similar, but smaller, scales. The acorns we have not seen. They are represented sessile, two or three together, large, oblong, with an hemispherical cup, which is faggy with long bristles, projecting in every direction. They are said to be peculiarly bitter and astringent.

Lamarrck affirms, from his own observation, that the Q. orientalis latifolia, glade maximâ, cupulâ cuntis, Tourn. Cor. 35, barely differs in any respect from this. If so, the term latifolia is not appropriately applied, unless Tournefort had also noticed, as in our leaf, the deep divisions of the leaves, which are full as remarkable in the present species.

84. Q. aegilops. Austroian Oak. Wild. n. 76. (Q. Cerris; Hoff. Syn. 520. x and z. Alt. n. 28. Q. cirtina, c. Linn.; Lamarrck Dict. v. 1. 718. Q. calyce hispido, glade minor; Bauh. Pin. 420. Cerris; Cluf. Hift. v. 1. 20. excellent. Cerris minoris ramulus cum flore; Ger. Em. 1346, with Clufius's figure. Cerris Plinii minoris gladio; Lob. l. c. v. 2. 156. Ger. Em. 1345. Aegilops minore gladio; Dod. Pempt. 831. Halipheus, Cerris foemina; Dalech. Hift. v. 1. 7.)—Leaves on long stalks, ovate-oblong, slightly but copiously imbricate; downy and hoary beneath; lobes short, ovate, acute, entire. Stipulas shorter than the footstalks. Calyx of the fruit hemispherical, bristly.—Native of Aulania, Hungary, Carniola, Italy, and other parts of the south of Europe, in flary mountainous places. It occurs not unfrequently in plantations of exotic trees, both in France and England, being generally mistaken for Q. Cerris, from which it is only too easily be more certainly distinct. This tree is taller than the Common Oak, Q. Robur, and in favourable situations rises perpendicularly to a considerable height, as Clufius described it; though Lamarrck says it is smaller, less handsome, more twisted and knotty, than the last, as well as often hollow. The wood is whiter, softer, and less valuable, than Q. Robur; the bark grey, tolerably even. Branches forming a round
leaves two or three inches long, acute, generally rounded and a little unequal at the base; their upper surface of a fine shining green, and nearly smooth; the under whitish, clothed with fine dense down; the margin cut, at each side, into four, five, or six, tolerably regular, rounded or ovate, acute, pointed, entire lobes, more or less deep, separated by round sinus; the disk of the leaf being left entire, of a considerable width. Footstalks near an inch long, downy. Stipulas as in the foregoing, but smaller and shorter, usually about half the length of the footstalks. Acorns like those of the luff, but smaller. The figures of Lobel, Dodonaeus, and Ger. Em. 1346, do not well represent the leaves of this species, or indeed of the former: that of Clusius, adopted by the editor of Gerard, in p. 1346, is perfectly correct. The cuts of Dalechamp, both of one and the other, are sufficiently expressive, and very correct as to the footstalks. The lobes of either of these species are quite pointed, but rather more pointed, as well as acute, than those of Eustachus, n. 70.

We have thus added eight species of Quercus to Willdenow's list. Those botanists who may take the trouble of following us with attention, will perceive that this valuable genus itself requires elucidation, particularly with respect to the European, and, above all, the oriental kinds; some of which, barely indicated by authors, we have been obliged to leave unexplained. Of the most common and important species, Q. Robur, we have seen in Mr. Coke's woods at Holkham, some striking varieties, at least, whose distinctions and qualities are well worthy of examination. Two of these have shorter flower-stalks than the common Robur, and one of them is three weeks earlier in coming into leaf than the other. The footstalks of both are longer than is usual in Robur. How far a difference of quality in the wood may accompany these botanical distinctions, we must refer to the inquiries of those who are interested in, and have the means of investigating, so important a subject, which is indeed of the first economical, and even national, consequence. It is much to be wished that the species of the Norway Oak, so valuable for floors, on account of its straightness, and freedom from knots, could be determined. Perhaps these circumstances are owing to its being drawn up straight, with few branches, in its clove native forests, and therefore it may not be specifically different from one or other of our own species. Michaux, and other writers on the American Oaks, have taught us, that the pubescence of the leaves in this genus is of more specific importance than had previously been supposed, and we therefore have paid the more regard to it in discriminating those of the European kinds. The flowers, male and female, appear still to demand more precise investigation and comparison, than they have any where received. S.

Quercus, in Gardening, furnishes plants of the forest, deciduous, evergreen, ornamental tree-kinds, of which the species cultivated are, the common oak-tree (Q. robur); the willow-leaved oak-tree (Q. phellos); the chestnut-leaved oak-tree (Q. prunus); the black oak-tree (Q. nigra); the red oak-tree (Q. rubra); the white oak-tree (Q. alba); the Italian or small prickly-cupped oak-tree (Q. cifculus); the great prickly-cupped oak-tree (Q. argilopa); the Turkey oak-tree (Q. cerris); the evergreen or holm oak-tree (Q. ilex); the holly-leaved evergreen oak-tree (Q. grahamia); the cork-barked oak, or cork tree (Q. lubr); and the kermes oak-tree (Q. coccifera).

Of the first there are several varieties; as with the acorns on long peduncles. This is found in the woods of Kent and Sussex, where there are many large trees. The leaves are not so deeply sinuate, nor are they so irregular as in the common fort; but the indents are opposite; they have scarcely any footstalks, but fit close to the branches; but the acorns stand upon very long footstalks. The timber of this fort is accounted better than that of the common oak, and the trees have a better appearance.

The broad-leaved evergreen oak, which grows upon the Apennines, and also in Sicilia and Portugal. The leaves are broader, and not so deeply sinuate as those of the common oak; they are of a lighter green on their upper side, and pale on their under; have very short footstalks, and their points are obtuse; the acorns have very long footstalks, which frequently sustain three or four in a cluster.

The dwarf oak, which grows in the south of France and Italy, and is a low bushy oak, rises but six or seven feet high, sending out many slender branches the whole length. The leaves are oblong, and obtusely indented, about three inches long, and an inch and a half broad, standing upon slender footstalks; the acorns small, growing in clusters.

There are also many other varieties of common oak, which dealers in timber and woodmen distinguish by their use, qualities, and accidents, and to which they give different names; but these being merely local, and not founded on permanent characters, it is difficult to ascertain them.

In the second species they distinguish two sorts; one of which is called the Highland willow oak, and grows upon poor dry land; the leaves are of a pale green, and entire, shaped like those of the willow tree; the acorns are very small, but have pretty large cups. The other grows in low moist land, and rises to a much greater height; the leaves are larger and narrower, but the acorns are of the same size and shape. It is suggested, as probable, that their difference may be owing to the soil in which they grow. Martyn observes, that the latter becomes a large timber tree, and that there are said to be several varieties of it.

The third species has seemingly two varieties, one of which grows to a much larger tree than the other; but this may be occasioned by the soil, for the largest trees grow in rich low lands, where they become bigger than any of the North American oaks. The wood is not of a very fine grain, but is very serviceable; the bark is grey and leathery; the leaves are five or six inches long, and two inches and a half broad in the middle, indented on the edges with many transverse veins running from the midrib to the borders; they are of a bright green, and do nearly resemble those of the chestnut tree as scarcely to be distinguished from it. The acorns are very large, and their cups are short. The leaves of the other variety are not to large, nor so strongly veined; and the acorns are smaller, and a little longer. The different varieties are distinguished by the form of their leaves, which in the one is ovate, and in the other oblong.

The fifth fort has several varieties.

And in the ninth fort there are several varieties. The tenth species has likewise several varieties, differing greatly in the size and shape of their leaves; but these will all arise from acorns of the same tree: even the lower and upper branches have very frequently leaves very different in size and shape; those on the lower branches being much broader, rounder, and their edges indented and let with prickles; but those on the upper long, narrow, and entire. The leaves are from three to four inches long, and an inch broad near the base, gradually lessening to a point; they are of a lucid green on their upper side, but whitish and downy on their under, and do not fall till they are shrivel off.
off by young leaves in the spring. The acorns are smaller than those of the common oak, but of the same shape.

The twelfth species has also two or three varieties; one with a broad leaf, a second with a narrow leaf, both evergreen; and one or two which call their leaves in autumn; but the broad-leaved evergreen is the most common. The leaves of this are entire, about two inches long, and an inch and quarter broad, with a little down on their under sides, on very short footstalks; these leaves continue green through the winter till the middle of May, when they generally fall off before the new leaves come out, so that the trees are often almost bare for a short time. The acorns are very like those of the common oak.

The exterior bark forms the cork, which is taken from the tree every eight or ten years; but there is an interior bark which nourishes them, so that stripping off the outer bark is so far from injuring the trees, that it is necessary to continue it: for, when the bark is not taken off, they seldom last longer than 50 or 60 years in health; whereas trees which are barked every eight or ten years will live 150 years, or more. The bark of a young tree is porous, and good for little; however, it is necessary to take it off, when the trees are twelve or fifteen years old, for without this the bark will never be good. After eight or ten years, the bark will be fit to take off again; but this second peeling is of little use. At the third peeling, the bark will be in perfection, and will continue so for 150 years; as the bellow cork is taken from old trees. The time for stripping the bark is in July, when the second sap flows plentifully: the operation is performed with an instrument like that which is used for dibbarking the oak.

It is from the last species they collect the kermes, or scarlet grain, a little red gall, occasioned by the puncture of an insect called casculus. With this the ancients used to dye cloth of a beautiful colour.

Method of Culture.—These trees are all capable of being raised from the seed or acorns, which, in the common oak, should be gathered in autumn when quite ripe, just as they drop from the trees; but those of most of the foreign oaks are generally procured from abroad, and sold by the seedmen.

All the forts should be sown as soon after they are obtained as possible, as they are apt to sprout if they remain long out of the ground; and for their reception, a spot of light ground in the nursery should be prepared by digging or ploughing, dividing it into four feet wide beds, in which the acorns should be sown, either in drills, two inches deep, in five or six rows lengthwise of the bed; or rake the mould off the bed, the depth of two inches, into the alleys; then sow the acorns all over the surface, about two or three inches apart, press them down with the spade, and spread the earth evenly over them two inches thick. When they come up in the spring, they should have occasional waterings and weeding; and when the plants are one or two years old, it is proper to plant them out in nursery-rows: this may be done in autumn, winter, or early in the spring, taking them carefully up out of the feed-bed, shortening their perpendicular tap-roots, and trimming off any lateral shoots from the stem, leaving their top perfectly entire; then planting them in lines two feet and a half asunder, and fifteen or eighteen inches in the rows, where they should stand, with the usual nursery care, till of a proper size for final planting out either as forest trees, or for ornament, training them up asbool standards, with clean straight limbs, and with their tops still entire.

But in raising the stippled-leaved varieties of the common oak, and any particular variety of the other species, it should be by grafting, (as they will not continue the same form from seed,) which should be performed upon any kind of oakling stocks raised from the acorns, and trained for standards, as in other kinds.

With respect to the final planting out, it may be performed in all sorts of deciduous oaks any time in open settled weather, from November till February or March; and in the evergreen kinds in October, November, or the spring; and in a mild open season in any of the winter months.

When the trees of all the sorts are from about three or four to six feet stature, they are proper for being planted out for good; though, as forest or timber trees, it is better to plant them out finally while they are quite young, as from two to three or four feet in height; or when planted immediately from the feed-bed, where they are to remain, it may be advantageous, as the very young oaks root more freely than older trees, and take a freer growth. Those designed as forest or timber trees should be planted in large open tracts of ground, to form woods, placing them in rows only from four or five to ten feet asunder, and from two or three to five or six feet in the rows, to allow for a gradual thinning. But perhaps the best method of all for raising them, as timber trees, is from the feed, by fowing or setting the acorns. See PLANTATION and PLANTING.

Sometimes, indeed, large plantations of these trees, for woods, are raised by sowing the acorns at once in the places where they are to remain; it being generally found that the trees raised at once from the acorn, from their not being checked, much outstrip the transplanted trees in their growth. The method of performing it is this: the ground being prepared by good ploughing and harrowing in the autumn, having procured a proper quantity of acorns, draw drills across the ground four feet asunder, and two inches deep, dropping the acorns into them five or six inches asunder, allowing for failing and thinning, covering them in evenly with the earth the depth of the drills; or, instead of drilling them in, they may be planted with a dibble the same depth and distance.

The general management of these trees in woods, or timber plantations, is the same as directed for forest trees in general. See PLANTATION.

All the above sorts of trees may be employed to diversify large ornamental plantations in out-grounds, and in forming clumps in spacious lawns, parks, and other extensive open spaces: the evergreen kinds, in particular, have great merit for all ornamental purposes in pleasure-gounds and plantations. And all the larger growing kinds, both deciduous and evergreens, are highly valuable as forest trees for timber; but the first sorts claim precedence as a timber tree, for its prodigious height and bulk, and superior worth of the wood.

In planting any of the species for ornament or variety in large pleasure-gounds, some may be disposed in assemblage in any continued plantation, some in clumps, and others singly.

All the different sorts of the oak will succeed in any soil of a middle quality, where the exposure is not unfavourable; but to the most advantage, where the land is of a loamy nature: they, however, thrive tolerably in those soils which are of a gravelly, sandy, or clayey description.

Besides the great value of these sorts of trees for the utility and durability of their wood, as timber, for the purposes of ship-building, house-building in some parts, park-paling, poles, railings, and a variety of other strong uses; they, in many of the kinds, afford considerable additional advantage.
advantage by their produce in bark, for the use of the tanners and cork-cutters, in tanning leather, and being made into corks; after the former of which, it is also much employed in gardening, for the forming of bark hot-beds, in raising tender hot-houset plants; as well as in their annual crops of acorns, as an excellent food for the keeping and fattening of swine, deer, and some other animals.

Quercus, in Planting, a classical term sometimes applied to the oak-tree in nursery collections, intended for this sort of application. See Oak-Tree.

Quercus Marinus, the Sea-Oak, in Botany, the name of one of the broad-leaved dichotomous sea-facilies.

It is not agreed, among the late botanists, what was the sea-oak of Theophrastus; and the most ancient botanists, Clusius and Caelcipinus, suppose it to have been a species of the holly or common holly; but that seems by no means to have been the case, since Theophrastus says his sea-oak had a long, thick, and fleshy leaf, whence we may much more naturally conclude it to have been of the fucus clafs.

Quercy, in Geography, a province of France before the revolution, in the government of Guienne; bordered on the E. by Rouergue and Auvergne, on the S. by Upper Languedoc, on the W. by Perigord and Agenois, and on the N. by Limosin: it contained two bishoprics, viz. Cahors and Moatzauban. The air is good, and the land is fertile: its capital was Carhors. It now constitutes the department of the Lot.

Quereiva, in Ornithology, the purple-throated chatterer of Latham, a species of Ampelis.

Querela, Quarrel, in Law, denotes an action, or declaration, preferred in any court of judicce. See Quarrel.

In an action where the plaintiff is called querens, i.e. complainant, his brief, complaint, or declaration, is called querela.

Querela Audita. See Audita.

Querela coram rege et concilio, a writ by which one is called to justify a complaint of a trespass made to the king himself, before the king and his council.

Querela Duplex. See Double Quarrel.

Querela, ex gratia. See Ex Gratia, &c.

Querenghi, Antonio, in Biography, a man of letters, was born at Padua in 1546. He displayed, at an early period of his life, a decided attachment to literature; he wrote verses before he was twelve years of age, and soon became distinguished by his deep knowledge of the languages, civil laws, and the philosophy that was taught at that period. For some time he applied himself to theology, and made considerable proficiency in it. He next went to Rome, where he entered into the service of several cardinals, and at length became secretary of the sacred college, in which capacity he was present at the election of five popes. Clement VIII. conferred upon him the canonry of Padua, which occasioned him to reside in that city, but he returned to Rome in the pontificate of Paul V., by whom he was promoted to some offices of trust. He died at Rome in 1623, at the age of 87. He was a man of various and extensive literature, and was much regarded by the learned of the time in which he flourished. His writings were numerous, and comprehended the sciences and polite literature. He is chiefly known to poftlitry by his poems, which are correct and elegant, but by no means animated. Moreri.

Queretano, in Geography, a town of Mexico; 83 miles N.W. of Mexico. N. lat. 20° 25'. W. long. 101° 36'.

Querfalla, in the Materia Medica of the Arabians, a name given by Avicenna and others to cinnamon, when gathered with the wood of the young branches.

It was a common practice in the early times not to strip the small bark from medicinal trees, but to cut off the little boughs, and use the bark and wood together. This the Greeks called zeo cinnamon, or woody cinnamon; and the Arabs, querfa, quyrfa, or kvrs.

Querfurt, in Geography, a town of Saxony, situated on the little river Weite, not considerable in itself, but having large suburbs; the number of houses is estimated at upwards of 500. The old castle belonging to it stands on a hill, and it has likewise a superintendency; 16 miles S.W. of Halle. N. lat. 51° 23'. E. long. 11° 45'.

Queria, in Botany, received that name from Loedling and Linnaeus, in compliment to Don Joseph Quey Martinez, a Spanish surgeon, who though he wrote against the Linnean system, and even the sexes of plants, contending that palm-trees ripen fruit without impregnation, was an affiduous practical botanist. He published a Spanish Flora, in his native tongue, consisting of four volumes quarto, of which the first three appeared in 1762, and the fourth in 1764. A fifth and sixth were added by Ortég in 1784. Queyr was professor of botany in the royal garden at Madrid, and died in 1764, aged 60. He wrote also on the Uovo Ufis, in which he removes from the genus Arbtrak, as a specific in calculous complaints; and on the medical use of Cicerute. —See Haller's Bibl. Bot. v. 2. 516, and Dryand. Bibl. Banks. —Linm. Gen. 43. Sched. 58. Wild. Sp. Pl. v. 1. 403. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 1. 185. Juff. 500. Lamarek Illusr. t. 52. Gärtn. t. 128.—Chaf and order, Triaendria Triphylla. Nat. Ord. Caryophyllis, Lin. Jull. Gen. Ch. Col. Peranther inferior, of five creet, oblong, acute, permanent, leaves; the outermost recurved. Cor. none. Stam. Filamentous, capillary, short, and anthers roundish. Pyf. Germin superior, ovate; styles three, the length of the filaments; stigmas simple. Peric. Capsule roundish, of one cell, with three valves. Seal solitary, roundish, compressed.

Eff. Ch. Calyx of five leaves. Corolla none. Capsule of one cell, with one seed.

Obi. Linneus remarks, that this genus differs evidently from Minuartia, see that article, in having a solitary seed. Q. canadenfis, figured by Gartner, is removed hence by Michaux to his genus Anycbia, which belongs to a different natural order, the Holarctae of Linneus, and has a capsule defitute of valves. Gartner indicates its close affinity, except in number of flaments, to his Paronychia, see that article. Michaux and Pursh affer that its flaments vary from two to five.

1. Q. biflurica. Spanish Queria. Linm. Sp. Pl. 132. Wild. n. 1. Ait. n. 1. Loed. It. 48. 83. Quer. Pl. Elpan. v. 6. 667. t. 15. f. 2.—Flowers crowded into a tuft. —Native of fandy grounds in Spain. Seeds were sent to Kew, in 1830, by the late marchionefs of Bute. The plant is a diminutive hardy annual, flowering most part of the summer. Root fibrous. Whole herb whitish, brittle, one or two inches high, with several leafy, round, rather downy, slightly redaht joints. Leaves opposite, fiform, awl-shaped, three-ribbed, curved to one side, rather longer than the joints of the stem. Head of flowers oblong quadrangular, deeply dichotomous, easily breaking off from the stem. Bractes opposite, awl-shaped, recurved, and hooked, easily catching hold of the coats of animals. Flowers very mimic.

Gron. Michaux, two of his celebrated from Mantes, the town determined four miles N. of Quimperle.

QUERON, a town of South America, in the jurisdiction of Risambala.

QUEREO. See Querepo.

QUEREOEDULA, in Ornithology, a species of Anas. See Duck and Teal.

QUERRE, in Geography, a town of France, in the department of the Mayence and Loire; 12 miles N. of Angers.

QUERRENIEN, a town of France, in the department of the Finisterre; six miles N. of Quimperle.

QUERRIES, or Equerries. See Equerry.

QUERRIEUX, in Geography, a town of France, in the department of the Somme; six miles N.E. of Amiens.

QUERRY, Gentleman of the, is an officer appointed to hold the king's stirrup, when lie mounts on horseback.

QUERS, in Geography, a town of France, in the department of the Upper Saone; three miles S.E. of Luxeuil.

QUESADA, a town of Spain, in the province of Jaen; 12 miles S.E. of Ubeda.

QUESENDORF, a town of Prussia, in the palatinat of Culm; four miles S.E. of Brenchen.

QUESNAY, Francis, in Biography, a celebrated French physician, was born at Mercy, a little town not very distant from Paris, in 1694. His family were employed in rural occupations, and gave him no other education than was deemed necessary for their mode of life; so that at the age of sixteen he was scarcely able to read. About this time, however, a thirst for information seized him, and partly by the indulgence of a country surgeon, and partly by his own labour, he acquired a knowledge of Latin and Greek, and entered with ardour into the study of the ancient and modern writings on philosophy. In opposition to the prevailing notions of his relations, he resolved to turn his pursuits to medicine, having perceived its connection with the various branches of physical science; and his master, the surgeon of Ecueville, was soon convinced of the superior acquirements of his pupil, some of whose essays he presented as his own, on applying for admission into the college of St. Côme, and they were received with great applause. This still farther routed the zeal of Quefnavy, and he repaired to Paris, where he entered with great avidity into the studies connected with the profession. After some time he settled at Mantes, a considerable town in his native province. Here he was discovered by Garengeot, an eminent surgeon, who was engaged with Peyronie in an attempt to establish an academy of surgery, for the collection of surgical knowledge. Having written a refutation of the doctrines of Silva, respecting blood-letting, which led him to a public controversy, in which he was deemed victorius by Peyronie, he displayed such profound views, indefatigable zeal, and great general knowledge, as determined Peyronie to appoin him the secretary of his new academy. This distinguished post raised him still higher in the public estimation; but the labours connected with it at length injured his health, which had been for some time delicate, and he determined to turn his attention to medicine more particularly, and took the degree of doctor of physice. He had been employed during the campaigns of the king, and on the death of M. Terray was appointed consulting physician to his majesty; and was much esteemed and favoured by madame de Pompadour; she seems, indeed, to have been much employed, and to have been held in high consideration by the dauphin.

Vol. XXIX.
the father of Louis XVI., and by the whole court. After the dauphin had undergone the small-pox, the king presented him with letters of nobility, unfilicted, as a mark of his esteem. He was appointed also first physician in ordinary to his majesty. He was a member of the Academy of Sciences, of the Royal Society of London, &c. Notwithstanding his long life, and his courtly favour, as well as extensive employment, he died possessed of little fortune; his liberality to his friends having prevented him from accumulating money. His death took place at Verfaillles, in December, 1774, at the age of eighty.

This able and indefatigable man left several works, which bear the stamp of considerable research, clear and methodical views, and acute observation, mixed, however, with some disposition to hypothesis. His first essay on blood-letting, already mentioned, was published in 1730, under the title of "Observations sur les Effets de la Saignée, avec des Remarques critiques sur la Traité de Silva;" and a second edition, considerably enlarged, was printed in 1750. But in the mean time he published another work, entitled "L'Art de Guerir par la Saignée," Paris, 1736, in which he recommends blood-letting in many diseases. In the same year appeared his "Essai Physique sur l'Economie Animale," in two volumes, 12mo., which was reprinted in 1747, in three volumes. This work, however, was deemed very imperfect by Haller, and is in fact characterized by a love of hypothesis, rather than by the details of experience and observation. In 1743, his "Preface des Memoires de l'Academie de Chirurgie," gained him considerable applause, as a work of literary research. In 1744 he published his "Recherches critiques et historiques sur l'Origine, sur les divers Etats, et sur les Progrés, de la Chirurgie en France," which called forth some remarks on the alleged inaccuracy of some of the historical statements. His other publications were entitled, "Testament de M. de la Peyronie du 18 Avril, 1747;" "Examen impartial des Confections des Medecins et des Chirurgiens de Paris," 1748, 12mo.; "Memoire préfenté au Roi par son premier Chirurgien, où l'on examine la Sageffe de l'Ancienne Législation sur l'Etat de la Chirurgie en France," 1749, 12mo.; "Traité de la Suppression," 12mo.; and "Traité de la Gangrée," 12mo.; all in the year 1749. And lastly, his "Traité des Fièvres continues," 1753, in two volumes, 12mo. Eloy Dict. Hifi. de la Médecine.

QUESTE, ABRAHAM DU, an able French naval commander, was descended from a noble family in Normandy. He was born in 1610, and was brought up to the sea-service under his father, who gave him the command of a vessel when he was only seventeen years of age. In 1637 he was present at the attack of the isles of Sainte Marguerite, and in the following year contributed greatly to the defeat of the Spaniards before Gattori. He was afterwards in various actions on the coast of Spain. In 1644 he went to serve in Sweden, and was promoted to the rank of vice-admiral of the Swedish fleet. In this station he had a command in the famous battle in which the Danes were entirely defeated, and his vessel was one that boarded and took the enemy's admiral ship. On his return to France he commanded an squadron sent to the expedition against Naples. The French navy being in a low state on account of the minority of the king, he fitted out several ships at his own expense in 1650, with which he sailed in the reduction of Bordeaux, which had revolted, and was aided by a Spanish fleet. In 1676 he had the glory of being opposed to the great De Ruyter. The Spanish and Dutch fleets had united to prevent the French from succouring the inhabitants of Melfina, but Du Quefne, after a desperate fight, succeeded in entering the port. He was also engaged with De Ruyter when the latter was mortally wounded. Du Quefne obtained a more glorious and decided success in another engagement with the Spanish and Dutch fleets at Palermo, when, by means of his fire-ships, he destroyed twelve large ships of the enemy, and thus procured for his king the sovereignty of the Mediterranean. In 1692 he was sent with a fleet to awe the piratical states of Barbary, which had committed depredations on the French coasts, and in the following year he failed to Algiers, and bombarded the town with such fury as nearly to lay it in ruins. In the following spring the admiral anchored before the city, and did not leave it till he had destroyed almost all the buildings, with the whole of the shipping and fortifications, the consequence of which was they were obliged humbly to sue for peace. He struck equal terror into the fleets of Tripoli and Tunis, which were likewise compelled to purchase peace with France by submission. He performed other great and important services for his sovereign, but the recompense due to him on account of all he did was impeded by his firm attachment to the reformed religion in which he was bred, and which the bigotry of the king regarded as criminal. He received, however, the royal gift of a fine estate, which was erected into a marquisate, and gave him a title; and on the repeal of the edict of Nantes, he was the only person exempted from its penalties. This great hero, one of the chief boals of the French navy, preferred an extraordinary degree of health and vigour, notwithstanding the many wounds which he had received, till his death in 1688, when he had attained to the 78th year of his age. He left a son, of whom we shall say a few words.

QUESTE, HENRY DU, was born in 1652, and at the age of fourteen he entered the French navy, and served with great distinction under his father. He was present at the bombardment of Algiers in 1683, and negotiated the peace of Tunis. At the period when the highest prospects in his profession lay before him, his attachment to the Protestant religion caused him, at the repeal of the edict of Nantes, to quit his country and the service, but he refused with indignation the offers that were made him to take a command in the armies of his enemies, and retired to Switzerland. His high reputation raised him to great credit with the Protestant powers, which he employed in engaging them to undertake the protection of his persecuted brethren; and through his means a great number of victims of the most cruel intolerance procured their liberation from the galleys. In 1751 he told his estate in Switzerland, and retired to Geneva, of which he was admitted to the citizenship. Here he died in 1753, respected alike for his learning and piety. As an author he had taken a considerable share in the version of the New Testament published by the pastors of Geneva, and he was author of a work entitled "Refections Anciennes et Modernes sur l'Eucharistie."

QUESTE, FORT DU, in Geography. See PITTSBURG.

QUESTENEL, PASQUIER, in Biography, a French priest of much celebrity, was born at Paris in the year 1634. Having completed his education, and being admitted a member of the congregation of the oratory, he took priest's orders in 1659. From this time he devoted himself, with great diligence, to the study of the scriptures, and of the fathers, and to the composition of books in practical piety. At the age of 28 he was appointed first director of the institution belonging to his order at Paris. The first of his publications was entitled "Moral Reflections upon the Gospels." After this he was employed in preparing for the press a new edition of "The Works of St. Leo," in two volumes, 4to. in which he has given a vast number of notes that
that reflect great honour on the learning of the editor. Its value was enhanced, in the judgment of his countrymen, by his introducing into it an able defence of the sentiments of the Gallican church, in opposition to the pretensions of the church of Rome. This circumstance gave great offence to the papal government, and the edition was condemned in the following year at Rome. On account of his attachment to father de Sainte-Marthe, general of the oratory in France, he was obliged to quit his diocese, and from other unpleasant circumstances he thought it right to withdraw privately from France into foreign countries. He took refuge at Bruxelles, where he continued his "Moral Reflections" on the acts of the apostles, and the epistles. This, with his former work, he published in 1687. He afterwards revised and made additions to the former work on the Evangelists, and printed an uniform edition of the whole in 1693 or 1694, in four vols. 8vo. In the year 1703 the Jesuits, always inimical to the rights and liberties of mankind, and who, to the utter disgrace of the present period, have been but re-established in their powers, availed themselves of their influence with an ignorant and bigotted king of Spain, to obtain an order for the arrest of father Quefin, who was now thrust into a dungeon belonging to the archiepiscopal palace at Bruxelles. From this situation he was unexpectedly delivered in less than four months by the ingenuity of a Spaniard, who contrived to open a passage through the walls of the prison sufficiently large for his escape. Having thus obtained his liberty, he made the best of his way to Holland, where he published several pieces in vindication of himself and writings from charges preferred against both before the ecclesiastical court of Mechlin, and the sentence of condemnation pronounced by the archbishop. In the year 1705 the enemies of Quefin applied to the pope Clement XI. for the condemnation of the "Moral Reflections," to which he acceded, although he had some years before expressed his decided approbation of them, and even wished to engage the author to come to reside at Rome. Such, however, was the pontiff's inconsistency, that he inferred a decree which condemned the "Moral Reflections" in general, but without specifying any particular doctrines which merited such a sentence. At length, at the instigations of the Jesuits, eager in the cause of perfecution, Lewis XIV. joined himself against Quefin, and applied to the pope for a more definite decree; his holiness, for so much wicked as well as most virtuous of the popes have ever been denominates, in consequence of this application, established a congregation of cardinals, prelates, and divines, to enter into a particular examination of the doctrines and maxims which Quefin had advanced. That his work might not be condemned without any efforts on his part to vindicate it from the accusations of his enemies, our author wrote, on this occasion, two letters to the pope, which were safely conveyed to Rome, but Clement did not deign to give a reply. State policy had already determined what measures he should adopt, and, after the seissions of the congregation were ended, he issued the celebrated bull Unigenitus, in September 1713, which pronounced a sentence of condemnation upon 101 propositions extracted from the "Moral Reflections."

Father Quefin spent the last years of his life at Amsterdam, where he formed some Janesinists churches, and published his apologetic and controversial pieces against the bull Unigenitus, and its abettors. He died in 1719, in the 80th year of his age. Independently of his "Moral Reflections," he was author of several other works of high reputation, of which we may mention, a treatise on "Predestination and Grace," in four vols. 12mo. under the fictitious name of fieur German; and "The Discipline of the Church deduced from the New Testament," in two vols. 4to. A list of this author's works may be seen in Moreri.

QUESNOM, FRANCIS DU, called the Fleming, an excellent sculptor, was born at Brussells in 1594. He learned his art under his father, who was a sculptor, and at an early age displayed so much ability, that the archdeke Albert gave him a pension and sent him into Italy. After the death of that prince, he was patronized by the confiable Colonna; and the celebrated Poupin refiding with the confiable at the same time, the two artificers contracted an intimate friendship, and studied together. Quefini formed himself upon the taste of the ancients, and chiefly excelled in making bas-reliefs and models in a small size, representing cupidus and children, to which he gave singular grace and delicacy. He employed himself several years on a marble faint, for the chapel of Loretto, in which he imitated the genuine beauties of the antique. When the canopy of St. Peter's was finished, pope Urban VIII. ordered four colossal statues to be placed in the niches. That of St. Andrew was given to Quefini, and although one of his competitors ventured to affirm that he would only produce a great child, yet when the figure was completed, it entirely effaced his own performance. Notwithstanding the talents of this artist, which were united to much perseverance and industry, he could barely earn a subsistence, and was in a very low state of health and spirits, when, in 1642, Lewis XIII. engaged him as his sculptor, and as the head of an intended school for that branch of art, at a very liberal salary. This change of fortune he was unable to bear, and as he was on the point of letting out, he sunk into a melancholy derangement, from which he never recovered. His death, which happened at Leghorn in 1645, has been imputed, but probably on insufficient evidence, to poison administered by the hand of a brother with whom he lived on very bad terms. He was mild in his manners, but of a reserved disposition. His reputation is chiefly founded upon the exquisite softness which he gave to marble, and the peculiar grace and beauty of his infantile groups, finished with perfect anatomical exactness.

QUESNOM, Le, in Geography, a town of France, in the department of the North, and chief place of a canton, in the district of Avesnes. The place contains 2960, and the cantons, to which belong the east and west divisions, 9099 each, on a territory of 235 kilometres, in 29 communes. N. lat. 50° 15', E. long. 5° 43'.

QUESNOM-sur-Douve, a town of France, in the department of the North, and chief place of a canton, in the district of Lille. The place contains 4062, and the canton 15,047 inhabitants, on a territory of 82½ kilometres, in nine communes.

QUEST, or INQUEST, an inquisition, or inquiry, made upon oath of an impannelled jury. See INQUEST, and JURY.

The word is formed from the French quête, search; of the Latin quaestum, a thing sought.

QUEST, in Hunting, the seeking out of hounds, or the venting and winding of spaniels. See HOUND.

QUESTEMBERT, in Geography, a town of France, in the department of Morbihan; five miles W.S.W. of Rochfort. The place contains 3668, and the canton 12,187 inhabitants, on a territory of 257½ kilometres, in nine communes.

QUESTION, Questio, in Logic, &c. a proposition, whose truth a person being inquisitive about, propoves by way of interrogation to another.

Logical questions are variously distributed; the ordinary
division is into first or primary questions; as, *Quid est?* What is such a thing? And secondary, which arise out of the former; as, *How is it?*

**Question.** Quadrilateral. See Quadrilateral.

**Question, in Law.** The *quæstio de jure* is generally to be distinguished from the *quaestio de facto.*

**Question is also sometimes used for torture;** which fee.

**QUEST-MEN.** Persons chosen yearly in each ward, to inquire into abuses and misdemeanors, especially such as relate to weights and measures.

**QUEST-MEN, in Ecclesiastical Law.** See Sidesmen.

**QUESTOR.** *Questor,* formed of a quæresto, seeking, searching, or collecting the revenues of the state, an officer in ancient Rome, who had the care of the public treasure.

The questorialship, *quaestura,* is very ancient, as having been established under the kings, probably in the time of Romulus or Numa, or at least under Tullius Hostilius. Tacitus (Ann. xi. 22) says, that the first questors were elected by the people, 64 years after the foundation of the republic; but he is of opinion that they had, long before that period, been annually appointed by the consuls, and even by the kings. But this obscure point of antiquity is contested by other writers. Dionysus and Livy date the original of questors about A.D. 269. Plutarch refers the institution to the time of Valerius Poplicola, when he allotted the temple of Saturn for the treasury, and granted the people the liberty of choosing two young men for the treasurers. Afterwards, viz. A.D. 322, two others were created to take care of the payment of the armies abroad, of felling the plunder and booty, &c. for which purpose they generally accompanied the consuls in their expeditions; and they were distinguished by the name of *pergrini* from the other questors, who assumed the title of *urbanii.*

This number continued till the entire conquest of Italy; and then, A.D. 439, it was again doubled. The four that were added refided with the proconsuls and propraetors, in the provinces, where they were employed in regulating the taxes and customs due to the state.

In the time of the republic, the senate appointed questors in each province, to affist the proconsuls, as lieutenants or treasurers, in the administration of the revenues; but, under the emperors, there was properly but one questor, or treasurer-general of the empire; those other inferior or subordi- nate questors were then called aeditants of the questor, *adjutores quaestorum.*

The questor's office was originally confined to the army. They paid the fuldierry, and took charge of monies coming by spoil and plunder, &c.

At length there were new ones erected to reside in the city, and to receive the public money, taxes, tribute, &c. Their number was increased as the empire increased. Sulla augmented it to twenty; Julius Caesar to forty; some being nominated by the emperor, and the others by the people. Tacitus (Ann. xi. 22) seems to consider twenty as the highest number of questors; and Dion (lib. xiii. p. 374) intimates, that if the dictator Caesar once created forty, it was only to facilitate the payment of an immense debt of gratitude. Under succeeding emperors their number was not fixed. Of those, two were appointed for the city, to take care of the public treasury, and to keep the laws and decrees of the senate; the others pertained to the provinces and the armies.

The questorialship was the first office which any person could bear in the commonwealth, and might be undertaken at the age of twenty-four or twenty-five years. Accordingly, the questorialship was called the first step of honour, and the questors, who were generally employed in the provinces abroad, assigned to them severally by lot, no sooner returned from their provincial administration than they took their places in the senate; and from that time forward, from the rank of equestrians, or what we commonly call knights, became senators for life.

The youth and inexperience of the questors, who entered on that important office in the 25th year, engaged Augustus to remove them from the management of the treasury; and though they were restored by Claudius, they seem to have been finally dismissed by Nero. In the provinces of the imperial division, the place of the questors was more ably supplied by the procurators, or, as they were afterwards called, "rationales." But in the provinces of the senate we may still discover a series of questors till the reign of Marcus Antoninus. From Ulpian we may learn, that under the government of the house of Severus, their provincial administration was abolished; and in the subsequent troubles, the annual, or triennial elections of questors, must have naturally ceased.

There was also another kind of questors, called *quaestores particulares,* whose office was to enquire into, and take cognizance of capital crimes, after the consuls had denied their privilege.

**QUESTOR, sacri palatii, or of the sacred palace, was one of the first dignities under the emperors of Constantinople.**

It was this questor that subscribed the receipts of the emperor, and the answers to the petitions and supplications presented to him. He also drew up and signed the laws and constitutions which the emperor thought fit to publish; and took care of the administration of justice.

Some compare his function to that of our lord high chancellor. It was usually one of the jurisconsulti that was charged with this office; it being required, that he should know the laws of the empire, be able to prefer and see them executed, and judge of cases brought by way of appeal before the emperor.

Constantine was the first who erected questors of the sacred palace.

**QUESTUS, or QUESTUS.** See Questus.

**Questus est *nobilis,* a writ of nuance, which, by Stat. 15 Edw. 1. lies against him to whom a house, or other thing, that breeds a nuance, is defended, or aliated; whereas before that statute, the action lay only against him who built the dwelling, or caused the nuance, to the damage of his neighbour.

**QUETIF, James, in Biography, a learned French Dominican monk, was born at Paris in the year 1618.** He embraced the monastic profession among the preaching friars when he was not more than 17 years of age, and having completed his philosophical course at Paris, he was sent by his superiors to Bordeaux, where he studied divinity, and received priest's orders in 1648. He lived to a great age, excelling his talents in various ways, and died in the year 1698, highly respected for his great erudition, his extensive knowledge, and his virtues. He published a new edition of the "Summa Theologica" of Aquinas, in three vols. folio, with notes. He did the same by a work entitled "Concilia Tridentinæ Canonum." He was editor of "The Spiritual and Aetical Letters of Savonarola;" and he published, with his own notes, "The Life of Savonarola," from the Latin of John Picus, count of Mirandula, with considerable additions. He wrote the preface to "The Letters of Peter Morin," which he published from the author's manuscripts; and he also did his treatise "On the Good Life or Abufe of the Sciences." He was author of a considerable part of the work.
work entitled "Scriptores Ordinis Pradicatorum, cum notis Historicis," which was completed by father Echard.

QUESTREVILLE, in Geography, a town of France, in the department of the Channel; six miles S. of Con-
tances.

QUETTEHOU, a town of France, in the department of the Channel, and chief place of a canton, in the dis-
trict of Valognes; nine miles N.E. of Valognes. The
place contains 1,291, and the canton 14,957 inhabitants, on a
territory of 150 kilometres, in 18 communes.

QUETTENBRUN, a town of Austria; eight miles
E. of Laab.

QUETZ, a town of Saxony, in the circle of Leipfic;
two miles S.S.E. of Zorbig.

QUEVACAMPS, a town of France, in the depart-
ment of Jemappe, and chief place of a canton, in the dis-
trict of Tournay. The place contains 953, and the canton 10,264 inhabitants, on a territory of 1074 kilometres,
in 15 communes.

QUEVAUVILLERS, a town of France, in the depart-
ment of the Somme; eight miles S.W. of Amiens.

QUEVE, in Commerce, a wine measure used in
some parts of France. A queue of Champagne contains 384
pintes of Paris, or about 95 English gallons; a queue of
Burgundy contains 432 pintes of Paris, or 107 English gal-
lons.

QUEL, Fr. tail, as applied to the heads of musical
notes; the minim is the only white note with a tail to it, and the
crotchet the first black note with a tail to it.

QUE, in Heraldry, the tail of a beast.
If a lion has a forked tail, he is blazoned by double-
queued.

Queue d'Aronde, q. d. swallow's tail, in Fortification, a
term applied to outworks, when narrower at the gorge than
at the face or front; i.e. where the sides open towards the
champaign, and contract towards the gorge. The name is
occasioned by its resemblance, in figure, to a swallow's tail,
which the French call queue d'aronde.

Of this kind are some fingle as well as double tenails;
and some horn-works whose sides are not parallel.

On the contrary, when the sides are less than the gorge,
the work is called contre queue d'aronde.

Queue d'Aronde, in Carpentry, a method of jointing,
called also dove-tail.

QUEVEDO DE VILLARES, FRANCISCO, in Biogra-
phy, a celebrated Spanish writer, was born at Madrid in 1570.
He became distinguished at an early period for his literary
attainments, and obtained the honour of knighthood, but
indulging his satirical vein too freely against the administra-
tion of count d'Olivares, he was thrown into prison, from
whence he did not make his escape till the disgrace of that
minister. He died in the year 1645, at the age of 75. He
is regarded by his countrymen as having attained to a con-
iderable degree of excellence in most of the different kinds of
composition. His historical poems are said to be characterized
by energy and spirit; his lyrical by sweetness and beauty;
and his humorous poems by ease, pleasantries, and ingenious
invention. His printed works fill three vols. 40. of which
two are occupied by poetry and one by prose. The former
were collected by Joseph Gonzales de Salas, who illustrated
them with notes and differtations. They were published in
1650, at Madrid, under the title of "Il Parnasso Espagnol."

The humorous pieces of Quevedo have rendered his name
familiar in foreign countries, and have been translated
into the English and other languages.

QUEVILLY, in Geography, a town of France, in
the department of the Lower Seine; three miles W. of
Rouen.

QUEULEN, a river of Chili, which runs into the Pacific
ocean, S. lat. 39° 10'.

QUEYPO, a town of Mexico, in the province of Costa
Rica, near the Pacific ocean.

QUEYRAS, a town of France, in the department of
the Higher Alps; 12 miles S.E. of Briançon.

QUETO, a name sometimes given to the river Ava,
at least to that part which runs between Ava and Prom.

QUI, in Rural Economy, a common term frequently ap-
plied to the female of the cow kind of animals while in the
young state. It is the most generally employed in the northern
parts of the country. See Why.

QUI-Calf, a name usually made use of in the northern
parts of the island, to signify a female or heifer calf. See
Why-Calf.

QUI Tam, in Law, is used where an information is exhi-
bited against any person on a penal statute at the suit of the
king and the party who is informer, when one part of the
penalty for breach of the statute is to be given to the
king, the poor, or to some public use, and the other part to the
former or prosector and the party informing prosectors for
the king and himself. The suit is called a qui tam action,
because it is brought by a person, "qui tam pro dominio rege,
&c. quam pro fe ipso in hae parte fequitur." If the king,
therefore, himself commences this suit, he shall have the
whole forfeiture. (2 Hawk. P. C. 268.) But if any one
hath begun a "qui tam" or "popular" action, no other
person can pursue it; and the verdict passed upon the defendant
in the first suit is a bar to all others, and conclusive even to
the king himself. This has frequently occasioned offenders
to procure their own friends to begin a suit, in order to
forestall and prevent other actions; which practice is
some measure prevented by a statute made in the reign of a
prince very sharp-fisted with regard to penal laws, 12 Hen. VII. c. 20; which enacts, that no recovery, otherwise
than by verdict, obtained by collusion in an action popular,
shall be a bar to any other person prosecuted bono fide. A
precedent, says judge Blackstone, that was borrowed from
the rule of the Roman law, that if a person was acquitted of
any accusation, merely by the prevalency of the accuser,
a new prosecution might be commenced against him. Ff. 47:
13. 3. See Information.

QUIA, in Logic, See Reason.

QUIA dominus remiti curiam, in Law. See Recto.

QUIA emprendas, a denomination given to the statute
of Wiltm. 3. 18 Edw. I which directs, that upon all fines or
feoffments of land, the fee-foe shall hold the same, not of
his immediate feoffor, but of the chief lord of the fee, of
whom such feoffor himself held it; and hence it is held that
all manors existing at this day must have existed by immem-
orial prescription, or at least ever since this statute was made:
for no new manor can have been created since that statute;
because it is essential to a manor, that there be tenants who
hold of the lord, and that statute enacts, that for the
future no subject shall create any new tenants to hold of
himself.

QUI improvidit, a superfeoffed granted in many cafes where
a writ is erroneously sued out, or misawarded.

Such is that granted in behalf of a clerk of the chancery
sued against the privilege of the court, in the common pleas,
and pursued to the exigent.

QUIADKOUA, in Geography, a town of Prussia,
in the province of Bartenland; nine miles S.E. of Allerburg.

QUIBBLETOWN, a town, or rather a village of Ameri-
QUIBERON, a fortified town of France, in the department of Morbihan, and chief place of a canton, in the district of L'Orient, situated at the extremity of a peninsula, to which it gives name, opposite to the island of Belle Isle; remarkable for an unfortunate expedition of English troops and emigrants against France, in the year 1795: 17 miles S.E. of Port Louis. The place contains 1916, and the canton 5618 inhabitants, on a territory of 95 kilometres, in three communes. N. lat. 47° 30'. W. long. 3° 21'.

QUIBO, a small island on the outer part of the bay of Panama; it is uninhabited, but affords wood and water for shipping.

QUIBONDO, a small island in the Indian sea, near the coast of Africa. S. lat. 8° 8'.

QUIBOR, a town of South America, in the government of Caraccas; 15 miles S.W. of Segovia Nuova.

QUIBURI, a town of New Navarre; 20 miles S.S.E. of Cáfa Grande.

QUICAPOUX, a river of America, which runs into the Mississippi, N. lat. 43° 4'. W. long. 92° 5'.

QUICARO, a town of New Navarre; 150 miles S.S.E. of Cáfa Grande.—Alfo, a small island in the Pacific ocean, near the coast of Veragua. N. lat. 7° 54'. W. long. 82° 42'.

QUICI, in Entomology, a species of the cerambyx, mentioned by Maregrave.

QUICK, in Gardening, a term applied to signify any fort of young plant, but especially those of the white-thorn kind. By it is also often understood a live hedge, but more properly the shrubs of which live hedge is formed. In a strict sense it is, however, applied to the Crataegus oxyacantha, or hawthorn, the young plants or sets of which are commonly sold by the nursery gardeners under the name of quicks.

In the choice of these sets, tho' which are raised in the nursery are in general to be preferred to such as are drawn out of the woods, as the latter have seldom good roots: many persons, however, prefer them, as they are larger plants than are commonly to be had in the nursery. See CRATAEGUS.

Quick. See Medlar and Pyrus.

Quick-Beam. See Pyrus, and Service-Tree.

Quick-Beam, in Planting, a name given in some places to the tree usually known by the title of mountain-ash. It has been recommended as useful for forming fences, in some cafes, by Dr. Anderfon, and others. Where it is employed in this way, the plants must be kept down to the proper height, by being cut over as often as there may be occasion; and thus encouraging them to throw out lateral branches in a greater abundance, and, of course, induce the fence to become more clofe and thick in its lower parts. By these means a tolerably perfect hedge may be raised, from plants of this fort, in situations where the white-thorn will not succeed in any proper manner.

Quick-Hatch, in Zoology. See Ursus Lupus.

Quick-Hedges, in Agriculture, a name given to all fuchs as are raised from quicks, or any other fort of living plants. The proper forming and planting of quick-hedges have hitherto been much too little attended to by the farmer, as it is a matter of great importance, and which interrelates him in a very high degree. Whatever fort of plants may be employed for this purpose, the work should constantly be well performed in the first instance, and the hedges and plants be afterwards kept in due order and regularity by suitable pruning, cutting in, and other proper management. There is a great number of different methods of raising and making hedges of this kind, as by planting the sets on the plain surface, or the mould a little raised above it, or on mounds, formed by the fods and mould dug up in the line of the hedge, elevated to different considerable heights; by setting the plants out in one row only, in double ones, or sometimes in a still greater number; by putting them in, in straight lines, in irregular manners, in the triangular form, or in the quincunx method. They are sometimes cut over at certain heights, at others not cut down at all; the fides are also in some cafes clipped or cut in, but in others this is avoided altogether. When planted on banks, they are mostly cleaned and moulded up annually.

A great variety of different forts of plants is employed in forming and constructing thes hedges, as those of the hawthorn, the black-thorn, the crab-tree, the hazel, the willow, the beech, the elder, the poplar, the alder, and several other kinds, according to particular circumstances and situations. And on the exposed coasts or shores of the southern parts of the kingdom, a new fort of shrub or plant has lately been recommended for this ufe, which is that of the tamarisk, or tamarix gallica, as it thrives rapidly, it is said, when planted in situations most exposed to the blast or broale of the sea; forms an admirable shelter, and being of quick growth, soon comes to answer the end designed.

The writer of the agricultural report of the county of Cornwall has known a hedge of it, which he has been told was planted about seven years ago, and the bushes, apparently, cannot be left now than from ten to twelve feet in height, and are feathered to the very bottom. It thrives well about the Lizard, bears cutting perfectly well, and in exposed situations, where it might be injured if left to grow high, may be kept clofe and low to much advantage. It unfortunately, however, will not fand the froft, and should never be attempted, of course, in situations exposed to the severe effects of it. The propagation of it is by cuttings, which take root without any difficulty. It is fuppofed that this shrub was brought by the monks from Normandy to Mont St. Michael in the above county, and thence spread to other parts. See HEDGE, and Quickset Hedge.

The quick-hedges of this country are in a very great degree raised from the white-thorn, which unquestionably forms the cheapest and most durable kind, where the nature of the soil, situation, and other circumstances are favourable for the purpose. It will not, however, flourish in bad land, in exposed situations, where the bottom is wet and springy, or where the growth of weeds is very abundant. In all such cafes other kinds of plants are therefore had recourse to in the formation of them.

In many upland districts beech-hedges have been planted to considerable extents, and found, when kept under proper management, to be very handsome, and of great service in such exposures. Birch-hedges have likewise been tried in different cafes, and found to grow remarkably fast, even in cold bare tilly soils, but they require to be cut over at the time they are about four feet in height and carefully ploughed. Both these forts of hedges have this in their favour, that they will grow in very poor soil as well as in very exposed situations; and both will flourish and grow strongly where the white thorn cannot live. Their want of prickles, however, is a great objection to them in this view: but they afford good shelter.

Quick-hedges constitute the ordinary fort of fences in this country, and unless in particular situations, and for particular purposes, are the most proper and eligible. It has been
been observed by the writer of a late work, that in parts which have been long inclosed without arable cultivation, hedges, of seemingly great age, are met with, which are many times crooked, ragged, and irregular, as though they had been, in the first instance, formed and laid out from the wild underwood of such places. While in other cases, low plants of the various copice kinds rise and grow on dikes or mounds but little raised above the surface of the land, seemingly as though they had formerly been collected from brugh-woods and replanted on such banks, in somewhat the same manner as is still practiced on higher banks in particular districts towards the west, and in South Wales. But taking the country at large, the method of raising quick-hedges by setting grown plants taken from such situations, has long ceased to exist and prevail as a general practice; young plants of white-thorn, or other forts, set out in the bank and ditch mode with a low protecting dead fence on the side contrary to the ditch at first, is the plan commonly had recourse to, such plants being first raised in small grounds for the purpose in regular rows, and not taken, as formerly, from brugh-woods and waste commons.

**Quick-Lime,** in Rural Economy, such lime as is in the caufic or mott active flate, and which poifefles the greateft power of operating upon different fubflances with which it may come in contact. It is quite the opposite in its qualities and properties, to that which has fallen down into a powdery flate, in confequence of being faturated with water and carbonic acid gas, or fixcd air, or which is flaked and become effete. Its powers, when applied upon land in this condition, have already been noticed in speaking of lime. See **Lime.**

But it poifefles qualities and properties in the way of a cement, the utility of which for building, for various do-mericl purpoefes, properly belong to this place. According to Dr. Anderfon, lime is in the belt and mott fit flatc for this ufe when the moft perfectly caufic, or in the moft cryftallizing condition. It is remarked, that the powder of lime, when reduced by means of water into a thin or fluid fort of pale-like form, and then fuffered to become dry, concretes into a coherent mafs, which fixes to iones and other rough bodies in a very firm manner, and in this way becomes a proper cement for building any fort of walls. And that, after this pafly material has once become firmly dry, it is quite indiflufible in water, and incapable of ever being caftagain by the caufe of the atmosphere or other similar caufes. Hence it excels many other forts of cements.

When compofed for the purpoef of building walls, &c. it is ufually denominated mortar; but when formed as an application in the way of a smooth coating upon any plain surface without intermixture with ifony matters, it is commonly here termed playfier.

When made from the lime of the purer fort of lime-flone, it is found to be more soft and crumble, and to acquire a fels degree of hardnefs, and to be broken with much fels force, than where the lime-flone from which it is made contains a large proportion of fand, in which cafe it becomes much more hard, firm, and durable.

It has, however, been discovered that the pureft lime may be rendered a firm cement by adding a proper proportion of clean hard fand to it; hence the practice of blending fand with lime, when intended for mortar, has become fo universal. This is fully flown to have been very early the cafe, by the oldest lime-built walls which are now to be met with.

It nevertheless still remains a defideratum to afcertain the due proportion of fand which is neceffary, as both writers and practical masons greatly difagree in opinion on this matter, as well in their directions about the mode of mixing the materials, as of applying the cement; some of the more modern, especially, affuming extraordinary effects to a small variation in these particulars, while others deny that these circumstances have any sensible effeet on the durability and firmnefs of the cement.

It is conceived that these different and contradictory opinions arife from an imperfect knowledge of the nature of quick-lime, and the variations it may admit of; for these variations are fo very great, as to render it impoffible to afford any general rules that can possibly apply in all cafes. It is, therefore, conceived to believe those who are defirous of acquiring any confluent and satisfactory knowledge on this head, to endeavour to afcertain, in the firft place, the circumstances which render calcareous fubflances at all capable of becoming a cement, and then to trace the feveral changes that may be produced upon it by other extraneous caufes.

Having explained the circumstances which cause the differences in lime-flone, and pointed out the different constituting principles of it, as well as various other peculiarities; it is flated that lime, which has in any way abforbed its full quantity of air from the atmosphere and became mild, is altogether unfit for becoming a cement, and that, of cafe, it is evident, that a great change may be produced upon the quality of any lime, by having allowed lefs or more of it to be in this flate before it is worked up into mortar. And further, that if a large quantity of water be put to fresh flaked quick-lime, and beat up with it into a thin fort of pale, the water diffofes a fmall portion of the lime, which as it gradually abforbs its air, is converted into cryftals; between the particles of which cryftals, that part of the lime which was not diffofed, and the other extraneous matters which may have been mixed with it, are entangled, fo as to form a firm coherent mafs of the whole. And that the pafly fubflance formed in this manner, is the well-known article mortar; and this heterogeneous, imperfectly semi-cryftallized mafs, constitutes the common cement employed in building ordinary walls or other erecitions. These circumstances, therefore, being known, it is thought that it will not be difficult to comprehend what are the particulars that are neceffary to form the most perfect cement of this nature. That fine lime becomes a cement only in confequence of a certain degree of cryftallization taking place in the whole mafs, it is sufficiently obvious that the firmnefs and perfection of that cement must depend upon the perfection of the cryftals; and the hardnefs of the matters that are entangled among them; for if the cryftals are ever fo perfect and hard of themselves, if they be separated from one another by any brittle incoherent medium, it is evident that the whole mafs must remain in some degree brittle and incoherent. That as water can only diffofe a very small proportion of lime, even when in its moft perfect fialine or caufic flate, or while it remains deprived of its carbonic acid gas, and as happens in other fimilar cafes, no more of the lime can be reduced to a cryftalline mafs than has been actually diffofed in the water; it happens of cafe, that if mortar be made of pure lime and water alone, a very small proportion only can be diffofed by that small quantity of water that is added to it; and as this small proportion alone can afterwards be cryftallized, all the remaining undiffofed particles of the lime will be entangled among the few cryftals that are formed. And as the undiffofed lime in this mafs will in time abforb its air, and be converted into mild calcareous earth without having had a sufficiency of water to allow it to cryftallize, it must concrete into a friable mafs exactly refembling chalk; it follows, that this kind of mor-
tar, when as dry as it can be made, and in its highest degree of perfection, will always be soft, and easily crumbled into powder.

But that, if, instead of forming the mortar of pure lime alone, a large proportion of sand be added to it, the water will in this case diffuse as much of the lime as in the former; and the particles of hard sand, like sticks or threads, when making sugar-candy or other crystals, while surrounded by the watery solution, will help to forward the crystallization, and render it more pure than it otherwise might have been, so as firmly to cement the particles of sand to one another. And as the granules of sand are perfectly hard of themselves, so as not to admit of being broken down like the particles of chalk, it necessarily follows, that the cement made of these materials must be much more perfect in every respect than the former.

After considering a variety of circumstances in regard to the solubility of lime in water, and its crystallization, it is remarked, that when a large quantity of sand is mixed in the mortar, that sand will of course bear a great proportion to the whole mass; so that the water that may be mixed with the mortar will be much greater in proportion to the quantity of lime contained in this mortar, than if the whole had consisted of pure calcareous matter. And that, as the sand absorbs none of that water,—that water, now pure, is at liberty to act once more upon those few particles of caustic lime that still remain in the mortar, which will be diffused and converted into crystals in their turn. In this way it may happen, in some circumstances, that a very large proportion of the lime may become crystallized; so that the mortar will consist almost entirely of sand enveloped in crystalline matter, and become in due time as hard as stone itself; whereas mortar, consisting of pure lime, without sand, can hardly ever be much harder than chalk. It is not, however, to be supposed, that in any case this dried mortar will assume that transparent crystalline form, or the compact form of some sorts of calcareous matters, such as marble and lime-flour. In mortar, in spite of the utmost care that can ever be taken, a very considerable quantity of the lime must remain undiffused; which undiffused lime, although it may be so much separated by the sand and crystalline lime-flour as not much to affect the hardness of the mortar, yet it must still retain its white chalk-like appearance. As marble and lime-flour are, however, always formed by those particles of lime that have been wholly diffused in water, and from which they have been gradually separated by a more flow and more perfect mode of crystallization, they have nothing of that opaque calx-like appearance, but assume other colours, and appear more firm, uniform, and compact; the sand and other matters that may be enveloped in them being entirely surrounded with a pure crystalline matter.

But to obtain the most perfect kind of mortar, it is not, however, enough that a large proportion of sand should be employed, and that the sand should be intimately mixed with the lime; it is also of the utmost importance that a large proportion of water be added; for without this it is impossible that a large proportion of the lime can be crystallized; and the mortar, in that case, would consist only of a mixture of chalky matter and sand, which could hardly be made to unite at all, and would be little more coherent than sand by itself, and less so than pure chalk. In that case, pure lime alone must afford rather a firmer cement than lime with sand. It is also of very great importance that the water be retained as long in the mortar as possible; for if it be suddenly evaporated, it will not only be prevented from acting a second time upon the lime, after a part of what was first diffused has been crystallized, but even the few crystals that would be formed when the water was suddenly evaporating, would be of themselves much more imperfect than they otherwise must certainly would have been. In proof of which, in cases of the crystallization of common salt, lump sugar, and sugar-candy, are added; after which it is noticed, that every one knows what a difference there is between the firmness of the finest substances; and that as great must be the difference between the firmnofs of that cement which has been slowly dried, and that which has been hastily hardened by the powerful action of a warm air.

It is contended, that it is owing to this circumstance that the lime, which remains all winter in a mortar tub filled with water, is always found to be much firmer and more coherent than the mortar that was taken from the same tub and used in any work of masonry, although in this case the materials were exactly the same. From the same cause, any work cemented with lime under water, if it has been allowed to remain undisturbed and uninjured until it has once become hard, is always much firmer than that which is above the surface of the water.

In order to render the force of the above reasoning more strong and convincing, lime cement or mortar is compared to a mass of matter consisting of a congeries of stones closely compacted together, and united by a strong cementing matter that had, while in a fluid state, pervaded all the interstices between the stones, and afterwards become a solid indiffusable substance. If the cementing matter be exceedingly hard and coherent, and if the stones bedded among it be also very hard and firm, the whole mass will become like a solid rock, without fissures, that can hardly be broken to pieces by the power of man. But, although the cement should be equally firm, if the stone, of which it consists, be of a soft and friable nature, suppose chalk or sandstone, the whole mass will never be capable of attaining such a degree of firmness as in the former case; for when any force is applied to break it in pieces, although the cement should keep its hold, the solid matter cemented by it would give way, and the whole would be easily broken to pieces. Whereas in mortar, the sand that is added to it represents the stones of a solid matter in the composition, the particles of which are united together by the lime which had been formerly diffused, and now crystallized, which becomes an exceedingly solid and indiffusable concretion. And as the particles of sand are of themselves exceedingly hard, and the cement by which they are united equally so, it is plain that the whole concretion must be extremely firm, so as to require very great force to disintegrate any particle of it from the whole mass. But if, instead of employing sand, the only solid body that is entangled among the cementing matter should be chalk, (as in all cases where the mortar consists of pure lime alone,) or any other slightly cohering substance, let the cementing particles of that composition be ever so perfect, it is impossible that the whole can ever attain a great degree of firmness, as these chalky matters will be easily broken afunder.

It is remarked, in addition, that a variety of conjectures have been made about the nature of the lime cement employed by the ancients. It has been thought that they possessed an art of making mortar, which has been long since entirely lost; as the cement in the walls which have been built by them, appears to be, in many cases, much firmer than that which had been made in modern times. Yet, when the mortar of these old buildings is analyzed, it is found to consist of the same materials, and nearly in the same proportions, in which they are now made use of.
QUICK-LIME.

And it is thought probable, that their only secret confisted in mixing the materials more perfectly than the rapidity or avarice of modern builders will permit, in employing their mortar in a much more fluid state than is done now, and in allowing it to dry more slowly, which the immoderate thickness of many of their walls would naturally produce, without any preconcerted design on their part. Tradition has even handed down to the present times the memory of the most efficient of these particulars; as the lower class of people, in every part of the nation, at this moment invariably suppose and believe that these old walls were composed of a mortar so very thin, as to admit of its being poured, like a fluid, between the stones, after they were laid in the wall: and the appearance of these old walls, when taken down, seems to favour this popular tradition. Nor is it doubted but that this may have been the case. The stones in the outer part of the wall, it is thought, were probably bedded in mortar nearly as is practised at present; and the heart, after being packed well with irregular stones, might have the interstices between them entirely filled up with fluid mortar, which would infuse itself into every cranny, and in time adhere as firmly as the stones themselves, or even more so, if the stones were of a sandy friable nature. And that, as these walls were usually of very great thickness, it might often happen, that the water in this mortar, by acting successfully upon different particles of caustic lime, would at length be entirely absorbed by successive crystallizations, so as to become perfectly dry, without any evaporation at all; in which case, a very large proportion of the original lime must have been regularly crystallized in a slow and tolerably perfect manner, so as to attain a firmness little inferior to lime stone or marble itself.

It is supposed that, upon these principles, it is easy to account for the superior hardnes of some old cements, when compared with that of modern times, in which a practice very different is usually followed, without having recourse to any wonderful arcana whatever.

Monseur Loriot, a late French writer, imagined that he had made a perfect discovery of the way in which the ancients employed their quick-lime, so as to obtain such an extraordinary firm cement; from which discovery, he conceived, very important benefits might be derived to society. According to his opinion, the ancient cement consisted of lime and sand nearly in the same proportions as are commonly employed for that purpose at present. But instead of making it of flaked lime entirely, as is done now, he contends that they employed a certain proportion of their lime unsketched, which they mixed with their mortar immediately before it was used. And it is further noticed, that this newly discovered cement dries and hardens almost under the hand of the operator, without cracks or flaws of any sort; that it neither expands nor contracts with the air;—that it is impervious to moisture, and may not only be employed for making roofs of houses that are subject to the continual dripping of water, basins, aqueducts, canals, &c. which will infallibly contain water in any quantities, but even finer works of the pottery kind; that it perfectly refits frosts, and has a variety of other interesting qualities. The trials of Dr. Anderson with the same sort of materials do not, however, confirm the great certainty and utility of this discovery. "That such effects as the writer describes," says the doctor, "will invariably be produced, merely by adding a certain proportion of unsketched lime in powder to mortar, or even by making the mortar entirely with powdered quick-lime, I may without hesitation venture to deny, not only from the reasoning that has been given, but from actual experiment, again and again repeated by myself, and which is likewise, in some measure, corroborated by the experience of Mr. Doffe." On these accounts, it is supposed, that if Monseur Loriot, has really experienced the uncommon effects from the mortar he has tried, it must have been occasioned by some other unobserved peculiarity, and not merely by the circumstance to which he seems to ascribe it. Possibibly the doctor supposes the lime he employed may have been impregnated with a gypsum, or the sulphate of lime, as is probable, for many reasons. The effects and qualities of which, as to becoming a fine powder, and of suddenly setting, are well known, but it never acquires the flinty hardnese that lime cement is sometimes endowed with, although it takes the smoothest polish of any cement we know; on which account, it has long been employed as a plaster where fine ornaments are required.

There are unquestionably, however, many doubtful and mysterious circumstances connected with this matter, which require the aid of further trials and experience in their full explanation.

There are still further a few other circumstances that may influence the quality of common lime-mortar. If lime-flone be sufficiently calcined, it is deprived of all its moisture, and of all its carbonic acid gas, or fixed air. But experience shews, that lime-flone will fall to powder on the effusion of water upon it, when it is much less perfectly calcined, and while it still retains almost the whole of its fixed air. And that as masons have hardly any other rule for judging whether lime-flone be sufficiently calcined, except this single circumstance of its falling to a powder when water is poured upon it, it may thus easily be perceived, that the same lime may be more or less fitted for making good mortar, according to a circumstance that, in a great measure, eludes the observation of operative masons; for if it should happen that all the pieces of lime drawn from a kiln at one time, were just sufficiently calcined to make it fall to a powder with water and no more, that powder would be altogether unfit for making mortar of any kind. This is a case that can seldom happen; but as there are a great many intermediate degrees between that flake and perfect calcination, it must often happen that the flone will approach nearer to one of these extremes at one time than at another; so that the mortar may be much more perfect at one time than at another, owing to a variation in this particular.

All those who have written on the subject of lime as a cement, have endeavoured to ascertain what is the due proportion of sand for making the most perfect cement. But a little attention to the matter will shew, that all rules, which could be prescribed as to this particular, must be so vague and uncertain, as to be of little utility to the practical mason; as, besides the variation which may arise from a more or less perfect degree of calcination as above, it is a certain fact, that some kinds of lime-flones are much more pure, and contain a much smaller proportion of sand than others do; some being found almost perfectly pure, while others contain eleven-twelfths of sand and all the intermediate proportions of it. Therefore it would be absurd to say that pure lime would require as small a proportion of sand when made into mortar, as that which originally contained in itself a much larger proportion of sand than any writer has ever ventured to propose for being put into mortar.

Besides, there are differences caused by the different nature of the calcination in the different sorts of lime-flone, from which it may, upon the whole, be concluded, that
about one-tenth of pure lime-stone is not enough calcined to admit of being made into mortar; and that of the most impure sorts of lime-stone, not above one-fourth of the lime contained in it is so much calcined as to be in a calculic state.

The variation that is produced by these means in regard to the proportion of sand that will be required to the lime in the one or the other case, is found to be so extremely great as hardly to be conceived. It is, however, stated, that the best mortar that has been seen made was formed of lime which had been found to contain eleven parts of sand to one of lime: to this there was added between twice and thrice its whole bulk of sand by measure; which may be allowed to have been at least twice its quantity by weight. Therefore, supposing that every particle of that lime had been so perfectly calcined as to be in a calculic state, there could not be less than forty-seven parts of sand to one of lime. As much may, however, be allowed for the uncalculic part of the lime as is pleased, and the calculation made accordingly. But it is hardly possible to suppose that above one-hundredth part of this mass, independent of the water, consisted of pure calcic calculic earth.

On these considerations it is conceived, that it is impossible to prescribe any determinate proportion of sand to lime, as that must vary, according to the nature of the lime and other incidental circumstances, which would form an infinity of exceptions to any general rule. But it would seem that it might be safely inferred that the moderns in general rather err in giving too little sand, than in giving too much. It deferves, however, to be noticed, that the sand, when naturally in the lime-stone, is more intimately blended with the lime than can possibly be ever effected by any mechanical operation; so that it would be in vain to hope to make good mortar artificially from pure lime, with such a small proportion of calcic calculic matter as may sometimes be effected when the lime naturally contains a very large proportion of sand. But there seems to be no doubt, that if a much larger proportion of sand were employed, and if that were more carefully blended and expeditiously worked than is common, the mortar would be much more perfect than is usual in modern times, as has been proved by actual trials.

Another circumstance that tends greatly to vary the quality of cement, and to make a greater or smaller proportion of sand necessary, is the mode of preparing lime before it is beaten up into mortar. When for platter, it is of great importance to have every particle of the lime-stone flaked before it is worked up; for, as smoothness of the surface is the most material point, if any particles of lime should be beaten up in it, and employed in work before sufficiently fallen, the water, still continuing to act on them after it was worked up, would infallibly flake such particles, which forcibly expanding themselves, would produce those effects on the surface of the platter commonly termed blisters. Consequently, in order to obtain a perfect kind of platter that will remain smooth on the surface and free of blisters, there is an absolute necessity to allow the lime to lie to lie for a considerable time macerating or souring in water, before it is worked up. And the same sort of process is necessary for the lime when intended for use as mortar, though not so absolutely. Great care is, however, required in the management in this respect; the principal things being the getting of well-burnt lime, and the allowing it to macerate or sour with the water for only a very short time before it is used; but that which is the best burnt will require the maceration of some days in the water before it is sufficiently flaked in the whole mass for this purpose. See Souring Lime for Mortar and Plaster.

It has been almost universally admitted, that the hardest lime-stone affords a lime that will consolidate into the firmest cement; and hence generally concluded, that lime made of chalk, produces a much weaker cement than that is made of marble or lime-stone. It would seem, however, that if ever this be the case, it is only incidentally, and not necessarily so. As from the nature of calcic calculic matter, every kind of lime is equally fit for becoming a firm cement, if it be first reduced to a proper degree of caulicity, and has afterwards a due proportion of sand properly mixed with it, before it is employed in work. Different sorts of lime, without doubt, differ much from each other in the proportion of sand they naturally contain, and, of course, require very different proportions of sand to be added to them before they can be made equally perfect as a cement; which is an economical consideration, of no small moment in some cases, as it may make one sort of lime a great deal cheaper than another on some occasions, and, of course, deserves the attention of builders in general. See Lime.

The excellencies and defects of other substances that may be occasionally mixed with lime in making cement may be justly noticed. Those commonly used as an addition to mortar, besides sand of various denominations, are powdered sand-stone, brick-dust, and sea-shells. And for forming platter, where clozeness rather than hardness is required, they are lime that has been flaked and kept long in a dry place, till it has become nearly effeet, powdered chalk or whiting, and gypsum in various proportions; besides hair and other materials of that nature. But some others have been more lately advised, such as earthy balls, slightly burnt and pounded, powdered and sifted old mortar rubbish, and others of a similar kind. All of which substances are found objectionable in some respect or other for this use, being the only perfectly suitable material that can be easily blended on; on which account it has been always justly preferred. Pure form crystallized sand is the best, but all pure sands are not equally proper in this intention. See these substances respectively. See also Cement and Sand.

It is stated by Sir Humphry Davy, in his work on "Agricultural Chemistry," that there are two modes in which lime acts as a cement; in its combination with water, and in its combination with carbonic acid. When quick-lime is rapidly made into a paste with water, it soon loses its softness, and the water and the lime form together a solid coherent mass, which consists of nineteen parts of water, to fifty-five parts of lime. When this hydrate of lime, while it is consolidating, is mixed with red oxide of iron, alumina, or silica, the mixture becomes harder and more coherent than when lime alone is used; and it appears that this is owing to a certain degree of chemical attraction between hydrate of lime and these bodies; and they render it less liable to decompose by the action of the carbonic acid in the air, and less soluble in water. It is thought that the basis of all cements that are used for works which are to be covered with water must be formed from hydrate of lime; and that the lime made from impure lime-stones answers this purpose very well. Puzzolana, it is said, is composed principally of silica, alumina, and oxide of iron; and it is used mixed with lime, to form cements intended to be employed under water. It is stated that Mr. Smeton, in the construction of the Eddystone lighthouse, used a cement composed of equal parts, by weight, of flaked lime and puzzolana. Puzzolana, it is said, is a decomposed lava. Tarraz, which was formerly imported in considerable quantities from Holland, is found to
to be a mere decomposed bafalt : two parts of flaked lime and one part of tarsas form the principal part of the mortar used in the great dykes of Holland. It is supposed that fulbances which will answer all the ends of puzzolana and tarsas, are abundant in the British islands. An excellent red tarsas may be procured in any quantities from the Giant's Causeway, in the north of Ireland: and decomposing bafalt is abundant in many parts of Scotland, and in the northern districts of England in which coal is found.

It is observed that Parker's cement, and cements of the same kind made at the alum-works of Lords Duncas and Mulgrave, are mixtures of calcined, ferruginous, siliceous and aluminous matter, with hydrate of lime.

It is noticed, that the cements which act by combining with carbonic acid, or the common mortars, are made by mixing together flaked lime and sand. These mortars at first solidity as hydrates, and are slowly converted into carbonate of lime by the action of the carbonic acid of the air. It was found by Mr. Tennant, that a mortar of this kind, in three years and a quarter, had regained sixty-three percent. of the quantity of carbonic acid gas, which constitutes the definite proportion in carbonate of lime. The hardness of the mortar in very old buildings is also thought to depend upon the perfect conversion of all its parts into carbonate of lime. The purest lime-flakes are the best adapted, it is said, for making this kind of mortar. The magnetite lime-flakes make excellent water cementes, but act with too little energy upon carbonic acid gas to make good common mortar.

The Romans, on Pliny's authority, made their boil mortar a year before it was used; so that it was partially combined with carbonic acid gas before it was employed, it is supposed.

It is likewise suggested, in regard to the cultivation and improvement of land by means of this material, that quick-lime in its pure state, whether in powder, or diffused in water, is injurious to plants; graves in several instances having been killed by watering it with lime-water: but that lime, in its state of combination with carbonic acid, is a useful ingredient in soils. Calcareous earth is found in the ashes of the greater number of plants; and exposed to the air, lime cannot long continue caustic, but soon becomes united to carbonic acid. That lime, when combined with about one-third of its weight of water, constitutes hydrate of lime; and that it becomes carbonate of lime by long exposure to the atmosphere, the place of the water being supplied by carbonic acid gas. On mixing freshly burnt or flaked lime with any moist fibrous vegetable matter, a strong action occurs between them, and they form a sort of compost, part of which is commonly soluble in water. In this way, lime renders matter, before comparatively inert, nourishing; and from charcoal and oxygen, abounding in vegetable matter, it becomes converted into carbonate of lime at the same time.

Mild lime, or powdered carbonaceous substances, have no action in this way upon vegetable matter; by their operation they prevent the too quick decomposition of bodies previously diffused; but do not tend to form soluble matters. Consequently it is clear that the operation of quick-lime and mild carbonaceous substances, depend upon wholly different principles. The former, on being applied to land, tends to bring the hard vegetable matter contained in it into more rapid decomposition and solution, as a proper food for plants. The latter only improve the texture of it, or its relation to absorption: it is merely an earthy ingredient. Quick-lime, in becoming mild, has a similar action, but while taking on that state, prepares soluble out of insoluble matter. On this depends the operation of lime in the preparation for wheat crops, its efficacy in fertilizing pasts, and in bringing into cultivation all sorts abounding in hard roots, dry fibres, or inert vegetable matter. The question, of course, whether quick-lime should be applied to land or not, depends on the quantity of inert vegetable matter it contains; and that whether mild lime, marle, or powdered lime-flakes, should be used or not, on the quantity of calcareous matter already in the land. All sorts of land are improved by mild lime, and ultimately by quick-lime, which do not effervesc with acids; and the sandy sorts more than the clayey kinds.

In land deficient in calcareous matter, but containing much soluble vegetable manure, the use of quick-lime should constantly be avoided, as tending either to decompose the soluble matters, by uniting to their carbon and oxygen, in becoming mild, or to combine with the soluble matters, and form compounds with less attraction for water than the pure vegetable substance. The fame is the case in regard to most animal manures; but its operation is different in different cases, according to the nature of the animal matter. On the whole, it should however never be employed with animal manures, except when too rich, or for preventing noxious effluvia. It is hurtful in mixture with common dung, and tends to produce infoliabillty in the extractive matter. It is useful in mixture with simple vegetable barks, &c.

The solution of the question about the inutility and disadvantage of magnesian lime, which has lately been found useful in small quantities on the poorer lands in Leicestershire, as from twenty-five to thirty bushels the acre, and in larger ones, on the rich soils; it is supposed to depend upon that fort of lime having a less attraction for carbonic acid than the other, in consequence of the portion of that substance in it, and thereby remaining longer in the caustic state; and its becoming sooner a carbonate of lime in the rich than in the poor soils. Magnesia, while in the caustic state, is poisonous to certain kinds of plants, and acts in the mixture as lime. It may be usefully applied in large quantities to peat-earths; and to lands injured by too much of this fort of lime, peat-earth will be a proper and effectual remedy, when used in a suitable proportion.

More full information may be met with in this curious and interesting subject, in the first volune of Anderson's Essays on Agriculture and Rural Affairs, in Dörfle's Memoirs of Agriculture, vol. ii. and in Sir Humphry Davy's "Agricultural Chemistry."

Quick-Manure, a term sometimes applied to that fort which is sowed over crops upon the surface of the land, such as foot, small dung, different kinds of ashes, &c. As manures in this intention on pasture lands, wheat, clover, tare, and other similar crops, twenty bushels of foot is recommended to the acre, sixty bushels of rabbit or poultry dung, and fifty of pigeons' dung and ashes; but much larger as well as smaller proportions are made use of in different circumstances. The foot and dung should be sown over the crops about the middle of March, the ashes in February, and all in the most equal and exact manner possible, as much depends upon this being properly performed. See Ashes, Dung, and Soot.

In different counties there is much difference in the use of substances of these kinds in this way as manures. In Hertfordshire the usual quantities of foot employed in this manner are from about twenty to forty bushels, on the wheat crops; but in some places they are used to the extent of fifty or more on the acre. The application of this material is universal throughout almost every parish in the whole county, in this mode and intention. Ashes in the same district are considered by some as rendering the soil more light and open, without contributing, in any great degree,
to the nutrition of the crops over which they are sown. The proportions in which they are used to the acre over the clover, and occasionally the wheat crops, are from fifty to one hundred bushels. They are supposed to be very serviceable to the two clover crops, and greatly beneficial to the succeeding wheat one, by some persons; but others are of quite the contrary opinion, thinking them of very little use to the wheat, except by increasing the quantity of the clover. They are also useful in destroying mosls in the surface of grass lands. They are to be kept dry, and commonly sown over the crops in November or January in mild moist weather.

In Oxfordshire, peat-ashes are made use of from about twelve to forty bushels upon the acre; and those of coal from sixteen to upwards of fifty. They are sown over the wheat, clover, saffron, and turnip crops, the coal being somewhat on the clovers, and the peat on the turnips.

In Berkshire, peat-ashes are used very generally for most of the crops, except wheat, barley, and peas, either sown with the fellows and harrowed in together, or sown on the land as a top-dressing, only; but they are more preferred for all sorts of artificial grass crops, and on natural meadow and pasture grasses, as well as turnips. The quantities employed are from fifteen to twenty bushels and upwards on the acre. They are applied in March or April, several acres being capable of being sown in the course of the day. They only last about a couple of years in the land. The ashes of bean fubble are likewise found beneficial heretofore, bringing up white clover when put upon the grass lands.

Different sorts of ashes have been found very useful on the grass lands in Suffolk, at the rate of from twenty to thirty bushels on the acre, employed as a manure.

In Essex coal-ashes are laid upon the clover, saffron, and grass crops to the quantity of fifty bushels on the acre or more, with very great effects in promoting their increase.

In the county of Hertford they manure for turnips and some other crops with rabbit and poulty dungs, at the rates of from fifty to sixty bushels or more on the acre, with good success. And in some part of the Oxford district, pigeons' dung is found an excellent manure when thrown over the young barley crops, mixed with that of poultry. In Essex too, it is found beneficial for promoting seed when sown over the rape or cole crops in the proportion of eight bushels to the acre.

There are several other articles which are occasionally thrown over crops on the surface of the land as a manure, in this intention, such as those of the duff of malt, rape-cake, bones, phialer of Paris, and some others. Malt-duff is made use of on wheat and barley in many parts of the county of Oxford, and on the young wheat in Hertfordshire, in the quantity of five quarters to the acre. In Berkshire thirty bushels per acre. Rape-cake duff is also used in the former of these last counties on the wheat with success. Pounded bones are likewise greatly beneficial when strewed over the grasses and some other sorts of crops, being sometimes a very forcing manure, and at the same time killing. The phialer of Paris has been used on clover, saffron, lucerne, and other crops with immense effect, in some parts of Oxfordshire, sown over them about March, to the quantity of six bushels per acre. But in Suffolk, in the proportion of eight bushels to the acre, when sown over natural grasses, bean, potato, pea, and barley crops, it had not the least good effect. Nor even when tried on other sorts in the quantity of six bushels to the same extent of land.

Powdered oil-cake that has been spoiled by keeping, is an excellent application as manure in the above way. The fame is also the cafe with chopped tanners' hair, which has been found superior in this use to either malt-duff or any fort of calcarceous matter. Horn-leadings are likewise very beneficial when laid on in this manner to grass lands, in the proportion of from fifty to one hundred bushels to the acre, lasting five or six years, and being of very easy carriage they should be employed in damp weather about February or March. See Manusure.

All these different sorts constitute excellent quick forcing manures, when applied in some of these ways for some of the above purpofes, and should be much more generally employed in such methods than is at present the cafe.

Quick Match, in Artillery, is formed of three cotton threads drawn into length, and dipped in a boiling composition of white wine vinegar, falt petre, and mealed powder. After this immersion, it is taken out hot, and laid in a trough where some mealed powder, moistened with spirits of wine, is thoroughly incorporated into the twists of the cotton, by rolling it therein: thus prepared, they are taken out fervently, and then through the mealed powder, and then hung upon a line to dry. There is also quick match made of worf tide instead of cotton. For its use, see Fire-Ship.

Quick with Child, in Law. See Reprieve.

Quick Pulse, in Medicine. See Pulse.

Quick Sand, in Sea Language, denotes a loose quaking sand, into which a ship sinks by her own weight, as soon as the water retreats from her bottom. See Quicksand.

Quick Thorn, in Agriculture, a name formerly applied to young plants of the hawthorn or white-thorn kind, which are fit for being planted out for the purpose of forming a hedge-fence. See Quicks, and Quickset.

It also signifies this fort of thorn generally.

QUICKEN TREE, in Gardening, the common name of a tree of the ornamental fruit kind. See Sorbus.

QUICKENING, in Midwifery, the first perception women have of the motion of the fetus. This usually happens in the third or fourth month of pregnancy. It has puzzled physiologists to explain why the motion of the fetus should not be perceived earlier, as it is endowed with life from the first moment of conception. But, besides that the parts of the fetus are too soft and tender to affect the uterus by its motion, the membranes enveloping it are too thick, and there is then a proportionally larger quantity of fluid in the ovum than afterwards, which keeps the embryo from touching the sides of it. The uterus also during this period is confined in the cavity of the pelvis, which being of small capacity, and every way surrounded with bones, leaves little room for the motion of the fetus. But as soon as the uterus emerges into the cavity of the abdomen, it readily yields to the motion of the inflating fetus, and the parts by which it is now surrounded being extremely deli- cate and tender, they are affected by the slightest flitting of it. In some women of delicate habits, the moment of quickening is marked by a slight hysteric paroxysm. In thefe cases it seems probable, that the uterus has been suddenly into the abdomen, but ordinarily it rises slowly and gradually, whence the shock on the bowels is so incon- siderable, as scarcely to make any sensible impression. See Conception.

QUICKING-Drag, in Agriculture, a name sometimes given in different districts to the couch and quitch drag. See Drag.

QUICKJOCK, in Geography, a town of Sweden, in the Lapmark of Lutec; 15 miles N.W. of Lutec. N. lat. 69° 20'. E. long. 17°.
QUICKS, in Agriculture, a name commonly given to the young fps of the white-thorn, which are used in planting hedges of that sort. See Quickset Hedge.

It is thought to be indispensably necessary to the success of this sort of fets, as hedge plants, in every situation, that they be well provided with roots and root fibres of the healthy kind, by Mr. Nichol, who has had much experience upon the subject. And this is best secured by taking them from a seminary of rich mould at the end of the first or second year, according to their strength; and nursing them, after that, likewise in rich earth, for one or two sasons longer at the fart: but, in the latter case, removing them into fresh rows at the end of the first year. It is contended, that plants of this age, and thus treated, will outgrow those of greater size in any fort of foil or situation. This has been repeatedly proved by impartial trials; and the caufe, it is supposed, is obviously this, that small plants, even by the fame treatment, are raised with better roots, in proportion to their items, than large ones. Therefore in the choice of quicks, regard should be had to the roots, not the tops of the plants. Their being nurfed the fennon previous to their being removed for hedging purpofes, in rich mellow earth, and being allowed a [ficiency of room, kept clear of weeds and other matters, is the fett mode of preparation, it is imagined, that can possibly be adopted.

There is, however, it is maintained, a double advantage in making use of young plants of this nature. They are cheaper and fitter for exposed situations than thofe of older growths; not becaufe their tops are less bulky, which, fince they are to be cut over about half their lengths before being planted, is immaterial, but becaufe they have better proportioned roots to the fize and Strength of the items, and of courfe are better fitted to feed palturage for their common fuffence and support.

The items of the plants, as has been fugged above, fhould be cut over about half their lengths, or, in general, about six inches above the ground mark: an operation which may be performed by the common hedge fhears, a large sharp knife; or by gathering a handful of them eveny, and laying them upon a block or other familiar body, and chopping them off by means of a hatchet. They fhould always be carefully fifted, and even the smalllef fibre be retained. And at all times, until replanted, the roots fhould be exposed as little as possible to the air or atmosphere. See Quickset.

Quick is also a term sometimes applied to the weed called couch-gras, in different places, and which is of a very troublesome nature, not being extirpated out of the land without much difficulty. See Couch.

QUICKSAND, any fort of spot or bed of running fand, either near to the surface of the foil, or at any depth below it, which has a finking quaggy feel under the root at certain times or feafons, in confequence of containing certain proportions of water. The writer of the work on "Laided Property" has remarked, that they are for the most part topical, and in general only temporary, commonly appearing in and after wet feafons only; clofing and becoming firm when their supplies of moisture are exhausted by long drought. In thofe fites the surfaces are free from the deposition of the mooy earth of bog plants, which demand a conftant coolness, if not a perpetual supply of moisture, being caused by heads or small beds of fand or gravel rising through firmer frata to the surface. They are of courfe apt to be farked in dry hot feafons. In order to remove them, the fame writer advises, that the centre of the part which is aflecd fhould be marked out when the feafon is wet, in order that a drain may be cut, when it is dry, of a fufficient depth quite up to the mark, letting it have the neceffary defcent, and then filling it with suitable materials to admit of the water being conveyed off as it is collected in the flub-foil. When the defect has been thus removed, where it is situated in the area of a field, it is a good practive to cover the part by foil of the fame nature as that of the field where it is situated, by bringing it from thofe parts which are the moft elevated, as by this means it may be rendered of an uniform quality with the reft, and of courfe have a better appearance, as well as be more advantageous in the growth of crops.

Dangerous tracts and spots of this nature are frequently found in marshy and sandy lands, which are occasionally covered by the tides. And large deep beds or layers of quick or running sand are often met with in digging pits, quarries, mines, and other forts of shafts, to great depths under the ground, and cause much trouble and dificulty in getting on with fuch kinds of work, on account of the quantities of water which they contain and let pafs off into them: thus occafioning the neceffity of much difficult drainage, and other inconveniences. See Quarries, Pits, &c. Draining of.

QUICKSAND BAY, in Geography, a bay on the west coast of North America. N. lat. 45° 50'. W. long. 124°.

QUICKSET, in Agriculture, a term generally applied to the white, or hawthorn plant, the fets or young plants of which are raised by nurferymen for fale, for the purpofe of planting and forming hedge-fenees. The roots of the thorn will, however, anfwer equally well, and in fome cafes much better, as there is a certainty of their being of the right fort, or fuch as have prickles upon them, which does not always happen in uifing the quicklets, as they are liable to diaparre when raifed in this method, but which is never the cafe in the root-mode. See Fence-Thorn, and White-Thorn.

Young plants of the quicklet kind are belf raifed in small portions of ground fett apart for them; in which, after they are come up from the feed to fome height, they fhould be tranplanted in lines at narrow diftances, in a ftraight manner, with fmall intervals between the rows; where they are to remain from three to five years or more, being annually well cleaned and moulded up. Some, however, tranplant them more than once, and think it an advantageous way, but they do well in either method. Well grown plants, with ftout clean items, are the moft proper for planting out as hedge plants.

QUICKSET Hedge, a name given to all forts of hedge-fenees which are confituted of any fort of living plants, but more especially of thofe of the white-thorn kind. Hedges of this nature compose the principal feneses of this country. In the drier and better forts of foil, thofe of the thorn kind generally prevail; but in moft other fitations, thofe of fome other forts of plants, according to the particular nature of the fols and exposure. The quicklets or quickfets of the thorn forts are commonly fuppofed to form the bent hedges, when planted in the raifed bank or dike method. The manner of placing them out in these is different in different cafes, both in regard to the form and number of the rows, as well as the diftances of the plants from each other. Some think one regular or irregular row the moft proper, others prefer two ftraight ones; and some fuppofe a few inches diftance from plant to plant the moft benefcial; while others think eight or nine inches to be much better. Strong well-grown quicklets are commonly preferred in all cafes. It is remarked in the Essex Report, by one of the perfons engaged in drawing it up, that in the
parish of Birdbrook, in the north-east part of it, "some excellent hawthorn hedges have been lately raised, by planting one row only at six inches asunder, rather than two rows nine inches or a foot apart. The hedges have not been cut down, nor do they require it, to thicken their bottoms, as they are, at this time, a complete protection against hogs, and in other respects form a beautiful and effectual fence. Nothing can be more evident, it is thought, than that a row of plants set thus . . . . six inches distant from each other, will form a more complete and effectual fence at the bottom, than an equal number planted thus . . . . at a double distance, and occupying the same length, but a greater depth of ground upon the hedge row." This reasoning of Mr. Vancouver's, Mr. Young observes, may, for aught he certainly knows, be conclusive, but it strikes him in a different light. It is true, that the plants in each row are, in the latter mode, at double the distance from each other than they are in the former; but it is to be observed, that in the double row, the plants are diagonally as near each other as in the single row, and, consequently, there is the same vacant space for any animal to pass through in the single row as in the double; and what must be a great advantage to the latter, the plants will shoot out their branches laterally on the outside at least, just as those in the single row, and twice as far lengthwise, meeting with no obstruction in their progress. Of course, it is naturally to be concluded, that the double-rowed plantation must form a fence, if not altogether twice as strong and secure, yet vailly stronger and fiercer than the single one. He does not, however, presume to fet speculation against fact, as he has not seen the hedge noticed above, while Mr. Vancouver has. He has, however, himself planted one in a single row, as above described and recommended; the plants have grown well; the hedge is a good one, but would, he thinks, have been till better, if there had been two rows instead of one, as some others are that he has of that description.

In Sulixe, the quickset hedges at Goodwood are capital, and deferving of every attention, being raised and trained in a most mallerly manner. The duke of Richmond planted them about eighteen or twenty years ago. They surround a very considerable farm, and are in a wonderful state of preservation. They form an excellent fence, without the alliteration of any ditch, bank, rail, or pale; confid of three rows of white-thorn plants, which spread three or four feet at bottom, but are clipped regularly and gradually to a thin edge at top; the shoots are fo numerous, and trained with such care, that even in winter, without a leaf, the thicknes is uncommon. By the young hedges now in training, it appears that one method purfued has been to plant the centre row first, and when that is well established, to add another on each side of it; at least this is done in these new hedges. They are kept in a flate of garden cleaness; the branches are drawn into the line desired, by being tied with mat, or other lines, and the clipping done with the exactest attention; the union of the hedges with the gate-polls is close and pefect, and as to gap, &c. there is no such thing. How they have been preferred from cattle, but especially from heep, is marvellous, if either are ever allowed to enter these clofes; an attention never ceasing, and a boundless expense, fo far as neceffary, mull have been exerted. They cannot be recommended to the imitation of farmers on account of the trouble and expense of them, but they are beautiful as an object to the farming eye, and for their perfection, they merit all that can be laid of them.

On the Walburton farm in the same district, there are some very good quickset hedges, which were planted about twenty-three years ago; the quick was set about two inches asunder, and single; they are cut twice in a year; are four and a half feet high, and two feet thick. There is very little ground boil by the hedge, as it occupies only four feet. The fame excellent fort of quickset hedges has also been made in some other places.

Here two rows of white-thorn plants are common, which are put on the bank of the ditch, care being taken not to have them too near it, for fear of its draining them too much and preventing their growth. In some districts, where the cultivation is principally of the arable or tillage kind, and in exposed upland situations, there is frequently a great prejudice and objection to the introduction and formation of any fort of live hedges, whether of the quickset or any other description, as they take up much space, harbour birds and insects, greatly shade the grain, and tend to promote blight, rust, and mildew, by preventing the free circulation of air. Also in bleak exposures they are not raised without great difficulty. Such objections, however, speedily vanish where they are kept sufficiently low and well cut in and trained on the sides. See HEDGE and FENCE.

QUICKSILVER, a very ponderous fluid mineral, by the chemists called mercury. For the method of gaining, preparing it, &c. with its properties, uses, &c. see MERCURY.

Quicksilver, when rubbed down and blended with unctuous matters, forms a fort of ointment, which is useful in the curing of different diseases of the cutaneous kind, as well as in destroying lice and other vermin that infest animals of different kinds, which form the live-stock of the farmer.

It has also been flated on the authority of Mr. Bradford, as communicated to the Society for the Encouragement of Arts, &c. to have been found useful in its crude state in destroying insects on fruit trees. On a plum-tree he made the following trials; he took a small awl, and pierced, flogging, through the rind, and into part of the wood of the branch, but not to the heart or pith of it; and poured in a small drop or two of the quicksilver, and flogged it up with a small wooden plug, made to fit the orifice: and the result was, he says, that the insects all dropped off from that very branch the next day; and in a day or two more, from off the other branches of the tree, without any other punctures; and the tree continued in full vigour, and throve well all the summer after. Encouraged by this success, he next tried it upon a honey-fuckles, the leaves of which were quite covered with them; and there he scraped away the top of the ground with a trowel, and run his awl, in the same flogging manner, into the main stem, just above the roots; but with the fame caution as above, not quite to the inner pith; and the success was the same as before. The insects all dropped off dead the next day after the experiment was made.

These trials are said to have been confirmed by other experiments; but they are still in want of full and satisfactory confirmation.

QUICKSILVER, Virgin. See VIRGIN.

QUICKSILVER WATER. See WATER.

QUICKSTADT, in Geography, a town of Norway, in the province of Aggerhus; 42 miles N. of Christiania. QUICK-WORK, in a Ship, is a general name given to all that part of a ship which is under the surface of the water, when the same is laden for a sea-voyage. The term is also applied, occasionally, to that part of the side which is above the sheer-rail, and which is usually painted with trophies, &c. on the outside. Falconer.

Quick-work is likewise applied to the frakes that shut in the infide, between the sparsitting and clamps.
QUID, What, in the Schools, is used to denote the definition of a thing.

It is thus called, because the definition answers to the question, quid est? what is it?

Hence we have two kinds of quids; nominal, quid nominis; and real, quid rei.

Quid juris clamat, in Law, a writ that lies where I grant the recovery of my tenant for life by fine in the king's court, and the tenant will not attorn; then the grante shall have this writ to compel him.

This writ seems to be obsolete, since the fourth and fifth of Anne. See Atournment.

Quid pro quo, q. d. what for what, denotes the giving one thing of value for another; or the mutual consideration and performance of both parties to a contract.

Quid pro quo, or Qui pro quo, is also used, in Physic, to express a mistake or cheat of an apothecary, in administering one medicine for another; or in using an ingredient in a composition different from that prescribed.

A northern physician, in a printed thesis on quid pro quo, owns ingeniously, that they are very frequent. He distinguishes very accurately a great variety of kinds of quid pro quo; some with regard to the operation, others with regard to the subject; and others with regard to their form, or effects.

The first comprehends the quid pro quo of the physician; the second, theoé of the patient; the third, theoé of the apothecary.

Quid Lo, a term which signifies the loss of the ruminant power in animals of the live-stock kind. It is mostly produced by local weakens of the stomach, caused by eating improper coarse kinds of food in too large quantities, or other similar means. It may be best restored by the use of strong acids of the vegetable and other kinds, and its return prevented by strong bitter infusions, as theoé of gentian, bark, &c. See CU.

QUIDDEINEN, in Geography, a town of Prussia, in Oberland; 6 miles S.E. of Holland.

QUIDDENY, Quiddiny, (of the Latin cydonium, or cydonium,) a conserve of quinces, called also marmalade.

QUIDDITY, Quidditas, in the Schools, a word of the same signification with essence.

The name is derived hence, that it is by the essence of a thing that it is take quid, such a quid, or very thing, and not another. When upon seeing, or hearing, the name of a thing, with whole nature, &c. we are unacquainted, we ask, Quid est? What is it? We mean no more by the interrogation, but that we desire to have its nature and essence explained by a definition. Whence quiddity is usually defined the essence known or expressed in a definition.

And hence what is essential to a thing is said to be quidditive; as quidditative knowledge, &c.

QUIEBOU, in Geography, a town of France, in the department of the Channel; 5 miles S.W. of St. Lo.

QUIEN, Michael le, in Biography, a learned Dominican monk, who flourished in the latter part of the 17th and in the 18th century, was born in the year 1661. He received a liberal education, having been instructed in classical learning at his native place, and he was then sent to study philosophy at the college du Plessis, at Paris. At twenty years of age he determined to renounce the world, and took the habit in a Dominican convent. Here he studied with uncommon facility and proportionate success, the Greek, Hebrew, and Arabic languages, criticism, divinity, the sacred scriptures, and ecclesiastical antiquities. In the year 1690 he first appeared as an author, by publishing "A Defence of the Hebrew Text and the Vulgate Version," against a work, entitled "The Antiquity of Time restored," written by father Pescor. The latter having published a reply, Quien anwered in a work entitled "The Antiquity of Time exploded." He next attacked him in "Remarks" on his "Attempt at a literal and historical Commentary on the Prophets," printed in the Memoires de Trevoux, for March 1711. During the following year he published "S. Ioannis Damasceni Opera quae extant Gr. et Lat." in 2 vols. fol., accompanied with diffutations abounding in erudition. He intended to have given a third volume, containing such pieces as had been falsely attributed to that father, but it was never sent to the press. The same fortune has attended his labours on "The Works of Leo of Byzantium," to which he had paid a considerable share of attention. Towards the close of his life he entered into a controversy with father Courayer, concerning the validity of the ordinances of the church of England, in which the palm of victory was given to his opponent. Le Quien died in 1753, at the age of 72 years, respected for his piety, and uniform correctness of conduct. He was author of various "Dissertations" to be found in Defmolets "Memoires de Litterature et d'Histoire," and the "Mercure de France." At the time of his death he was engaged in printing the most considerable of his works, relating to the ancient and present state of the eastern churches. "His plan includes the whole of his churches, under the four grand patriarchates of Constantinople, Alexandria, Antioch, and Jerusalem; presents a geographical description of each diocese, and of the episcopal cities, and then gives a particular account of the origin and establishment of the churches, their extent, their jurisdiction, their rights, their prerogatives, the succession and order of their bishops, their political government, the changes which they have undergone," &c. As the author did not live to finish his work, it was published with additions, in the year 1740, under the title of "Michaelis le Quien Orientis Christianus, in quatuor Patriarchatus dignitums, quor exibentur Ecclesiæ Patriarchæ, cæteris Prefeula Orientis," &c. in 3 vols. fol. Moreri.

QUIENFIORD, in Geography, a bay on the coast of Norway; 27 miles N. of Christiania.

QUIENS, a river of Norway, which runs into the sea, 18 miles N. of Cape Lindeiæs.

QUIESCENT, something at rest.

QUIETISM, in Ecclesiastical History, the sentiments of the Quietists, a religious sect, which made a great noise towards the close of the 17th century.

Molinos, a Spanish priest, who died at Rome in the prison of the inquisition, pales for the author of Quietism; and yet the Illuminati in Spain had taught something like it before.

A sect similar to this had appeared at Mount Athos, in Thessaly, towards the close of the fourteenth century, under the appellation of Hesychasts, which denotes the name with Quietists. These were a branch of the Mystics, which fect, or those more perfect monks, who, by a long course of intense contemplation, endeavoured to arrive at a tranquility of mind entirely free from every degree of tumult and perturbation. These Quietists, in conformity to an ancient opinion of their principal doctors, (who imagined that there was a celestial light concealed in the deepest retirements of the mind,) used to fit every day, during a certain space of time, in a solitarie corner, with their eyes eagerly and immovably fixed upon the middle region of the belly, or navel; and boasted, that, while they remained in this posture, they found, in effect, a divine light beaming forth from the soul, which diffused through their hearts inexplicable sensations of pleasure and delight. To such as inquired what kind of light this was, they replied, by way of illustration, that it was the glory of God, the same celestial radiance that surrounded Christ.
Chrrl during his transfiguration on the mount. Barlaam, a monk of Calabria, from whom the Barlaamites derived their denomination, tyed the monks, who adhered to this institution, Maffalian and Euchites: and he gave them also the new name of Umbilican. Gregory Palamas, archbishop of Thessalonica, defended their cause against Barlaam, who was condemned in a council held at Constantinople in the year 1341.

The name is taken from a fort of absolute reft, and inaction, which the soul is supposed to be in, when arrived at the state of perfection, which in their language is called the unitive life. To arrive at this, a man is first to pass through the purgative way; that is, through a course of obedience, infpired by the fear of hell: hence he is to proceed into the illuminative way, before he arrives at perfection.

The sentiments of the Quietists, with regard to God, are wonderfully pure and disinterred. They love him for himself, on account of his own perfections, independently of any rewards or punishments: the soul acquiefces in the will of God, even at the time when he precipitates it into hell; in so much that instead of flomping him on this occasion, B. Angelo de Foligny cried out, "Haftte, Lord, to call me into hell: do not delay if thou hast abandoned me: but finish my destruction, and plunge me into the abyss.".

At length the soul, after long travail, enters into rest, into a perfect quietude. Here it is wholly employed in contemplating its God; it acts no more, thinks no more, defires no more; but lies perfectly open, and at large, to receive the grace of God, who by means thereof drives it where it will, and as it will.

In this state it no longer needs prayers, or hymns, or vows; prayers where the spirit labours, and the mouth opens, are the lot of the weak, and the imperfect: the soul of the faint is, as it were, laid in the bosom, and between the arms of its God, where, without making any motion, or exerting any action, it waits, and receives the divine graces. It then becomes happy; quitting the exilence it before had, it is now changed; it is transformed, and, as it were, sunk and swallowed up in the Divine Being, insomuch as not to know or perceive its being distinguished from God himself. Penel. Max. des Saints.

QUIETISTS, the disciples of Mich. de Molinos; or the adherents to the opinions delivered in the article Quem. The sentiments of Molinos were contained in a book, which he published at Rome in the year 1681, under the title of the "Spiritual Guide": in consequence of which he was cast into prison in 1685, where he was soon obliged to renounce, in a public manner, the errors of which he was accused: and this solemn recantation was nevertheless followed by a sentence of perpetual imprisonment, from which he was in an advanced age delivered by death, in the year 1696. Molinos had a considerable number of disciples in Italy, Spain, France, and the Netherlands. One of the principal patrons and propagators of Quietism in France, was Marie Bouvieres de la Mothe Guyon, a woman of fashion, remarkable for the goodness of her heart, and the regularity of her manners; but of an unsettled temper, and subject to be drawn away by the seduction of a warm and unbridled fancy. This female apostle of mysticism derived all her Ideas of religion from the feelings of her own heart, and described its nature to others as she felt it herself. Accordingly, her religious sentiments made a great noise in the year 1687; and they were pronounced unfound, after accurate examination by several men of eminent piety and learning; and professedly confuted, in the year 1697, by the celebrated Bossuet. Hence arose a controversy of great moment, between the prelate last mentioned, and Fenelon, archbishop of Cambry, who seemed disposed to favour the religiously infen Madame Guyon, and who, in 1697, published a book, cited in the last article, containing several of her tenets. Fenelon's book, by the interest of Bossuet, was condemned by the year 1699, by Innocent XI. and the council of condemnation was read by Fenelon himself at Cambry, who exhorted the people to respect and obey the papal decree. Notwithstanding this seeming acquiescence, the archbishop perilled, to the end of his days, in the sentiments which, in obedience to the order of the pope, he retracted and condemned in a public manner. See the article Fenelon.

QUIETO, in Geography, a river of Ilfria, which runs into the Adriatic, two miles W. of Bafia.

QUIETUS, fixed or acquifited, a term used by the clerk of the pipe, and the auditors in the exchequer, in their acquittances or discharges given to accountants, which usually conclude with the words abinde reeetfis quietus; which is called a quietus eft.

A quietus eft Granted to a sheriff, discharges him of all accounts due to the king.

QUIFORD, in Geography, a district of Africa, on the Gold Coast.

QUIIGNONES, Francis de, in Biography, an eminent Spanish cardinal in the 16th century, who embraced the religious life at an early age, in a monastery of Franciscans, and subsequently afforded such evidence of superior talents, that he was elected general of his order in the year 1522. He obtained the office of confessor to Charles V. and upon the capture of Rome by the imperial army in 1527, and the imprisonment of pope Clement VII. in the castle of St. Angelo, his services were solicited by that pontiff, in negotiating for his liberty, and were afterwards rewarded with a cardinal's hat. After this, he was by the fame interest nominated bishop of Currila, and lent in the capacity of apolitical legate into Spain, and the kingdom of Naples. He died in the year 1540. He was author of a reformed brevity printed at Rome in 1536, which met with the approbation of popes Clement VII. and Paul III. but it was afterwards suppressed by Pius V.; hence it has become rare, and is sought after by collectors. Several spurious editions have been printed at different times. It is inserted in the "Annales Minores" of Wadingus, and in the second edition of Joly's treatise "De Reformandis Horis Canonicos."

QUIJUBATUI, in Ornithology, the name of an American species of parrotake.

It is of the size of a lark, and in general of a yellow coloured. Its eyes are black, and its beak grey. The edges of its wings are of a dusky green, and its tail long and yellow. It is a very beautiful bird, and very easily tamed. See Psittacus Guarancia.

QUIKNE, in Geography, a town of Norway, in the province of Bergen; 105 miles N. of Christiana.

QUIL, in Zoology. See Quirpele, and Vivera Mungo.

QUILAQUIIL, in Ornithology, the name given by the people of the Philippine islands to a very beautiful species of parrots, which is commonly found wild in the woods there. It is all over of a fine green colour, and is smaller than the common parrots, and has a broad black bill, and black legs. It is a very wild bird, and will not learn any thing.

QUILATE, in Spanish and Portuguese Coinage, a term used for carat; which is.

QUILEA, in Geography, a sea-port town of Peru, near the Pacific ocean, which gives name to a fertile valley, in the jurisdiction of Arequipa. S. lat. 16° 45'.

QUILICI,
QUILLICI, Gaetano, in Biography, an Italian opera- 
finger, with a bafe voice: a good musician, who arrived 
here in 1759, during the performance and opera regency of 
the Mattei. He continued to perform on our lyric stage 
near thirty years, and is, we believe, still living in London, 
we fear, in penury and obscurity. Since quitting the 
stage, he has supported himself, a bed ridden wife, and an ideot 
son, by teaching to sing, and has made some admirable 
performances.

QUILLIMANCY, in Geography, a river of Africa, 
which runs into the Indian sea. 20 miles S. of Melinda. S. 
lat. 3° 16'. E. long. 40° 16'.—Also, a sea-port town of 
Africa, in the kingdom of Melinda, at the mouth of the 
before-mentioned river, belonging to the Portuguese. S. 
lat. 3° 10'.

QUILLAMANE, a town of Africa, in Mozambique. 
S. lat. 18° 15'. E. long. 37° 50'.

QUILLAJA, in Botany, a genus of plants found in 
Chili, and described by Molina. Jull. 444. Lamarck Il-
luibr. t. 774.—Clafs and order, Monoeia Dodecaandra. 
Nat. Ord. uncertain. 

Eff. Ch. Male, Calyx five-cleft. Corolla none. Sta-
mens twelve, or more. 

Female, Calyx five-cleft. Corolla none. Germens five, 
superior, opposite to the segments of the calyx. Styles 
five. Capsules five, carious, of two valves, and one 
cell. Seeds numerous, oblong, inserted into the bottom of 
the capsule, dilated and winged at the summit. 

Such is the character made out by Jullien, from the 
publications of Molina and Frezier, and from specimens of 
the fruit, brought to Europe by Dombey. They belong to a 
tree, whose bark has a foamy quality. The leaves are 
alternate, simple, evergreen. Flowers axillaries.—The gen-
us appears akin to the Magnolie of Jullien; but whatever 
it may be, the name is barbarous and quite inadmissible; 
only tolerable for a time, till some botanist, furnished with 
better materials to define the genus, shall be entitled to give 
it a more classical appellation. Jullien remarks, that another 
plant of Dombey's appears to belong to the above genus. 
This is a tree referred by him to Dioscu Ieofandria, whose 
fruit is called Gayo colorado, and which is the same with the 
"Loque, or Peruvian tree with five capsules," of Jofeph de 
Jullien, whose branches, according to his manuscript ac-
count, are fo long and plant, as to be twitted into 
cors, serving, in the province of Cufco, for the support of 
hanging bridges.

QUILLALA, in Geography, a town of Chili, on the 
Aconcagua: 30 miles E.E. of Valparayso.

QUILLAN, a town of France, in the department of 
the Aude, and chief place of a canton, in the district of 
Limoux: 10 miles S. of Limoux. The place contains 1568, 
and the canton 9195 inhabitants, on a territory of 724 
kilometres, in 22 communes. N. lat. 42° 51'. E. long. 
2° 16'.

QUILLAYACU, a town of Peru, in the diocese of 
Lima: 60 miles E.E. of Guanaco.

QUILLE, a town of Sweden, in Well Gotland: 23 
miles N. of Uddevalla.

QUILLEBEUF, a town of France, in the department 
of the Eure, and chief place of a canton, in the district of 
Pontaudemer, seated on the Seine; eight miles N. of 
Pontaudemer. The place contains 1200, and the canton 
7272 inhabitants, on a territory of 107½ kilometres, in 16 
communes. N. lat. 49° 29'. E. long. 0° 38'.

QUILLET, Claude, in Biography, born at Chinon, 
in Touraine, about the year 1602, was brought up to med-
icine, which he practised some years, till he was obliged to 
quit the country on account of his opposition to a measre of 
Richelieu, which is thus narrated. Quillet was at Loudun 
at the time that Loudernont, a creature of the cardinal, 
was sent thither to take informations respecting the pretend-
ed poiffion of some nuns by the forceries of Urban Gran-
dier (fee his article), an imposture which Richelieu thought 
fit to favour. The counterfeit Satan on one day threatened, 
that on the morrow he would lift up to the roof of the church 
any one who should presume to call his power in question. 
A large company appeared on the next day with M. Loubarde-
mont, when Quillet, who also was present, challenged the 
devil to keep his word. To the surprize of the superlilious 
who had met on the occasion, nothing followed, but the 
changer found to his colt that he had given offence to a 
mightier power than Satan, and felt it necessary to quit 
Loudin in hafle, and retire to Italy. He went to Rome, 
and was engaged as secretary to the French ambassafador at 
that court. He probably returned to France with that mi-
niiter, after the death of Richelieu, and in 1655, he publish-
ed at Leyden, under the name of Calvidius Letue, the 
poem by which he is chiefly known, entitled "Calippedia 
dive de pulchrae Prolis habendae ratione." In the first 
version were some farical lines against Mazarin. The cardin-
als sent for him, and having gently remonstrated with him 
for treating his friends with severity, promised to give him 
the first vacant abbey. Quillet threw himself at the cardinal's 
feet, asked pardon, assured him he would infallibly oblitera-
the offensive lines, and begged, as a sign of his penitence, 
to be allowed to dedicate the poem to him. This was done 
in the Paris edition of 1656, and Quillet became the flatterer 
of him who had been the object of his satire. He 
died at Paris in 1661, repeating not of his abdution, but 
of the licentious calf of some of his verses. The 
Calippedia has gone through many editions, and has been tr
lated into various languages. "It is," says an able critic, "an 
genious performance, agreeably varied by fable and episode, 
but frivolous in its main topic, and in its reasonnings. Its 
details are frequently loose and inflammatory, and that a car-
dinal should have allowed it to have been dedicated to him, is 
a proof bow little regard was paid, at that period, to the 
rules of decorum. The verification, though generally free 
and flowing, is by no means correct, and the diction is 
frequently impure." Quillet composd a version of Juvenal 
in French verse, and a Latin poem in twelve books, entitled 
"Henriados," or the actions of Henry IV. This, with 
other papers, he left to Menage, with 500 crowns to defray 
the charge of printing them, but the abbe took the money, 
and neglected the conditions.

QUILLIGA, in Geography, a country of Africa, in 
Upper Guinea, near the river Maqualbary.

QUILLOBO, in Botany, a name given by some to a 
species of ketmia, called ali quingombo.

QUILLOT, Killoo, or Killo, in Commerce, a Turkish 
corn measurer, weighing, in wheat, about 23 oke, or 60lbs. 
avoidoops: 4 kilos make 1 fortin; ¾ kilos answer 
nearly to 1 English quarter. A killo of rice contains 10 
okes, and the oke is 400 drachmas.

QUILLOTA, in Geography, a town and jurisdiction of 
Chili. The town does not contain above 100 families, but 
those scattered over the country exceed 1000.

QUILL, a town of France, in the department of the 
Loire Loire; 7 miles N. of Savanay.

QUILOA, a country and kingdom of Africa, situated 
near the east coast, near the mouth of the Coavo, about 
180 miles from north to south; but the extent inland towards 
the west is unknown. This country was first discovered by 
the Portuguese, in the year 1498. The king and his sub-
jects
jects are Mahometans; the latter partly black and partly tawny. They all speak the Arabic and several other languages, which they learn from the nations they traffic with. Their dress is that of the Arabian Turke: the women especially affect finery, with variety of ornaments about their necks, arms, wrists, and ankles; particularly bracelets made of ivory, curiously wrought; which upon the death of a parent, husband, or near relation, they break in pieces, in token of sorrow, whilst the men express theirs by shaving their hair, and abstaining from food. The capital of the kingdom is situated on an island near the mouth of the Convo, and is laid to be large, rich, and well built. The houses are of stone and mortar, handsome, and after the Spanish manner. They are several stories high, and have each a pleasant garden behind, well watered and cultivated, here being plenty of springs of fresh water. The houses are finely furnished within, and terraces on the top, with a kind of hard clay, and the streets so narrow, that one may easily step from one side to the other. On one side of the town is the citadel, where resides the Mahometan prince. It is adorned with flatly towers, and surrounded with a ditch and other fortifications. It hath two gates, one towards the port, whence one may see the ships falling in and out; the other looking towards the land. The country about Quilao, though low, is yet very pleasant and fertile in rice and millet, fruits and good pasture; so that they breed abundance of cattle, besides poultry of all sorts, both wild and tame. They have fift likewise in great plenty, and very good. The climate is likewise affirmed by moit travellers to be very temperate and healthy; Sanut being the only author we know of who hath ventured to assert the contrary in all these respects. S. lat. 8° 35'.

QUILONNE, a province of Africa, in the kingdom of Sabia.

QUIOLOA, a small island in the Indian sea, near the coast of Africa. S. lat. 13°.

QUILTAiNEN, a town of Prussia, in the province of Oberland; 8 miles S.E. of Holland.

Quiltaon, one of the Laccadive islands, in the Indian sea. N. lat. 12°. W. long. 72° 45'.

Quilling denotes the operation of weaving a fort of coat or texture, formed of the strands of rope, about the outside of any vessel, to contain water, &c. as a jar, cask, bottle, &c.

Quimichpatlan, in Zoology. See Sciuens Vo|bacela.

Quiminatin, in Geography, a small island in the sea of Mindoro. N. lat. 10° 55'. E. long. 120° 40'.

Quimiri, a town of Peru, in the diocese of Lima; 40 miles N.E. of Naca.

Quimo, a small island on the east side of the gulf of Bothnia. N. lat. 63° 17'. E. long. 21° 52'.

Quimper, a city of France, capital of the department of Finistère, and chief place of a district, seated on the Oder; before the revolution the see of a bishop, the seat of a governor, an admiral, &c. The place contains 66,088, the canton 17,028 inhabitants, on a territory of 90 kilometres, in seven communes. N. lat. 47° 50'. W. long. 4° 16'.

Quimperle, a town of France, and chief place of a district, in the department of the Finistère. The place contains 41,672, and the canton 91,278 inhabitants, on a territory of 125 kilometres, in 15 communes.

Quin, Dr., of Dublin, in Biography, an eminent physician, and one of the most enlightened dilettante musicians with whom we have ever been acquainted. This gentleman, who, during his travels, resided in Italy some years, had heard and studied music with such taste and intelligence, that his opinions and conversations on the subject were equally entertaining and instructive. He resided in Dublin at the time of Handel's arrival in that city, 1742; and perfectly remembering his performance, person, and manners, in 1788 wrote us word, that he (Handel) was received in Ireland by persons of the first distinction with all possible marks of esteem, as a man, and admiration as a performer and composer of the highest order. And adds, 'the Messiah, I am thoroughly convinced, was performed in Dublin for the first time, and with the greatest applause. Mrs. Cibber and Signora Avolio were the principal performers. These, with the assistance of the choristers of St. Patrick's cathedral and Christ-church, formed the vocal band; and Dubourg, with several good instrumental performers, composed a very respectable orchestra. There were many noble families here, with whom Mr. Handel lived in the utmost degree of friendship and familiarity. Mrs. Vernon, a German lady, who came over with king George I. was particularly intimate with him, and at her house I had the pleasure of seeing and conversing with Mr. Handel; who, with his other excellencies, was pelless to a great lock of fortune; no man ever told a story with more. But it was requisite for the hearer to have a competent knowledge of at least four languages: English, French, Italian and German; for in his narratives he made use of them all.'

Quin, James, was born in London in 1693. He was the son of an Irish gentleman, and received his education in the capital of that country. His father had, ignorantly, married a woman supposed to be a widow; whole husband, after a long abstinence, returned and claimed her. The subject of this article was the offspring of this connection, and was accordingly illegitimate, and upon his father's death, in 1716, was left almost destitute. For want of education he was, at the age of twenty-one, without a profession, and was under the necessity of appearing on the stage at Dublin, in the very lowest characters. He displayed, however, rising talents, which induced a friend to advise him to attempt some better parts in London, and he was accordingly admitted into Drury-lane company in 1715. After the experience of a year or two, he entered himself under Rich at Lincoln's-Inn theatre, where he continued to perform during seventeen years. He was allowed, by the most competent judges, to shine both in tragedy and comedy. His utterance was weighty and impressive, which, however, was accompanied with various defects. He was, from cauuses not well ascertained, continually changing from one theatre to another, and perhaps he may be ranked among that number with whom it was difficult to keep terms. His passions were strong, his temper irritable, and his language often coarse. He was of convivial habits, and, it has been said, grossly attached to the pleasures of the table. There was, however, a fund of generosity in his temper, which shewed itself in many sentiments, and, occasionally, in benevolent actions. The circumstance of his giving a 1000l. to the poet Thomson, when he was under an arrest for debt, has often been told to his honour. It was the commencement of a strong friendship between them. After Thomson's death, he appeared in that poet's tragedy of Coriolanus, and spoke a prologue, written on the occasion by lord Lyttleton, with a pathos that did honour to his feelings. His last performance was the favourite part of Fallstaff, for the benefit of his friend Ryan in 1753. He now retired to Bath, where his fund of anecdote, and strong pointed sense, rendered his company much sought after. He had good breeding, which fitted him for the highest societies, when he chose to act the gentleman; and his frankness and candour were frequently
frequently put up with for the sake of his companionable qualities. Quin died at Bath in 1766, at the age of seventy-three. Garrick, whose superior talents are suppos'd to have driven him from the stage, but afterwards his steady friend, wrote a poetical epitaph for his monument. While Quin continued on the stage, he constantly kept company with the most celebrated geniuses of the age. He was on intimate terms with Pope and Swift; and was frequently invited by the earl of Chesterfield to his table. His peculiar judgment in the English language recommended him to his royal highness, Frederic prince of Wales, who appointed him to instruct his children in speaking and reading with graceful propriety. When Quin was informed of the elegant manner in which his present majesty had delivered his first gracious speech from the throne, he was in raptures, and the king soon after gave orders, without any application on the part of Quin or his friends, that a genteel pension should be paid him during his life.

Quin, in Geography, a village of the county of Clare, Ireland, where are the remains of a monastery, which was founded for Franciscan friars in 1402, and repaired by the Roman Catholics in 1604. Bishop Pocock speaks of it as one of the finest and most entire monasteries he saw in Ireland. It is situated on a fine stream, with an ascent of several steps to the church; at the entrance one is surpris'd with the view of the high altar, entire, and of an altar on each side of the arch of the chancel. The building is quadrangular, with piazzas supported by a number of pillars; there are apartments on three sides of the cloisters, with a vaulted room under them all. A round tower and some other ruins are adjoining. Quin is 15 miles from Limerick, on the road to Galway, and about 106 miles W.S.W. from Dublin. Archdall's Monasticon. Carlisle.

Quina-Quina, in Botany. See Leaf.

Quinabaug, in Geography, a river of America, formerly called "Mobegan," which rises in Brimfield, Massachusetts, and is joined at Oxford by French river, which has its source in Sutton, Worcester county. It runs a southerly course, and discharges itself into Shetucket, about three miles above Norwich Landing, in Connecticut. In the first part of its course it furnishes many good mill-sites: as it advances, the intervals in many places are wide, and afford a most excellent foil.

Quina-Quina, in Botany, a Peruvian name, generally applied to the Peruviann bark. (See Cinchona.) Jussieu, however, in his Gen. Pl. 336, informs us, that it properly belongs to a tree, nearly if not entirely agreeable in genus with Myropermum of Jaccquin, or Myroxylon of Linnaeus. (See the last-named article.) An account of the Quina-quina may be found in the Memoires de l'Acad. des Sciences for 1738, p. 237.

Quinaria, so called by Loureiro, Fl. Cochinch. v. 1. 272, from the prevalence of the number five in the parts of fructification, is the Wampfo or Wampi of the Chineef, now established as a genus by the name of Cookia. (See that article.) This plant passed long, in the gardens of England, for Gaura trieblioides, according to the observation of the late Mr. Dryander.

Quinarius, Quinary, in Antiquity, a little Roman coin, equal to half the denarius. See Coin.

The quinarius was properly the Roman halfpenny.

Medalists indeed use the term quinarius in the general for a medal of any matter, not exceeding the size of our six-pence; but F. Chamillart, in an express dissertation, shews this to be an abuse. The silver coins, current under the republic, he shews, were two: the one weighing a drachm, and called denarius, as containing ten as; the other weighing half a drachm, and called quinarius, as containing five as; which coins continued on the same footing under the emperors.

Hence the origin of the word quinarius: and hence, in propriety, it is only the silver medal of the weight of half a drachm that the name belongs to; the Romans having never given it to any other species of the same size with it. It is only by way of analogy, therefore, that the moderns apply it to the medals of gold, or copper, of the same size with the silver quinarius; those of gold being fixed at a value much above, and those of brass much below five a.

The only relation between these quinarii is, that the gold quinary is the half of a gold medal, as to weight and value; and the brass quinary half a brass medal, as the silver quin

Hence a feries of quinarii should seem at least a necessary in the cabinets of the curious, as the feries of great medals; they being all equally different species of money, which teach us how many kinds of pieces there were of any metal current in commerce.

Add to this, says our author, that the quinarii were of a finer and more finished coin than the other medals, being wrought by the hands of the maffers; which seems owing to the nicety required in engraving whole figures in fo small a compass. He adds, that though quinarii are very scarce, yet M. the duke of Maine had almost a complete set of them.

Quinaul't, Philip, in Biography, a French poet, was born in 1560, probably in a low condition; though while some may he the son of a baker, others maintain that he was descended from a family of consequence at Paris. He had, however, very few advantages of education, but was soon found to possess a talent for poetry and the belles lettres. Before the age of twenty he brought out some pieces on the stage; and for a number of years, he continued to produce dramatic works of different kinds, which were much applauded by the public voice; but some of which drew upon the author the satires of Boileau, who carried the matter so far as to injure his own reputation. Quinaul't now associated himself with Lulli in the composition of operas, and displayed an excellence in lyric poetry, or that adapted to music, which placed him beyond competition in that branch, and has ranked him among the distinguished characters of the age of Lewis XIV. Nothing, it is allowed, can be more tender, delicate, and ingenious, than the turn of his fongs and love-dialogues; and no one has more happily accommodated the melody of French verse to musical expression. His "Armida" and his "Atthys" are spoken of as master-pieces of their kind. Notwithstanding the high reputation which he enjoyed as a poet, he applied himself to the study of the law, and eventually made his fortune by marrying the rich widow of a merchant, to whom he had been useful in his profession. After this, he purchased the place of an auditor in the chamber of accounts. He was received into the French academy, and, in the name of that society, harangued the king on his return from the campaigns of 1675 and 1677. He died in 1688, having enjoyed a pension from Lewis XIV. several years previously to his decease. In his last illness he was extremely penitent, on account of his having devoted his talents too frequently to the excitement of the licentious passions. He left a family of five daughters, and was esteemed in society attentive, polite, and mild. Besides his numerous pieces for the stage, he wrote occasional poems. His works were printed at Paris in 5 vols. 12mo., 1739, and again in 1778.
It has been said that Quinault’s apprenticeship to poetry was served under Trifian l’Hermite, by being his domestic. The lessons of Trifian were probably of some use to him, as that author had had long experience in theatrical matters; but Quinault owed still more to nature; as before he was twenty years old, he had distinguished himself by several pieces for the stage, which had considerable success; and before he was thirty, he produced sixteen dramas, some of which were well received by the pit; but not all equally. It is supposed that some of these early pieces prejudiced Boileau against Quinault early in his career. There was neither regularity in the plan, nor force in the style: romantic lovers and commonplace gallantry, in scenes which required a nervous pencil and vigorous colouring. These were defects not likely to escape the laf of the French Juvenile. He covered the young poet with ridicule; reproached him with the affectedly soft and languishing dialogue of his lovers, by whom even I hate you was said tenderly.

Quinault, born with great sensibleness, was so wounded by his severity, that he applied to the magistrates, not only to silence Boileau, but oblige him to remove his name from his fates; but the attempt was vain. His enemy insulted him still more cruelly by an epigram on the subject.

"—Peace! peace! my friend—
If from the public thou’ld avoid disgrace,
From thy own works, not mine, thy name efface."

It was not till after Quinault was inlifed by Lulli to write for the opera, that he silenced all his enemies, except Boileau and his party, who envied him his successes. The French nation knew no better music than that of Lulli, and thought it divine. Quinault’s was thought of secondary merit, till after his decease; and then, in proportion as the glory of Lulli faded, that of Quinault increas’d. Voltaire, in the first edition of his „Siecle de Louis Quatorze,” in 1749, seems to have been the first who spoke out on the subject; not forry, perhaps, to lower Boileau a little in the eyes of the public. He there says, that “Quinault was celebrated for his beautiful lyric poetry, and for the gentleness with which he opposed the unjust fates of Boileau. His poetry was greatly superior to the muse of Lulli. It will always be read; and Lulli, except in a few of his recitatives, can no longer be supported. However, it was long believed that Quinault entirely owed his fame to Lulli. Time appreciates all things.”

After this, his writings began to be examined and felt; and of late years, his name is never mentioned by his countrymen without eloge. His operas, though admirable to read, are ill calculated for modern music; and are obliged to be now written, ere they can be new set, even in France. Marmontel, who had modernized several of them for Piccini to set in 1788, gave M. Laborde a differtation on the dramatic writings of Quinault for music; which is published in the fourth volume of his „Effais sur la Musique.”

He begins by allering that Quinault was the creator of the French opera upon the most beautiful idea that could be conceived: an idea which he had realized with a superiority of talent, which no writer has since approached. His design was to form an exhibition, composed of the prodigies of all the arts; to unite on the same stage all that can interest the mind, the imagination, and the senses. And this illusive theatre Voltaire has admirably descrived:

"Il faut se rendre à palais magique,” &c.

"Haste to the magic palace, where abound
The joys sublime of verse, of dance, and sound;

Where bright illusion facinates the sight,
And firen-notes the enchanted ear delight;
Where all the plactic powers of art are shewn,
And joys unnumber’d are combind in one.”

For this purpose a species of tragedy is necessary, that shall be sufficiently touching to move, but not so audble as to refute the enchantments of the arts that are necessary to embellish it. Historical tragedy, in its majesty and gloomy simplicity, cannot be sung with any degree of probability, nor mixed with festival and dances, or be rendered susceptible of that variety, magnificence, show, and decoration, where the painter and the machinist ought to exhibit their enchantments.

In Italy, where genuine tragedy has no theatre appropriated to its use, a people passionate for music have permitted Regulus, Themistocles, Alexander, and even Cato himself, to utter their speeches in song; but a people, whose taste ought to be more ferre, and more delicate, as to probability, having for comparison the school of Corneille and Racine, would have been very unwilling to substitute the recitative of Lulli to the declamation of Baron. Melody itself is a fabulous and magical language; and in a theatre where all is prodigy, it seems consistent that the manner of speaking should be that of enchantment as well as the rest. We are then in a new world: it is nature beautified, and vividly animated by a crowd of intelligences, whose wills are laws. Music there plays a marvellous part; music there constitutes the probability of the marvellous; but in a representation where all palies for nature, according to truth and history, by what means can we be prepared to hear Augustus, Cornelia, Agrippina, or Brutus singing? Might it not be replied, “By the same means as the French are reconciled to these fame exalted characters conversing in rhyme.” When once it is settled that all the characters converse in a musical language, no other is expected, and the audience is soon reconciled to it. But all this is to prove that the French alone are right, and Italy and all the rest of the world wrong as to the musical drama. The rest of Europe is tired and ashamed of flying gods and goddeses, and have long since surrendered mythological wonders both in poetry and music to their children. But all people are thought barbarians, who do not implicitly adopt the tall and fashions of France.

But to return to Quinault, whom all the wits of the time tried to write down. Ignorant of music and its powers, they thought Lulli always right, and the poor, modest, unpretending Quinault always wrong. P롤erity has long discovered the converse of this supposition to be the truth. Quinault’s great mistake and misfortune, says La Harpe, was the calling his pieces tragedies, and not operas. He would not then have been regarded as a rival of Racine, or have offended classical hearers or readers with the little resemblance these compositions had to Greek and Roman dramas, or to the genuine tragedies of the moderns.

QUINCE Tree, in Gardening, the common name of a tree of the apple kind. See Pyrus Cydonia.

QUINCE, in the Materia Medica. The fruit of the quince is alluring and aromatic; and its expressed juice, in small quantities, as a spoonful or two, is of considerable service in nausea, vomitings, madorous eructations, and some kinds of alvine fluxes. This juice was formerly ordered in the Lond. Pharm. to be made into a fyrup, called “fyrupus cydoniarum,” or fyrup of quinces, prepared by digestion three pints of the deputred juice with a drachm of cinnamon, half a drachm of ginger, and half a drachm of cloves, on warm ashes,
QUINCHAC, a small island in the Pacific ocean, between the island of Chloé and the continent of Chili. S. lat. 43° 36'.

Gen. Ch. Cal. Perianth superior, of one leaf, in four deep, ovate, unequal segments, one larger than the rest. Cor. of one petal; tube funnel-shaped, much longer than the calyx, quadrangular, curved; limb in five lanceolate, acute, spreading segments. Stam. Filaments five, very short, inserted into the top of the tube; anthers oblong, the length of the limb. Fil. Germen roundish; style thread-shaped, the length of the tube; stigma capitate. Peric. Berry (rather drupa) roundish. Seed solitary.

1. Q. chilensis. Willd. n. 1. (Quinchantamali hiis folio; Feuill. Plantes Médicinales, 57. t. 44.)—Gathered by Feuillé on the mountains of Chili, and by Dombey, among stones on the hills about Lima, flowering in December and January. The root is annual, composed of a few simple yellow fibres. Stem several, prostrate, simple, round, leafy, from four to six inches long. Leaves scattered, linear, linear, entire, fleshy, smooth, bluntish with a small point. Flowers in simple, terminal, solitary, dense spikes. Corolla green externally, of a saffron yellow within. Seed round, uncon

Something of this mode of arrangement has always a good effect in the disposition of shrubby plants, &c. though not in the regular order of it, but something nearly so, which gives the shrubs a greater scope of growth, and shews them to greater advantage. It is likewise a mode of planting that is proper in the kitchen-garden, in transplanting many kinds of eucalyptus trees; such as lettuces, endive, strawberries, and even all the cabbage kinds, and many other plants, which gives them a greater scope to grow than if planted exactly square at the same distance from each other.

It is of this kind of quincunx that Cicero speaks, in his Cato Major; and Quintilian, lib. viii. cap. 3.

The modern quincunces, Daviller observes, are made like those of the ancients, except for the fifth tree, which is now generally diffused; so that, being as it were netted, and their avenues viewed by the side of the rectangle, they formed a perfect chequer.

QUINCE, in Astronomy, &c. denotes a position, or aspect of the planets when distant from each other a hundred and fifty degrees, or five signs.

QUINCY, in Geography, a town of France, in the department of the Seine and Marne; six miles S.W. of Meaux.

Quincy, a port-town of America, in Norfolk county, Massachusets, taken from Braintree; 10 miles S. of Boston. It contains 1281 inhabitants, most of whom are farmers; but large quantities of shoes and boots are manufactured for exportation. The town has an episcopal and congregational church.

QUINDECAGON, in Geometry, a plain figure which has fifteen sides and fifteen angles.

The word is formed somewhat irregularly, from the Latin quinque, five, and the Greek πέντε, and γωνία, angle. Pentadecagon would be a more regular term.

If the sides be all equal, it is a regular quincunx.

Euclid shews how to inscribe it in a circle, Prop. xvi. lib. 4. And the side of a regular quincunx so described, is equal in power to the half-difference between the side of the equilateral triangle, and side of the pentagon; and also to the difference of the perpendiculars let fall on both sides, taken together.

QUINDECIM VIR, XV. VIR. a Roman magistrate, who
who had fourteen colleagues joined with him in the same function.

Under Tarquin the Proud, there were first two magistrates erected to take care of the sacrifices to be performed; these were called duumviri. Their number, at length, grew to ten, and then they were called decemviri. In the time of Cicero it had reached to fifteen, when they assumed the name of quindecimviri; and though their number grew to forty afterward, yet Servius oberves, on the sixteenth of the Æneid, that their name never after changed, but they still continued to be called quindecimviri.

They were the persons who examined the Sibyls' books, and were the interpreters of them; yet they never did this but by public order of the senate, declared by a senatus consultum. They also presided at the sacrifices, and all other extraordinary ceremonies of religion.

On medals, a dolphin joined with a tripod marks the priesthood of the quindecimviri; who, to publish their solemn sacrifices, used on the eve of them to carry a dolphin at the end of a pole throughout the city; that fish being esteemed sacred to Apollo, as the crow was among birds.

QUIPAUGE, or East River, in Geography, a river of America, in Connecticut, which runs a southerly course into the N.E. corner of New Haven harbour.

QUINEY, a town of France, in the department of the Doubs, and chief place of a canton, in the diocèse of Besançon; nine miles S.W. of Besançon. The place contains 1,079, and the canton 11,734 inhabitants, on a territory of 372\(\frac{3}{4}\) square kilometres, in 36 communes. N. lat. 46° 0'. E. long. 5° 57'.

QUINGOMBO, in Botany, the name given by the people of Congo to a species of ketmia, distinguished by M. Tournefort by the name of the ketmia Brunfeli's folio focus, fruictu pyramidato fulcato, the fig-leaved Brazilian ketmia, with a pyramidal fulcated fruit.

QUINISDAI, in Geography, a town of Norway, in the province of Christianfand; 35 miles W.N.W. of Christianfand.

QUINSEXTUM, in Ecclesiastical History, denotes a council held at Constantinople in the year 692; called also the council in Trullo, and by the Greeks Pentébê, q. d. fivesith; as intimating that it was only a supplement of the two preceding councils. Though, in propriety, Fleury oberves, it was a council itself.

Marshall observes, that the fifth and sixth general councils having made no canons relating to the external celebration of divine worship, the government of the church, and the lives and manners of Christians, the Orientals judged it necessary to supply that defect by this; so that the 102 canons falsely attributed to these, were in reality made here. See Trulum.

QNINET, in Mining, the name of a tool used in the cleaving rocks by means of gunpowder. This is a sort of wedge fitted to the flat side of what is called the gun; that is, a cylindric piece of iron, only flattened in one part to receive this, and drilled through. When a proper hole has been made in the rock by the borer, the powder is put in, and then the orifice being fitted by the gun, and that wedged in by this quinnet, the powder being fired by a train communicating with the hole drilled through the gun, exerts all its force on the rock, and splits it in several directions at one explosion. Phil. Trans. No 167.

QUINOAL, in Geography, a town of Mexico, in the province of Culiaca; 50 miles S.E. of Culiaca.

QUINQUAGENARIUS, among the Romans, was an officer in the army, who had the command of a company of fifty men.

Quinquagenarius was also an officer of policy, who had the inspection of fifty houses, or families.

And in the ancient monasteries, quinquagenarius was a superior who had fifty monks under his guidance.

QUINQUAGESIMA-SUNDAY, Shrove-Sunday. It is thus called, as being about the fiftieth day before Easter. Anciently they used quinquagesima for Whitunday, and for the fifty days between Easter and Whitunday; but to distinguish this quinquagesima from that before Easter, it was called the Paschal Quinquagesima.

QUINQUANGULAR LEAF. See LEAF.

QUINQUANNION, QUINQUENNALTA, in the French Cycles, a respite of five years, which insolvent debtors formerly obtained by virtue of the king's letters, to have time for the payment of their debts.

When the thing intended was only to prevent the sale of their effects at an under-value, the term of one year was ordinarily granted, and this was called the benefit of anion.

But when the debtor would avoid the surrendering of his effects, upon proving that he was reduced by poverty, looses, &c. to make use of this expedient, the term of five years was granted, and called the benefit of quinquanion.

QUINQUATRIA, in Antiquity, a name given to the feasts of Minerva, otherwise called Panathenea.

Some think they were termed quinquatria, because they lasted five days; but others, with more reason, think it was because they fell out five days after the ides of the month.

QUINQUE PORTUS, the five cinque ports.

"Servitum quod barones quinque portuum praescriptum recognoverint facere ad fundationem regis per annum, ni contigerit per 15 dies ad cultum eorum proprium; ita quod primius dies computatur a die quo vel a navium excre- runt, usque partes ad quas tendere debent, vel uterius, quamdiu rex voluerit ad cultum ejus." Thorn.

QUINQUEFOLIUM, in Botany, Cinquefoil, the old name of the Linnean genus Potentilla, many, but by no means a majority, of whose species have five leaves on a stalk. Gmitter, who, like many others, was discontented with Potentilla, substituted the word Pentaphyllum. See POTENTILLA.

QUINQUEMPOIX, in Geography, a town of France, in the department of the Lower Seine; seven miles N. of Rouen.

QUINQUENNALIA, in Antiquity, games, or feasts founded at Tyre, celebrated every five years, in honour of the deified emperors.

The quinquennalia began to be expressed on medals about the middle of the third century. F. Pagi produces a medal whereon are engraven those of the emperor Posthumus; they are not found on any medals of his predecessors.

QUINQUENNALS, a magistracy in the colonies, and municipal cities of the Roman commonwealth; much the same with tible at Rome.

They were not thus called from their continuing in their office five years; but because they were elected every fifth year, to reside at the cenus, and to receive the declaration each citizen made of his effects.

QUINQUENNES, in some old Historians, a name given to a certain people of India, among whom the women began to bear children at five years old, and seldom lived to more than eight years. Pliny gives us this account; and Solinus, who repeats it from him, increases the miracle by telling us, that...
that they were a nation of women who had no men among
them.

**QUINQUEPARTITE LEAF, among Botanists. See Leaf.**

**QUINQUEPRIMI, among the Romans, the five principal
men in the Senate of every municipal town.**

**QUINQUERMIS, in the Naval Architecture of the
Ancients, a name given to a galley which had five rows of
oars. They divided their oars in general into monocrora
and polycrota; the former had only one tier of rowers;
the latter had several tiers of them, from two or three,
up to twenty, thirty, or even forty; for such a vessel
we have an account of in the time of Philopater, which
required no less than four thousand men to row it. See
POLYCROTA.**

**QUINQUETIONES, among the Romans, an appellation
given to those who had gained the victory in the quinquemiviris,
or pentathlon.**

**QUINQUERTIUM** was the name of the same Grecian
pentathlon, comprehending the five exercises of running,
leaping, throwing, darting, and wrestling. See PENTATHLON.

**QUINQUE VIR, frequently wrote V. VIR, a Roman
magistrate, who had four colleagues joined with him in the
same function.**

There were various kinds of officers thus denominated.
Pomponius the lawyer mentions quinqueviri on this and on
that side of the Tiber, established for the administration of
justice in the night-time, in lieu of the ordinary magistrates,
who were not judged proper to run up and down the streets
in the dark.

Rofinus tells us, that they were sometimes the quinquemiviri
who conducted the colonies, and divided the lands assigned
to them among the several families.

Sometimes the epulones were five in number; in which
case they were called quinqueviri. See EPULO.

**QUINQUEVIRI MONETAII, were officers first erected
under the influence of Valentius Poplicola, to moderate the
excessive usury, or interest, which creditors or bankers used
to exact from the people.**

**QUINQUINA. See Cortex Peruvianus.**

**QUINASY, sometimes written Quinansey, and Quinya,
in Medicine, a corruption of the French word quinquains,
which again is derived from the Greek, cinanthe, cinaxynyn,
signifying fore-throat, or inflammation and tumour of the internal
fauces. The term is applied generally to inflammations of the throat,
but more particularly to the acute inflammation of the tonsils.
A tonsil, enlarged from inflammation, is also emphatically
called a quinya. See CINANCHE TONSIILARIS.**

**Quinya,** among domestic animals of the live-stock fort,
is an affection about the throat and breast, which often
attacks them, and which is very obstinate and troublesome.
In horses it is usually called anticor. See FIFTHS.

**QUINSIEME, or Quinzieme, in our old Law Books. See FIFTHS.**

**QUINSIGAMOND, or Long Pond, in Geography, a
lake of Massachusets, between Worcester and Shrewbury.
This is a beautiful lake, in form of a crescent, about five
miles long, and from 30 to 100 rods broad. It is intersected
with a number of islets, one of which is upwards of 200
acres in extent.**

**QUINSON, a town of France, in the department of the
Lower Alps; 25 miles S.S.W. of Digne.**

**QUINT, a sequence of five cards of the same colour.
Seem SEQUENCE.**

**QUINT, Ital. QUINT, Fr. (See FIFTH and DIA-
FENTE.) The chord of the 5 in thorough-bass is resolved
two ways: first, by the base rising one note, and the lowest
trebble note descending; secondly, by the highest note of
the chord rising, and the lowest remaining stationary, when
the discord is resolved upwards. This is what Rameau calls
le double emploi de la dissonance.**

**QUINTA Pars, in old madrigals, a 5th vocal part, com-
pared of the refule of the other four.**

**QUINTA Effentia, See Quintessence.**

**QUINTAIN, Quintana, in Ancient Customs, a post,
or pillar, driven into the ground, with a buckler fixed to it,
for the performance of military exercises on horseback,
the throwing of darts, breaking of lances, &c.**

Mathis, Paris describes the quintain as a kind of mark,
formed like a man from the waist upwards, holding a shield
in his left hand, and in his right a sword or flieck; the
whole is fitted as to turn round on its foot, and has a
sharpened running blade against it with a lance, if he hit it in
the breast, it wilted round, and, unless he were very dexterous,
struck him with the sword held in the other hand.

In other places, at the top of a pole, was erected a slender
beam fitted to turn round a spindle; at one of whose ends
was a slop or flat board, and at the other a bag of sand or
dirt. The sportal was, with a long staff, or wooden lance,
to ride a-tilt at the board, and to be either so skilful or lucky
to escape the blow of the sand-bag.

This same take to be the fame with the arculum levatio,
frequently prohibited in our old fynods and episcopal
constitutions.

The custom is still retained in Shropshire, and some other
counties, among the nuptial solemnities. He that breaks
the most poles against the quintain, has the prize; which
was anciently a peacock, but is now a garland.

Some derive the word from an ancient game called quintus;
others from a man of the name of Quintus.

The vallus and palus, mentioned in Cæsar, are taken by
Vignere, for a kind of quintain, or wooden man, fixed up
as an adversary, or man of straw, to prove one's dexterity
against.

Mention is made of this exercise in the Code, De Ale-
toribus, and in the Parrotilles of Cujas on the same. Juvenal
speaks of women engaging in it:

"Aut quis non vidit vulnera pal? &c.?"

**QUINTAIN was also a right which the lord had to oblige
all the millers, watermen, and other young people unmarried,
to come before his castle every three years, and break several
lances or poles against a post, or wooden man, for his
diversion.**

**QUINTAL, in Commerce, the weight of a hundred
pounds.**

The quintal admits of some difference in different places,
according as the pound consists of more or fewer ounces,
and as the ounce is lighter or heavier.

Thus, a quintal the Parisian quintal, or pound, in the old
sylemen, yields 123 lbs. at Montpelier; and the Montpelier
hundred only 81 lbs. 9 oz. 18 gr. French poids de marc, or
88 lbs. avoirdupois nearly. The quintal of Contantinople is
equivalent to the weight of all those used in the Levant;
it contains 44 oke, or 100 rotolli; the oke being 4 yu-
dromes or chequees, or 400 drachmas, and the rotolli 176
drachmas. The quintal, or kintal, of cotton yarn is 45 oke.
The quintal, or cantaro, weighs about 123 lbs. avoirdupois,
and the oke 2 lbs. 13 oz.; the rotolli, 196 oz. and the che-
quee, 14 oz. avoirdupois. The quintal is equal to 112 lbs.
Amsterdam; 124 lbs. of Venice; and 160 of Leghorn.
The quintal of Lignons contains 4 arrobas, the arroba
32 pounds, the pound, libra, or arrate, 2 marks, or 16 ounces;
the ounce, 8 outavas; 13½ quintals make a ton. The

8 pound
A pound of Lisbon weighs 9552 Dutch ales, 70844 grains English Troy weight; and therefore 83 lbs. of Lisbon = 87 lbs. avoirdupois weight.

The English quintal usually consists of 112 lbs. avoirdupois, and is divided into four quarters.

**Quintal** was also formerly used for a weight of lead, iron, or other common metal, usually equal to a hundred pounds, at six feet to the hundred.

**Quinte, Ille de, in Geography,** an isle in lake Ontario, Upper Canada, which lies close off the shore of Ameliaburg, and opposite the W. point that forms Sandy bay.

**Quinte,** in French music, is the name of the instrumental tenor part in full pieces, usually written in the mezzo soprano clef on the second line. All the instrumental tenor or alto viola parts, in Purcell's time, were written in this clef, as may be seen in his overtures and act-tunes. This was an imitation of France, where all the tenor parts in Lulli and Rameau's operas are in the mezzo soprano clef.

**Quintello,** Ital. Quinque, Fr. a vocal or instrumental composition in five parts, allargado, and generally a pertu equale. The instrumental quintets of Boccherini and Mozart are sublime productions: there is, perhaps, no instrumental music in which more genius and abilities are manifest, than in the quintets of these great masters.

**Quintenar,** Et. in Geography, a town of Spain, in New Castile; 37 miles S. of Huetta.

**Quinter, Quintoiqer,** Fr. in the first attempts at harmony, was counterpoint in a series of 5ths, any two of which, in aftertimes, would ruin for ever the reputation of a composer.

**Quintessence, quinta effentia,** in the old Chemistry, properly denoted the fifth essence, or the result of five successively distilled fractions. The term, now obsolete, was used to express the highest degree of rectification to which any substance could be brought. It also signified a preparation consisting of the essential oil of some vegetable substance, mixed and incorporated with spirit of wine.

Thus, on a proper quantity, e. gr. of essential oil of fenoff, pouring twelve times the quantity of pure alcohol prepared per 6, they instantly unite into one similar liquor, which is the quintessence of that plant.

The ancients were perfectly acquainted with the method of dissolving oil in spirit of wine; and even some of the moderns have questioned its reality; but the certainty of the thing is easily proved, from the instance above, and from a thousand others.

If such quintessence be several times digested, cohabated, &c., the oil will at length be broken so fine, as, like the spirit itself, perfectly to mix with water; which is one of the most extraordinary effects in all chemistry.

After the like manner is made a quintessence of camphor, by only pouring on it spirit of wine.

Quintessences, thus prepared, were supposed to have great medicinal virtues; on account of the pure and potent ingredients used in their composition; which retain, in a great degree, all the virtues of the plants they are procured from; and hence their denomination.

Boerhaave thinks, they might properly be called vegetable sulphurs made potable, and raised to their utmost degree of power and efficacy.

Dry quintessences may be made from the liquid ones, by adding to them some more essential oil of the same vegetable from whence the liquid quintessence was procured, with a little sugar, all mixed together, and distilled by a very gentle heat, till all the moisture is come over; the matter remaining is then a dry quintessence.

This form was deemed principally useful for travellers, sailors, &c., inasmuch as it renders the quintessence portable; so that the quantity, e. gr. of a pin's point, shall be an efficacious medicine.

**Quintessence,** in Alchemy, is a mysterious term, signifying the fifth, or last and highest essence, or power, of a natural body.

This is supposed to be, as it were, the soul drawn from the gross body and its four elements, by a most perfect distillation; and, by means of which, the thing is said to be spiritualized, i. e. rendered exceedingly pure, spiritual, and, as it were, incorruptible.

The ancients, who allowed nothing to be real but what has a body, would have the soul of man to be a fifth element, a kind of quintessence without a name, unknown here below, indivisible, immovable, all celestial, and divine. Fenelon.

**Quintessence of the Elements,** is the hermetical mercury.

**Quintessence of Wine,** a term used by Glauber to express an essential oil of wine, which he directs to be made by a careful distillation; and which he is very fond of, as having a power to meliorate, improve, and even to specify the poorer wines into the nature of those from which it was obtained.

This is one of the schemes of Glauber, generally esteemed an impracticable one, though very plausible in theory; but though in general there is a disagreeable flavour in the quintessence drawn after his method, which is different from the true flavour of the wine, and spoils the liquor it is added to; yet, by proper care, there is a possibility of succeeding so far as to render this extraneous flavour almost imperceptible, and produce an oil that will mend poor wines extremely, and give a truly vinous flavour to such as are in themselves tallowy. But whatever may be done by this method, may also be done with much more certainty, and much less trouble, by the concentration of wines by freezing. This may be easily practiced in the wine countries; and by this means Burgundy, Champagne, and other the most valuable wines, may be reduced into thick extracts and rogs, by the means of which wines may be made in England; a very small quantity of these concentrated wines being sufficient to convert the whole of any of the poor tallowy and inipid wines, which are of themselves of little or no value, into the very wine from which the rob was made; and that in such perfection, that the nicest judge cannot find out the difference.

These robs of wine, made and preserved upon the spot, would also be of infinite use in the wine countries, as they might be kept to improve the wines of bad years. Stahl, De Concentr. Vin. Shaw's Chem. Enl.

**Quint-Exact,** in old Low Books, the last call of the defendant sued to an outlawry. If he appear not to it, he is, by the judgment of the coroners, returned outlawed, if a feme, waived.

**Quint1, Bay of,** in Geography, a bay and harbour in the N.E. part of lake Ontario, at the mouth of the Trent; formed by a large peninsula, confining of the townships of Ameliaburg, Sophiaburg, and Maryburg, extending easterly from an isle, which is a portage at the head, or W. end of the bay, to Point Pleasant, the easternmost extremity of the peninsula, opposite to Amherst island. The river Trent discharges itself into the head of the bay, westward of the portage, and supplies it with the waters of the Rice lake. Westward of the portage in lake Ontario, is the harbour of Prique Ille de Quinté, now called Newcastle. The fertility of the soil about the bay of Quinté is Generally allowed. The land is rich and easily wrought, and produces several crops without manure; 25 bushels of wheat being often
often produced from an acre. The timber, like that of the
other parts of the province, consists of oak, elm, hickory,
maple, &c. The bay is narrow throughout, and about 50
miles long, through which distance it is navigable for the
small vessels that are used on the lakes. It abounds with
wild fowl, and various kinds of fish. The river Trent
affords a salmon fishery. In palling from the head of the
bay of Quinto into lake Ontario, you cross a short portage,
in front of the township of Murray, being the isthmus
between it and the peninsula of Prince Edward. At the
end of the portage, and before you enter lake Ontario, is
a small but very beautiful lake, having very good land on its
banks. To the northward of this portage it has been pro-
posed to make a canal for connecting the waters of the bay
with those of the lake. A little to the westward of the
portage and proposed canal, is the harbour of Newcastile, a
situation well suited for commerce and protection, and
sheltered from all winds. A knoll on the peninsula affords
a healthy site for the town.

QUINTILIUS, Quintilis, in Astronomy, an aspect of
the planets, when they are seventy-two degrees distant from
one another, or a fifth part of the zodiac.

QUINTILIUS, Marcus Fabius, in Biography, a cele-
brated teacher of eloquence, was born about the year 42
of the Christian era, during the reign of the emperor Clau-
dius. He is supposed to have defended from a family ori-
ginally Spanish, but that his father, or grandfather, had
settled in Rome. The place of his birth is not known, but
it seems certain that he was educated in that capital, where
he studied rhetoric under Domitian Afer, a celebrated
orator. He opened a school at Rome, and was the first
who obtained a salary from the state as a public teacher.
After he had remained twenty years in this laborious em-
ployment, and obtained the applause of the most illustrious
Romans, not merely as a preceptor, but as a pleader at the
bar, Quintilian retired to enjoy the fruits of his labours and
industry. In his retirement he assiduously devoted his time
to the study of literature, and wrote a treatise on the
"Causes of the Corruption of Eloquence." Some time
after, he wrote his "Institutiones Oratoriae," the most
perfect and complete system of oratory extant. It is, in
truth, one of the most valuable remains of antiquity. It
was composed for the use of his son, whose early death he
had occasion to deplore, and is an institute for the education
of an orator, whom he takes up from the cradle, and con-
ducts through all the periods of instruction to the exercise
of his proper art. It accordingly contains many excellent
precepts with respect to education in general, especially the
earlier part of it, which are applicable in all times and
countries, as being founded on the nature of the mind.
The style of Quintilian is said, by critics, to exhibit tokens
of the deterioration of the Latin tongue; but, on the other
hand, it must be observed, that every deviation from the
usage of the Augustan age has been too readily regarded as
a depravation. Quintilian was appointed preceptor to the
two young princes whom Domitian dignified for his succesor
on the throne; but the celebrity which the rhetorician re-
ceived from the favours and attention of the emperor, and
from the succesors which his writings met with in the world,
were emblazoned by the loss of his wife, and of his two sons,
one of whom he describes as a prodigy of early excellence.
It is said that Quintilian was poor in his retirement, and that
his indigence was relieved by the liberality of his pupil,
Pliny the younger. He is supposed to have died about the
year 95. His "Institutiones" were discovered in the year
1415, in an old tower of a monastery at St. Gall, by Poggio
Bracciolini. The treatise on the "Causes and Corruption
of Eloquence" has not come down to us. The name of
Quintilian is affixed to certain "Declamations," of which
there are 19 of moderate length; but as the style, method,
and manner, are totally different from the rules laid down
in the "Institutiones," no good judges attribute them to
the name of Quintilian. Of the editions of Quintilian some
of the most valuable are those of Geller, 4to. Gotting. 1738;
of Lug. Batavorum, 8vo. cum notis variarum, 1665; of
Gibson, 4to. Oxon. 1693; and that of Rollin, re-published
in London in 1792. There is an English translation by Mr.
Guthrie.

QUINTILIUS, Quintiliani, in Ecclesiastical History,
a sect of ancient heretics, the same with the Pepuzians;
thus called from their prophetess Quintilia.

In this sect, the women were admitted to perform the
facerdotal and episcopal functions; grounding their practice
on that passage of St. Paul to the Galatians, where he says,
"That in Christ there is no distinction of males and females."
In their assemblies, it was usual to see the virgins enter
in white robes, perforating the prophetesses. The Quin-
tilians bore some resemblance to the modern Quakers.

QUINTILIS, in Chronology. See July.

QUINTIN, or Quin, in Commerce. See Quentin.

QUINTIN, in Geography, a town of France, in the
deptartment of the Northern Coasts, and chief place of a
canton, in the district of St. Brieuc; nine miles S.W. of St.
Brieuc. The place contains 3976, and the canton 12,510
inhabitants, on a territory of 147½ square miles, in eight
communes.

QUINTINIE, John de la, in Biography, famous for
his skill in horticulture, was born at Poitiers in 1626.
He received a learned education, and was brought up to the
profession of the law, in which he gained reputation as a pleader
at the bar. A passion for agricultural knowledge led him
to study, with great attention, all the authors, ancient and
modern, upon that topic; and on a visit to Italy as tutor to
a youth, he made great additions to his knowledge from
actual observation. On his return he devoted himself almost
entirely to experiments on the culture of trees and plants,
and made many discoveries which greatly improved the art
of gardening. He was the first person who laid down just
principles of the art of pruning fruit-trees. He also
remarked that a transplanted tree grew only by the new roots
which it threw out, and that the old fibres were useless,
and ought to be cut off. It does not appear at what time he
began to follow gardening as a profession, but he had cer-
tainly acquired a high degree of reputation in it when he
was invited to England by Charles II. who offered him
a considerable pension to engage him in his service. He
twice visited London, and a paper of his was published in
the Philosophical Transactions, on the culture of melons.
He was made, by Lewis XIV., director-general of the
gardens in all the royal palaces. In 1668 he published
"Instructions pour les Jardins Fruissiers et Potagers," which
obtained a high degree of popularity, was frequently re-
printed, and was translated into several modern languages.
The last edition was entitled "Parfait Jardinier," in two
vols. 4to. The author died at Paris in the year 1700.

QUINTO, in Geography, a town of Spain, in Arragon;
20 miles S.E. of Saragossa.

QUINTUS CALABER, in Biography, a Greek poet,
who wrote a supplement to Homer's Iliad, in 14 books,
in which a relation is given of the Trojan war from the death
of Hector to the destruction of Troy. He is suppos-
ed, from the style of his work, to have lived in the fifth
century, but nothing certain can be collected concerning his
person and country. His poem was first made known by
cardinal Bellarion, who discovered it in St. Nicholas' church, near Otranto in Calabria; hence the author was named Quintus Calaber. It was published at Venice by Aldus, but there is no date attached to the title page.

**Q U I**

**QUINTUS CURTIUS.** See Curtius.

**QUINTUS FEMORIS, in Anatomy,** a name given by Fallopius and many others to one of the muscles of the thigh, now called the plosus magnus.

**QUINTUS OCULORUM,** a name given by Vefalius and some others to one of the muscles of the eyes, more expressively called by others obvius superior oculi, and opifex circumgyrationis oculi.

**QUINVA,** in Botany, a name by which some authors have called the amaranth, or cockcomb.

**QUINZANO,** in Geography, a town of Italy; 18 miles S.W. of Brescia.

**QUINZIEME,** Fr. in Music, the double octave, above or below any found (see Fifteenth); which is the name of a stop in our organs, equidistant from the diapason.

**QUIOPELA,** in Zoology. See Viverra Mungo.

**QUIPOS,** in Literary History, a name given to knots on cords of different colours, in Peru, which imperfectly supplied the place of writing. This device was adopted, as it has been said, for rendering calculation more expeditious and accurate. The various colours denoted different objects, and each knot expressed a distinct number. Thus an account was taken, and a kind of register kept of the inhabitants in each province, or of the several productions collected there for public use. But as these knots, however varied or combined, no moral or abstract idea, no operation or quality of the mind could be represented, they contributed little towards preserving the memory of ancient events and institutions. The Mexican paintings and symbols, rude as they were, conveyed more knowledge of remote transactions than the Peruvians could derive from their booted quipos. If, indeed, the latter had been of more extensive use, and better adapted to supply the place of written records, they perished so generally, together with other monuments of Peruvian ingenuity, in the wreck occasioned by the Spanish conquest, and the civil wars subsequent to it, that no accession of light or knowledge is derived from them. Robertson's Hist. Amer., vol. iii.

**QUIQUI,** in Zoology, a species of Musflea; which see.

**QUIRAZAL, or CURRAZ, in Ornithology.** See Cran Alco. or Cran Alco.

**QUIRE of Paper,** of the French cabier, the quantity of twenty-four or twenty-five sheets.

**QUIRICA,** a name given by some to the stone called quiris by the generality of writers.

**QUIRICU,** in Geography, a town of France, in the department of the Iere; 12 miles E. of Bailly.

**QUIRINACIUM OPUS,** in the Materia Medica, a name given by some to the gum we know by the name of asa ficta.

**QUIRINALIA,** in Antiquity, feasts celebrated, among the Romans, in honour of Romulus, who was called Quirinus. See Quirites.

The Quirinalia, called also flutorum sere, were held on the 13th of the calends of March, i.e. on our 17th of February.

**QUIRINI, ANGIOLO-MARIA,** in Biography, a learned cardinal, by defeat a Venetian, was born in the year 1685. While young he entered into the order of the Benedictines of Monte Cassino. At Florence he pursued a very extensive course of study under several of the most eminent men in science and literature of that age.

Upon his entering a profeship in his convent, he delivered an oration "De Moificio Historiz Preftantia," which was printed. His studies were interrupted some time, by an imagination that he was afflicted with a stone in his bladder; but the death of his physician, who fell a victim to a false impression respecting his own face, freed him from his fancied complaint, and in the year 1710 he set out upon his literary travels. He visited Germany, Holland, England, and France, making in the latter country an abode of more than two years, during the greatest part of which time he resided in the Benedictine abbey of St. Germain des Pres. In the course of his travels he formed an acquaintance with almost all the literary characters in those countries, and visited every object of learned curiosity, at the same time every where exciting a general eftrem of his talents, his industry, and his conduct. Upon his return to Italy he published a Dissertation containing a Plan for a History of Italy;—an Essay on the History of Farfa, in the Duchy of Spoleto;—and an edition of the Office for Divine Service according to the Use of the ancient Greek Church. He was soon after created bishop of Corfu, by pope Innocent XIII., a dignity which he filled in such a manner as to inspire the Greek separatists with veneration for his person. His residence in Corfu was the cause of his composing a learned work, "Primordia Corcyre ex antiquissimis Monumentis illustrata," 4to. 1725.

In the year 1727, Benedict XIII. raised Quirini to the cardinalate, after having nominated him to the bishopric of Brescia. His promotion to that see was followed by some publications relative to the literature of Brescia. His attachment to the see of Rome was displayed by a life of pope Paul II. printed in 1740, the object of which was to defend the memory of that pontiff against the attacks of Plinio. Soon after this he was appointed librarian to the Vatican; in this and other posts he continued to serve the cause of literature. It was through his means that a new edition of the works of St. Ephrem was given in 6 vols. fol. in the Greek, Syrian, and Latin languages. He likewise edited the letters of cardinal Pole, written against the principles of the reformers. This prelate died, greatly regretted, at his episcopal residence, in 1755, at the age of 75. Though a vigorous champion of the papacy, he wrote with a spirit of candour and moderation, which obtained the applause of the Protestants themselves. He was associated to several literary societies, among which were the academies of Peterburg, Berlin, and Vienna, and the Institute of Bologna. He enjoyed a large revenue, which he expended with munificence, on objects of charity and public splendour. At Rome he beautified the church of St. Mark, whence he derived his cardinal's title, and he contributed liberally to the fine Catholic church at Berlin. He laid the foundation, by a valuable gift of books, of a public library at Brescia. His own select and valuable library he presented to the Vatican. His charities were numerous and extensive, and he was indefatigable in performing his pastoral duties, visiting the alpine parts of his diocese in the most inclement seasons. Besides the works already mentioned, he published an account of his own life, and a narrative of his travels.

**QUIRIQUING,** in Geography, an island on the coast of Chili, near the entrance into the bay of Concepcion. S. lat. 36° 35'.

**QUIRIS, Quirisus lapis,** a name given, by the writers of the middle ages, to a stone famous among them for its imaginary virtues, but of which they have left us no description.

**QUIRISTER, CHORISTER, or Chorista,** a person appointed
pointed to sing in the quire, or choir, of a cathedral. See Anthem, Chantor, and Choir.

Quirites, in antiquity, an appellation given to the people of Rome, chiefly the common citizens, as distinguished from the soldiers.

It took its rise from the Curetes, the inhabitants of the Sabine town Cures. On this occasion Romulus, and Tatius king of the Sabines, having united their two people, and their two flates, into one; upon Romulus's death and defection, the Sabines, outdoing the Romans in number, became masters of the councils; and accordingly appointed, that Romulus should be denominated Quirinus, from Cures, a city of the Sabines; or rather from Quirinus, the name of a god worshipped in that city.

From the new Quirinus, all the people came afterwards to be called Quirites; unless we will suppose, that the same authority which denominated Romulus Quirinus, from Cures, did also denounce the people Quirites, immediately from the Curetes.

Some authors derive the word Quirinus from Curis; which, in the Sabine tongue, figured a pike, or halbert. Struvius adds, that Romulus was always painted with a pike in his hand.

Julius Cæsar, as Tacitus informs us, (Annal. i. 43.) appeared a sedition by the use of this word Quirites, which opposed to soldiers, expressed contempt, and reduced the offenders to the less honourable condition of mere citizens. The emperor Alexander also applied it to the same purpose. See his biographical article.

Quirk, in building, a piece of ground taken out of any regular ground-plot, or floor. Thus, if the ground-plot were square, or oblong, and a piece be taken out of a corner, to make a court, or yard, &c. the piece is called a quirk.

Quiroga, in Geography, a town of Spain, in Galicia; 24 miles N.E. of Orense.

Quiros, Cape, lies on the E. coast of the island of Efpiritú Santo, in the South Pacific ocean. S. lat. 14° 56' 8"; E. long. 167° 20'.

Quirpele, in zoology, the name of a small animal, called by some authors the Indian ferret, or viverra Indica, and by others guilt. See Viverra Mungo.

Garcia and some authors give very remarkable accounts of the eminence this creature has to ferrets of all kinds. They tell us, that when this little creature intends an attack upon one of these animals, it first prepares against danger, by gnawing a quantity of the root of the lignum colubrinum, or snake wood; and when it has thoroughly impregnated its fæva, it wets with it first its fore-feet, and with them daubs over its head and its whole body; and that thus prepared, it boldly attacks the snake, and never leaves off till it has killed it. Garcia affirms us, that many of the Portugueze have been eye-witnesses of these combats.

It is probable enough, that this creature may attack a snake when thoroughly hungry, knowing its flesh to be good food; but the story of the antidote is to be suspected. See Ichneumon.

Quirpen, in Geography, an island in the North Atlantic ocean, near the N. coast of Newfoundland. N. lat. 51° 40'; E. long. 52° 22'.

Quirsvyk, a town of Norway; 60 miles N.E. of Romfidal.

Quis, in Natural History, a kind of marcasite of iron or copper, from which vitriol is drawn. It is more frequently called pyrites.

Quisbro, in Geography, a town of Sweden, in Nericia; 12 miles S.W. of Örebro.

Quiscalus, in Ornithology, a species of Gracula; which see.

Quisibi, in Geography, a town of Arabia, in the province of Oman; 180 miles W. of Julfar.

Quisil auren, a town of Asiatic Turkey, in Caramania; 15 miles W. of Cogni.

Quisongala Islands, a cluster of small islands in the Indian sea, near the coasts of Africa. S. lat. 10° 40'.

Quispichanchi, a jurisdiction in the diocese of Cufco in Peru, beginning at the four gates of Quito, and stretching from E. to W. about 20 leagues. The lands of this jurisdiction belong, in general, to the richer inhabitants of Cufco, and produce plenty of wheat, maize, and fruits.

Here are also manufactures of baize and coarse woollen stuffs. Part of the jurisdiction borders on the forests inhabited by wild Indians, and produces great quantities of coca, or cacao, an herb greatly used by the Indians working in the mines, and forming one of the principal branches of its commerce; the town lies 12 miles S. of Cufco.

Quisqualis, in Botany, a name combined by Rumphians of quis, who, and qualis, what kind or manner, by which he intended to express the singular variableness of the plant, as if nothing could be found like it.—Linn. Gen. 215; Schreb. 292. Wildl. Sp. Pl. v. 2. 579. Mart. Mill. Dict. v. 4. Julf. 78. Lamark Illuftr. t. 357; Clafs and order, Decandria MonogaMy. Nat. Ord. Ver. p. 109; Linn. Thyrselce, Julf.

Gen. Ch. Cal. Perianth inferior, tubular, thread-shaped, very long, deciduous, its border in five spreading segments. Car. Petals five, inserted into the mouth of the tube, femail, oblong, obtuse, spreading, much larger than the segments of the calyx. Stam. Filaments ten, bristle-shaped, inserted into the tube of the calyx, five of them below the vent, others oblong, or in above the mouth of the tube. Pist. Germen superior, ovate; style thread-shaped, longer than the stamens; stigmas obtuse, dilated. Peric. Drupa dry, with five unequal angles. Seed. Nut elliptic-oblong, penta-gonal.

Eff. Ch. Calyx with a thread-shaped tube; five-leaved. Petals five. Drupa superior, with five angles.

1. Q. indica. Linn. Sp. Pl. 556. (Quisqualis; Rumph. Ambv. v. 5. 71. t. 48. Q. pubescens; Burm. Ind. 104. t. 35. f. 2, and Q. glabra; t. 28. f. 2.)—Native of Java, and the Molucca isles; naturalized by Rumphius in Amboyna. The fæm is shrubby, at first low and flumpy, but subsequently throwing out long trailing or twining shoots, which become as thick as a man's arm. To this diversity of habit, and the changeable hue of the flowers, the name alludes. The young branches are clothed with fine soft down. Leaves opposite, occasionally scattered, on shortish downy stalks, ovate, pointed, entire, two or three inches long; their ultimate veins finely reticulated; both surfaces more or less downy, rarely smooth. Flowers in axillary or terminal branched spikes. Bracteas ovate, downy. Corolla two inches long, downy, whitish in the morning, turning pale red in the afternoon, rofe-coloured in the evening, and the next morning of a blood red. Fruit as big as one joint of the finger. Nut eatable when quite ripe, having the flavour of a filbert. When unripe, Rumphius compares its taste to that of a radish. These nuts are a popular remedy, among the Malays, for worms in children. Two or three of the pungent unripe ones, or five of those that are arrived at maturity, are a dose. Some persons are attacked with a dangerous hiccup from eating two or three of the nuts in question, whilst others find no such effect from a considerable number. The integuments are carefully removed. They probably partake of the poisonous
poisonous qualities of the Mezereon tribe; though in a mild degree, as Rumphius speaks of the flavour of several parts of the plant, without mention of any very hurtful properties. Even the kernels of our European Daphne are highly acrimonious.

QUIQUISANA, in Geography, a town of Peru, in the diocese of Cufco; 32 miles S.S.E. of Cufco.

QUISSAC, a town of France, in the department of the Gard, and chief place of a canton, in the district of Le Vigan, having a mineral spring; 20 miles N. of Montpellier. The place contains 1310, and the canton 3884 inhabitants, on a territory of 160 kilometres, in 12 communes.

QUISTELLO, a town of Italy, in the department of the Milan; 15 miles S.S.E. of Mantsua.

QUISTORP, John, in Biography, a German Lutheran divine and professor, was born at Rollock in the year 1584. He pursued his academical studies at his native city, at Berlin, and at Frankfort on the Oder; and afterwards travelled through Holland, Brabant, and Flanders, in the capacity of governor to the son of a patrician of Lucbc. In 1614, his learning and abilities pointed him out as a fit person to fill the divinity chair at Rollock; but before he entered upon the duties of his office, he was created doctor of divinity. He obtained other preferments in the church, particularly the archdeaconry of St. Mary’s at Rollock. In 1645 he was appointed pastor of the same church, and superintendent of the churches in the district of that city. He had the felicity of rendering important services to the celebrated Hugo Grotius, during his last fatal illness at Rollock. Upon the death of that great man, he wrote a Latin letter to Calovius, containing an account of his kindness and last sentiments, which is inserted in the “Bibliotheca Choifée” of Colomes; and in the “Vindiciae Grotianae,” under the title of “Grotii Manes.” Quistorp died in 1648, at the age of 64. He was the author of “Annotationes in omnes Libros Bibliicos,” “Commentarium in Epitola Sancti Pauli,” and several other works. He left a son of the same name, who was born at Rollock in 1624, and died in 1669. He became pastor, professor of divinity, and rector of the university in that city.

QUISTRUM, in Geography, a town of Sweden, in the province of韦est Gotland; 5 miles N.W. of Uddevalla.

QUITANGONE, a river of Africa, which runs into the Indian sea, 15 miles N. of Mozambique, S. lat. 14° 40'.

QUITAPABILLA, a river of America, being a branch of the Swetara, which falls into the Sulqueannah at Middleton.

QUITAPORA, a town of the state of Georgia. N. lat. 33° 25'. W. long. 80° 58'.

QUITCH, in Agriculture, a name frequently applied, in many districts, to a very troublesome set of plants of the weed kind; for though it properly belongs to the couht-grafs plant only, it is much used to defign other of the creeping perennial rooted fort, as the bent, creeping, soft, and tall oat-grafs, as well as others, which are only capable of being destroyed by repeated summer ploughings, or forking them out and burning them on the ground. See COUCH.

QUITCH-GRAFS, the common name given in some places to a very troublesome weed of found, in various districts, and which requires great exertion to eradicate it out of the land. See COUCH.

QUITCH-DRAFS, that ferrt of useful tool of the drag-kind, which is employed in the dragging out and removing this ferrt of weed from ploughed lands. It is made in several different methods, according to circumstances; but has mostly something of the long triangular form in the beam part, into which the teeth or tines are fixed. These are seldom made so large in this as in the heavy ferrts of drag; but they are mostly a little hooked, or bent forward, towards the points or lower ends. The frame-part is sometimes fitted with two rows of tines, or more.

It is a ferrt of tool which is frequently made ufe of for rendering arable ground perfectly clear of root weeds, being had recourse to before the late ploughings. Where the land has been crois-ploughed, this kind of drag may be employed with great advantage in bringing it into proper order. It has some other names in different counties. See COUCH-DRAFS, and DRAG.

QUITCH-RALES, a name given in many districts to the rake used in collecting the weed called couch, from the surface of ploughed ground, as well as some other ferrts in particular cases. The head of this tool, into which the teeth or tines are fastened, is usually about five feet in length; the tines are made in a round form, having a projection of about eighteen inches below the head, each being gradually turned or crooked forward about two inches; the distance from each other also about two inches. There is commonly a small beam made to fasten in the middle with two pieces of wood, which come from each corner of the rake-head, into which the tines are fastened by means of a pin that goes through the beam, and keeps the rake steady. In working, this implement may be put on the carriage-part of a two-wheeled plough, to be drawn by one horse; a man going behind to occasionally lift up the rake when full, in order to leave the couph and other weeds in rows, for the purpose of burning them. In this manner, a great deal of weeds and trumpery may be collected together in the course of a day. See COUCH-grafs Rake.

QUIT-CLAIM, a release, or quitting one’s claim or pretensions to a thing.

QUITERVA, in Geography. See SOFALA.

QUITEVA, or KITEA, a town of Africa, in the country of Darah, defended by a castle; 75 miles S.E. of Morocco. N. lat. 28° 6'. W. long. 5° 26'.

QUITO, an extensive province of South America, which was subject to the Peruvian empire, by Huana Capac, about the year 1526, at the time when the Spaniards first visited the coast of Peru. Huana prevailed on his immediate and eldest son Huncan to allow one of his natural children, Atahualpa, by the daughter of the last king of Quito, to hold this kingdom as a vassal of the empire. Atahualpa, however, rebelled, fized the empire, emplimned his brother, and soon after put him to a violent death. His prosperity was of short duration; for in the year 1535 he suffered the same fate, by order of Don Francisco Pizarro, who had deputed Sebastian de Benalcazar to conquer the kingdom of Quito. Having by a series of victories made himself master of the kingdom, he proceeded in the year 1534 to rebuild the capital, which had suffered much from internal communions, and called it “San Francisco de Quito,” a name which it still retains, though it was not till seven years after this date that it obtained the title of city. The province, which the Spaniards found annexed to the kingdom of Peru, continued in that state till the year 1718, when it was daimonized from Peru, and attached to the viceroyalty of New Granada. At the same time the audience of Quito was suppressed, together with that of Panama, in the kingdom of Terra Firma: though the latter continued dependent on the viceroys of Lima. See NEW GRANADA and PERU.

This province is bounded to the north by that of Santa Fe de Bogota, and includes part of the government of Popayan; on the south it is limited by the governments of Peru
Quito.

The capital of the above described province, rebuilt in the year 1534, (see the preceding article,) and situated in the inland parts of the continent of South America, on the eastern skirts of the West Cordillera of the Andes; distant from the coast of the South sea about thirty-five leagues to the west. On the N. W. is the mountain and desert of Pichinche (which fea), on the acclivity of which the city is built, and also among the breaches that are formed by the eminences of this mountain; so that many of the buildings stand upon arches, and the streets are of course very irregular and uneven. With regard to magnitude, this city may be compared to one of the second order in Europe; but the unevenness of its situation is a great disadvantage to its appearance. Near the city are two spacious plains, one on the S., called Turu-bamba, three leagues in length; and the other on the N., termed Inna-Quito, about two leagues in extent; both of which are intermixed with fields and cultivated lands, which much contribute to the variety and beauty of the scenery. These plains contract as they approach the city, and at their junctions form a tract of land, covered with the eminences on which part of Quito stands. The principal square in Quito has four sides, in one of which stands the cathedral, and in the opposite the episcopal palace; the third side is taken up by the town-house, and the fourth by the palace of the audience: this square is very spacious, and has in its centre an elegant fountain. The four streets terminating at the angles of the square are straight, broad, and handsome; but at the distance of three or four quadras, (each quadra being about one hundred yards,) the troublesome declivities commence; and on this account the inhabitants cannot enjoy the benefit of coaches, or wheel carriages. The principal streets are paved; and those which are not paved are almost impassable after rain, which is here very common. Besides the principal square, there are two others, that are very spacious, and several that are smaller. In these most of the convents are situated, and these make a handsome appearance, and some of them, particularly that of the order of Franciscans, are elegant structures. The principal houses are large, and some of them have spacious and well-appointed apartments, though none are above one story in height, but their doors and windows are low and narrow. The materials made use of in building at Quito are "adobes," or unburnt bricks and clay, cemented by a substance called "fangay a," a species of mortar that is uncommonly hard, used by the ancient Indians for building all kinds of houses and walls. The city is divided into seven parishes; the cathedral is richly adorned with tapestry hangings and other costly decorations; but the parish churches are of mean appearance. The convents of monks are those of the Augustines, Dominicans, and Fathers of Mercy, &c. colleges, &c. Quito has also several numeraries. The college of Jesuits, as well as all the convents of monks, are large, well built, and very splendid. Here is also an hospital, with separate wards for men and women, under the name of the order of our Lady....
of Bethlehem. Among the courts whose seions are held at Quito, the principal is that of the Royal Audience, establishe there in 1563; the exchequer or chamber of finances, a treasury for the effects of persons deceased, &c. The corporation consists of a corregidor, two ordinary alcaldes chosen annually, and regidores. The cathedral chapter consists of the bishop, dean, archdeacon, chanter, treasurer, a doctoral, a penitentiary, a magislar, three canons by presentation, four prebends, and two demi-prebends, with the following salaries; that of the bishop $24,000 dollars, the dean $500; the four succeeding dignities, $3000 each, the canons $1500 each, the prebends $600, and the demi-prebends $400. This church was created into a cathedral in 1545, and among other festivals celebrated in it, the most magnificent are those of Corpus Christi, and the Conception of our Lady, when all the courts, offices, and persons of eminence assist. In the former there is a singular pomp of the procession of the host, and here are also dances of a peculiar nature, which were performed before their conversion to Christianity. The corporation and cathedral chapter keep, by vow, two annual festivals in honour of two images of the Virgin, which are placed in the villages of Guapulo and Quirincha, belonging to this jurisdiction. These images or statues are brought with great solemnity to Quito, and each festival is succeeded by nine days' devotion, the audience and other courts afflicting on the occasion. These festivals are held in commemoration of the assistance vouch- safed by the holy Virgin, at the time of an earthquake and terrible ejection from Pichincha, by which Latacunga, Hambato, and a great part of Riobamba, were utterly destroyed; whereas by the supposed interposition of the Virgin, the city escaped even the slightest damage.

The celebrated city of Quito is said by Alcedo to contain 58,000 persons, some of whom are distinguished by their rank. These are the descendants either of the original conquerors, or of other persons who in succeeding times came over from Spain invested with some lucrative office, and who have preferred the lucre, both of their decent wealth, by intermarriages, without mixing with meaner families though famous for their riches. The lower orders of people consist of four classes, Spaniards or whites, Mefitizos, Indians or natives, and Negros, with their progeny. The former, according to the statement of Uleoa, compose about a sixth part of the population; the Melissaos, or descendants of Spaniards and Indians, amount to about a third part; the Indians form another third; and the others, who are about one-sixth, are the Cafts. The Spaniards are prevented by their pride from applying to any kind of busines, and therefore many of them are poor and wretched. The Melissaos occupy themselves in arts and trades, but principally in those of the highest repute, such as painting and sculpture, in which they excel. These men of talents, however, are indolent and slothful, so that they loiter about the streets during the whole day. The Indians, who are generally shoemakers, bricklayers, weavers, or engaged in similar occupation, are not more industrious. Persons of fortune among the Spaniards affect great magnificence in their dress, wearing the finest gold and silver tilities; but that of the middling and lower class is a black cloak, and under it a long coat, reaching down to their knees, with a close sleeve, open at the sides, without folds, and ornamented with rows of buttons. The Melissaos generally wear blue cloth, manufactured in this country. The dress of the Indians consists only of white cotton drawers, made either from the fluffs of the country, or from others brought from Europe, reaching down to the calf of the leg, and edged with lace suitable to the stuff. The use of a shirt is supplied by a black cotton frock, wove by the natives; and over this is a kind of ferge cloak, through which the head paffes, and a hat made by the natives. The men, both Creoles and Spaniards, are well made, of a proper stature, and of a lively agreeable countenance. The Melissaos in general are also well made, often taller than the ordinary size, very robust, and have an agreeable air. The Indians, both men and women, are generally low, but well proportioned and very strong. The Indians have no beard, nor have either males or females any indications of the age of puberty. The youths of family are instructed in philosophy and divinity, and some, with reluctance, proceed to the study of the civil law. The country is observed to abound more in women than men; and it is observed, that nature begins to decay at the age of thirty in the male sex, especially among those who have been tenderly brought up; whereas the females enjoy a more confirmed state of health and vigour. This difference is ascribed partly to the climate and partly to the food, but principally to early intemperance and voluptuosities, and also the want of proper employments. The liquors that are used here are rum and brandy, in which they freely indulge, and also the infusion of the Paraguay herb, which serves for tea. The vices prevalent here are dice-los, drunkennes, and gaming. The common people and Indians are much addicted to theft, in which they are very artful and dextrous. In Quito, and in all the towns and villages of its province different dialects are spoken, Spanifh being no less common than the Inga.

Quito is so happily situated, that neither the heat nor cold is troublesome; though the extremes of both may be felt in its neighbourhood. An equality of temperature takes place throughout the whole year, the difference between the mornings being scarcely perceptible. The winds are fabricious, and blow continually, but never with any violence. The rain occasionally descends in impetuus torrents. Earthquakes are not uncommon, and when they occur very violent; that of 1775 was very destructive. The great earthquake on the 4th of February 1797, which changed the face of the whole province, and in one instant destroyed thirty-five or forty thousand persons, has so altered the temperature of the air, that the thermometer is now commonly 41° to 54°, and seldom rises to 68° or 70°; whereas Bouguer observed it constantly at 66° or 68°. Since this catastrophe earthquakes are continually recurring; and such shocks, it is probable, that all the higher ground is one vast volcano. Von Humboldt adds, that what are called the mountains of Cotopaxi and Pichincha are but little summits, the craters of which form different conduits terminating in the same cavity. The earthquake of 1797 afforded a melancholy proof of this; for the ground then opened every where, and vomited forth sulphur, water, &c. Notwithstanding the dangers and horrors that surroun, the people of Quito are gay, lively, and variable, and very much addicted to pleasure, luxury, and amusement. Humboldt informs us, that the volcanos of Quito eject pumice, basalt, and porphyry, &c.; with enormous quantities of water and liquid clay, which diffuse fertility eight or ten leagues round. The fertility of this country is such, that, as we are informed, a full description of it would appear incredible. The equality of the climate, as well as the fertility of the soil, occasion a regular succession of the productions of the earth: when the fruits have obtained their maturity, and the leaves begin to change their colour, fresh leaves, blossoms, and fruits, are seen in their proper gradations on the same tree. The fame incessant fertility is conspicuous in the corn, reaping and fowing being both carried on at the same time. This remarkable fecundity of the soil is naturally productive of excellent
excellent fruits and corn of every kind, as is evident from
the delicacy of the beef, veal, mutton, pork, and poultry
of Quito. One of the principal foods used by the inhabi-
tants is cheese, of which it is computed that the quantity
annually consumed amounts to between seventy and eighty
thousand dollars of the money of that country. The vicin-
ity also affords excellent butter. The manufactures of this
province are cottons, some white, called tucuyos, and others
striped bays and cloths, which meet with a good market
at Lima, for supplying all the inward provinces of Peru ;
and the returns are made partly in silver, and partly in gold
and silver fringes made in that city, wine, brandy, oil, copper,
tin, lead, and quicksilver. The products of the earth are
chiefly consumed within the province; except the wheat,
part of which is sent to Guayaquil. But this trade is
carried on by Metzigos and poor people. Goods, manu-
factured by the public, or woven by private Indians, are sent,
together with some kinds of provisions, to the jurisdic-
tion of Barbascoas. These provisions are exchanged for gold, found
in that country, and which is afterwards sent to Lima, and
disposed of at a greater price. Their stuffs find a vent in
the governments of Popayan and Santa Fé. The coast of
New Spain supplies this province with indigo, of which a
great quantity is consumed; blue being universally the col-
our which these people affect in their apparel. They also
import, by way of Guayaquil, iron and steel, both from
Europe and the coast of Guatamala. S. lat. 0° 13' 27".
W. long. 78° 10' 15". Ulloa's Voyage, vol. 1.
QUIT-RENT, q. d. quiet rent, a certain small rent,
payable yearly, by the tenants of moft manors, in token of
subjection; upon the payment of which, they are quiet, and
free. It includes both rents of affile and chief rents.
These rents differ very greatly in different manors, being
in some a mere trifle, while in others they are very heavy
and oppressive to the tenants. This part of the feudal
system is now considerably on the decline.
In some ancient records it is written white rent, because
paid in silver, to distinguish it from rent-corn, rent-pepper,
&c.
QUITTA, in Geography, a town of Africa, on the
Slave coast. N. lat. 6° E. long. 0° 8'.
QUITTANCE. See Acquittance.
QUITTER, or Quittor, in hores, is an ulcer formed
between the hair and hoof, usualy on the inside quarter
of a horse's foot; it often arises from treads and bruises,
sometimes from gravel, which by working its way up-
wards, lodges about the coronet; if it is only superficial,
it may be cured with cleansing dressings, bathing the coronet
every day with spirits of wine, and dressing the fore with
lime-water, or a detergent application, such as red precipi-
tate. But where the matter forms itself a legement under
the hoof, there is then no way to come at the ulcer but by
taking off part of the hoof; and if this be done well, the
cure may be effected without danger.
When the matter happens to be lodged near the quarter,
the farrier is sometimes obliged to take off the quarter of the
hoof, and the cure is then for the most part palliative;
for when the quarter grows up, it leaves a pretty large seam,
which weakens the foot; this is what is called a false quarter,
and a horse with this defect seldom gets quite found.
If the matter, by its confinement, has injured or destroyed
the coffin-bone, which is of so soft and spongy a nature that
it soon becomes cavernous, it will be necessary to enlarge the
opening, cut away the spongy flesh, and apply the actual
cautery, or hot iron, pointed pyramidically, dressing the
bone with dofts of lint dipped in tincture of myrrh, and
the wound with the green or precipitate ointment. When
the fore is not enlarged by the knife, which is the best and
least painful method, sublimate is generally applied; or blue
vitriol powdered, and embued with a few drops of oil, is
also used for this purpose, and is paid to act as effectually,
and with less pain to the animal.
In the time of the action of these caustic remedies, the
foot should be kept in a poultice. And where sinuses form
they should be laid open by a knife, and be afterwards stimu-
lated by the application of some detergent remedy. The
following has been advised by a late writer: Take of corro-
vive sublimate, red precipitate in fine powder, of each equal
parts; honey sufficient to form a paste.
The wound is advised to be afterwards dressed with com-
mon digestive ointment, preferable being given by means of a
bandage. It is sometimes written quitter.
QUITER-BONE, another term applied to the same diseae
by farriers and perfons engaged in husbandry.
QUITY, in Botany, a Brazilian name used by some au-
thors for the sapindus, or soap-berry tree of the West
Indies.
QUIVER, seemingly corrupted from the Fr. couvrir,
to cover, a cag or sheath for arrows.
QUIVISA, in Geography, a town of Hindostan, in
Babur; 25 miles S. W. of Bettyah.
QUIVISIA, in Botany, from the vulgar name of this
tree or shrub in the isles of Bourbon and the Mauritius,
bos de guaiwi. Juf. Gen. 264. Cavan. Diff. 367. (See Gil-
LIBERTIA.) One cannot but wonder how a writer of Juf-
fiets's learning could, for a moment, tolerate fo faulty a
name; especially as his authority leads heedlefs perons into
the adoption of such, for want of reading his preface;
where, in a note to p. 24, he declares these rude and bar-
barous names to be merely borrowed for a time, till the gen-
era to which they belong are better determined.
QUIXOS, in Geography, a jurisdiiction of South Ame-
rica, attached to the province of Quito, on the east side of
the Cordillera of the Andes. Quixos on the north side bor-
ders on the jurisdiction of Popayan; reaching caightward to
the river Aguarico, and towards the west separated from the
jurisdictions of Quito, Latacunga, and the town of San Mi-
guel de Ibarra, by the Cordilleras of Cotopaxi and Cayam-
buro. This country was first discovered in 1536, by Gonzalo
de Pineda, one of the officers sent from Popayan by Sebastian
de Belalcazar (or Benalcazar), to trace the course of the river
Magdalena; and in consequence of his report, Gonzalo Pi-
zaro, in 1539, reconnoitred its whole extent, and esta-
blisbed settlements in it. But upon the failure of his expe-
tration, the conquest of this country was suspended till the
year 1549, when the marquis de Canete, viceroy of Peru,
gave a commision to Gil Ramirez Davalo, a man of un-
daunted courage, for reducing the Indians, and making set-
tlements in the country. This object he accomplished;
and founded the town of Ibarra, the capital of the govern-
ment, in the year 1559; and this was soon followed by other
towns and villages, the principal of which are Archidona
and Avila. The temperature of this country is hot and
moist, the rains being almost continual. It is covered with
thick woods, some trees being of a prodigious magnitude.
In the S. W. part of the jurisdiction of Quixos is the canela
or cinnamon tree, which led Gonzalo de Pineda to call the country
Canos, a name which it still retains. The other products
of Quixos are the fame with those in all the other lands under
the frame climate as this government. Adjoining to this is the
district of Macas and Maynas. See MACAS and MAYNAS.
QUIZA, in Ancient Geography, a town of Africa, in
Mauritania Cufariaenis. This was a fortres, according to
Pomponius Mela and Pliny. Antonine makes it a muni-
cipium, and places it between Portus Magnus and Arbe-
naria.

QUIZAMA,
QUIZAMA, in Geography, a province of Africa, in the southern part of Angola; the country is extensive, mountainous, and badly cultivated; but it produces abundance of honey, wax, and salt. The inhabitants are warlike, and have not submitted to the Portuguese.

QUIZIBA, a small island in the Indian sea, near the coast of Africa. S. lat. 12° 30'.

QUIZIMAJOGO, a river of Africa, which discharges itself into the Indian seas, S. lat. 8° 50'.

QUIZIMA, or Teusin, a chain of mountains in Fez, 90 miles in extent.

QUIZUMGO, a river of Africa, which runs into the straits of Mozambique, S. lat. 17° 20'.

QUO JURE, in Law, a writ that lies for him who has land, wherein another challengeth common of pasture time out of mind: its design is to compel the party to fly by what right or title he challengeth it. This is now out of use, as, on the claimant's putting his cattle in, the owner may bring trespass, when the claimant must plead and prove his title.

Quo Minus is also a writ which lies for the king's farmer or debtor in the court of eschequer, against him to whom he feltheth any thing by way of bargain, touching his farm, or against whom he hath any cause of personal action; because by the vendee's detaining any due from him, the farmer is les able to pay the king's rent. This was formerly allowed only to such persons as were tenants or debtors to the king: at this day the practice is become general for the plaintiff to furnish, that, for the wrong which the defendant doth him, he is les able to satisfy his debt to his majesty; which furnish gives jurisdiclion to the court of eschequer to hear and determine the cause. Finch. 66. Old N. B. 148.

Quo minus is also a writ that lies for him who has a grant of house-bote and hay-bote in another man's woods, against the grantor making such waife, as that the grantee cannot enjoy his grant.

Quo Warranto, a writ that lies against any person or corporation (which fee) who usurps any franchise, or liberty, against the king; as to have waive, flary, fair, market, court baron, leet, or such-like, without good title; to inquire by what authority he supports his claim, in order to determine the right. Finch. L. 322. 2 Inst. 258.

It also lies for mid-inter or non-inter of privileges granted; and even, according to Bracton, against him that intrudeth himself as heir into land. See Intrusion.

This writ was originally returnable before the king's justices at Westminster; but afterwards only before the justices in eyre, by virtue of the statutes of "quo warranto," 1 Edw. 1. c. 1. and 18 Edw. 1. ft. 2. (2 Inst. 498. Rath. Entr. 540.) but since those justices have given place to the king's temporary commissioners of affize, the judges on the several circuits, this branch of the statutes hath lost its effect: and writs of "quo warranto" (if brought at all) must now be prosecuted and determined before the king's justices at Westminster. And in case of judgment for the defendant, he shall have an allowance of his franchise; but in case of judgment for the king, for that the party is entitled to no such franchise, or hath diffused or abided it, the franchise is either feised into the king's hands, to be granted out again to whomever he shall please; or, if it be not such a franchise as may subsist in the hands of the crown, there is merely judgment of "ouster," to turn out the party who usurped it. Cro. Jac. 259. 1 Show. 280.

The judgment on a writ of "quo warranto" (being in the nature of a writ of right) is final and conclusive even against the crown. (1 Sidd. 86. 2 Show. 47. 12 Mod. 225.) This circumstance, together with the length of its process, probably occasioned that it difuse into which it is now fallen, and introduced a more modern method of prosecution, by information filed in the court of king's bench by the attorney general, in the nature of a writ of "quo warranto," in which the process is speedier, and the judgment not so difficult. This is properly a criminal method of prosecution, as well to punish the usurper by a fine for the usurpation of the franchise, as to out him, or lefe it for the crown; but hath long been applied to the mere purposes of trying the actual right, feizing the franchise, or outhing the wrongful possessor: the fine being nominal only. Blackit. Com. b. iii. See Information.

QUOD HOC, a term often used in law reports to signify, "as to the thing named" the law is fo, &c.

QUOCOLONOS, the name of the stone found in Tuscany, as hard as a flint, somewhat transparent, and, in some measure, resembling marble. In the fire it loses its transparency, and becomes less ponderous, and white; and a strong fire readily converts it into glass. It has no medicinal virtues, but is used at some glafs-houses.

QUOD, Cape, or Quado, a cape on the coast of Patagonia, in the straits of Magellan. S. lat. 53° 33'. W. long. 74° 6'.

Quod clerici beneficiati de cancellaria, in Law, a writ to exempt a clerk of the chancery from the contribution towards the proctors of the clergy in parliament. Rep. Orig. 261.

Quod clerici non elegantur in officio ballivi, &c. is a writ that lies for a clerk, who, by reason of some land he hath, is made, or like to be made, a bailiff, beadle, reeve, or such-like officer.

Quod sum, that whereas, being by way of recital, and not positively, is not good in indictments. 3 Salk. 188. See Indictment.

Quod ei defecaret, a writ for tenant in tail, tenant in dower, by the courtesy, or for term of life, having lost their lands by default, against him that recovers, or his heir. Reg. Orig. 171. Stat. Welfm. 2. cap. 4.

This, though not strictly a writ of right, so far partakes of the nature of one, as that it will relieve the right to him who has been thus unwarily deforced by his own default. (F.N.B. 155.) But in case the recovery were not had by his own default, but upon defence in the inferior polleffion action, this still remains final with regard to these particular offences, as at the common law: and hence it is, that a common recovery (on a writ of entry in the poff/) had, not by default of the tenant himself, but after his defence made, and voucher of a third person to warranty) by default of such voucher, is now the usual bar to cut off an estate-tail.

This writ may be brought against a stranger to the recovery: as, if a man recover by default, and maketh a feoffment, this writ may be had against the feoffor.

Quod medium. See Medium.

Quod permissat, in Law, a writ that lies where a man is dispossessed of his common of pasture, and the defier of aliens or dies feised, and his heir enters; then if the defier die, his heir shall have this writ. See Disturbance of Common.

Quod permissat proferenere. See Affife of Nusance.

Quod pernona nec probedari, &c. a writ that lies for spiritual persons, when disintrained in their spiritual polleffions, for the payment of a fifteenth, with the right of the parifh. F.N.B. 176.

QUODLIBETICAL Question, Questions quodlibetica, a college term for a thesis, or problem, anciently proposed to be debated in the schools, out of curiosity and entertainment, rather than for the settling of any useful point.
The term is formed from the Latin quodlibet, any thing, what you please: and so well satisfied were the public of the impertinences of these questions, that the term quodlibet has been since retained, to signify any little ridiculous quibble.

QUOJA, in Geography, a country of Africa, situated above 100 miles from the coast of the Atlantic, between the 8th and 10th degrees of W. longitude, and between the 7th and 9th degrees of N. latitude.

QUOIF, in Ship-Building, a piece of oak thickfluff on the deck-hook, to which the deck water-way on each side is butted, otherwise the butt would come in the middle, and could not be caulked.

QUOIL, or Cottle, in the Sea Language. A cable is said to be quoil’d, when it is laid round in a ring, one turn over another, on the deck of a ship.

The middle of such ring, or quoil, is a good place to lay shot in: they are more safe there, than in lockers along the side, where the enemy’s shot may fall into them.

QUOIU, Weather. See WEATHER QUOIU.

QUOIU, or Coin, formed from the French coin, of the Latin cuneus, wedge, a board a ship, is a wedge fastened on the deck, close to the breech of the carriage of a gun, to keep it firm up to the ship’s side, and prevent its rolling; and also to raise or depress it.

QUOINS, Cantic, are short three-legged quoins, put between casks to keep them steady. See Coin.

QUOINS, in Architecture, denote the corners of brick or stone walls.

The word is particularly used for the stones in the corners of brick buildings. When these stand out beyond the brick-work (their edges being chamfered off) they are called rustic quoins.

QUOIU, in Geography, a small island in the Indian sea, near the W. coast of Madagascar. S. lat. 14°. E. long. 45° 14′. Alto, an island in the East Indian sea, N. of the Nicobar islands. N. lat. 9° 56′. E. long. 93° 20′.

QUOITS, a kind of exercise or game, known among the ancients under the name of the discoil. See Disc.

QUOLL, in Zoology, a name given by the natives of New Holland to an animal resembling a pole-cat, with a brown back, spotted with white, and the belly of a pure white, in which it differs from others of these fœtid animals.

Cook’s Voy. 1770, vol. iii. p. 626.

QUONDANGA, in Geography, a town of the Birman empire; 32 miles N. of Prome.

QUORUM, a term frequently mentioned in our statutes, and often used in commissions, both of peace, and others. A justice of the quorum is thus called from the words in the commission, Quorum C. D. or A. B. aliquem vestrum unum effe volumus.

For an example: where a commission is directed to seven persons, or to any three of them, of which A. B. and C. D. are to be two; there A. B. and C. D. are said to be of the quorum, because the rest cannot proceed without them.

So a justice of the peace and quorum is one without whom the rest of the justices, in some cases, cannot proceed. See JUSTICES OF THE PEACE.

QUORUM Nominá. In the reign of king Henry VI. the king’s collectors, and other comptainers, were much perplexed in passing their accounts, by new extorted fees, and forced to procure a then late-invented writ of quorum nominal, for the allowance and suing out theirquietus, without the allowance of the king.

QUOTA, in Law, a tax to be levied in an equal manner.

Vol. XXIX.

QUOTATION, in Literature, a citation; or a passage recharged expressly in one author from another.

Quotations are usually distinguished by inverted commas. The manner of quoting by book, and chapter, or section, is chiefly affected by men of erudition; but it is abused: this method ought only to obtain where the whole chapter or section is expressly on the subject. On other occasions, quoting by page is more commodious; except in classics, and other ancient writings, of which there are many editions in different forms; where this method is of little use, unless the edition be also specified.

The quotations from the Old Testament, found in the New, have occasioned great doubt, dispute, and criticism. The apolites are frequently referring to the Old Testament, and quoting passages and prophecies thence, as fulfilled in our Saviour; yet these passages, thus quoted, are frequently either not found in the Old Testament at all, or they are not urged in the New, according to the literal and obvious sense they seem to bear in the Old.

A late ingenious author, in an “Effay upon the Truth of the Christian Religion,” frankly owns, that the evangelists sometimes apply to the Messias passages of the Old Testament, which, as they lie in our present copies, plainly relate to some other person, or thing. This is evident, e. gr. in the passage, Matthew, ii. 15. Out of Egypt have I called my son; which is quoted from Hoftes, xi. where it is plainly understood of the coming of the Israelites out of Egypt.

This circumstance has been urged as a great objection to Chriftianity, which the divines, commentators, critics, &c. have long laboured to remove, though by very different means.

Some have recourse to a double completion; and imagine, that though the prophecies were primarily accomplished in other events, yet they might have a secondary accomplishment in the Messias: but others set aside a double completion, except where the prophet himself declares as much, this otherwise making all prophecy useless. See PROPHECY.

The generality chooses, therefore, to have recourse to an allegorical, typical, or spiritual meaning in the prophecies, &c. and suppose them to have been thus understood among the ancient Jews, thus fulfilled in our Saviour, and thus applied by the apostles.

In effect, the Jewish rabbins, it is allowed, took great liberty in quoting and interpreting scripture; and it is supposed the apostles might follow these rules in their quotations.

Accordingly, M. Surenhusius, Hebrew professor at Amsterdam, has endeavoured to retrieve these rules, long since lost, in an express treatise on this subject, published in 1713. This author observes a great deal of difference applied in the different forms of quoting used by the sacred writers; as, It has been said; it is written; that it might be fulfilled which was spoken by the prophet; or the Scripture says; see what is said; the Scripture foretelling; it is not written, &c. He adds that the books of the Old Testament have been divided in a different order at different times, and having had different names, it is thence, that one book or writer is sometimes confounded with another.

For the rules of quoting and interpreting practiced among the rabbins, he gives us ten; recovered with much difficulty from the Talmud, and the ancient Jewish doctors; instances of which he gives us in the writings of the apostles; and by those rules he endeavors to explain and justify all the quotations made from the Old Testament in the New.

The rules are, 1. Reading the words not according to
the points placed under them; but according to others sub-
stituted in their stead; as is done by St. Peter, Acts, iii. 23.
by Stephen, Acts, vii. 43. and by Paul, 1 Cor. xv. 54.
2 Cor. viii. 15, &c. The second is by changing the letters;
as is done by Paul, Rom. ix. 33. 1 Cor. xi. 6 Hebr. viii. 9.
and xi. 5. and by Stephen, Acts, vii. 43. The third is by
changing both letters and points; as is done by Paul, Acts.
xiii. 41. and 2 Cor. viii. 15. The fourth is by adding some
letters and taking away others. The fifth is by transposing
words and letters. The sixth is by dividing one word into
two. The seventh, adding other words to make the sentence
more clear. The eighth, changing the order of the words.
The ninth, changing the order of the words and adding
other words. Both of which are done by the apostles.
And lastly, changing the order of words, adding words,
and retrenching words; which is a method often used by St.
Paul.

Other authors, as bishop Kidder, M. le Clerc, Mr. Sykes,
&c. solve the difficulty another way. That final
form of quotation among the evangelists. "That it might
be fulfilled which was spoken by the prophets" according
to these authors, means no more than an accommodation
of the prophet's words to the context in hand.

The word ἐρμηνεύω, fulfilled, does not necessarily determine us
to such a sense, as if the evangelists designed to speak of a
prediction of future events accomplished; but may rarely
express an accommodation of borrowed words. In effect,
says bishop Kidder, a scripture may be said to be fulfilled
two ways: properly, as when that which was foretold comes
to pass; and improperly, by way of accommodation, as
when an event happens to any place or people like to what
drew happen some time before. And thus it is that St. Matthew
says, on occasion of the murder of the innocents, that "then
was fulfilled what was spoken by the prophet Jeremy, In
Rama was a voice heard," &c.

This interpretation is confirmed by M. le Clerc, who observes
that the Jews, in their language, used to say, that a
passage of scripture was fulfilled, as often as any thing
happened to which it might be applied; so that the evan-
elist Matthew, who was a Hebrew, and wrote, as is
commonly supposed, in that language, intended no more in
the passage just cited, but that a thing happened, to which
one might apply what Jeremy had formerly said on another
occasion.

Accordingly, says Mr. Sykes, the evangelists, in citing
that passage of Isaiah, Behold, a virgin shall be with child,
&c. only use it as words of that prophet remarkably agreeing
to the miraculous birth of Jesus, and not as a prophecy
of his birth.

It may be added that this way of speaking was not un-
known among the heathen writers. Thus in Ælian, Di-
genès Simopénis used continually to say of himself, that he
fulfilled and underwent all the cruelties of tragedy.

The difficulty stated in this article has been already the
subject of discussion under the terms ACCOMMODATION and
PROPHECY. Whilst it is allowed, that here; passages in the
New Testament, and also in the writings of the Christian
writers, are very different from the corresponding passages as
they now stand in the Hebrew text; and that some words are
introduced as quotations which are no where to be found:
those who urge the objection should be disposed to pay due
attention to the various modes of replying to it, which bibli-
cal critics have propounded. Some have supposed, with Whiston,
those early Christian writers quoted from the LXX;
others have alleged that they sometimes quoted from their
memory; and this, it is said, is the more probable, because
the same passage is quoted in some cases by different authors
in very different words, even where the sense agrees. It is
moreover alleged, that the sense of the passages supposed to
be lost is still to be found in the Old Testament, though the
words be not; such especially are Matt. ii. ult. and
John, vii. 38. But if it were granted, that some of the
verbs originally belonging to the Old Testament are lost,
or materially corrupted, no objection could be justly alleged
against the authenticity and divine authority of the faced
writings in general. As for the quotations that occur in
the New Testament, the most probable opinion is, that
some of them are made from the Greek version and some
from the Hebrew text. To those who affirm, that though
such quotations are made from the Greek version, where
that differs from the Hebrew, yet both the text and the
version are in such places always the same in sense, we reply
with Dr. Kennicott, that this is not the case: and he thinks,
that the only way of doing justice to our Saviour and his
apostles in their references to the Old Testament, is to say
that for whatever purpose such quotations were made (whether
by way of expressing prophecy, or only of allusion and ac-
companiment) they were always conformable to the true sense of
the Hebrew text. For whenever he says it was not possible
to conceive, how any speaker or writer could quote truly such
and such words, as (εἰς) from Moses or from Isaiah, when
the words quoted are not the words of Moses or Isaiah,
and do not express even the sense of Moses or Isaiah; but
are only taken from some version, which (upon the present
supposition) was no version at all in these instances, because
it did not agree here in sense with its original. The founda-
tion of this mistake, as this learned writer adds, is the notion
that has prevailed of the integrity of the modern Hebrew
text; for the writers who have held this to be per-
fekt, have never been able and never will be able to vindicate
the prophetical quotations. Passages quoted from the several
Jewish writers by inspired men must (he thinks) have been
quoted agreeably to the sense of the Hebrew text; but such
quotations do not agree in sense with the printed Hebrew
text. Therefore some alterations have happened, either in
the Greek text of the New Testament, or the Hebrew text
of the Old. Collins says that the Hebrew text has been
delivered down perfect, and therefore that the quotations
are either forged or falsified in the New Testament. To this
it is replied, that as it appears from a collation of the Greek
MSS. of the New Testament, that the words of the
quotations are not corrupted in the Greek text, so it ap-
ppears from a collation of the Hebrew MSS. that the
words have been corrupted in the Hebrew. And this is
an answer which should approve itself to all Christians. See
Kennicott's State of the Hebrew Text, vol. ii. p. 345-
347. &c.

Upon the whole we observe, that the writers of the New
Testament did not make it a constant rule to quote from the
Greek version, because there are many places where their
quotations differ from those where there is agreement with the Hebrew.
And as the quotations now agree with the Hebrew, fre-
cently in the express words, generally in the sense; so it
is most probable, that they always agreed at first, and that
where the Hebrew was expressed properly in the Greek
version, they used the words of that version; and where
the version was not proper, they translated for themselves.

With regard to Matt. ii. ult. the first of the passages
above cited, Dr. Doddridge (Fam. Expof. in loc.) observes,
that Nazareth was a little city on the confines of Zabulon
and Issachar; so contemptible among the Jews, that it
was a proverb among them. No good thing can be expected
from thence. Thus was fulfilled what was spoken in effect by
many of the prophets, "he shall be called a Nazarene;" i.e. he
shall
shall appear in mean and despicable circumstances, and be treated as the mark of public contempt and reproach. If this sense be not approved, Dr. Doddridge professes to acquiesce in Chryfotom's opinion, that the passage referred to is lost, avouching his dissatisfaction with other interpretations of this passage. The second passage, viz. John, vii. 38, our learned expositor thus explains. "He that believeth in me, as the scripture hath said, out of his belly shall flow rivers of living water, i. e. as the scripture has in many places said and promised, he shall receive those supplies in to great an abundance, that he shall not only be refreshed himself, but out of his belly, or from within him shall flow vital spirituals, and as it were rivers of living water for the refreshment and comfort of others." Chryfotom, and after him many other eminent writers, particularly Zegerus, and I. Capelius, refer the words "as the scripture hath said," to the former clause, and understand them, as if our Lord had said, "He that hath faith in me," which the scripture requires, and thus they avoid the difficulty, which arises from our not finding the following words in scripture. But Grotius, with whom Dr. Doddridge agrees, supposes, that here is a general reference to the several prophecies which refer to the effusion of the spirit by the Messiah, under the similitude of pouring out water. See Isaiah, lii. 15. xiv. 3. lviii. 11. Joel, ii. 28.

**QUOTIDIAN**, in Medicine, signifying literally daily, is applied to all interimmitting diseases, which return once in twenty-four hours. As the most remarkable of these is the ague, or intermittent fever of marshy countries; so the term quotidian signifies emphatically a quotidian ague. The paroxysm usually returns in the morning. See Ague.

**QUOTIDIAN, Double**, returns twice in twenty-four hours.

**QUOTIENT, Quotiens**, formed from the Latin quotiens, q. d. how often is such a number contained in such another, in Arithmetic, the number resulting from the division of a greater number by a smaller; and which shews how often the smaller is contained in the greater, or how oft the divisor is contained in the dividend.

In division, as the divisor is to the dividend, so is unity to the quotient. Thus the quotient of 12 divided by 3 is 4; which is thus disposed, 3) 12 (4 quotient.

**QUOVEDO**, in Geography, a town of Ifria; six miles E. of Capo d'Ifria.

**QUOUSQUE**: Execution with a Quousque. See Execution.

**QUOYL**: See Quoij.

---

**R.**

A liquid consonant, and the seventeenth letter of the alphabet.

The grammarians hold it a semi-vowel; especially in the Greek, where, in common with the other vowels, it admits an aspirate, &c. though whether the aspirate should be founded before or after it, is some doubt. We find instances of each.

Thus *dein* the Latins wrote *redetis*; and *inde* the *Ætolians* wrote *inden*; and in English words derived from the Greek it is followed by an *h*, as *rhapsody*. The ancient Goths, and Teutones, Littleton observes, always prefixed *b* to *r*. See H.

The sound is formed by a guttural extrusion of the breath, vibrated through the mouth, with a fort of quivering motion of the tongue drawn from the teeth, with the tip a little elevated towards the palate.

In some words, as *Rome*, rape, and river, it has a rough sound; in others, as *hard*, card, regard, its sound is smooth. *R* at the end of many words is pronounced like a mute *r*, as in *theater*, *sepulcher*, and *massacre*. *Rh* is used in words derived from the Greeks, as *myrrh*, *rhenum*, and *rhyme*.

The Hebrews allow the *r*, or *z*, the privilege of a guttural; that is, they never double it, which yet is done by the Arabs, Greeks, and Latins, &c.

Periuss calls the *r*, *litera canina*, because the dogs seem to pronounce it in snarling; yet it should seem to have had a foother found among the Romans than among us, by its being frequently interposed to prevent the clashing of vowels; as in *rurus*, in *nurus* from *nus*, *musurus* from *musurus*; and this softness was such as frequently occasioned its being dropt as useless in writing. Thus for *Heracles* they frequently wrote *Thbas*, and even *Thbas*; and for *jurium* *jurius*; *profrus* *profrus*; *sujum*, *sujus*, *profrus*.

In effect, there was that agreement between the sound of the *s* and *r*, that as the Romans avoided the doubling of their consonants, it was no wonder they here dropped the *r* in such words; the *s* supplying the place of both. Hence too it came to pass, that what they at first pronounced *afa*, *afena*, *casmen*, was afterwards *ara*, *arena*, *cornm*; and those words named *Psasu* and *Valesii*, were afterwards called *furii* and *Valerii*. Cicero tells us, the *Papirii* were first called *Papirii*; and even fixes the time when the change was made, viz. in the year of Rome 415. Feustas adds, that *olea*, *pignora*, *plurima*, were anciently written *olia*, *pignoja*, *plisma*.

From the same softness of the sound of the *r*, it came to be used indifferently with the *l* in many words; e. g. *Latioris* and *Lateilis*, *Palitha* and *Parilia*, &c.
