Though the *r* more frequently degenerated into *l* thus *remures* became changed into *lemures*; *interlego*, into *inlego* and *pellaco*; *frater* into *fratellus*, &c.; and the same is sometimes done between *n* and *r*, as *acrus*, and *ancus*, &c. In the notes of the ancients, *R.* or *RO* signified *Roma*; *R. C. Roma* civitas; *R. G. C. ret gerenda causa*; *R. F.* *vexa feuctum et diutum*; *R. G.* *regis filius*; *R. P.* *res publica* or *Romani principes*; and *R. R. R. F. F.* *res Romana non ferro*, *sane flamma*.

R was anciantly a numerul letter, signifying 80; according to the verse,

"O octoginta dabiti tibi R, siquis numerabit."
When a dash was added at top, as $\overline{R}$, it signified eighty thoufand.

The Greek $\gamma$, with a small mark over it, signified a hundred; with the fame mark under it, it denoted $1000 \times 100$; thus $\gamma$ signified $100,000$.

In the Hebrew numeration, $\gamma$ denoted 200; and with two horizontal points over it, $1000 \times 200$; thus $\gamma$ = 200,000.

R on the French coins, denotes their being struck at Orleans.

R, or R, in Medicinal Prescription, stands for recipes, tales.

RAA, in Geography, a town of Norway; 10 miles N.E. of Frederickfadt.

RAAB, Gy, or Javariti, a town and fortrefs of Hungary, situated in a pleafant level country, at the confluence of the Danube, the Raab, and Rabnitz, which furround it. Its houses are conftucted of stone, and their streets are large and bright. It is the fea of a bishop. Its fortifications conftitute feven bailions, and it has always a strong garrifon, provided with military fторes. The fortifications of the city and caftle are chiefly the works of the emperors Ferdinand I. and Maximilian II. In this place are feen some Roman antiquities; 56 miles S.E. of Vienna. N. lat. 47° 42'; E. long. 18° 45'.

RAAB, a river of Stiria, which rifes near mount Rettlein, and runs into the Danube, near Raab in Hungary.

RAAF, or RAFF, Anthony, in Biography, the moft exquisite and celebrated tenor singer of the last century, was born at Bonn in 1710. He was a scholar of Bernacchi, and equally admired for his talfe, expenditure, and style of finging, by the Italians and Germans. In 1729 his voice was fettled from a high treble to a fweet and ftrong tenor, sufficiently for him to perform a capital part in an opera at Naples. After finging in all the great cities of Italy, he returned to Germany, where he was courted and careful by all the princes of the empire. He was knighted by the elector of Bavaria, and appointed his chamber musician. In 1751 he performed again at Naples in Mettaltano's "Attilo Rigolo," with the Mingotti, and in the letters of Mettaltano of that period, we have the poet's opinion of his performance. (Men. of the Life and Writings of Mettaltano, vol. i. p. 403.) He performed in an opera composed by Chrifitian Bach at Mannheim in 1770, when the celebrated air "Non fo donde vieni" was in his part, and which was afterwards fungs on our opera stage with fuch effect by Cipriani. Raff was at Paris more than once; for in 1780, his 70th year, Laborde fungs of him with great regard. "This celebrated tenor has acquired great reputation, and though at prefent d'un certain age, he oblige us still to admire his talfe, and regret all that he has left." According to Gerber, Musical Lexicon, vol. ii. he fungs at Mannheim in 1783, and was living in 1792.

RAAGO, in Geography, a small island of Denmark, near the N. coast of the island of Lolland. N. lat. 54° 58'. E. long. 11° 14'.

RAAGAUR, a town of Hindooftan, in the county of Malwa, near the river Niommudge; 74 miles N.E. of Ouein. N. lat. 24° 21'. E. long. 76° 56'.

RAALBRANN, a town of Auffria; seven miles S.E. of Meiſau.

RAAN, a town of Auffria; four miles E.S.E. of Hooren.

RASAY, an island of the Hebrides, or Western Islands, Scotland, is situated between the main land and the Ifle of Skye, and is included within the parish of Portree and shire of Inverness. It is about fifteen miles in length, and from two to five in breadth. On all sides the caftle rises to a great height above the level of the fea; and on the caft side its afcent is peculiarly bold, and almost perpendicular. The interior is throughout its whole extent mountainous; and hence it better adapted for paffage than for tillage, but there are nevertheless several spots of very fertile and well cultivated land. The supply of free-tone is almost inexhaustible, and there is likewise plenty of lime-tone. Formerly there were in Raafay several ancient chapels, but these are now ruined and only used as places of burial. Here are likewise remains of two forts, the high which was fituated at the southern extremity of the ifland, and is called Dunn-Cam, as tradition records, from Camin, cousin to one of the ancient kings of Denmark. The other fort, called Callie-Brochin, is a well-known land-mark among sailors. The rock on which it is fituated is nearly round, covering an area of little more than seventy feet square; is forty feet high, except at the fpot where the fcarf leads up to it; and is fifty feet above the level of the fea at its base. The caftle is built of tone and lime, and seems to have been no lefs strongly fortified by art than by nature. It was anciently the chief seat of the lairds of Raafay. Now, however, the family residence is at Clachan, or Kirk-town, near the opposite extremity of the ifland. One of the old Highland alliances has continued for more than two hundred years, and is still fubfiding between Macleod of Raafay, and Macdonald of Skye, in confequence of which the survivor always inherits the arms of the deceafed; a natural memorial of military friendship. At the death of the late Sir James Macleod, his fword was delivered to James Macleod, esq., the prefent laird of Raafay. Dr. Johnston, in his Tour to the Hebrides, fpeaks in warm terms of the elegance and hospitality with which he was entertained by this truly respectable family. Carliſe's Topographical Dictionary of Scotland, 2 vols. 410. 1813. Pennant's Tour through Scotland, vol. ii.

RAASS, a town of the duchy of Stiria; five miles W. of Marburg.

RAASTORF, a town of Auffria; four miles N. of Entzertorff.

RAAT, a town of Hindooftan, in the county of Agra; 128 miles S.S.E. of Agra. N. lat. 25° 37'. E. long. 79° 58'.

RABAÇAL, a town of Portugal, in the province of Beira; 12 miles S. of Coimbra.

RABANUS, Maurus Magnentius, in Biography, a celebrated German prate in the ninth century, was born at Fulda in the year 785. He was educated partly at Fulda, and partly at Tours, under the famous Alcuin. In the latter situation he distinguished himself by an unwearying application to his studies, and his almost unequalled proficiency in all the learning of the times, both profane and sacred. Not long before the death of Alcuin he returned to Fulda, and embraced the religious profession in its abbey. In the year 810 he was placed at the head of a school belonging to the abbot Rattrarius, and the fame of his superior learning soon raised the seminary into great reputation, and filled it with pupils, many of whom were afterwards promoted to the highest ecclesiastical dignities, and proved the brightest ornaments of the age. In 815 he was ordained priest, and in 822 he was elected abbot of Fulda. About 830 he was, by his prudence and good conduct, the means of effecting a reconciliation between the emperor Lewis le Dechonnare and his foes. Shortly after this, Ebbo, archbishop of Rheims, who had been condemned for high treason, was committed to his custody. In 838, at the request of
of count Erldrid, he sent a colony of monks from Fulda, to occupy a monastery lately founded by him at Hirchau; and at the same time, in order that he might be enabled to pursue his studies with less interruption, he devolved upon another person the care of governing the abbey. In the following year the monks expelled him from his post, complaining, that in consequence of his devoting himself to his studies, the necessary affairs of the monastery were neglected, and its estates suffered to be much dilapidated. He now retired either to St. Peter's Mount, or, as others report, to an humble apartment in the outer court of the abbey, where he spent his time in devotion, the study of sacred literature, and the composition of his various writings, devoted to the repeated entreaties of the monks who exalted him to resume his authority. In 847 he was elected to the archbishopric of Mentz, and in the following year he summoned a council, in which he procured the condemnation of Godofchale, for maintaining the doctrine of St. Augustine respecting predestination and grace. Rabanus died in 856, at the age of 71. He is described by Dupin as "having excelled all his contemporaries in the learning of those times, in explaining the principles of the liberal arts and sciences, and the rules of grammar and rhetoric; in a readiness in collecting from the fathers of the church common places upon the sacred Scriptures; in allegorizing the historical parts of the Bible; in an exposition of the mystical reasons of the ceremonies; in a facility at turning prose into verse, and in the manner of reducing all common places in precepts and instructions." And Mohheim says "he is deservedly placed at the head of the Latin writers of this age; the force of his genius, the extent of his knowledge, and the multitude of productions that flowed from his pen, citherto to this distinguished rank, and render improper all comparison between him and his contemporaries." He was the great light of Germany and France, because from his fund of knowledge those nations derived principally their religious instructions. His writings were everywhere in the hands of the learned, and were held in so much veneration, that during four centuries, the most eminent Latin divines referred to them as authority in religious matters. His writings consist of Commentaries on the Scriptures; Homilies on the Epistles and Gospels; Scripture Allegories, and a great many theological and literary pieces. Of which the most considerable number were collected and published at Cologne in 1627, in six vols. folio. Some other pieces of this author, not to be found in that collection, may be found in Baluze's "Miscellanées," among Father Sirmond's publications, and in the eighth vol. of the Collect. Concil. Mohheim. Dupin.

RABASTENS, in Geography, a town of France, in the department of the Upper Pyrenees, and chief place of a canton, in the district of Tarbes; 10 miles N.N.E. of Tarbes. The place contains 7590, and the canton 7422 inhabitants, on a territory of 150 kilometres, in 25 communes.

Rabastens, or Rabastins, a town of France, in the department of the Tarn, and chief place of a canton, in the district of Gaillac; 21 miles S.S.W. of Alby. The place contains 6076, and the canton 8124 inhabitants, on a territory of 152½ kilometres, in five communes. The principal article of its trade is wine.

RABAT, a town of Africa, in the empire of Morocco, situated on the S. side of the river Sallee. Rabat had formerly, at intervals, a number of European factories; but the difficulty of navigating the river, the obstacles arising from the arbitrary power of the sovereign, and the disposition and prejudices of the Moors, have disgustet the Europeans. Nevertheless, Rabat is the most proper place for trade of any upon this coast, both for its vicinity to Europe, and the quantity of wool, leather, and wax, which it is capable of furnishing. From its central situation in the empire, it is also better adapted for the conveying the commodities imported to every part of the country; but a despotic government acknowledges no principle but the convenience of the moment; it commands, judges, and executes, without considering either cause or consequence. At Rabat, near the mouth of the river, are the ruins of a castle, built in the twelfth century by Jacob Almanzor, but entirely destroyed by the late emperor. The walls, which still remain, are near two miles round, and fortified by square towers. They enclose the castle, the town of Rabat, and a large space of ground where J. Almanzor built beautiful palaces, and laid out delightful gardens, watered by plentiful fountains, which he brought from the neighbouring springs. These walls, as well as the palace and the town, were built by Spanish slaves, whom he took prisoners in his first campaign. Within the same inclosure he also built a very large mosque, of which the ruins still remain. The roof was supported by 360 columns of rough marble. Near it was a handsome square tower, strongly built with stone, near 200 feet high, and called the tower of Hassan. From this tower might be had an extensive view over the sea, and ships may be discovered at a prodigious distance. This monument is in almost perfect preservation. There are some docks for building ships both at Salée and Rabat; but the difficulty of navigating the channel, and the probability that the sand will continue to accumulate, give ground for apprehending, that very soon, only vessels with oars will be able to enter the river. Chénier's Morocco, vol. i.

RABAT Affirmawan, a town of Peru, in Farilistan; 120 miles E. of Schiras.

RABAT Arood, a town of Peru, in the province of Kerman; 40 miles E. of Keluh.

RABAT el Cadu, a town of Peru, in the province of Kerman; 40 miles E. of Maltih.

RABAT Maalad, a town of Peru, in the province of Kerman; 60 miles N. of Kabi.

RABAT el Niffa, a town of Peru, in the province of Kerman; 60 miles N.E. of Maltih.

RABAT Shekarzian, a town of Peru, in the province of Chorasan; 260 miles N.E. of Iphahan.

RABATE, in Falconry. A hawk is sometimes said to rabate, when, by the motion of the hand of the bearer, the lure, call, &c. the leaves pursueth her prey, or quarry, and recovers the fitt.

RABATE, in Commerce. See REBATE.

RABBIA, in Ancient Geography, a town of Judea, which belonged to the tribe of Gad; situated upon the torrent of Jaba; it was besieged by Joab, after he had defeated the Ammonites. Here was seen the head of Og, king of Bashan, who alone remained of the race of giants. — Abo, a town of Paleline, in the tribe of Judah. See RABBAN.

RABBATH-AMMON, or PHILADELPHIA, a town of Asia, situated in the mountains of the southern part of Palestine; S.E. of Tiberias, and S. of Bethra.

RABBATH-VOAB, or AREOPOLIS, a town of Asia, situated at some distance to the east of the lake into which the river Jordan discharges itself.

RABBEN, in Geography, a small island in the gulf of Bothnia. N. lat. 63° 14'. E. long. 22° 14'.

RABBET, in Carpenter, is a deep groove or channel, cut in a piece of timber longitudinally, to receive the edge of a plank, or the ends of a number of planks, which are to be securely fastened in it. The depth of this channel
Thus over colleges, and a school, and it order have any equi-
acquired, whereas it used no and a denoted an. The word evidently appears to have been equivalent to the
term רַב, rab, among the Hebrews. Accordingly, he who is styled by Daniel, in the above cited passage, רַבְכָּה, is, in the name man-
ner, level with the side of the keel at the extremities of the vei\emis.

RABBET-Plane. See Plane.

RABBETING, the planing or cutting of channels, or
grooves, in boards.

RABBI, or RABBIN, a doctor of the Jewish law.
The word in its original, רַב, signifies master.
The words rabbi and rabbain have the same signification; yet
is there some difference in their use. When we speak abso-
lutely, and without applying the term to any proper name, we
say rabbain, not rabbi. Thus we say, it would be unjust to
attribute to the ancient rabbains all the notions of the modern
ones.

On the other hand, when we prefix the term to the proper
name of some Jewish doctor, we say rabbi, not rabbain; rabbi Salomon Jarchi is of this opinion.

Yet rabbi having no plural, we say, the rabbins Juda
Chiog, and Juda ben Chabin, are the authors of two ancient
Hebrew grammas.
The title rabbi is said to have been first assumed, as a
distinguishing title of honour, by men of learning, about
the time of the birth of Christ; though it had been anciently
given to several magistrates and officers of state, and to those
who were of superior rank and condition in life. See Esther,
The first Jewish rabbi said to have been distinguished with
any title of honour, was Simeon, the son of Hillel, who
succeeded his father as president of the faneredom; and his
title was that of rabbain. The later rabbins tell us, that this
title was conferred with much ceremony. When a person
had gone through the schools, and was thought worthy of
this degree, he was placed in a chair raised above the com-
pany; and then were delivered to him a key and a table-
book; the key as a symbol of the authority conferred on
him to communicate the knowledge he had acquired, which
key he wore as a badge of honour, and when he died, it
was buried with him; and the table-book was a symbol of
his diligence in his studies, and desire of farther improvement.
To these ceremonies were added the imposition of bands by
the delegates of the faneredom, and the proclamation of his
title. It has been disputed, chiefly between Vitringa and
Selden, whether our Lord had taken the degree and title of
rabbi in the Jewish schools; Vitringa maintains the affirmative,
and Selden the negative. See Jennings’s Jewish Ant. vol. i.
400. 8c.
The Jewish writers distinguish betwixt the titles rab, rabbi,
and rabbain.

In the Old Testament we find the term רַב, rab, in com-
position with some other words, employed as a name of
office and dignity, but not till the people became acquainted
with the Chaldeans, concerning whom only it is used. The
word, both in Hebrew and in Chaldee, signifies sometimes
great, sometimes many, and when used flippantly, denotes
one who is at the head of any businesses, of whatever kind it
be. Thus רַבְכָּה רַבְכָּה, rab butchkel, is, in the LXX, ἰερόπο-
κράτος ἱερόποκράτος, rab tecbchim, εἰς τὸν ἱερόποκράτος, chief cook. (Jonah, i. 6.
Jer. xxxix. 11, see also Dan. i. 3.) It is used in the plural
also for chief men in general, superintendents, or those at the
head of affairs. Thus רַבְכָּה רַבְכָּה, rab hamnuteb, are
the chief men employed by the king over the different de-
partments of the state. (Jer. xxxix. 13.) The original term
futs entirely the import of the Latin word princeps, but
not of the English word prince, at least in its most common ac-
cception; for they are not the king’s sons, or nobles of
any order, who are so denominated among the Chaldeans.
The word evidently appears to have been equivalent to the
term רַב, rab, among the Hebrews. Accordingly, he
who is styled by Daniel, in the above cited passage, רַבְכָּה, is, in the name man-
ner, level with the side of the keel at the extremities of the vei\emis.

Again, the word rab is sometimes found in that version,
combined not with the title of any fort of officer, but with
a term denoting the office or charge itself; in which case it
always means the person who is principally entrusted with
the business. Thus, rabbeith (Matt. xx. 8.) is the steward,
who is over the housefciid; and rab-congobetha (Mark, v. 35.)
is the ruler of the synagogue, εἰς τὸν ἱερόποκράτος. It is not unlikely, though no example occurs in scripture,
that the term has at first been similarly compounded with
some word signifying a school, or, perhaps, with the
name of the art or science taught, in order to denote the
overseer of such a seminary, or the teacher of such an art.
When the term rab came to be peculiarly applied, as an
honourable compellation of the learned, the word with
which it was, at first, for distinction’s sake, compounded,
would be superceded as unnecesary. It is, at least, certain,
that the Jewish doctors, who resided at Babylon about the
time of our Saviour, were called simply rab. But in the
Old Testament there is no trace of such a title as rab,
rabbi, or rabbain, given to a man of letters; nor is any one
of the old prophets, or scribes, or indeed any other peron,
distinguished by this mark of respect prefixed to his name.
Although the introduction of titles is always occasioned by
the creation of useful important offices, it is commonly in
the decline of merit that pompous titles are most affected.
At first, without doubt, vain-glory has led many to assume
them, to whom they did not belong, in right of office, and
an interested adulation has induced others to give them.
Some of them, however, came soon, among the Jews, to be
converted into a kind of academical distinctions, which, in
order to give them more weight, are said to have been con-
ferred solemnly in their schools or colleges, accompanied
with certain religious ceremonies. From this practice
sprung literary degrees in Christian universities, to which
there is nothing similar in all Pagan antiquity, either Greek
or Roman, but to which the Jewish custom above-mentioned
bears an evident and close analogy.

As for rab and rabbai, the only difference, it hath been
said, betwixt them is, that rab was the title of such as had
had their education, and taken their degree in some foreign
school, e. g. at Babylon; whereas rabbain was the title of such
as were educated in the land of Judea, and more honourable
than the other. But the highest and most honourable
title was rabbain; which they, say, was never conferred
on more than four persons; viz. on R. Simeon, one of
his
his descendants, and R. Jochanan, who was of a different family.

Those who belonged to the Jewish schools were divided into three classes or orders. The lowest was that of the disciples or learners; the second, that of the fellows, or companions, who, having made considerable progress in learning, were occasionally employed by the masters in teaching the young students; and the highest was that of the preceptors, or teachers, to whom they appropriated the respectful title of doctor, or rabbi, differing, as some have said, from rab only by the addition of the affix pronoun of the first person. This title rabbi was the highest academical honour. In the gospels, ἀναφέρεται is given as the Greek translation of the Syriac rabbi. (John, i. 38.) Yet this word does not, as the Greek, literally signify teacher; but, having been conferred at first, as a mark of respect on actual teachers, and afterwards on other learned men, was justly accounted as apposite a version as the Greek language afforded.

In process of time, the term rabbi was used with great latitude; being bestowed on those who were not actual teachers; and yet it always retained, ever since it had been appropriated to the learned, a relation to learning, and denoted that the person who enjoyed it, though not actually employed in teaching, was well qualified for the office. Rabban, as some have alleged, is not the name of a degree superior to rabbi, though it seems intended for heightening the signification, and may be understood to denote eminent or learned rabbi, but it was very seldom used. The title rabbanon, which we find to have been twice given to our Lord, (Mark, x. 51, John, xx. 16.) is rabban, with the addition of the affix of the first person, and accommodated to the pronunciation of Judea. The use of the term rabban does not seem to have extended far beyond Palestine, as we may conclude from the following circumstance. Although the word rabbi is very common in the Syriac translation, the Greek ἀναφέρεται being generally so rendered; yet in the only place where that translator introduces the word rabbanon, which is that quoted from John, where prefaces in Hebrew, that is, in the dialect of Palestine, which was then so called, adding the explanation given by the evangelist, that is, teacher; which plainly shows that the word rabbanon was not Syriac. This is the more remarkable, as in the other passage, where the historian interprets, in the same manner, the word rabbi, adding (John, i. 38.) "αὐτοὶ ἀναφέρεται σπουδοῦντες," that interpreter omits this explanatory clause as intended only for the Greek reader, and of no use to those who understand Syriac. In the passage in Mark, where rabbanon occurs, as the evangelist had added no explanation, his interpreter has not thought it necessary to change their own word rabbi; thus regarding the difference in signification between the two words as unimportant, to which we may add, that the apostle John explains both by the same Greek word. It may be here observed that it was customary to enhance the import of a title by doubling it. Thus our Lord, speaking of the Pharisees, says, (Matt. xxii. 7.) "they love to be called of men, rabbi, rabbi." In this manner he was himself addressed by Jews, at the time when that disciple chose to assume the appearance of more than ordinary regard. (Mark, xiv. 45.) The title rabbanon seems to have been used in the same manner. (Matt. vii. 21.) The words Jewish rabbi and Jewish doctor were commonly used synonymously. In Justin Martyr's dialogue with Trypho the Jew, the rabbies are always called ήλεγχοι. But some may object that this does not account for the application of the title to our Lord, as he did not derive his doctrine from any of those learned sennaries, frequented by men of the youth as were reckoned

the flower of the nation, the name doctor could not, with propriety, be applied to him. To this objection it may be replied, that as in Judea at that time they spoke not Greek, but a dialect of Chaldee, not differing considerably from that which is called Syriac, it is evident that the actual composition by which our Saviour was addressed, was rabbi, equivalent to the Greek ἀναφέρεται. Besides, though the title rabbi could regularly be conferred only by those who had the superintendency of their schools, yet the people would be disposed to give the composition through courtesy, and on the presumption that it had been conferred, wherever they saw or supposed distinguished abilities in teaching; and this probably was the reason why it was given to John the Baptist. (John, iii. 26.) Moreover, in the Jewish state, a divine commission was conceived to confer all sorts of dignities and honours, in an eminent manner, and thus superceded all ordinary rules and human distinctions. Accordingly, some of those who gave the title of rabbi to our Saviour, were willing, either sincerely or pretentiously, thus to account for their doing so. Thus Nicodemus affirms the reason why he saluted him rabbi (John, iii. 1. &c.), although he knew that he had not been educated in human literature, and had not received from man any literary honours. Upon the whole we may remark, that the term ἀναφέρεται may be fitly expressed, either by the English term doctor, or by the Syriac rabbi, which is now so much naturalized among us, that its meaning, as a Jewish title of literary honour, can hardly be mistaken. It must also be allowed, that the rabbi among the Jews of our Saviour's age, was a title in the highest degree respectful; and on that account it was interdicted by their master, even to the apostles themselves. Campbell's Seventh Preliminary Dissertation.

The modern rabbins are entitled to a considerable respect among the Jews: they have the first places in the synagogues; they determine all matters and controversies of religion, and very frequently pronounce upon civil affairs. They have even a power to excommunicate the disobedient.

They retain a vall number of superfluous traditions, from the writings of their predecessors; which they observe as scrupulously as they do the law of Moses.

The ancient rabbins were infinite dealers in allegories. Their writings are almost wholly allegorical, particularly their comments and interpretations of the scripture.

They had a great number of rules, and forms of interpreting and quoting, which some modern writers suppose to have been followed by the apostles, in their interpretation and quotation of the prophecies of the Old Testament, in the New. See Quotation.

Rabbinical Character. See Hebrew.

Rabbinical Hebrew. See Hebrew.

Rabbinist, a follower of the doctrine of the rabbis; a term used in contradistinction to Carait.

Father Simon contends for Rabbanis, or Rabbanites, instead of Rabbanis; in effect, the former readings are apparently preferable to the latter; the word being derived from the Hebrew Rabbanim, which is the name of the sect, and which the Jews use to distinguish their doctors from those of the Carait Jews.

Rabbinis, then, signifies a Jewish doctor who adheres to the traditions of his fathers; not simply a rabbin or doctor; for the Caraites, who oppose those traditions, have their rabbins as well as the other Jews.

Rabbit, Cuniculus, in Zoology, a well-known animal of the bare kind, or the lepus cuniculus of Linnaeus, with a short tail and naked ears. In the wild state the colour of the fur is brown; but in a tame state it varies to a black, pied,
pied, and quite white: the eyes are of a fine red. In their wild state they inhabit the temperate and hot parts of Europe, and the hottest parts of Asia and Africa. See *Lepus Cuniculus*.

The female, or doe rabbit, goes with young thirty days, and then the kindles; and if the doe not buck presently the lobs her month, or at least a fortnight, and often kills her young and eats them.

In England they begin to breed at a year old, but in some places much sooner; and they continue breeding very early in the year, from four to eight in a litter, and hence it is that a small number at first will soon flock a whole warren, if left to breed a little while undisturbed. The does cannot fickle their young till they have been at buck again; this therefore is not done prestantly, else there is a fortnight lost of the time for the next brood, and the present brood also probably lost. When the buck goes to the doe, he always first boats and flamps very hard with his feet, and when he has copulated with her, he falls backwards, and lies, as it were, in a trance; in this state it is easy to take him, but he soon recovers from it.

The buck-rabbits, like our boar-cats, will kill the young ones, if they can get at them; and the does in the warrens prevent this, by covering their licks, or nests, with gravel or earth, which they close so artifically up with the hind part of their bodies, that it is hard to find them out. They never fickle the young ones at any other time than early in the morning, and late at night; and always, for eight or ten days, close up the hole at the mouth of the nest, in this careful manner, when they go out. After this they begin to leave a small opening, which they increase by degrees, till it is large, when they are about three weeks old, the mouth of the hole is left wholly open, that they may go out; for they are at that time grown big enough to take care of themselves, and to feed on grafs.

People who keep rabbits tame for profit, breed them in hutches; but these must be kept very neat and clean, else they will be always subject to diseases. Care must be taken also to keep the bucks and does apart till the latter have just kindled; then they are to be turned to the bucks again, and to remain with them till they foon and run from them.

The general direction for the chooing of tame rabbits is, to pick the largest and fairest; but the breeder should remember, that the skins of the silver-haired ones fell better than any other. The food of the tame rabbits may be celer-roots and cabbage-leaves, carrots, parsneps, apple-rinds, green corn, and vetches, in the time of the year; also vine-leaves, grats, fruits, oats, and oatmeal, milk-thistles, four-thistles, and the like; but with these moist foods they must always have a proportionable quantity of the dry foods, as hay, bread, oats, bran, and the like, otherwise they will grow pot-bellied, and die. Bran and grains mixed together have been also found to be very good food. In winter they will eat hay, oats, and chaff; and these may be given three times a day: but when they eat green things, it must be observed, that they are not to drink at all, for it would throw them into a droopy. At all other times, a very little drink serves their turn, but that must always be fresh. When any green herbs or grafs are cut for their food, care must be taken that there is no hemlock among it; for though they will eat this greedily among other things, when offered to them, yet it is hidden poison to them.

Rabbits are subject to two principal infirmities. First, the rot, which is caused by the giving them too large a quantity of greens, or from the giving them fresh gathered, with the dew or rain hanging in drops upon them. It is excess of moisture that always causes this disease; the greens, therefore, are always to be given dry, and a sufficient quantity of hay, or other dry food, intermixed with them, to take up the abundant moisture of their juices.

On this account, the very best food that can be given them is dry hay and fresh thistle that can be got, of which one flack will serve two hundred couples a year; and out of this flock of two hundred, two hundred may be eaten in the family, two hundred fold to the markets, and a sufficient number kept in cage of accidents.

The other general disease of these creatures is a sort of madness: this may be known by their wallowing and tumbling about with their heels upwards, and hopping in an odd manner into their boxes. This ditemper is suppos'd to be owing to the rankneas of their feeding; and the general cure is the keeping them low, and giving them the prickly herb, called turf-thistles, to eat.

The general computation of males and females is, that one buck rabbit will serve for nine does; some allow ten to one buck: but those who go beyond this always suffer for it in their breed.

The wild rabbits are to be taken either by small cur dogs, or by spaniels bred up to the sport; and the places of hunting those who escape from their burrows are under clofe hedges or bushes, or among corn-fields and fresh pastures. The owners use to confine them with small grey-hounds; and though they are seldom killed this way, yet they are driven back to their burrows, and are prevented from being a prey to others. The common method of taking them is by nets, called purse-nets, and ferrets. The ferret is sent into the hole to force them out, and the purs-net being spread over the hole, takes them as they come out. The ferret's mouth must be muffled, and then the rabbit gets no harm. For the more certain taking of them, it may not be improper to pitch up a hay-net or two, at a small distance from the burrows that are intended to be hunted: thus very few of the number that are attempted will escape. The method by the dog, called the lurcher and the huffer, is also a very good one; and more.

Some, who have no ferrets, smock the rabbits out of their holes with burning brimstone and opium. This certainly brings them out into the nets, but then it is a very troublesome and offensive method, and is very detrimental to the place, as no rabbit will for a long time afterwards come near the burrows, which have been fumigated with these stinking ingredients.

The tefticles of a rabbit is a very good object for examining the structure of this part of generation in animals. The tefticles of various animals are very variously composed, but all, in general, of vesels variously rolled and folded together; and even the human tefticles are of the fame fort, being composed solely of rolls of vesels, without any intermediate substance, only confiting of vesels and their liquors. Phil. Trans. Ns 52.

The skins of rabbits are a great article of commerce, numbers being exported to China: the fur is of great use in the hat-manufactory.

*Rabbit*, in *Agriculture*, is sometimes employed as farming flock. It is sufficiently evident, however, that this is a description of farming flock that can only be attended to with advantage under particular favourable circumstances of soil and situation.

*Situation proper for Rabbits.—*The practice of forming rabbit warrens, can only be beneficially introduced where the lands are not capable of affording crops of tolerable grain or grafs. The great uncertainty of this sort of husband
hubbard renders it much more advantageous for the farmer to depend upon such crops, than on it. In hilly tracts of land, where the plough cannot be introduced, and where the soil is of such a light sandy porous nature, as to afford little or no grases for the paturage of sheep, or in rocky situations, this system of management may take place with profit to the farmer. And it has been observed by the author of the Rural Economy of Norfolk, that this sort of animal is there confined to the heaths, and the barren hills upon the coast. A level country is unfit for rabbit-warrens, but convenient for the plough; on the contrary, rabbits delight in the sides of sandy hills; which, where turn-wriff ploughs are not in use, are extremely inconvenient for tillage; and, when cultivated, are generally unproductive. For the rabbit, on level ground, finds it difficult to make its burrow; the excavated mould is all to be dragged upward to the surface; hence, a piece of ground altogether level, can seldom be stocked successively with rabbits; unless it be first laid up by art, at a great expense, into inequalities. While, on the contrary, against the side of a steep hill, the rabbit has no difficulty to encounter; the declivity affords him a ready vent for his mould; his work is all down hill; and, unless the soil be too stubborn, or too rocky, for the rabbits to work freely among, a broken hilly country may generally be stocked with advantage; provided a tolerable market for the carcasses can be had within reach. He thinks there are, perhaps, few sandy or other loose-foiled hills, which would not pay better in rabbit-warrens, than under any other course of husbandry that could be introduced on them. And it is afterwards flatted, in a minute, that on a considerable part of a farm which lies towards the coast, being hilly and very badly foiled,—more especially the tops and sides of the hills, which have always been full of rabbits in spite of all endeavours to destroy them,—the tenants last year (1782) applied for leave to convert this part, about ninety acres, into a rabbit-warren. Leave was given, and an allowance made them of half the estimated expense of raising a fold-wall fence round these ninety acres. He adds, that the fence was nearly finished, and the warren had, that year, turned beyond expectation; it was valued by one who ought to be the best judge of its worth, at forty pounds a year; which is nine shillings an acre. And that, as the part of a farm, these ninety acres were not worth five shillings an acre; at the then present price of barley, they were not worth more than four shillings an acre. It is, therefore, observed, that for ten pounds a real improvement of twenty pounds a year has been made and secured; for the warrenier will, through necessity, hereafter keep the fence in repair for his own advantage. He remarks, that the fence is made about four feet high, and three feet thick; faced with green-ward; and capped with furze, so as to project eight or ten inches over the face. Some of it was done for a shilling a rod; but the spring putting in, fourteen or fifteen pence a rod of seven yards was obliged to be given. And a neighbouring warrenier, that winter, gave nippers for the wall without the capping; which he does not mean to put on till the wall be thoroughly settled. This is very judicious; as several rods of that above-mentioned shot down in different places, as is often the case in such fort of work. It is further observed, that there are several patches in the valleys, and some on the tops of the hills which have usually been tilted. Some of these were last year (1781), and some of them ought to be every year, cultivated for the rabbits; thus, when the grases gets foul or mossy it should be ploughed up; fallowed, lowing turnip-feed for present feed, (they will not let rape get up,) and to prepare the foils for barley and grases-feed the ensuing year. Thus a regular succession of feedage might be kept up for the use of these animals. And in the Rural Economy of Yorkshire it is stated, that at Dalby there are two pretty large warrens. At Lockton there is one now (the time of writing) planting. And there are other parts of these heights which might be profitably stocked with rabbits. In general, however, property is too much intermixed to admit of an improvement, which isingularly adapted to the nature of these high grounds. And, that in situations where the ground, as well as the soil, is suitable to rabbit-warrens, and where an extent of it, sufficiently large, can be collected together in one property, there is a very strong reason why it may be profitably stocked with rabbits. It is added, that one of the warrens of this district contains eighteen hundred acres of surface; most of it covered with a black moorland soil; part of it a barren gravel; some little of it a thin lime-stone loam; not worth perhaps, on a par, for the common purposes of husbandry, a shilling an acre; nevertheless, these eighteen hundred acres are let, as a rabbit-warren, for three hundred pounds a year! He will not pretend to say, that this warren is worth three hundred pounds a year, nor affirm that it is not worth a shilling an acre to a husbandman. If it be worth two hundred and fifty pounds, as a warren, and supposing it to be worth even two shillings an acre, as a farm, it still is sufficient evidence of the profitableness of rabbit-warrens, in proper situations.

And in speaking of the wolds, he observes, that the warrens are numerous, and some of them very extensive. Coldham warren is at present, he believes, the largest upon the wolds; and, probably, the most valuable warren in the island. The Coldham farm contains about nineteen hundred acres; and, speaking generally, it is all warren; not, however, wholly appropriated to rabbits, a flock of from fix to eight hundred sheep being kept within the warren walls; principally, however, on one side of the warren, away from the burrowing grounds. And this appears to be a practice peculiar to the wolds of Yorkshire and Lincolnshire, whose hills likewise abound much with rabbit-warrens, and where better foil is appropriated to rabbit-warrens, than is perhaps in any other part of the island. The Coldham warren, in point of foil, is most of it worth from ten to twelve shillings an acre; some of it fifteen or sixteen shillings. But the present bleakness of the situation renders it of little more than half the value. As these better parts become mofly, they are inclosed by a fold-wall, the surface pared and burnt, and the foil broken up for arable crops. Having afforded a succession of crops of corn, turnips, &c. they are fown with grases-feeds, and again thrown open to the rabbits and sheep.

In 1783, there were about two hundred acres of this farm under the plough, besides some little sheep-walk which lay without the warren walls. The warren therefore, at that time, contained from fifteen to sixteen hundred acres; and, adjoining to Coldham, are two more considerable warrens; so that there are, perhaps, three or four thousand acres of tolerably good land, lying together, and appropriated principally to rabbits.

But it is remarked in respect to foil, that there is a disadvantage in stocking a rich foil with rabbits; a flux of grases, after a dry seasaon, is found to produce a fouling; which sometimes carries off great numbers. With regard to the burrows on the high wolds, they are mostly on the sides of hills; at Coldham, principally in one deep valley; whole sides are steep; giving the rabbits great freedom in working. The foil, in this case, is about eight or ten inches deep, under this a chalky rubble, of some inches thick, lying on a chalk-stone rock. The burrows are in the sub-foil.
RABBIT.

between the soil and the rock, and chiefly towards the tops of the hills. And thousands of days build their nests in the burrows, to the great annoyance of the rabbits. But at Drifflefield, near Driffle, where there are two large warrens, the surface is a dead flat; nevertheless, the warrens are well stocked and productive; a proof that a flat surface may, in some cases, be profitably stocked with rabbits. The soil, in that case, is a light sand or gravelly loam, which is very proper for the purpose to which it is applied.

In some of the richest districts, rabbits occupy the different sandy hills, and many of the rocky wales; but there is nothing of any great importance in the management of them. Both the grey and black forts prevail in some instances. The writer of the Sussex Report on Agriculture thinks, that this fort of rock is the nuisance of a county; it increases and flourishes in proportion to the size of the wales, and is, of course, productive in this country. From Horsham forest, Ahebown, and other parts, very considerable quantities of rabbits are sent to be disposed of in London.

In some of the midland counties they are found to be sufficiently abundant upon the sandy parts of wale lands; in inclosed level land, it is thought that they are no better than vermin, and that should the commons be properly generally inclosed, they must be in a great measure exterminated to make way for a better fort of rock; in inclosed land, they can only be kept with propriety, either in small warrens near the house, well fenced in, for family consumption; or on sandy or rocky precipices, impracticable to the plough, where they should also be fenced in. It is well known, that in the neighbourhood of commons abounding with them, great pains and expense are often used to fence the inclosed adjoining lands from their depredations. Rabbits are certainly a fort of rock unworthy of being cultivated, or bred in any considerable numbers, on inclosed and cultivated land; yet doubtless defering considerable attention on impracticable sandy or rocky reefs, which may at the same time be planted; and when properly fenced in, and thus stocked, such land seems in a fully of the highest improvement of which it is capable.

In Cheshire many doubts have been entertained as to the advantages of encouraging the breed of rabbits, and many farmers are so utterly averse to them, that they would with the whole race to be entirely exterminated. Where land is inclosed, and applied to arable purposes, it seems agreed that by the injury they do to the fences, by the interfering with the cultivated land, and by the destroying of its produce, they are much more detrimental than profitable. It is, however, thought to be a question for consideration, whether, if a portion of weak land, or dry heath land, was set apart for a rabbit-warren, well fenced, and kept difficult for this purpose; it might not, in some situations, be more profitably employed in this than in any other manner.

By fome it is supposed, that it may be occasionally necessary to refrain them, on account of their alluring succulence; but that to attempt to exterminate them, if it were possible, could not be polite or advisable, as they furnish food for foxes, which would otherwise prey on game and poultry.

This fort of rock is frequently met with in many other districts on tracts and spots of similar kinds of barren and uncultivable forts of land, and is probably the most convenient, appropriate, and beneficial description of any by which they can possibly be occupied and managed.

Stocking.—In the second of the above districts, it is stated, that in focking a warren, whether the surface be flat or hilly, artificial burrows are made, to reconcile the rabbits to the ground, and to preferve them from vermin, until they have time to make their own burrows. And that in making these burrows, an improvement has lately, it is observed, been hit upon. They are bored with an auger, of a diameter large enough to make a burrow of a sufficient width. In a level warren, these augers may, from time to time, be found useful in forming such holes. They, however, in most cases, are capable of making burrows for themselves without any difficulty.

But in regard to focking in Lincolnshire, according to the agricultural survey of that district, some of the warren lands are focked in the proportion of three couple only to the acre; while in others, it is in a considerably larger proportion. And one buck or male rabbit is said to be there sufficient for one hundred does, or females; but this is certainly a much larger proportion of the latter forts, than is allowed in most other districts. On the bold warrens of Yorkshire, according to Mr. Marshall, one male is considered as sufficient for only five or seven females. In the other cases, the nearer they can be brought to that proportion, the greater the flock of young ones that may be expected, it being the nature or economy of the males to destroy their young, especially when the proportional number is too great.

Fencing.—The fencing in these situations is not well enough camed with furze, or of late with fluff straw, forming a kind of thatch. And it is supposed, that reed would be found admirable in this intention. The warrens near Driffield are fenced with paling; an expensive fence in the out-let, and always under repairs. A brook, though ever so deep, is found to be insufficient as a fence against rabbits; one side of Drifflefield warren is bounded by a brook but it is nevertheless fenced with paling. When the rabbits can evade this, they readily swim the brook. The necessity of good fences is of course sufficiently evident in this view, as well as that of preventing them from the destruction of vermin, and birds of prey, such as eagles, kites, &c. which are taken in feel traps, placed on elevated mounds of earth, where they delight to sit. It is this kind of fencing and coping, or kidding the top, together with food in winter, nets, traps, and other things for taking them, with charcoal for drying the skins, warrens' men for killing and carrying, horses for carrying them to market, &c. which constitute the great expence of this fort of management.

Different Breeds.—There are many different breeds or varieties of these animals, but those that are employed as flocks for warrens are the common grey and silver-grey breeds: the former of which is found to be considerably more hardy and much better for the purposes of food; but the latter has greatly the advantage in the value of the skin. In the above warrens, till lately the common grey rabbit, probably the native wild rabbit of the island, was the only species. At present, the silver-haired rabbit is found the better, and has, within the few last years, been introduced into most warrens. The skin of the grey rabbit is cut; that is, the wool is pared off the pelt, as a material of hats; whereas, that of the silver-haired rabbit is dressed as fur; which, the writer understands, goes principally to the East Indies. The colour is a black ground, thickly interlaced with white hair. The skins of this variety fall for about a shilling a dozen more than those of the common fort; a sufficient inducement for propagating it in preference to the grey fort in most cases. If the white forts could be introduced they might be still more valuable.

Management, Expenses, Profits, &c.—This is a fort of flock that on the whole only requires a slight attention; it is, however, necessary to supply the rabbits with additional food in the winter season, when the weather is severe, such
and was much more productive than old warren land is found to be, as they breed much better on such new than on old land. Used to kill about 2000 couple; flock left about 700 couple. Sod banks that colt, thirty-five years ago, 11. 2d. a rood of seven yards, would now cost 2s.; furze faggots were 7s. a hundred, that is, 5s. for the furze, and 2s. kidning, now doubled. Banks will last about seven years, in a middling way; from three to twenty: want facing once in seven years, at half the first expense; want capping in three years with the furze. Laying on, or capping, 3d. a rood now. It was then reckoned that 250 acres would clear 300l., besides rent, which then was 1s. an acre. Fencing annually half a mile 800 yards 133 roods at 1s., 6l. 15s.; for facing furze, a kid will do a yard; 2s. 5d. killing, at a kid a yard, 4400 yards and kidds, at 15s. now, for 120 or 27l. 10s., or per annum 9l. 3s. 4d. add 6l. 15s., it is 15l. 16s. 4d. per annum. A warrener 33l., a cow, fuel, and house: in all 40l. Extra labour, killing 18s. a-week for sixteen weeks, 13l. 8s. Also for a month 18s. a-week, 3l. 12s.: in all 18l. Befides nets and thread, 12 at 60s. yards each; last fit or seven years; would cost 1l. 11s. 6d. Traps 5s. a-year. The men who kill will carry. Four horfes for six weeks, 1l. 4s. a-week, 7l. 4s. Charcoal for drying skins, 5s. A perfon to order skins, that is, clear from fat, and drying, five weeks; a useful woman will do it, 1l. Winter food (after three days now they must be ferved) cannot be less than 10l. a year on 250 acres.

RABBIT.

such as fine green hay, fainfain, clover, turnips, and others of the fame fort, which must be distributed over the warrens. It is fuppofed that turnips anfwer the beat in deep fnows, as the rabbits can difcover them by the fcent. This fort of food is given in the quantity of two or three large cartfuls to a thousand couple per day, and one load of hay in the fame time during a ftoam. It is likewife fometimes the practice to diftribute billets of new cut alth-boughs, gorfce or whins, and other fimilar woods in the warrens, the bark and other parts of which is eaten, by which the proportion of hay is leffened in a confiderable degree. In great fnows, it is neceffary to clear them away from the ditches or fences, to prevent the rabbits from getting over them.

It may be obferved, that the rabbit is a fort of flock that begins to breed at an early age, as at eight, ten, or twelve months, going only about thirty days with young, the young being a little more than three weeks old before they appear from the burrows, during which time they are fuccked twice in the day by the mother. It is therefore evident, that they may breed three or four times in the course of the year under good keep, as the does take buck almoft immediately after producing their young. In warrens that are inclofed, it is however faid, that they feldom breed more than two or three times in the year. The annual produce per acre, is moftly estimated at from three or four, to eight or ten couple, yielding a profit of from eight, ten, or even fifteen fhillings, where they are conducted under a good fystem of management. And the produce is, as has been feen, the largeft on new lands; however, much of the profit muft always depend on situation, fo 2s. to be near good markets.

These animals are in what is termed feanfom from the end of October to the beginning of January, in which period the fett skins are produced; of course a large proportion of them is killed in this short time. The farmer often fustains great lofs in what by the purchasers are called half skins, quarter skins, and rachis, fixteenth of which are only confidered as a whole skin. The rabbits are difpofed of by the hundred, fix fcore couple being confidered as an hundred.

The following ftatements are given in the Agricultural Survey of Lincolnshire, on this fort of management. On the authority of Mr. Chaplin, it is fated that on 1000 acres it is fair to kill 2000 couple, which are fold by the hundred, as above; which have fold at 10l. an average of ten years; last year 13l.; killing and looking after, 60l. for 1000 acres. And on the warrens between Gayton and Tathwell, sliver skins have been from 15s. even to 21s. a dozen; but the common grey rabbit is fo much hardier, that if a warren be focked with both, there will, in a few years, be nothing but greys. It is added, that from Louth to Caflor, 18 miles, 10 of them are warrens, chiefly fivers; rent 2s. to 3s. an acre. They plough a part every year for corn and turnips; and laying down again with feed, let down the fences for the rabbits to enter. Warrens are reckoned profitable, fo that some fortunes have been made on them. It is further fated, that in point of skins, tho' bred about May-day undergo no change from their white colour, but from a white rack become a whole skin; bred at Lady-day, become black; in June, white; in July, black; in November, white again: then in full feanfom, as the carcafses are alfo. The skins ought to have those colours on the inftide, whenfyed, or stripped off from the rabbits. The writer further fates, that from 250 acres of land, that were fainfain worn out, and planted with rabbits, the following was the account many years ago; but all prices, rent, &c. &c. are calculated at the present rates; and it is to be noted, that the ground being thus new to rabbits

But it is, notwithstanding this ftatement, fuggefled, that if he had a warren of his own, he would plough it up for corn, &c.; thinking tillage now more profitable than rabbits. And the author adds, that at Partney fair, meeting with Mr. Grant of Withgal, and discourseing with him upon warrens, he informed him that a common flock in winter was three couple per acre, and the produce five or fix couple
RABBIT.

That killing, carrying, &c. might amount to something more than 1s. an acre: the best silver furs, which will not do well in other counties, where they have been tried. He has now 1000 acres of warrens; and upon 1000 acres the flock is 2600, and kill 5000 couple annually.

New land is the most productive. On such a warren, the rabbits must have two loads of hay a day in a form, or two or three large waggon loads a day of turnips. The warren has 20l. a-year, and two cows; the killers 8s. or 9s. a-week, and board for ten weeks.

Silver skins now are 10s. a dozen; have been 14s. to 15s. Fences 60 a-year; no crops ones; no buildings. The immense occupation of Mr. Grant and his sons, being much the most considerable in the county, with the circumstance of making an ample fortune, made him desirous of tending it. He is added, that 20 years ago, Drifby had a warren of 12 or 1300 acres; and the rent of the farm including it, 300l. a-year, which rent has been doubled by ploughing.

And Mr. Kerstow observed, that the community received next to nothing from warrens; which is probably the case, as has been seen above, where the land is capable of being managed under the plough, or the system of grazes.

And the calculation of Mr. Parkin, of a warren of 700 acres under rabbits, in the same district, stands thus: rent 6s.; standing stock 200 couple of silver hair, valued to the incoming tenant at 2s. 6d. a couple ten years ago, and demanding a capital of 1400l.; and carefully typed to catch all extra bucks, so as to leave only one-fourth of the total number of bucks.

Produce 3000 couples for sale, worth, on an average of seven years past, 15l. a hundred

But as some arc greys, the price 10l.

Take the average of the two, that is, silver hair of the Wolds, and greys of Lincoln Heath, it will be on a medium

Or about 10s. 10d. an acre. And add to these, 550 sheep, kept by a course of tillage; that is, ploughing up 50 acres annually for paring and burning for turnips; then spring corn and feeds, which feeds sheep-fed one year, and thrown open to the rabbits: the sheep at 2d. per week for 25 weeks, will amount to 72l. 10s. This is inferior to the common produce of sheep; but the rabbits will demand hay, &c. to the amount of the difference; and also a team of horses must be kept for the cultivation of 100 acres of land, and carrying the rabbits to market. Hence,

The 50 acres of corn will be consumed by the horses, and master's and warreners's cows, &c.

It is noticed, that as the family is maintained out of the farm, the interest of the capital of about 1400l. is not charged, because the interest would be only 76l. per year, when they are maintained out of the farm, with a profit of 294l. 3s. 10d.
RABBIT.

will quite depopulate the warrens. A considerable expense also attends the necessity there is for night-watchers, to protect them from the infinitely worse vermin, the poachers. With him the silver-grey skins have been sold from 8½d. to 15d. and 16d. per skin: the last two years they have only brought from 10d. to 11d. per skin; but to obtain even these prices, they must be what is called full seafoned, whole skins, and of the choicest colours, with respect to which the fashion varies very greatly. The carcasses, of late years, have not averaged net into pocket more than 4d. per couple, after the expense of drying them, and by means of light diligence carts, having them carried to markets 30, and sometimes more than 60, miles to obtain even that sum. This inconvenience is occasioned partly by its being necessary to kill eight or ten parts of a year's slaughter in so short a time, as between the second week in November and Christmas, on account of their skins being then only in full prime, and as they are also very soon subject to become putrid, much more so than hares; and their being obliged to be packed close together, very greatly increases the mischief.

The estimate of the warren on the estate at Thoresbyway of 1700 acres, as given by the tenant Mr. Holdgate, with the silver fort of rabbits, is this:

<table>

Or about 22d. per cent. (the 5 per cent. included) on capital employed. This the writer observes is very great, reckoned on the capital, but small reckoned by rent, as it amounts to only half a rent. But suppose the grovs produce of 1500, which he takes to be nearer the fact; then the account will stand thus:

<table>
<thead>

Or 45 per cent. on the capital.

But it is supposed that, in whatever way it is taken, it explains the reason of so many of these nuisances remaining. The investment of a small capital affords a profit or interest that nothing else will, and of course the proprietor will be sure never to convert them to better use. But, it is asked, what pays the public interest? Here are only 200l. expenses to 600l. rent, what is the population, the industry, the improvement! The landlord gets the lowest of rents, the tenant makes a good profit, they divide all, and the rest of the world is little or no better for them.

Rabbit-warrens are met with in most other districts of the kingdom, both towards the southern and northern parts of it; but more abundantly in those of the north. In the south they have in most places been got quit of from any tolerable fort of land which is capable of affording any other better kind of useful produce, but in some parts of the north they still occupy spaces of ground which are of a good quality, and which might be converted to better purposes with great advantage to the proprietors, as well as farmers. Warrens of this nature, in some cafes, in both these situations, however, still continue to be well flocked, and in the latter, are in particular instances of pretty considerable extents.

In Cheshire, the principal rabbit-warrens are on Delamere forest, though on several of the heaths and sand-hills these animals are frequently met with, but not in such numbers together as to constitute warrens.

In the north riding of Yorkshire, also, a few rabbit-warrens are met with on the detached moors, as well as on the skirts of the higher moors; but they are not so extensive as to make them an object of much attention. The kind of rabbits here are mostly the common grey, with the exception of the flock on a warren at Nappa, in Wenlove-dale, of about one hundred and fifty or two hundred acres, which consists of silver-greys, and is the only warren which is known, in this district, to be entirely flocked with this sort: they are flat to have been brought some years since from a warren in the above noticed district of Lincolnshire, to which they had been originally introduced from Ireland. The skins of this kind of rabbits are supposed to be worth double those of the grey; they are not used for felts, as the last, but dressed as furs, and ultimately exported in that state for the China market, where they are worn by the principal people; an use which has been already noticed and confirmed in regard to the demand which it creates.

But in the northern parts of Lancashire, warrens of this kind are more frequent. At Rosscarroll-hall, in the tract called the Fild, one of great extent has existed for a very great length of time; but the present proprietor, B. F. Halkett, esq., has, with great propriety, lately reduced it very considerably, by taking two large fine farms from it, so that it now consists only of about a hundred acres of the most sandy barren part.

This warren formerly supplied a great number of rabbits for sale in the markets and hat manufactories of the neighbourhood, and of course became a source of profit to the owner, though the management was very imperfect. The farms taken from it will, however, become far more advantageous to him.

The flock here was formerly of the grey rabbit kind, and it is still the same on the warren which remains, which is however far from being sufficiently flocked.

There was formerly no fort of green food ever cultivated for this fort of flock; nor has it been yet attempted on the present warren, but the proprietor intends to have it done in an effectual manner. Nor have the rabbits ever been fed in the winter seafon with either hay, bark, or any other fort of
of food; their being so near to the sea-coast perhaps renders it unnecessary.

The only mode of taking the rabbits here has hitherto been in nets, by what is termed running them by means of dogs.

At Heylam, the Rev. Mr. Clarkson has a tract of coarse flatory land above his house, of about twenty acres, which has a great number of grey rabbits in it, and is well suited for a rabbit-warren, as it is incapable of being converted to any better purpose on account of the frequency of the west winds, and the effects of the sea-spray thrown up by them, as well as its rocky, winny nature.

The principal rabbit-warrens in this county are, however, those in the sandy tracts in the south and north ends of the isle of Walton, and in the neck of land from which it seems to have been separated. The rabbit-warren at the north end of this little island occupies a considerable space of ground of this barren sandy quality, as well as that at the southern point. The former is stocked wholly with rabbits of the grey kind, this fort being in great demand. There is much expense attending these warrens in many cases.

The expense of stocking in order to keep them up is sometimes very considerable. In this instance the farmer has upwards of two miles of dike fence composed of sod and flone to keep up and in repair, which costs from five to ten shillings the rod of seven yards. The expense of a man constantly to look after the rabbits, and keep the dike fences in proper order and repair. That of the purchase of the traps or types, which cost 57. a-piece, and eighteen are required; but they last long, and cost little in repairs.

The providing net and dogs, which is annually about 10L.

The charge of taking the rabbits at Uverton, twice in the week, during ten weeks, which is 5L. each time.

The sale of rabbits is annually from one hundred and fifty couple upwards, at the rate of 2L. 6d. each couple. They are usually sold to Lyons of Preston, who takes the charge of them after they have been delivered at the above-named place.

Not any sort of dry or green food is ever given to the rabbits in this warren during the winter season; but there is not any snow, and very little frost taking place; in consequence of the situation being surrounded by the sea.

The warren at the south end of the same little island is of similar extent, and exactly under the same fort of management; but it is said to be earlier, by a month at least, in the breeding of the rabbits, and the quality of their fur; which is supposed to arise from its being more fully exposed to the influence of the morning sun, in which the rabbit delights, and by which it is greatly benefited.

The rabbits are here likewise affected to fall for a higher price, as 5L. the couple, than in the warren at the north end of it.

The rabbit-warren at Sand-scale is another farm of this fort in this neighbourhood, under similar regulations, but somewhat smaller than those in the isle of Walton; and there is a hill smaller one attached to a farm at Roanhead, the property of Miles Sandyes, esq. of Graythwaite, which is conducted in much the same manner, and with the same results as in the above case.

It may be noticed that this fort of flock is mostly taken by nets or traps, set in the form of a fold between the places where they run, and those where they feed, the rabbits being hunted into them as they return from feeding. But the wold warrens, Mr. Marshall says, have three ways of catching their rabbits: with fold-nets, with snares, and with "types," a species of trap. The fold-nets are set about midnight, between the burrows and the feeding-grounds; the rabbits being driven in with dogs, and kept inclosed in the fold until morning. But the spring-net, when used, is, he believes, generally laid round a hay-field, or other place, where rabbits collect in numbers. It is added that the trap is a more modern invention. It consists of a large pit or cistern, formed within the ground, and covered in with a floor: or with one large falling door, having a small trap-door towards its centre, into which the rabbits are led by a narrow muce. And this trap, on its first introduction, was set more by a hay-field; hay being, at that time, the chief winter food of rabbits; or on the outside of the warren wall, where rabbits were observed to scratch much, in order to make their escape. Since the cultivation of turnips, as a winter food for this species of flock, has become a practice, the situation of the trap has been changed. Traps being cultivated in an inclosure within the warren, a trap is placed within the wall of this inclosure. For a night or two, the muce is left open, and the trap kept covered (with a board or triangular rail), in order to give the rabbits the requisite haut of the turnips: which having got, the trap is barred, and the required number taken. He adds, that in emptying the cistern, the rabbits are forced; those which are fat, and in season, are slaughtered; those which are lean, or out of condition, are turned upon the turnips to improve. And that, at the close of the season, the buck and doves are forced, in a similar way; the bucks are slaughtered, the doves turned loose to breed. Mr. Marshall also remarks, that great caution is requisite in the use of these traps. If too many rabbits be admitted at once, and the cistern be kept closed only for a few hours, the birds and inordinate heat takes place, and the carcasses, at least, are spoiled. Many thousand carcasses have been wasted through this means. The traps are therefore watched; and when the required number is caught, the muce is stopped, or the trap covered in a proper manner.

There is often much inconvenience in this fort of flock, from their getting out of their inclosures, and destroying the young corn-crops, new sown grasses, young turnips, and the quick hedges as well as young plantations of apple-trees that may be in the neighbourhood. This forms a material objection to this fort of flock by the farmer.

Tame Rabbits.—In respect to breeding and rearing tame rabbits with the view of profit, those who are engaged in the business perform it in hutchies, which must be kept very neat and clean, otherwise the rabbits will be subject to disease. Care must be taken also to keep the buck and does apart, till the latter have just killed, then they are to be turned to the bucks again, and remain with them till they run and run from them.

And the general rule for the shooving of tame rabbits, is to pick the largest and fittest: but the breeder should remember, that the flocks of the silver-haired and white furs fettle better than any other. The food of the tame rabbits may be calewort and cabbage-leaves, carrots, parsnips, green corn, and vetches, in the time of year; also parsley, grasses, green leaves, milk, and low-thistles, and other similar plants, but with these mossy foods they must constantly have a proportionable quantity of dry food, as hay, bread, oats, bran, and other similar matters, otherwise they grow pot-bellied, and die. Bran and grain mixed together have been found to
RABBIT.

to be very good food. In winter they eat hay, oats, and chaff, and these may be given them three times a day; but when they eat green things, it must be observed that they are not to drink at all, as it throws them into a dropdy. At all other times a little drink serves, but it should always be fresh. When any green herbs or grasses are cut for their food, ears must be taken that there is no hemlock among it, for, though they will eat this greedily among other things, when offered to them, it is a sudden poison to them. In this mode of breeding, one male to eight or ten females is sufficient.

It is remarked, that the author of the Treatise on Agriculture and Gardening, has bred these animals with much success and ornamental effect in a small artificial warren, in a lawn in the garden, made in the following manner.

"Pare off the turf of a circle, about forty feet diameter, and lay it on the outside; then dig a ditch within this circle, the outside perpendicular, the inner sloping, and throw earth sufficient into the middle to form a little hill, two or three feet higher than the level of the lawn; the rest must be carried away. Then lay down the turf on the hill, and beat it well to settle. The ditch at bottom should be about three feet wide, and three and a half deep, with two or three drains at the bottom, covered with an iron grate, or a fence with holes, to carry off the hay-stains in order to keep the rabbits dry. In the outside bank should be fixed alive, the fides and top supported, either by boards or brick-work, to give the rabbits their dry food in; by their different situations, some will always be dry, set boxes, or old tea-chiefs, let into the bank, will do very well. If the ground be very light, the outside circle should have a wall built round it, or some flaves driven into the ground, and boards or hurdles nailed to them, within a foot of the bottom, to prevent the bank from falling in. The entrance must be either by a board to turn occasionally across the ditch, or by a ladder. The turf being settled, and the grasses beginning to grow, turn in the rabbits, and they will immediately go to work to make themselves burrows in the fides, and in the hill. By way of inducing them rather to build in the fides, to keep the turf the nearer, make a score of holes about a foot deep, and they will finish them to their own mind; and if there be a brick-wall round it, it should be built on pillars, with an arch from each, to leave a vacancy for a burrow." But there is, he says, another way that may be practised, which is, "to dig the ditch only about two feet deep, which will yield about earth enough to make the hill; put some pales, about a foot high, on the outside, for that will be a sufficient height to keep the rabbits in. Feed them as other tame rabbits are fed; and in wet weather sprinkle sawdust at the bottom, by which means the quantity of manure will be increased; once a week is often enough to take it away: the quantity will be surprising, nor will the smell be in the least offensive, even though it be quite close to the house. In a very large lawn, two or three of these hills, with the rabbits feeding on the tops, will not be unpleasing objects. If the bucks happen to be mischievous in killing the young ones, they must be chained in an alcove; or else have their liberty as in a warren. After a great snow they will want some affillity early next morning; because the ditch will be nearly filled, and perhaps the alcove, where the hay is, will be blocked up."

He adds, that "it is a great improvement to cultivate the young bucks, and keep them till they are full grown, before you kill them; the flesh will be amazingly finer, whiter, and tenderer. But then it will be best to take them away, and keep them in another warren, left they should be too numerous, and disturb the breeding does; or else have a few hutchies in the alcove to fatten them in."

It is suggested, that "as oil-cakes are found of great use in fattening cattle, it is probable they would be useful in fattening rabbits: and it is ascertained, that some of the oil mixed with the pollard or buck-wheat, is cheaper than the cakes; but having never made the experiment, he cannot ascertait its superior advantages."

In this mode, attention should be had to the breeding that all of rabbits whole skins are in the greatest esteem with the furriers and hatters. These skins are generally of more value than the flesh, especially in the winter, against which time contrive to have the greatest quantity of these fattened bucks.

Profes.—It is remarked, in respect to profit in this way, that where does are kept in hutchies, they are supposed to breed six times a-year, and only five young ones are left to each, which is thirty from each doe; but as these are in a more natural way, and the young ones difficult to be gotten at, let us suppose about thirty-six to be produced from each doe, reckoning only seven-pence for each; there is a guinea profit from each doe; as the additional value of the skins in winter, and the dung, will more than pay the expense of food and attendance on them. And it is quite necessary that those who keep many rabbits in this way, should cultivate some lucern, parsley, and carrots, as no other vegetables are such proper food for them as these; they should also be fed upon some of the best upland pasture-hay; for if it be coarse, so far from eating, they will waste it. Lucern hay is very proper for them in these cafes.

In some districts very considerable profits and advantages are derived from the breeding and keeping of white tame rabbits. The skins of this fort having lately been much employed in trimmings, have sold at a much higher price than those of the common kinds. Their dung is also found of very great utility in the cultivation of large farms.

Difficult.—When kept in this way, rabbits are subject to several diseases, as the rot, which is caused by the giving them too large a quantity of green food, or the giving it fresh gathered, with the dew or rain hanging in drops upon it, as it is over-moisture that always causes the disease; the green food should, therefore, always be given dry, and a sufficient quantity of hay, or other dry food, in combination with it, to counteract the bad effects of it. And a fort of madness often seizes them: this may be known by their tumbling about; their heels upwards, and hopping in an odd manner into the boxes. This dillemer is supposed to be owing to the rankness of their feeding; and the general cure is the keeping them low, and giving them the prickly herb called tare-thistle to eat as much as possible. They are also subject to a fort of scabby eruption, which is seldom removed. These should, however, be distinctly separated from the rest of the flock.

It is noticed that the profit in this mode of management cannot, however, be well ascertained, as much will depend on the care which is taken in the feeding, and other management.

RABBIT-WARREN, the place where these animals breed and rear their young. The land for this purpose should be of a light sandy quality, and it is best to have a hilly situation, with a sunny exposure, being well inclosed by means of old-walls, or palings-fences: any fort of waste, craggy, or rocky land, on which nothing else can be cultivated, answers very well for this purpose. See RABBIT.
Rabbit—Warren Farm, that sort which is chiefly managed under the rabbit system. These sorts of farms are now much less common than formerly, but in some instances, as has been seen, they afford the best and most advantageous means by which lands can be turned to any account in the way of cultivation. They, however, in most cases require no little capital, exertion, and attention, to manage them in the best and most profitable methods. See Rabbit.

Rabbit Manure, that which is collected from the dung of these animals, and which is said to be very valuable. See Manure.

It is found beneficial in different modes of application, as by being intimately mixed and blended with the main particles of the soil or mould in arable lands, and by being thrown on the surface of it, in the way of a top-dressing, when they are in a state of crop. When used in this last manner, it is likewise highly advantageous on most sorts of grass land; and in both these cases of top-dressing with it, there is a very quick and powerful state of vegetation produced in the crops, which can hardly be gained in any other way. See Quick Manure, and Top-Dressing.

In Oxfordshire, Mr. Fane has raised a small building for keeping rabbits in hutch, for the sake of the manure; he is said to have some hundreds, and to meditate the erection of a second building for keeping double the number; the present quantity make a load of manure in the course of the week; and as two loads manure an acre, they are the means of fully dressing twenty-six acres annually; it is not conceived by them that they produce any other profit, nor is it necessary; for to be able to fell so much food at home, and to pay attendance, the profit of manuring such a breadth of land, it is supposed, must be considerable. Three dozen of rabbits in the week are mostly sent to the London market during the season in which they can be used.

This is a sort of dung or manure, which has yet been but little subjected to chemical examination, consequently its real properties, or constituent principles, are very imperfectly known or understood; it would appear, however, from the effects which it produces, that it may be employed with the most advantage, when laid upon the land, in its more raw, crude, or fresh state, before it has undergone much decomposition by the processes of fermentation or putrefaction. It has, perhaps, never yet been kept dry and reduced into a powdery condition, so as to be put in along with the seed, in the manner of rape-dill, though it seems probable that it would go farther, and be more beneficial, in some cases, if used in this way. See Dung.

Rabchorcado, in Ornithology, the name of an American bird, described by Nieremberg with many fantastic circumstances. All that seems certainly known is, that its tail is very remarkably forked.

Rabda, in Geography, a town of Arabia, in the province of Yemen; 30 miles N.W. of Sana.

Rabdiun, in Ancient Geography, Tur-Rabidin, a town of Asia, upon a mountain, at some distance from the Tigris, south of Tygrancocerta, and east of Nisibis.

Rabdoides. See Rabdoides.

Rabdoglogy, see Rabdology.

Rabdomancy, see Rabdomancy.

Rabebola, a name given by some to the roots of the flaminula major.

Rabela, Francis, in Biography, was born about the end of the fifteenth century at Chinn, in Touraine. At an early period he entered himself among the Cordeliers, and became well skilled in the learned languages, and the literature of the age. He acquired a good share of popularity as a preacher; and what he gained by his sermons, he expended in the purchase of a small library. His private life was not so exemplary as his public discourses were edifying; and for some misconduct, which caused scandal in the monastery, he was imprisoned in his cloister. By his wit and facetiousness he obtained his liberation, with the pope's permission to quit his order, and remove to that of St. Benedict. Not being able, however, to bear any kind of restraint, he laid aside his religious habits, and, in 1530, went to Montpelier to study medicine. After some time he repaired to Lyons, where he printed a collection of pieces of Hippocrates and Galen. Here he likewise published several other works, among which were some of the books of his History of Pantagruel, which gave him a distinguished place among burlesque writers. In 1535 he went to Paris, and waited on cardinal John du Bellay, to whom he had been known when they resided in the same convent; and he now made himself so agreeable to his old friend, that he was taken into his house in the several capacities of physician, reader, librarian, and steward. Du Bellay, in the following year, going out as ambassador to the court of Rome, took Rabelais with him, where his wit so much interested the pope and cardinals, that he very readily obtained a full abjuration for the crime of sacrilege. In 1537 he took his doctor's degree in physic at Montpelier; and returning to Paris soon after, his friend the cardinal presented him with a prebend in the chapter of St. Maur. He was afterwards made the curé of Meudon, which office he held from 1545 to his death, in 1553, being, according to one of his biographers, in the 62d, and according to another, in the 70th year of his age. His Pantagruel, which was finished about the time that he accepted the cure of Meudon, brought upon him the hostility of the monks, whom he had severely fatigued, and who procured its condemnation by the Sorbonne and the parliament; but it caused his company to be much sought after, as the wittiest writer of his time. The want of decency was easily pardoned at that period, and Rabelais had some estimable qualities, and possessed extensive and various erudition, with a ready eloquence, and an inexhaustible store of ludicrous ideas. "The Pantagruel and Gargantua of Rabelais," says a critic, "are to be regarded as comic fables, often concealing, under a whimsical extravagance, attacks upon follies which it would not have been safe seriously to expose. It is in vain, however, that commentators attempted to find out the meaning in much that is mere ribaldry and nonsense, and even to discover real history veiled in the allegory of burlesque, where the author meant nothing more than to make his reader laugh or wonder. His satire, where it is intelligible, is often just and ingenious; but the obscurity of his language, and eccentricity of his conceptions, render the perusal of his works, to a modern at least, rather a task than an amusement." The most complete editions of his works is that published in Holland, in 5 vols. 8vo., 1715, with notes by Duchat; and that at Amsterdam, in 3 vols. 4to., 1741, with plates by Picart. The letters of Rabelais were published in an octavo volume, with notes by St. Martin. The memory of Rabelais is perpetuated in the medical school of Montpelier, where men are invested with a scarlet robe, said to have been the very robe which that wit himself wore.

Rabelhorst, in Geography, a town of the duchy of Holstein; 5 miles W.N.W. of Cifmar.

Rabenau, a town of Saxony, in the margraviate of Meissen;
RABNECK, a town of Bavaria, in the bishopric of Bamberg; 3 miles S.W. of Weissenfeld.

RABERNE, Theophilus William, in Biography, a celebrated German writer, was the son of an advocate at Leipzig, and born at Wachau in 1714. He was educated at home, by tutors employed for the purpose; but when he was 14 years of age, he was sent to the college of Meifen, where he had for fellow-students Graber, Gartner, and Gellert, with whom, and particularly with the last, he formed a friendship which continued through life. In 1735 he went to the university of Leipzig, where he applied himself chiefly to the study of juriprudence, without entirely neglecting the Muses. In 1741, professor Schwabe having begun a journal in the German language, entitled "Amusements of Reason and Wit," Rabener became one of his principal coadjutors, and continued to assist him in his contributions till the year 1744. He is chiefly known as a writer in the first volume, by a humorous piece entitled "Proofs of the Necessity of employing Rhyme in German Poetry." This periodical work was, for some time, carried on with spirit and success; but at length it became degraded by literary disputes, which finally put an end to it; and another was established, under the title of "Contributions of Bremen." The writers engaged in this work were all the most celebrated persons who flourished at that period, among whom were Gartner, Schmidt, and Rabener, to whom were united Gellert, Klopotock, and others. The Journal of Bremen forms an epoch in the history of the German literature, as it introduced into the country a better taste, and tended greatly to improve the language, which, previously to this, had been much neglected. Rabener had before this been appointed controller of the taxes in the circle of Leipzig, a place of great labour, and which required an exact knowledge of the laws of the country, and the most inflexible integrity. Notwithstanding, however, the attention which the duties of this office required, he found leisure to continue his literary pursuits; and towards the end of 1751, composed his fortior letters, in which he introduces perorations of every latitude and character, all of whom speak in the language suited to their condition. In 1753 he was appointed chief secretary to the directors of the taxes at Dresden; and two years afterwards he published the fourth and last volume of his fatres, which contains "A Burlesque Explanation of the Proverbs of Sancho Panza," the "Jest of April," and "The Exchange and Reparation." After this he began to write for the stage, and composed a comedy in four acts, entitled "The Free-thinker," which, with many other papers and letters, were burnt, together with his house, during the siege of Dresden, in 1760. He now abandoned his literary labours, but his friends obtained from him a collection of letters, which were afterwards published by Wels. These were never intended for the public, but they are written with so much truth and sincerity, and exhibit a more correct picture of the author than any pen could have drawn. His health began to decline soon after his loss in 1750, and in 1765 he experienced a paralytic stroke, which was repeated in 1769; but he lingered out till March 1771, when he died. "He was," says his biographer, "among the small number of those privileged men, whom nature has endowed with every quality necessary to their fame. He thought and spoke in a manner peculiar to himself; his pleasingly flowed as from an abundant source; he never fought for them; and they appeared to natural, pleasant, and lively, that it was impossible not to be struck by them. But he displayed his wit only among his friends; he never lavished it on the rich and great; on the contrary, he concealed it, when invited merely for the purpose of being heard. He always spoke the truth, without regard to person or rank." Rabener, says he, was the favourite author of Germany, who wrote poetically in prose, whose fatrical, spective geniuspossessed itself without gail. Rabener's works are generally known throughout Europe, having been translated into the French, English, Dutch, and Swedish languages. Gen. Biog.

RABENSPURG, in Geography, a town of Austria; 8 miles S.E. of Lifferdorff.

RABENSTAIN, a town of Austria, on the river Bie- lach; 8 miles S. of St. Polten.

RABENSTEIN, a town of Bohemia, in the circle of Leitmeritz; 40 miles E. of Prague. N. lat. 50°. E. long. 13° 20'.—Also, a town of the duchy of Sturia; 11 miles N.N.W. of Graz.—Also, a town of Bavaria, in the bishopric of Bamberg; 2 miles S. of Weissenfeld.

RABIA PINU, in Chronology, is the name of the third month of the Arabic year, consisting of thirty days; and Rabia posterior is the name of the fourth month, consisting of twenty-nine days.

RABICHS, a name given by Leo Africanus to a tree or shrub growing very plentifully in many parts of Africa, the fruit of which is much esteemed by the natives. He says that the tree rabich is prickly, and that the fruit is round, and like a cherry, but smaller, and of the taste of the jujube.

RABIEL, a name given by some authors to dragon's blood.

RABIES, in Medicine, that peculiar state of the nervous system, which is produced by the bite of a rabid animal, and which is commonly, but improperly, called madnus. As the dog is the principal source of this disease, the word rabies is commonly united with the epithet canina. See Hydrophobia.

RABINAL, in Geography, a town of Mexico, in the province of Vera Paz; 40 miles S.S.W. of Vera Paz.

RABINET, a name formerly given to a small piece of ordnance, between a falconet and a bateau. Its dimensions, &c. see under CANNON.

RABIRA, a word used by some of the chemical writers to express tin.

RABISHI, in Geography, a river of the island of St. Vincent, forming a bay on the eastern coast, near the southern extremity, where it runs into the sea. N. lat. 13° 5'; W. long. 61° 11'.

RABLAY, a town of France, in the department of the Mayne and Loire; 9 miles N. of Villiers.

RABLES, jux. aux, a cluster of small islands at the entrance of lake Superior, in Upper Canada, and at the eais of it, eait of White-Fish island, and pretty close to the main land.

RABNABAD, a town of Hindoostan, in Bengal, at the mouth of the Ganges; 90 miles S.S.E. of Mahmundpore.—Also, a small island on the coast of Bengal, at the mouth of the Ganges. N. lat. 22°. E. long. 90° 30'.—Also, one of the mouths of the Ganges, which opens into the bay of Bengal. N. lat. 22°. E. long. 90° 26'.

RABNITZ, a river of Hungary, which runs into the Danube, a little below Raab.

RABOGH, a town of Arabia, in the province of Yemen, near the coast of the Red sea, where the Arabs live in huts; 105 miles S.W. of Medina.

RABOLAN, in Ornithology, a name given by many to the lagopus, a bird found on the snowly mountains, and called by some the white partridge.
RABRI, a name given by some authors to hole Armenian.

RABUEL, CLAUDE, in Biography, a French Jesuit and able mathematician, was born at Pont-de-Veyle, in the county of Bresse, in the year 1668. About the age of 18 he was entered into the society of Jesus, and principally distinguished himself by his proficency in mathematical learning, of which he became the professor in Trinity college at Lyons, performing its duties with great reputation and success. He died in 1728, in the 60th year of his age. His chief work was "A Commentary on the Geometry of Descartes," which was published after his death in 1730, under the care of father L'Epinal. This was the first illustration of the whole of that work, which had been given to the public. The labours of Fermat, De Witt, and others, extended only to particular parts of it. Rabuel left behind him other works on algebra, the conic sections, and the geometrical loci of the differential calculus, and of the integral calculus; and he was one of the few infallances of persons who, with a passion for the mathematics, had a fine taste for polite literature.

RABUTAH, in Geography, a town of Africa, in the kingdom of Senmaar; 35 miles S.S.W. of Sennaar.

RABUTIN, FRANS DE, in Biography, who flourished in the sixteenth century, was of an ancient and noble family in Burgundy, and served in the army with the duke of Nevers, under Henry II. and Charles IX., with a high reputation for valour and fidelity. He lived in 1581, but nothing is known of him beyond that period. He was author of "Commentaires de dernieres Guerres du Roi Henri II. et de l'Empereur Charles Quint," first printed in 1555; a continuation was printed afterwards, in 1558; and the whole work together in 11 books, in 1574. It contains a history of the wars in the Low Countries, from 1550 to 1558, and is said to be written in a simple style, with a great appearance of vivacity.

RABUTIN, ROGER DE, count of Buffi, a very distinguished character in the reign of Lewis XIV., was born at Epire, in the Nivernois, in 1618. He entered very young into the army, in his father's (Leonor Baron of Buffi) regiment, of which he became colonel. After serving in a number of battles and sieges, he rose to the rank of major-general of the Nivernois. He looked for still higher honours, and being disappointed, engaged in lampoons upon persons about the court, which drew upon him the king's displeasure; and in 1665, in which year he was admitted a member of the French Academy, a manuscript history of the amours of two court ladies, of which he was the writer, being handed about, under the title of "Histoire Amoureuse des Gales," a complaint was laid before his majesty, in consequence of which he was sent to the Bastille. Imprisonment had nearly proved fatal to him, and he was liberated, but was obliged to resign the office which he held under-government. After this he was exiled to his country-seat, where he remained 17 years, during which he did not cease to importune the king to be allowed to return, by letters conceived in terms of abject humility and base adulation. In 1682 he was allowed to return to court, but finding himself generally neglected, he retired of his own accord to his estates. He died at Autun in 1693, at the age of 75. He was author of several works, among which were "Difficultes des Enfans, pour le bon Usage des Adverstices;" "Memoires," published first at Paris in two, and afterwards at Amsterdam in three volumes, 4to.; "Letters," 7 vols. 12mo.; and "Histoire Abregée de Louis le Grand." His son the abbé de Buffi became bishop of Liége in 1723, and was a learned and ingenious member of the French Academy.

The sister of the bishop, a nun, published an abridgment of the life of Madame de Chantal, and of the life of St. Francis de Sales.

RABY, in Geography, a small township of America, in New Hampshire, in Hillsborough county; about 65 miles W. by S. of Portsmouth; incorporated in 1750. Its name has been since changed.—Also, a town of Bohemia, in the circle of Prachatitz, containing a citadel, at the siege of which, Zicca, general of the Hussites, lost his only remaining eye; 4 miles S. of Horazdowiz.—Also, a town of Sweden, in Sudermanland; 7 miles N. of Nyköping.

RACA, or RACHA, a Syriac term, found in the Gospel of St. Matthew, chap. v. 22, and preferred in most translations.

Father Simon observes, that the Greek translator of St. Matthew's Gospel retained the Syriac race, which he found in the original, because it was very common among the Jews. And St. Jerome, Luther, the English translators, chose of Geneva, Lowman, Port royal, &c. still prefer it in their respective languages.

F. Bouhours chooses rather to express the sense of it in a sort of paraphrase, thus: he that fays to his brother, whom you have done wrong, man of little understanding, shall deserve to be condemned by the tribunal of the council, &c.

Most translators, except the English, and F. Simon, for raca write racha; but the former orthography seems the best founded; all the Latin copies having raca, and all the Greek ones ᾲχα, or, with Hefychius, ἴχα, which is the same; all, we mean, but St. Irenæus, and Beza's copy, now at Cambridge, which have ἴχα. In effect, the origin of the word shews it should be racha; as coming from the Syriac ἱχα, raca, of the Hebrew rek, ἱχα, empty, shallow.

RACAISBONE, in Geography, a town of Hindoostan, in Aurungsabad; 30 miles S. of Aurungsabad.

RACAM, a town of New Mexico, in the province of Hiaquii; 60 miles S.W. of Riochico.

RACAN, HONORAT DE BUEIL, Marquis of, in Biography, a French poet, was born in 1589, of a noble family, in Touraine. When very young, he had a place in the king's bed-chamber, under the duke of Bellegarde. From Malherbe, who was at that time domiciliated with the duke, he acquired a fondness for poetry, and obtained instructions in the art of verifying. He at first bore arms, as a profession but after a time he devoted himself to the life of leisure. He was one of the earliest members of the French academy, and though almost wholly without the advantages of education, he obtained reputation as a writer. His most popular work was entitled "Bergeries." He composed in various styles, and wrote translations of Psalms, and many sacred odes taken from the Psalms, and other scriptural poems. In prose he published "The Life of Malherbe;" "A Discourse pronounced before the Academy;" and some "Letters." He died in 1670, at the age of 81. Of his works a new edition was given at Paris, in 1724, in 2 vols. 12mo.

RACCA, RACAH, Rika, or Raka-Rica, in Geography, a town of the Persian empire, in the province of Dazbekir, and pashahic of Orfu, the capital of the district named Dier Medzir. It is situated on the eastern bank of the river Euphrates, at the mouth of a small river named Beles, (the ancient Bilehca,) and was founded, according to Phiny, by Alexander the Great. It was first called Nicopolis, and afterwards Callinicum and Leonopolis, from Seleucus Callinicus and the Greek emperor Leo. It was the favourite residence of Haroun al Ralîhîd, the ruins...
runs of whole palace, it is said, are still visible. The position of Racca, in the parallel of 36° N., was ascertained by the celebrated oriental astronomer Mahomed Ben Jaiber, surnamed Al Batani, who passed many years of his life at this place. The town and adjoining country are inhabited by different tribes of wandering Arabs. N. lat. 36° 1'. E. long. 48° 50'.

**RACCA**, a river on the north coast of Sumatra, which runs into the sea, N. lat. 2° 30'. E. long. 100° 15'.

**RACCANATTO**, a river of Naples, which runs into the gulf of Tarento, N. lat. 39° 47'. E. long. 16° 42'.

**RACCIOON** in Zoology. See Raccon. Raccoon, in Geography, an island in the Atlantic, near the coast of South Carolina, nine miles long and one wide. N. lat. 33° 3'. W. long. 79° 22'.

**RACCIOON Creek**, a river of Pennsylvania, which runs into the Ohio, N. lat. 40° 58'. W. long. 80° 25'.

**RACCOON Island**, a small island in Offabaw sound, belonging to the state of Georgia. N. lat. 31° 47'. W. long. 81° 12'.

**RACCOON Key**, a small island or rock in the gulf of Mexico, near the south coast of West Florida. N. lat. 29° 46'. W. long. 89° 21'.

**RACCOON Key**, a cluster of small islands near the coast of South Carolina. N. lat. 24° 8'. W. long. 79° 15'.

**RACCOURCY**, in Heraldry, signifies the name as eoupé, that is, cut off, or shortened; and denotes a cross, or other ordinary, when it does not extend to the edges of the escutcheon, as they always do when absolutely named, without such distinction.

**RACE**, in general, signifies running with others, in order to obtain a prize, either on foot, or by riding on horseback, in chariots, &c.

Racing was one of the exercises among the ancient Greek games, which was performed in a course, containing one hundred and twenty-five paces; and those who contended in these foot-races were frequently clothed in armour. For a particular account of these races, see STADIUM.

There were properly but two kinds of horse-races at Olympia, namely, the chariot-race, introduced into those games in the 25th Olympiad (for an account of which see CHARIOT), and the race of riding-horses, which was not admitted till the 33d. Although chariots were in use before riding-horses, as we may conclude from the testimony of Homer, among all those heroes, Greek and Trojan, no one makes his appearance on horseback, except Diomedes and Ulysses mounted upon the horses of Rhesus (Il. xi.), it is neverthelss plain, from this instance, that neither the heroes nor the horses were utter strangers to the art of riding; and it is also evident, from another passage in the 15th Iliad, that horsemanship was carried even to some degree of perfection, at least in the time of that poet, who lived but in the next generation after the siege of Troy, according to Sir Isaac Newton. This passage, extracted from Pope's Homer (Il. xv. v. 822.) is as follows:

"So when a horseman from the wat'ry mead
(Shk'd in the manage of the bounding reed)
Drives four fair couriers, practis'd to obey,
To some great city, thro' the public way:
Safe in his art, as shade by shade they run,
He shifts his seat, and vaults from one to one;
And now to this, and now to that he flies:
Amusing numbers follow with their eyes."

Some authors (see Rolin's Anc. Hist. tom. v. p. 72-74. Amst.) have introduced an exerere like this into the Olympic games, though Mr. Weft professes himself disfavored with the authority upon which they depend; and says that in the books which he has consulted, he can find no mention of any other race of riding-horses, besides those of the Celts and the Caliphs. As to that particular branch of horsemanship, above described, Eustathius, in his comment upon Homer, tells us, that in the old scholia it is written, that Demetrius says he had seen a man, vaulting in the manner described by the poet, from the back of one horse to another, holding the bridles at the same time, and keeping the horses to their speed, without any interruption or incurrence. This assertion implies that such a fight was very uncommon, and consequently that no such exercise could ever have been admitted into any of the games of Greece. The word Kabe, used by the poet in the beginning of this simile, says Mr. Weft, may possibly have induced some people to imagine, that the riders of the horses called Kabe, celeres, were accustomed to leap from one horse to another, as if that word was a term of the manage, of which the ver fat followed were merely an explanation. It is certain, however, from a passage in the Odysseus (E. v. 371.) that by Kas, Homer meant to signify no more than a riding-horse, and consequently that by the word Kabe, Kabe, which is derived from Kabe, no more is to be understood in this place than simply to ride. This interpretation of Kabe, celeres, may be further confirmed by the authorities of Pindar and Pausanias, and particularly by a story related by the last mentioned author (lib. vi. c. 13.) of a mare, named Aura, belonging to one Phidolas, a Corinthian. This mare, says the historian, having accidentally thrown her rider long after she had startled from the barrier, continued the race of her own accord, and turned round the pillar as if the rider had been still upon her back; upon hearing the trumpet, she mended her pace, till coming in before her antagonists, she stopped short over against the judges of the games, as conscious of having gained the victory. The victory was accordingly adjudged to her master Phidolas, who, by erecting in return a statue to her honour, intimated to whom the merit of that victory was due. In this story, there is no mention of any other horse or mare, that shared the victory with Aura, and consequently that, in the race called Celtes, each competitor made use of but one single horse. Moreover, the victorious Aura was of the feminine gender, and hence we may infer, that in all the races, as well of riding horses as of chariots, mares or horses were indiscriminately used; excepting in the race named Caliphs, in which mares only were employed. And further it appears, that though the rider was thrown off in the very beginning of the race, yet the crown was awarded to Phidolas, the master of Aura; to whom certainly no less was due, than if his mare had conquered under the conduct and discretion of her rider. It appears also, by the circumstance of Aura's mending her pace upon hearing the trumpet, that the trumpet either did not sound during the whole race, but at the last round only, or that it sounded differently in different periods of the course.

There was, however, a meaning in the found of the trumpet, which Aura, probably an old fitter, understood.

The race of full-aged riding-horses was instituted in the 33d Olympiad, and that of the Horses, or aged under-aged riding-horses, in the 131st. It is a well-known fact that chariots were used in war above 1000 years before cavalry was introduced among the ancients. They seem to have had a terrible notion of being mounted upon the back of a horse, and have accordingly made monilars of their horse whom they first beheld in that attitude, to which they were not very speedily reconciled. Their amazement gradually diminished; and their intercourse with other nations not only rendered
rendered riding-horses familiar to them, but convinced them likewise of the advantages accruing from the use of cavalry. Hence it came to pass, that an order of equites, or horsemen, was instituted in most of their commonwealths; to whom, as in Athens, was allotted the second rank in the lists. Upon the same principle, perhaps, the #error start here.  

It is to be noted, that the name of the horse Phereinus, whose steeds gained for his master the Olympic crown. The race of the Caphé was performed by mares. (See Calpé.) The length of this race, and also that of the Celes, are not ascertained; but it is reasonable to suppose, that the latter, distinguished, as we have already observed, into two classes, one of full-aged, and the other of under-aged horses, consisted of the same number of rounds as those of the chariots, distinguished in like manner into two classes. Mr. Wells has not been able to determine the different ages that ranked the horses in one or the other class; nor whether the weight of the riders, or the sizes of the horses, were taken into consideration. These points seem to have been left to the discretion of the Hollendicks, who were appointed to examine the young horses that were entered to run for any of the equestrian crowns (Paul. I. iv. c. 24.), and who were sworn before the statue of Jupiter Horaeus, to give a true and impartial judgment upon the matters left to their examination, without taking any reward; and not to discover the reasons which disposed them to reject some, and admit others. Wells's Dissertation on the Olympic Games. Sec. 14. See Hippodrome.

Race, in Genealogy, a lineage, or extraction, continued from father to son.

The word is French, formed from the Latin radix, root; as intimating the root of the genealogical tree.

In several orders of knighthood, as in that of Malta, &c. the candidates must prove a nobility of four races or defectents.

In some republics the magistrates are to prove themselves of plebeian race, to be qualified.

The French reckon their kings by races; as, the first race, the second race, the third race. We also lay the race of the Ottomans, the Araphis, the Polesmens, &c.

Race, in Natural History. See Cibdeloplia.

Race, the mark made on timber, &c. by a tool called a racing-knife.

Race, Cape, in Geography, a cape on the S.E. coast of Newfoundland. N. lat. 46° 40'. W. long. 53° 3' 30'.'

Race Point, a cape on the coast of America, W. of cape Cod. N. lat. 42° 3'. W. long. 78° 12'.

Raceme, in Gardening, the long mode of cluster-flowering and fruiting which takes place in some sorts of plants and fruit-trees, as in the grape-vine, and the different kinds of currants. See Racemus.

Racemiferous, in Botany, denotes bearing in clusters.

Racemus, in Botany and Vegetable Physiology, a cluster, is a mode of inflorescence, in which several flowers, each supported on its own proper stalk, are connected by one common stalk, either simple or compound. A bunch of Crucifers is a simple racemus; the inflorescence of the Woody Nightshade, Solanum Dulcamara, is a compound one. In the American plant called Astra racemosa, the clusters are simple, but aggregate. A racemus differs from a spica, or spike, in having a partial stalk, as above described, to each flower; it is moreover generally understood to be drooping or pendulous, and to have the flowers expand all nearly at one time. On the contrary, a spike is most frequently erect; the flowers open in very gradual succession, insomuch that the lowermost may have partly perfected their seeds, before the uppermost expands; and especially, they are individually fertile, at least at the time of their expansion. To these characters may be added, that a spike is crowded or dense; a cluster lax or scattered. It must be allowed that botanists, even of the first rank, are incorrect in the application of these terms. The male inflorescence of Quercus, the Oak genus, because drooping and loosely disposed, with all the flowers in perfection nearly at the same time, is termed a racemus; though it poifesses the most essential character of a spica, fertile flowers. On the other hand, Veronica spicata, having a dense upright series of flowers, expanding gradually, is said to be spied, though each separate flower has a partial stalk. A little latitude must necessarily be allowed, though it is very desirable that botanists should be more exact in the use of these and other terms, than they sometimes are. See Spica and Inflorescence.

Racer, in Gardening, a name applied to a fort of fward-cutter, or cutting implement, used in racing out or cutting through the surface of grazs fward, and dividing it into proper widths, lengths, and thicknesses, for turf intended to be cut up, for laying in pleasure-grounds, or other places, and always necessary preparatory to the work of faying or cutting up the turf with the turfing-iron. It is also useful for cutting and straightening the edges of grass verges in such grounds, as well as for many other purposes.

It is a tool which is very simple in its construction, merely consisting of a strong wooden handle, about four feet long, having the cutter fixed at the lower end, in the form of a half moon, with the edge downward, to cut into the fward; the handle should be about an inch and a half thick, growing gradually thicker towards the lower end.

In using the tool, it is pulshed forward as to cut or race out the fward in an expeditious manner. And in cutting turfs with it, it is necessary first to mark out on the fward the width of the turf intended, which should generally be a foot wide, and a yard long, and about an inch or inch and a half deep; then itain a line tight, first lengthways, striking the racer into the fward clofe to the line, running it along expeditiously, so as to cut its way, and divide the fward to a proper depth, afterwards placing a line a foot farther, and racing it out as before, and so on, to as many widths as may be wanted; and then, with the line placed cross-ways, to race out the fward accordingly in yard lengths. The fward being thus raced out, the turf-cutter with the turfing-iron should proceed to cut them up and fay them off from the ground. This small implement is likewise very convenient for many other little purpofes about pleasure-grounds and gardens, as thoole of cutting the edges of the verges which are laid with turf, and straightening the edges of the borders in different parts. See Turf.

Racha. See Raca.

Racha, in Geography, a town of Bohemia, in the circle of Leitmeritz; 8 miles E. of Leitmeritz.

Rachelsdorf, a town of Bavaria, in the bishopric of Bamberg; 15 miles N. of Bamberg.

Rachetum, from the Fr. racheter, rudiment, the compensation or redemption of a thief.

Rachia,
RACHIA, in Geography, a town of Ilithri; 7 miles N.E. of Pedena.

RACHIALGIA, in Medicine, a term given by Alfric, and adopted by the nomenclaturists, to denote certain colicky pains in the bowels, which were supposed to originate from the nerves of the spine, and especially from the colic from the poison of lead, or COLIC PAINUM; which see. The word is from ραχία, the spine, and αἰχμή, pain. See Sauvages Nouf. Meth. cliv. vii. gen. 29.

RACHIS, or rather Rhachis, in Botany, from ραχία, the back-bone, is the common stalk, or receptacle, of the florets, in the spikelike clusters of grasses; or of the spikelike themselves in Lolium, Triticum, Scite, Hordeum, Reutiolias, &c. The same term is applied to the rib, or leaf-leaf, of ferns, which is often winged or bordered. The Rachis in both these inflorescences is frequently jointed; by which in the former, the ripe seeds of such grasses, wrapped up in their husks, are the more readily dispersed. The part in question being in some cases smooth, in others variously hairy or bearded, affords excellent specific distinctions; witness the genus Avena.

RACHISAGRA, a term used by some physicians for the gout in the spine of the back.

RACHITIS, a term used by some physicians for the gout in the spine of the back.

RACHITIS, a term used by some physicians for the gout in the spine of the back.

RACHISAGRA, a term used by some physicians for the gout in the spine of the back.

RACHITIS, a term used by some physicians for the gout in the spine of the back.

RACHISAGRA, a term used by some physicians for the gout in the spine of the back.
race, elegance, correctness, good taste, refined sentiments, and
the art of verifying in a supreme degree, so that his country-
men find a charm in his lines, which distinguishes them from
other French poetry. The criticisms of Boileau contributed
much to his excellence in this particular, and he is said to
have taught him, as a great secret, to write the second line of
a couplet first. With respect to the proper dramatic merit.
Racine must be judged by those who are formed to the
French school, and are not readily wearied with long speeches,
rather descriptive of feeling than expressing it, and all refine-
ments of the tender passion, often applied to characters, to
which is historically unsuitable. Many parts of his best
pieces, however, prove that his mind was well furnished with
elevated and dignified sentiments, which he probably derived
from an afflusive study of the ancients. Besides his dramatic
works, Racine was author of " Cantiques," replete with the
unction of tender devotion; " L'Histoire de Port-
Royal;" " Idylle sur la Paix;" " Epigrams;" Letters," and
some " Opuscules," as he was member of the French academy
from 1673, and as director of that institution he pronounced
the eulogy of Corneille. The best edition of his works is in
seven vols. 8vo. 1768.

RACINE, Louis, son of the preceding, also a disting-
guished poet, was born at Paris in 1692. He was, however,
not more distinguished for his poetry than for his piety, and
adopted the ecclesiastical habit. In a state of retirement,
in 1720, he published his poem " On Grace." The chan-
cello d'Audigeau, during his own exile at Frennes, brought
Racine again into the world, and cardinal Fleury afterwards
gave him a place in the finances. He married, and lived
very happily in his family, till the loss of an only son threw
him into a deep melancholy. His religious sentiments took
full possession of his soul, the fervour of which may be esti-
ated from the line by Tibullus which he inscribed on the
crucifix which ever accompanied him:

"Te fpeccem suprema mili cum venerit hora,
Te teneam moriens defciente manu."

He died in 1763, at the age of 71. His poetical writings are
"Poems on Religion and Grace;" " Odes," of which the
diction is splendid, and the sentiments elevated; " Epif-
tles," and a " Translation of Milton's Paradise Lost." In
profe he wrote " Reflexions sur la Poësie;" " Memoires sur
la Vie de Jean Racine;" " Remarques sur les Tragedies de
J. Racine;" besides these he contributed several disserta-
tions to the Memoirs of the Academy of Inscriptions, of
which he was a member. His works were collected and
published in 6 vols. 12mo.

RACINE, Bonaventure, a learned French priest and
ecclesiastical historian, was born at Chauny, in the diocese of
Noyon, in the year 1708. He received an excellent edu-
cation at the Mazarin college at Paris, where he not only
studied the ancient languages, but entered pretty fully into
the different branches of philosophy, divinity, and the stu-
dies connected with ecclesiastical history. At the age of
twenty-one he was entrusted by the archbishop of Alby, as
aift perfon, to re-establish the college of Rabaffens, a town
in his diocese. To this design he devoted his talents with
unwearied zeal and assiduity, and was abundantly compens-
ated by the successe which attended his labours. The in-
stitution was, in a short time, crowded with students who
unselfed from his lectures a taste for science and literature.
Thus usefully engaged, he became an object of the jealousy
of the witty Jefuits, who cauffered him to be banished from
Rabaffens. He retired to Montpelier, where M. Colbert
engaged him to undertake the direction of the college of
Jansen: from this place he was also driven by the fame per-
secutors, and he found it necessary to withdraw secretly to
Paris, where he was invited to undertake the education of
certain young perfon at the college of Harcourt, in con-
nection with some other ecclesiastics. Here his old enemies
the Jefuits pursuah him, and an order was obtained from
cardinal Fleury, in 1734, to deprive him of his office of
tutor. In the following year M. de Caylus, bishop of
Auzerre, nominated him to a canonry in his cathedral, and
ordered him priest; but his new dignity produced no al-
teration in his manner of living, nor in the distribution of
his time, which was as skilful wholly spent in devotion and
study. From this time he felt about preparing to publish the
collections that he had made in ecclesiastical history, and in
1748 he set into the world the first volumes of an " Abridg-
ment of Universal History," containing the principal Events
in every Century, with Reflections," in 12mo. These were
followed by others, to the number of thirteen, the last making
its appearance in the year 1753. This work, written in a neat,
peripetuous, and simple style, was well received, and be-
came extremely popular. The labour which it cost him his
weak constitution was unable to sustain; he sunk under his
exertions in the 47th year of his age. He was characterized
by the excellence of his manners and the amiableness of his
temper, and he had an ardent zeal for what he regarded as
truth, which approached to enthusiasm. Two other volumes
have been added since his death to the History, but they are
the work of an inferior hand, and unworthy of being placed
in conjunction with those of Racine. Morei.

RACING, the riding of heats for a plate or other pre-
mium. Horoes for this use should be as light as possible,
large, long, and well-shaped, nervous, of great mettle, and
good wind, with small legs, and neat small-shaped feet.

The first thing to be considered in this sort of gaming is
the choice of a rider; for it is not only necessary that he
should be very expert and able, but he must also be very
honest.

He must have a very close feat, his knees being turned
close to the saddle flirts, and held firmly there, and the toes
turned inwards, so that the fpurs may be turned outward to
the horse's belly; his left hand governing the horse's mouth,
and his right the whip. During the whole time of the
race, he must take care to fit firm in the saddle, without
waving or flanding up in the air. Some jockies fancy
this is a becoming feat, but it is certain, that all motions
of this kind do really incommodate the horse. In spurri-
ng the horse, it is not to be done by flicking the calves of
the legs close to the horse's sides, as if we were intended to
press the wind out of his body; but, on the contrary, the toes
are to be turned a little outwards, that the heels being
brought in, the spurs may just be brought to touch the
sides. A sharp touch of this kind will be of more service
toward the quickening of a horse's pace, and will sooner
draw blood than one of the common coarse kicks. The
expert jockey will never spur his horse until there is great
occasion, and then he will avoid striking him under the
fore-bowels between the shoulders and the girth; this is the
tenderest part of a horse, and a touch there is to be re-
served for the greatest extremity.

As to whipping the horse, it ought always to be done
over the shoulder, on the near side, except in very hard run-
ing, and on the point of victory; then the horse is to be
struck on the flank with a strong jerk; for the loin is the
most tender of all there, and most feasible of the lath.

When a horse is whipped and spurred, and is at the top of
his speed; if he claps his ears in his nose, or whisks his
tail, it is a proof that the jockey heats him hard, and then
he ought to give him as much comfort as he can, by faw-
...
ing the snaffle backwards and forwards in his mouth, and
by that means forcing him to open his mouth, which will
give him wind, and be of great service. If there be any
high wind stirring in the time of riding, the artful jockey
will let his adversary lead, holding hard behind him, till he
sees an opportunity of giving a loose; yet in this case, he
must keep so close behind, that the other horse may keep
the wind from him; and that he, sitting low, may at once
shelter himself under him, and afflict the strength of the
horse. If the wind happen to be in their back, a jilt con-
trary method is to be taken with it; the expert jockey is
to keep directly behind the adversary that he may have all
the advantage of the wind to blow his horfe along, as it were,
and at the same time intercept it in regard to his ad-
versary.

When running on level carpet-ground, the jockey is to
bear his horfe as much as the adversary will give him leave,
because the horfe is naturally more inclined to spurn him-
self on this ground; on the contrary, on deep earths he may
have more liberty, as he will there spare himself.

In riding up hill the horfe is always to be favoured, by
bearing him hard, for fear of running him out of wind;
but in running down hill, if the horfe's feet and shoulders
will bear it, and the rider dares venture his neck, he may
have a full loose. If the horfe have the heels of the reft,
the jockey must always spare him a little, that he may
have a reserve of strength, to make a pull at the last poft.

A great deal depends on the jockey's knowing the nature
of the horfe that is to run against him; for by managing
accordingly, great advantages are to be obtained: thus, if
the opposite horfe is of a hot and fiery disposition, the jockey
is either to run just behind him, or check by jowl with him,
imposing a noise with the whip, and by that means forcing
him on faster than his rider would have him, and confe-
quently spending him so much the sooner; or else keep
just before him, in such a flow gallop, that he may either
over-reach, or by treading on the heels of the fore horfe,
dernager tumbling over.

Whatever be the ground that the adversary's horfe runs
woret on, the cunning jockey is to ride the most violently
over; that by this means it will often happen, that in fol-
lowing he either flumbles or claps on the back fnews. The
several corrections of the hand, the whip, and the spur, are
also to be observed in the adversary, and in what manner he
makes use of them: and when it is perceived, by any of the
symptoms, of holding down the ears, or whifhing the
tail, or stretching out the nose like a pig, that the horfe is
almost blown, the businesfs is to keep him on to this speed,
and he will be foon thrown out, or dinned off. If the horfe
of the opponent looks dull, it is a sign his strength fails him;
and if his flanks beat much, it is a sign that his wind begins
to fail him, and his strength will soon do too.

After every heat for a plate, there muft be dry flraw, and
dry cloths, both linen and woollen, ready to rub him down
all over, after taking off the sweat with what is called a
sweat-knife; that is, a piece of an old sword-blade, or some
similar thing. Some advise the steeping of the clothes in urin
and saltpetre the day before, and letting them be dried in
the sun for this occasion. After the horfe has been well
rubbed with this, he should be chafed all over, with clothes
wetted in common water, till the time of starting again.
When it is certainly known that the horfe is good at the
bottom, and will tick at the mark, he should be rid every
heat to the best of his performance; and the jockey is, as
much as poffible, to avoid riding at any particular horfe, or
flying for any, but to ride out the whole heat with the
best speed he can. It, on the contrary, he has a fiery horfe
to ride, and one that is hard to manage, hard-mouthed, and
difficult to be held, he is to be started behind the reft of
the horfes with all imaginable coolnefs and gentleness; and
when he begins to ride at fome command, then the jockey
is to put up to the other horfes; and if they ride at their
cafe, and are hard held, they are to be drawn on faster; and
if it be perceived that their wind begins to rake hot, and they
want a lab, the businesfs is to keep them up to that speed;
and when they are all come within three quarters of a mile
of the poft, then is the time to pull for it, and use the ut-
moft speed in the creature's power.

When the race is over, the horfe is immediately to be
clothed up, and rode home; and immediately on his coming
into the Stable, the following drink is to be given him.
Beat up the yolks of three eggs, and put them into a pint
and a half of new milk made warm; let there be added to
this three pennychworth of faffron, and three spoufuls of
fallad-oil, and let the whole be given with a horn. After
this he is to be rubbed well down, and the saddle-place
rubbed over with warm fack, and the places where the
fpiurs have touched, with a mixture of urine and falt, and
afterwards with a mixture of powder of jet and Venice tur-
pentine; after this he should have a feed of rye-bread, then
a good malt, and at some time after these as much hay and
oats as he will eat. His legs, after this, should be bathed
fome time with a mixture of urine and saltpetre.

For the preparation of the horfe before running, &c. see
PLATE.

We shall here obferve, that horfe-races were a species
of amusement known in England in very early times. Fitz-
Stephen, who wrote in the days of Henry II. records
the great delight which the citizens of London took in the
divertion.  Racing appear likewise to have been in vogue
in the reign of queen Elizabeth, and to have been carried
to fuch excefs as to have injured the fortunes of the nobi-
licity. Lord Herbert of Cherbury (fee his Life by Mr.
Walpole, p. 51.) enumerates thefe among the fports which
he thought unworthy of a man of honour. " The exercife,"
says he, " I do not approve of is running of horfes, there
being much cheating in that kind; neither do I fee why a
brave man should delight in a creature whose chief ufe is to
help him to run away." Jarvis Markham, who wrote on the
management of horfes in 1599, mentions running horfes;
but at this time there were only private matches made be-
tween gentlemen, who were their own jockeys, and rode
their own horfes. However, in the following reign of
James I., public races were established; and Gartery, in
Yorkshire, Croydon, near London, and sometimes Theo-
hald's, near Enfield-chace, where the king refided, were the
courfes in which they were performed. The horfes at this
time were prepared for running by the discipline of food,
phyfic, airing, and fweats and clothing, which complete the
preffent syftem. The weight also which each horfe was to
carry was rigidly adjudged; the usual weight of the riders
being flated at ten flones, who were put into fcales, and
weighed before they started. Most of the celebratfed races
in the kingdom were called bell-courfes, the prize and re-
ward of the conquering horfes being a bell. To this pur-
pofe, Camden fays, that in 1607 there were races near York,
and the prize was a little golden bell. Upon this Be-
renger offers a conjecture, whether the phrase of bearing
the bell, which implies being comparatively the beft or most
excellent, and corresponds with the expreffion of bearing
the palm among the ancients, as a reward decreed to the
swiftest horfe in a race, is not more aptly deduced from this
custom,
custom, than from the method of tying a bell round the
neck of the sheep, which leads the flock, and is, therefore,
counted the bell.

About the latter end of the reign of Charles I. it was
customary to have races performed in Hyde Park. See the
Comedy of the Merry Beggars, or Jovial Crew, written in
1641, in Dudley's Collection of Old Plays.

Racing was much encouraged by Charles II. after his
restoration: he gave public rewards and prizes, and ap-
pointed races for his own amusement at Datchet Mead,
when he resided at WindSOR. But the most distinguished
spot for these exercizes was Newmarket, which was at first
frequented for the purpose of hunting, and seems not to
have been destined to be a horse-courfe till some time be-
fore the troubles of the reign of Charles I. when races
were discontinued; but they were revived soon after the
Restoration. The king attended in person, and established
a house for his accommodation, and kept and entered horses
in his own name. Instead of bells, a silver bowl or cup,
of the value of a hundred guineas, was allotted for a prize;
and upon this royal gift the exploits of the successful horse,
and his pedigrees, were generally engraved. The sum of
a hundred guineas is now given in lieu of the silver bowl.

When William III. was advanced to the throne, he
was only added to the plates given to different places in the
kingdom, but founded an academy for riding. Queen Anne
continued the bounty of her predecessors, with the addition
of several plates. George I., towards the end of his reign,
discontinued the plates, and gave the sum of a hundred
guineas in their room.

In the thirteenth year of George II. an act was passed
for the suppression of races by poneys, and other small and
weak horses, by which all matches for any prize under the
value of 50l. are prohibited, under a penalty of 500l., to
be paid by the owner of each horse running, and 100l. by
both as adverfite the plate; and by which each horse entered
to run, if five years old, is obliged to carry ten stones; if fix,
eleven; and if seven, twelve. It is also ordained, that no
perfon shall run any horse at a course, unless it be his own,
or enter more than one horse for the same plate, upon
pain of forfeiting both horses; and also every horse-race must
be begun and ended in the same day. Horses may run for the
value of 50l. with any weight, and at any place. 13 Geo. II.
vol. i. p. 52, &c. Berenger's Hist. and Art of Horfemen-
ship, vol. i. p. 185, &c.

We shall here add, that at Newmarket there are two
courses, the long and the round: the firit is exactly four
miles, and about three hundred and eighty yards, i. e.
seven thousand four hundred and twenty yards. Chil-
ders, the swiftest horse ever known, has run the first course
in seven minutes and a half, and the second in six minutes
forty seconds; which is at the rate of more than forty-nine
feet in a second. But all other horses take up at least
seven minutes and fifty seconds in completing the first and
longeft course, and seven minutes only in the shorteft,
which is at the rate of more than forty-seven feet in a
second, and it is commonly suppos'd that these courfer
cover, at every bound, a space of ground in length about
twenty-four English feet.

RACITZA, in Geography, a town of Bukovina; 7
miles N. of Czernaucli.

RACK, a small island near the coast of Virginia. N.
lat. 37° 19'. W. long. 75° 51'.

Rack, Lower and Upper, two small islands near the coast
of Virginia; the former in N. lat. 37° 20'. W. long. 75°
50', and the latter in N. lat. 37° 20'. W. long. 75° 45'.

RACK, an engine of torture furnished with cords, &c.
for extortiog confessions from criminals.

The duke of Exeter, confidible of the TOWER under
Henry VI., with the duke of Suffolk, and others, having
a design to introduce the civil law into England; for a
beginning, the rack, or brake, allowed in many cases by the
civil law, was first brought to the TOWER, where it is still
preferred; in those days the rack was called the duke of
Exeter's daughter. 3 Hift. 35.

It was occasionally used as an engine of state, not of law,
more than once in the reign of queen Elizabeth. (Barr. 92.
496.) But when, upon the affailation of Villiers, duke of
Buckingham, by Felton, it was proposed in the privy-
council to put the affailant to the rack, in order to discover
his accomplices; the judges being consulted, declared unani-
mosly, to their own honour, and the honour of the English
law, that no such proceeding was allowable by the laws of
England. The uncertainty of this punishment, as a test,
and criterion of truth, was long ago very elegantly pointed
out by Tully (pro Sulla, 28.) though he lived in a state in
which it was usual to torture slaves, in order to furnish
evidence. "Tamen," says he, "illa tormenta gubernat
dolor, moderatur natura cujusque tum animi tum corporis,
regit quaeque, flecit libido, corrupit IPSIs, infirmat metus;
ut in tot rerum angustias nihil veritati loci rehauatur."

The marquis Beccaria (ch. 16.), in an exquisite piece
of raillery, has proposed this problem, with a gravity and
precision that are truly mathematical: "the force of the
muscles, and the sensibility of the nerves of an innocent
perfon being given, it is required to find the degree of pain
necessary to make him confess himself guilty of a given
crime."

Rack, in the Mange, a pace in which a horse neither
trots nor ambles, but shuffles, as it were, between both.
The shuffling pace is much the fame as the amble (which
fees); only that it is a twifter time, and a shorter tread.

Rack is also a wooden frame, made to hold hay or fodder
for cattle. There has lately been much improvement made
in the forming of all sorts of racks, both for the flable,
cattle-sheds, and field. See CATTLE-sheds, STABLE, and
SHEEP-sheds.

Rack, in Rigging, a short thin plank, with holes made
through it, containing a number of bailing-pins, used
stead of cleats; it is fixed to the shronds, and nailed over
the bowsprit or windlafs. Also, a long shell, containing
a number of sheaves, formerly fixed over the bowsprit to
lead in the running rigging. At present, wooden faddles,
with holes in them, are nailed on the bowsprit for this purpose,
being more out of the way, and less liable to be out of order.
See SHOT-rack, and SHroud-rack.

To Rack Wines, &c. is to draw them from off their lees,
after their having flooded enough to clear and settle.

RACK-Vintage, is frequently used for the second voyage
of our wine-merchants used to make into France for raked
wines; whence they used to return about the end of De-
ember: To Rack, Holders, such tenants as hold their lands
under such leases.

Rack-Leaves, are such sorts of leaves as are granted for
one or more lives, at the full rack rents, as in Cornwall,
and some other counties. See LEASES of LAND.

Rack-Rent, is the full yearly value of land let by lease,
payable by tenant for life or years, &c. See RENT.
RACK, *Sheep*, a sort of long narrow crib, fixed upon wheels, for containing hay for sheep, having a lid or covering on the top. It is very useful in bad weather, in the winter season, as preventing the hay from being wasted, and admitting the sheep to feed conveniently.

RACKAMA, in Geography, a lake of Syria, south of Hella and the ancient Babylon, is about 30 miles long, and flows into the Euphrates.

RACKEBY, a town of Sweden, in Weft Gotländ; 40 miles N.E. of Uddevalla.

RACK, a kind of bat for striking the ball at tennis; consisting usually of a lattice, or net-work, of cat-gut, strung very tight over a circle of wood, with a handle or shaft of a moderate length.

The word is formed from the French 

*raquette*, which Menage derives from the Latin *reticulum*, a diminutive of *reticet*, net; whence also reticium, and reticulum.

Pasquier observes, that anciently they used no rackets at tennis, but played with the palm of the hand; and hence he conjectures it is that the French call tennis play, *jeu de paume.* He adds, that rackets were not introduced till a little before his time.

Racket is also a machine which the savages of Canada bind to their feet, to enable them to walk more commodiously over the snow; made much in the manner of a tennis-racket.

Its figure is a lozenge, of which the two obtuse angles are rounded off. It is bound about with very fine thongs of leather, and the meshes of it are much smaller and closer than those of our rackets.

In the middle is fitted a kind of shoe, lined with wool, or hair; to be tied on to the ankle: by which means the feet are prevented from sinking in the snow. Rackets oblige the performer to take very long steps, and, as we say, to walk a great pace, to keep them from knocking against each other.

Racket, in Geography, a river of New York, which runs into the St. Lawrence, N. lat. 45° 13'. W. long. 74° 42'.

RACKIBIRN, the name of a small island on the N.W. coast of Ireland, situated near Tighlin head, in the county of Donegal. N. lat. 54° 39'. W. long. 8° 44'.

RACKING, in Sea Language, denotes the softening of two opposite parts of a tackle together, so as that any weighty body suspended by it shall not fall down, although the rope, which forms the tackle, should be loosened by accident or neglect. This expedient is chiefly practised when the boats are hung up to the ship's side on shore, in an open road or bay, left the rope of the tackle should be untied by the intentionate of some of the crew, by which accident the boat might be considerably damaged, and probably lost or dashed to pieces. Falconer.

Racking Fruit Liquor, the operations of fining and drawing it off. See Cider.

RACKLIA, in Geography, a small rocky island in the Grecian Archipelago, inhabited by two or three poor monks, who take care of a few sheep and goats. N. lat. 36° 53'. E. long. 25° 38'.

RACKNITZ, a town of the duchy of Carinthia; 3 miles S. of Saxenburg.

RACKON, or Raccoon, the *uroctos totalis* of Linnaeus, in Zoology, the name by which we commonly know an American animal, called *coati* by the Brazilians. It is something smaller than the beaver, and is of the shape of the beaver in the body, and its legs are as short as in that creature. The face, cheeks, and chin are white; the upper part of the body is covered with hair, long, soft, and thick; black at the ends, whitish in the middle, and ash-coloured at the root. Sometimes from this mixture of colour the back appears plainly grey; and Marshgrave mentions another species, which is of a deep yellow or ochre colour.

The head is very like that of the fox in shape; but that the ears are shorter, roundish, and naked, and it has from the forehead to the nose a dusky line. The eyes are large, and surrounded with two broad patches of black; the nose is black and sharp-pointed; its tail is very bushy, and annulated with black. Its feet are each divided into five slender toes; by the help of which it climbs trees as expertly as a monkey, and uses the fore-feet as hands, to reach up its food to its mouth. It is a very cleanly animal; and if there be water near, it always washes its food, be it what it will, before it eats it. It feeds on vegetables, but is also fond of eggs, and will even seize birds if it can catch them. It is also very fond of sweet things and strong liquors, and will get exceedingly drunk: at low-water it feeds much on oysters, watching their opening, and with its paw snapping out the fish, and is sometimes caught in the shell. It is very common in the warm and temperate parts of America, in the mountains of Jamaica, and in the isles of Maria in the South sea, and is a creature easily tamed. It is hunted for its skin; the fur, next to that of the beaver, being excellent for making hats. Ray and Pennant.

RACLER, Fr., to scrape, to rasp, or file a hard body. It is said, in derision of a bad performer on the violin, or any other instrument played with a bow, that he scrapes or rasp the strings; because, in fact, he draws a harsh and disagreeable tone from his instrument, which resembles that produced by scraping or filing a hard body. Even good players on the violin sometimes scrape a little in the fore parts of their performance. Suppl. to Encycl., 18 edit.

RACLERGUNGE, in Geography, a town of Bengal; 50 miles N.W. of Burdwan.

RACONIGI, a town of France, in the department of the Stura, containing four gates, with as many foyers, well peopled. The king of Sardinia had a palace here. The police is conducted by fifteen counsellors, from whom two syndics are chosen every four months, who act as bailiffs or mayors of the town. It has two parishes, and several religious houses. The inhabitants are industrious, and much employed in making gauzes and silk flusses; 6 miles N. of Savigliano.

RACOPILUM, in Botany, from *rachis*, a stem or garden, and *pilum*, a hat or cap; the name of one of Palmstot de Beauvoir's genera of mosses, whose veil is torn at the side. It ought to be written Rhacopilum.

RACOBEA, a name of Auber's, of which we find no explanation. See Homalium.

RACOW, Catechism of, in Ecclesiastical History, a fyttern of theology compiled by the most eminent Socinian doctores, and first published at Racow, or Rakow, in Poland, in the year 1609, with a dedication to our king James I. This catechism, or a translation of it, was committed to the flames in England, in the year 1653, by order of parliament. A new edition of it, corrected and enlarged, was published at Stuapoli, in 1684. The Socinians consider this catechism as the great standard of Socinism, and an accurate summary of the doctrine of that sect. However, Mofheim observes, that it is, in reality, no more than a collection of the popular tenets of the Socinians, and by no means a just representation of the secret opinions and sentiments of their doctors. Hence he says it never obtained among them the authority of a public consecration or rule of faith; and hence the doctors of that sect were authorised to correct and contra-
tradiit it, and to substitute another form of doctrine in its place. But to this account it has been replied, that it would have been inconsistent with the liberty, for which they argue in the preface to this catechism, to have limited their religious inquiries to this standard; and by treating it as a rule of faith, they would have violated their express declarations, that they dictated to no one, and assumed no authority. Moth. Eccl. Hist. See RAKOW.

RACON-COMPON, in Geography, a mountain of Tibet. N. lat. 31° 50'. E. long. 86° 14'.

RADA, a town of Sweden, in Warmeland; 33 miles N. of Carlstadt.—Alfo, a town of Sweden, in Warmeland; 35 miles S.E. of Carlstadt.—Alfo, a town of Sweden, in West Gotland; 5 miles W. of Gothenburg.—Alfo, a river of Welfphalia, which runs into the Ocker, 5 miles N.E. of Goflar.

RADANAGUR, a town of Hindooftan, in Bahar; 32 miles E. of Ramgur.

RADANI, a town of Sweden, in West Gotland; 16 miles N. of Uddevalla.

RADAR, a town of Persia, in the province of Chor- fán: 48 miles N. of Mefchid.

RADASALMI, a town of Sweden, in the province of Savolax; 20 miles N.N.W. of Nylofht.

RADAVITZA, a town of Prufia, in the palatinate of Culm; 22 miles E.S.E. of Culm.

RADAUN, a town of Austria; 6 miles W.S.W. of Vienna.

RADAUTZ, or RADENTZ, a town of Bukovina; 22 miles W.S.W. of Sazava.

RADAWAIR, a town of Hindooftan, in Candeif; 14 miles S.W. of Burhanpore.

RADBUZA, a river of Bohemia, that rises in the S.W. part of the cliff of Pifen, and runs into the Miza, near the town of Pilen.

RADCLIFFE, John, in Biography, an eminent and eccentric physician, was born at Wakefield, in Yorkshire, where his father possessed a moderate estate, in the year 1650. He received the rudiments of his classical education at a school in that town; and at the age of 15, was sent to complete his studies at University college, in Oxford. He took his bachelor's degree in arts in 1669, and removed to Lincoln college, where he was elected to a fellowship. Having determined upon the profession of physic, he went through the courses of botany, chemistry, and anatomy, and was distinguished by the rapidity of his attainments in all these pursuits. Nevertheless he did not apply with zeal or industry to the studies of the closet, and recommended himself rather by his vivacity, acuteness, and wit, than by any extraordinary acquisitions in any department of knowledge. In the prosecution of his medical inquiries, he contented himself with looking into the works of Dr. Willis, who was at that time practising in London with much reputation. He was poliſhèd, indeed, of very few books; infomuch that when Dr. Bathurst, head of Trinity college, asked him once with surprize where his study was? he pointed to a few vials, a skeleton, and a herbar, and said, "Sir, this is Radcliffe's library." He took the degree of master of arts in 1672, and in 1675 he proceeded bachelor of medicine, and immediately began to practice in Oxford. He professed to pay very little regard to the rules which were generally followed, but confounded them on many occasions with great freedom and acrimony; a conduct which did not fail to draw upon him the censure of all the old practitioners. Nevertheless his reputation and his practice rapidly increased; and before he had been two years in the world, he was very generally consulted, even by those of the highest rank. About this time, in consequence of some witticifms, which he had launched with his accustomed freedom against Dr. Marshall, rector of Lincoln college, the latter unkindly opposed his application for a dispensation for taking holy orders, which the statutes required, if he retained his fellowship, and shewed other tokens of incivility; which induced Radcliffe to resign his fellowship, quit the college, and take lodgings in the town. He continued to practise at Oxford, increasing his wealth and reputation, until 1683, having taken the degree of doctor in 1682; and he then determined to remove to London, and settled himself in Bow-street, Covent Garden.

His success in the metropolis was unusually rapid; and doubtless his wit and pleasantry, which rendered him a most entertaining companion, contributed fearfully less than his reputed skill in his profession to forward his progress. In less than a year he was in full practice; and in the second year, he was appointed physician to the princesse Anne of Denmark. In 1688, when prince George of Denmark joined the prince of Orange, and the princesse retired to Nottingham, in a state of pregnancy, he was prefixed by bishop Compton to attend her, in quality of his office; but he excused himself on account of the multiplicity of his patients. After the revolution, he was consulted by king William and the nobility about his court; an honour which he must have owed entirely to his high reputation, for he never shewed any inclination to be a courtier. By his rough independence of spirit and freedom of language, indeed, he ultimately lost all favour at court. In 1669, when king William returned from Holland in a state of severe indisposition, he feot for Radcliffe, and shewing him his swollen ankles, while the rest of his body was emaciated, said, "What think you of this?" "Why truly," replied the physician, "I would not have your majesty's two legs for your three kingdoms." This freedom was never forgiven by the king, and no intercessions could ever recover his favour towards Radcliffe. In 1694, when queen Mary caught the small-pox, and died, Radcliffe was accused, bishop Burnet says, of negligence and unkindness. He feo afterwards lost the favour of princesse Anne, by neglecting to obey her call from his too great attachment to the bottle, and another physician was appointed in his place. When queen Anne came to the throne, the earl of Godolphin exerted all his endeavours to reinstate him in his former post of chief physician; but he refused, alleging that Radcliffe would lend her word again, "that her ailments were nothing but the vapours." Nevertheless he is said to have been consulted in all cases of emergency, in a private way. In 1705 Dr. Radcliffe had an alarming and dangerous attack of pleurisy, which he neglected, and increased in the outlet by drinking a bottle of wine: he had, however, 100 ounces of blood taken from him by Mr. Bernard, the surgeon; and the next day, in spite of all intercessions, was carried to Ken-ington. His escape was almost miraculous. The queen asked Mr. Bernard how he did? and when he told her that he was ungovernable, and would observe no rules, he answered, that then nobody had reason to take any thing ill from him, since it was plain he used other people no worse than he used himself. During these ill days he made a will, by which he dispofed of the greater part of his property for charitable purposes, appropriating particularly several thousand pounds for the relief of sick women on shore. He recovered, however, and continued in full occupation in his profession, increasing in wealth and influence to the end of his days, and waging a perpetual war with his brethren; who, in their turn, represented him as an active, ingenious, adventurous empiric, whom constant
practice had brought at length to some skill in his profession. His caprice in the performance of his professional duties appears to have been unbounded; and many anecdotes are related of his refusal to attend on persons of distinction, if he happened to be engaged in pleasanter company, or had any personal pique against the individuals, or if he conceived himself in any way affronted. Thus he fell off suddenly for Bath in 1704, while attending the lady of Sir John Trevor, because that gentleman sent to Oxford for Dr. Breach to consult with him; which he had done as a compliment to Radcliffe, rather than join any of the London physicians with him. When Mr. Harley was stabbed by Gufheard, Swift complains, that by the caprice of Radcliffe, who would allow none but his own surgeon to be admitted, "he had not been well looked after;" and adds in another place, "Mr. Harley has had an ill surgeon, by the caprice of that puppy Dr. Radcliffe, which kept him back so long." On the other hand, he attended the lady of Sir John Holt in a bad illness, with unusual diligence, out of pique to the husband, who was not suppofed to be over fond of her. In the last illness of Queen Anne, he was sent for to his country-house at Carfhaltton about noon, by order, as one account affirms, of the privy council; but he returned an answer, that "he had taken physic, and could not come." It has been flated, however, on the other hand, that he was only sent for on this occasion by Lady Marlham, without any order from the queen or the council; which is countenanced by the following circumstances. On the 1st of August, four days after the queen's death, a friend of the doctor's moved in the houfe of commons, that he might be fummoned to attend in his place. (Dr. Radcliffe had been elected a member for Buckingham in 1714,) in order to be cenfured for not attending on her majesty. A letter is prefered, faid to have been written by the doctor to one of his friends, on this occasion, in which he fays, "I know the nature of attending crowned heads in their laft moments too well, to be fond of waiting upon them, without being fent for by a proper authority. You have heard of pardsons being figned for physicians before a sovereign's demifne; however, ill as I was, I would have went to the queen in a horfe-litter, had either her majesty, or thofe in the commiffion next to her, commanded me to do so." Whatever was the true cafe of the cafe, it is certain that Dr. Radcliffe became so much the object of popular reftentment, that he was apprehensive of being affaiufated, as appears from a letter addressed by him to Dr. Mead, which is extant. "Nor shall I be at any time from home," he fays, "because I have received several letters, which threaten me with being pulled to pieces, if ever I come to London." He ferved the queen but three months, and died at Carfhaltton, on the 10th of November 1714, at the age of 64. It was believed, that the dread which he had of the populace, and the want of company in his retirement, which he did not dare to leave, contributed to accelerate his death. He was carried to Oxford, and buried in St. Mary's church in that city.

It does not appear that Dr. Radcliffe ever attempted to write, and probably he would not have succeeded as an author. He was beloved, indeed, to have been very little converfant with books; which made Dr. Garth humorously say, that "for Radcliffe to infituue a library, was as if an eunuch should found a feraglio." He was often the fubject of the attacks of ridicule from poets and wits, and even was not spared on the stage; having been severely fatirized in a piece acted in 1704, soon after a legal dispute with an apothecary, which was attended by the ladies of the court, and in which the passages affronting the doctor were much applauded. Swift, in Martinus Scriblerus, and Steele in the Tatler, levelled their ridicule at the doctor; and the following severe portrait of him was drawn by Dr. Mandleville, in his Elfsay on Charity Schools. "That a man with small skill in phyfic, and hardly any learning, should by vile arts get into practice, and lay up great wealth, is no mighty wonder; but that he should do deeply work himself into the good opinion of the world as to gain the general esteem of a nation, and eftablish a reputation beyond all his contemporaries, with no other qualities but a perfect knowledge of mankind, and a capacity of making the most of it, is something extraordinary. If a man arrived to such a height of glory, should be almost diftracted with pride, sometimes give his attendance on a fervant, or any mean perfon, for nothing, and at the fame time neglect a noblcman that gives exorbitant fees; at other times, refuse to leave his bottle for his buncffe, without any regard to the quality of the persons that fort for him, or the danger they are in;—if he should be furry and morofe, affect to be a humourif, treat his patients like dogs, though people of distincfion, and value no man but what would defy him, and never call in question the certainty of his oracles:—if he fhould influt all the world, affront the firft nobility, and extend his infolence even to the royal family:—if, to maintain as well as to increase the fame of his sufficiency, he fhould scorn to consult with his better on what emergency fooer, look down with contempt on the moft deferving of his profession, and never confer with any other phyfician but what will pay homage to his superior genius, creep to his humour, and never approach him but with all the fquivif obfquifonif were a court flatterer can treat a prince with:—if a man in his life-time should difcover, on the one hand, fuch manifeft symptoms of fuperlative pride, and an infatiable greediness after wealth at the fame time; and on the other, no regard to religion, or affe<;ction to his kindred, no compaffion to the poor, and hardly any humanity to his fellow-creatures:—if he gave no proofs that he loved his country, had a public spirit, or was a lover of arts, of books, or of literature:—what must we judge of his motive, the principle he acted from, when after his death we find that he has left a trifle among his relations, who fiook in need of it, and an imme<;lute treasure to an univerfity that did not want it." Whatever may be the motives of the endowers of splendid infitutions for the public ufe, the nation is at all events benefited for ages, by fuch noble establishments as the library and in{irmary which he founded at Oxford, and which bear his name. He also endowed two travelling fellowsfhips, with an annual income of 300l. attached to each. He had previously caufed the beautiful cafe window, over the altar, in Univerfity college, to be put up at his own expe<;nfe; and likewise gave the money, which was paid for the erection of the maiter's lodge there, making one fide to the extent almoft of fpurring, and never could be induced to pay bills without much following and impatience. A piece of waggery would fometimes conquer this difpo{;fion. A pavior, after long and fruitless attempts, once caught him just getting out of his chariot, at his own door, in Bloomsbury square, and fet upon him. "Why, you rascal," faid the doctor, "do you pretend to be paid for fhuch a piece of work? Why, you have spoiled my pavement, and then covered it over with earth to hide your bad work."—"Doctor," f aid the pavior, "mine is not the only bad work the earth hides."—"You dog you," f aid the doctor, "are you a wit? You must be poor; come in;" and he paid him. He told Dr. Mead, that the great fecre<;t by which he might make his fortune was to "ufe all mankind ill." Dr. Mead, however, adopted the contrary
contrary axiom, and succeeded even beyond his adviser. Notwithstanding that Radcliffe seems to have literally prac-
ticed this principle, in his dealings both with his patients and his brethren; and notwithstanding the severe ac-
culations of ignorance and empiricism, which were every where
levelled against him; the universal reputation, which he ac-
quired and maintained, seems to sanction the testimony of
Dr. Mead, that "he was deferredly at the head of his pro-
feffion, on account of his great medical penetration and ex-
perience." See Atterbury's Epitaphial Correspondence.

RADDELE, in Geography, a town of Ceylon, on the
east coast; 5 miles N.E. of Trincomah.

RADDINSDORP, a town of the duchy of Holstein; 6
miles E.S.E. of Eutyn.

RADDLE, in Agriculture, a red ochre of iron, which,
according to Dr. Darwin, has been found useful as a ma-
nure in the northern parts of Staffordhire. Its properties
have not, however, been yet chemically examined as they
relate to manure. See REDDY.

RADEBURG, in Geography, a town of Saxony, in
the margravate of Meillen; 12 miles N.E. of Dresden.
N. lat. 51° 8'. E. long. 13° 53'.

RADECHAU, a town of Bohemia, in the circle of
Koniggratz; 9 miles S.E. of Trautenau.

RADEGATZ, a town of Germany, in the principality
of Anhalt-Deflau; 13 miles S.S.W. of Deflau.

RADEGURRY, a town of Hindoostan, in Carnara;
24 miles S.S.E. of Mangalore.

RADENTHAL, a town of the duchy of Carinthia;
13 miles E. of Saxenburg.

RADERAN, a town of Bohemia, in the circle of
Kauzim; 3 miles N.E. of Kauzim.

RADERMACHA, in Botany, a name originally given
to the Bread-fruit, (see Artocarpus,) by Thunberg,
in honour of one of his great patrons, Joachim Cornelius
Matthew Radermacher, a member of the Dutch council,
and President of the Society of Sciences, at Batavia.
The author, in his Nova Genera, p. 25, represents this gentle-
man as a most distinguished Magus, and encourager
of Natural History. Nevertheless, the above name has,
by common consent, given way to the expressive one of Forfer,
Artocarpus, which is precisely synonymous with Bread-
fruit.

RADERSBURG, in Geography, a town of Germany,
in the principality of Culmbach; 7 miles E. of Bayreuth.

RADES, a town of Tunis, on the N.E. coast; 5 miles
S.E. of Tunis.

RADESHE, or Radeschach, a town of Lower
Carniola, on the Save; 10 miles N.W. of Gurkfeld.

RADHA, in Mythology, is the name of the comfort of
the Hindoo deity Krishna. As Krishna was an avatar,
or incarnation of Vishnu, fo Radha is understood to be similarly
an avatar of Vishnu's consort Lakshmi; thus incarnated
to accompany her lord in this, his most splendid terrestrial
manifestation. Under the articles KRISHNA and LAKSHI-
MMA some notice will be found on the subject of this. Radha is seen
very frequently portrayed and alluded to in the paintings
and writings of India: Krishna is, indeed, seldom seen with-
out her. She is represented of perfect beauty, and is warmly
cherished in the amatory poems of Hindoostan. In the
elegant work of Jayadeva, entitled Gita Govinda, a pastoral
play exhibiting the loves of Krishna and Radha, the lovely
nymph is thus described after a quarrel with her frolicksome
and licentious, in the morning after the night of reconcili-
ation, when affection confounded, and ecstacy crowned the recondi-
tion of past sorrows. "In the morning the arrow, dis-
arrayed, and her eyes betrayed a night without slumber,
when the yellow-robed god, who gazed on her with trans-
port, thus, in his heavenly mind, meditated on her charms:
'Though her locks be diffused at random; though the lustre
of her lips be faded; though her garland and zone be fallen
from their enchanting stations; and though she hides their
places with her hands, looking towards me with bashful
silence; yet, even thus disarrayed, she fills me with ecstatic
delight.' But Radha, preparing to array herself before the
company of nymphs could see her confusion, fpoke thus with
exultation to her obsequious lover.

'Place, O fon of Yadu! with fingers cooler than sandal
wood, place a circlet of musk on this breast, which resem-
bles a vase of consecrated water, crowned with fresh leaves,
and fixed near a vernal bowier to propitiate the god of love.
Place, my darling! The glossy powder, which would make
the blackest bee envious, on this eye, whose glances are
keener than arrows darted by the husband of Reti. (See
Reti.) Fix, O accomplished youth! the two gems,
which form part of love's chain, in these ears, whence the
antelopes of thine eyes may run downwards and sport at
pleasure. Place now a fresh circlet of musk, black as the
lunar spot, on the moon of my forehead; and mix gay
flowers: on my trefoles with peacock's feathers, in graceful
order, that they may wave like the banners of Kama. Now
replace, O tender hearted! the loofe ornaments of my
vulture; and reft the golden bells of my girdle on their
defined flation, which resemles those hills where the god
with five fhafts, who destroyed Sambara, keeps his elephant
ready for battle.' While he fpoke, the heart of Yadava
triumphed; and obeying her ipportive behalfs, he placed
musk fpot on her bosom and forehead; dyed her temples
with radiant hues: embellifhed her eyes with additional
blackness; decked her braided hair, and her neck,
with fresh garlands; and tied on her wrists the loofened bracelets,
on her ankles the beany rings, and round her waift the zone
of bells, that founded with ravifhing melody.'

But we must recollect, says the author of the Hindu
Pantheon, whence this article is chiefly taken, that the
feemingly amorous conflicts of these ardent lovers are mere
mythical descriptions of "the reciprocal attraction between
the divine goodnefs and the human foul." This is the
emblematical theology that Pythagoras admired and adopted;
that the Sufi poets, Hafez, Sadi, and many others among the
Perfians, and Solomon also, in his fine Song, fo beauti-
fully inculcates. Like the enthusiasts of other days, and
in a manner not easily comprehended by the unenlightened,
 nor believed by them to be permanently chafte, however in-
nocent its commencement, "they profess eager defire, but
without carnal affection; and circulate the cup, but no
material goblet: in their feft, all things are spiritual, all is
mystery within mystery." See fir W. Jones's admirable
Eflay on the Mythical Poetry of the Persians and Hindoos,
in the third volume of the Aflatic Researches, in which a
translation of the Gita Govinda of Jayadeva is introduced.
Under the article JAYADEVA of this work is a brief notice
of his poem; and under MAHES is an extract from it,
descriptive of the persons and loves of this interesting
couple. (See alfo PRABHA.) The reader delirious of
feeling what has been faid and believed on the curious
funjet of mythical or emblematical theology, may confult
our articles under MYSTERY, MYSTICS, and those thence
referred to.

Returning to Radha, we have to observe that among the
feft of Gokalaththa (see Sects of Hindoo) she is deemed a
personification of religion, and sometimes called Radhemi.
(See that article.) There is a sect said to worship her exclusively, and called Radha-balabhah; they consider her as the Sakti, or active power of Viṣṇu or Kṛṣṇa. (See Sakti.) The followers of this sect have attributed to them the singular practice of waking their own wives perfornate Radha, and of presenting to or through them the oblations propitiating the goddesfs, or Lakṣmī, of whom, as before said, she is an incarnation. There is no end to the whim- sicalities in the modes of human worship, to give them no harsher name, wherever, to use an oriental expression, we suffer our necks to slip out of the collar of reafon. Thus in India, as hath been the case in other countries, there is, with several sects, a right-handed and a left-handed mode of worship; one meaning a decent, the other an indecent mode. Thofe among the fools in question, who follow the left- handed path, require their wives to be naked, when attending them at their devotional abominations. She is sometimes called Radhika, and Kṛṣṇa, Radhikēsvara, or lord of Radhika; and sometimes the name of Kantamati is given both to her and Rukmēni. See Rukmēni and Yonī.

In Radha may be recognized the Grecian Juno, and of course in her husband Kṛṣṇa, or Viṣṇu, the amorous Jove of that imitative race. On this point we shall quote a paragraph from the Edinburgh Review, N° xxxiv.

"We translate a paflage from the Purana, entitled Brahma Vaivartica, to demonstrate the identity of character ascribed to Jupiter and Viṣṇu; only remarking, that in conformity to the peculiar tenets of its author, Viṣṇu is here filed Kṛṣṇa, and his godfesfs, Rādhā. Gangī (the Gangs) was originally a nymph of wonderful beauty, who inhabited Paradise. She became enamoured of Kṛṣṇa, and, concealing her face with her robe,浮动 immovable in his presence, her eyes fixed on his radiant countenance. The jealousy of Rādhā (Juno) was excited. Followed by her innumerable attendants, she repaired to the presence of the god, and sate herself on her throne of gems. The timid Gangī trembled at her aspect, and disfoved with terror. The godfesfs speak: "Who is this nymph, lord of the uni- vers, who, with half concealed visage, and eyes sparkling defire, thus gazes on thy faced person? This is not the first time the fifies have witneffed the infulence of their lord. When I detected thee dwelling in a grove of fandal with Vi- raja, the figure of a quadraped concealed thy fame, and she was changed into a river. Still purfued by thee became the mother of the mighty ocean. The fame fooriant was the fonce of thy fumors with the nymph Sūkhī, (beauty). Again thou aflumed the form of an animal; whilst her spirit fled to the moon, and thou difputed her body amongst gems, flowers, and black-eyed damafs. The woods of Vrindavan afford thee a retreat with the shepherdfes Prabhā (Jufer). On my arrival, her spirit tranfmiagrated to the solar orb; of her body thou madeft a distribution; the god of fire obtained a part; and fome, as gold, give brightnesfs to the crowns of the kings of the earth. When I found thee, unexpectedly, on a bed of veraf buds, reclined in company with the fair Xami (patience), alarmed at my voice, thou gatheredft as they lay defperfed, thy yellow robes, thy lyres, thy neckfafe of flowers, and thy creaf of gems. Thee I forgave when thou befpeafed a portion of her body on the pious anchoret, a portion on the fielk, and a portion on the fudius."

Such of our readers as have obtained a share in the latter portion, may, in the endeavour to expound this folar allegfry, be repaid perhaps for their pains; in perufing the Gita Govinda and the article in which it is compiled, above referred to, they affuredly will.

RADHIKA, a name of Radha, confort of the Hin- deo deity Kṛṣṇa, as sufficiently noticed under those articles.

RADHOST, in Geography, a mountain of Moravia, in the circle of Prerov; 12 miles E. of Meferitch.

RADHUA, a mountain of Arabia; 30 miles W. of Medina.

RADIÆUS, in Anatomy, an epithet applied to parts about the radius, and equivalent to radiusis; which fee.

RADIAL CURVES. See CURVES.

RADIALIS, in Anatomy, a name given to parts in the foarc-arm, situated near the radius. The adjective radial is also employed to denote the edge, surface, or aspect of any part, which is towards the radius; and in this way, with the term ulnar, affords the means of describing the organs much more accurately and intelligibly, than the indefinite exprefions of outer and inner, which vary constantly in the changing attitudes of the limb.

RADIALIS Arteris, is the artery of the wrist, in which the pulse is commonly felt. See ARTERY.

RADIALIS Carpi Extensor, Longior & Brevior. See CARPI.

RADIALIS Carpi Flexor. See CARPI.

RADIALIS Extensoris, Longior & Brevior, fynonym of the extenfoes carpi radiales, longior & brevier. See CARPI.

RADIALIS Internus, a fynonym of the flexor carpi radi- alis. See CARPI.

RADIALIS Nervus. The large nerve which goes behind the humerus, between two heads of the triceps, is called radial by some anatomists: others give this name to the nerve which lies parallel to and over the brachial artery. The frift of these is called also the muscular spiral nerve, the second the median. See NERVE.

RADIALIS Vena, the vein correfponding to the radial artery. See VEIN.

RADIANT Heat. See HEAT.

RADIANT Point, or Radiating Point, is any point of a visible object, whence rays proceed. Every radiant point diftributes innumerable rays all round; but only those radiants are visible, from which right lines may be drawn to the pupil; because the rays are all right lines.

All the rays proceeding from the fame radiant continually diverge; the crystalline collects or reunites them again.

RADIATED, in Botany, an epithet applied to round flat flowers, confluencing of a disk, and a fingle row of longifh pointed leaves, ranged all around it in manner of rays, or fpoifes.

Radiated flowers are properly fuch as have several femi- foliacs fet round a disk, fo as to refeemble a radiant ftar; fuch are daffies, chamomile-flowers, ran-flowers, &c. These are sometimes also called radiated diffuses flowers.

A radiated flower has two parts; its middle part, which is called the disk, and which is wholly made up of foliacs; and the other part, which is called the circle or border, which is wholly made up of semi-foliacs, or elle of plain flat leaves; but that is left common. The foliacs and semi-foliacs both usually adhere to the embryos, and to the thalamus of the flower, being contained in one general cup. These embryos finally ripen into seeds; sometimes furnished with down, sometimes with foliaceous heads, and sometimes without either, and sometimes margined. Of these seeds some are wrapped round with a kind of cafe or capfuie, others are separated from one another by small perpendi- cular leaves.

RADIATED Leaf. See LEAF.

The word is also used in speaking of medals, and in heraldry,
RAD

eraldry, where the ancient crowns are called radiated
crowns, corona radiatae. See Crown.

RADIATION, in Physics, the action of a body diffusing
rays of light as from a centre.

Every visible body is a radiating body; it being only by
means of its rays that it affects the eye.

The surface of a radiating body may be conceived as
consisting of radiant points.

Radiation, Place of. See PLACE.

Radiation, or Irradiation, is also used by some authors
to express the manner of the motion of the animal spirits;
on a supposition that they are diffused from the brain
towards all parts of the body, through the little canals of
the nerves, as light is from a lucid body. But in lieu of a
radiation, the moderns rather incline to the opinion of the
circulation of the spirits.

RADICAL, Radicis, in Physics, &c., something serv-
ing as a basis or foundation; or which, like a root, is the
foure or principle whence any thing arizes.

The schools talk much of a radical moisture inherent in
the feeds of all animals, which nourishes and preserves the
vital heat or flame, as oil does a lamp; and which, when
exhausted, life is extinguished.

Dr. Quincy observes, that this radical moisture is a mere
chimera; unless we thereby mean the mafs of blood, which
is the promptuary whence all the other juices and humoura
are derived; and which, while it circulates, sustains life, &c.

In grammar, we use the term, radical words, for roots
and primitives; in opposition to compounds and derivatives.
In the Hebrew language, the letters of the alphabet are
divided into radical and fervile. The first constitute
primitive or original words, which, by a significant metaphor,
ard called roots, מ radix. All the 22 letters of
the alphabet may be radicals; i.e., primitive words may consist
of any of these letters; but the following 11 letters properly
claim this title, because they can never be ferviles: aleph. gimel. mem.

Whichever letters any word contains, it must at least contain one of a
radical character. (See Root.) For an account of the
fervile letters, see SERVIL.

Radical Numbers, Numeri Radicales, in the Italian mufic,
are 2, 3, 5, 7, 8, 9, and sometimes 10, which are often
met with in musical compositions, to denote the acores of
the thorough basses; 2 stands for the second and its duplica
3 for the third; 4 for the fourth, &c.

Radical Life, among Botanists. See LEAF.

Radical Sign, in Algebra, the sign or character of the
root of a quantity.

\( \sqrt[n]{x} \) is the character of radicality, and expresses the square
root of a

Radicans, in Botany, rooting, a term applied to a
plant which throws out fibres as it extends itself; whether
these fibres be true radicles, by which the plant imbibes
nourishment, and is generally increased; or whether
they serve only for the support of the stem against walls, rocks,
or neighbouring trees. Of the first kind, the Strawberry
affords a familiar example; of the latter, the Ivy, the Vir-
ginian Creeper (Hedera, or rather Fitis, quinquifolia), and the
Bignonia radicans, are instances.

Radication, the action by which plants take root,
or flourishes.

The French Royal Academy of Sciences have made a
great number of curious observations on the germination
and radication of plants.

Radicle, in Agriculture, that part of the seeds of
plants which, upon vegetating, becomes their naifest roots.

It is, in fact, the main organ or medium of nutrition, and
the means by which food is imbibed or drank up from the
surrounding soil or earth. The radicles, together with the
leaves, therefore, constitute the absorbent organ of plants.
See RADICULA, and Root.

Radicofani, in Geography, a town of Etruria, near
which are two castles, one built by Didier, last king of the
Lombards, and the other by Colmo I.; 55 miles S. of
Florence.

Radicondoli, a town of Etruria; 24 miles N.E.
of Florence.

Radicula, in Botany and Vegetable Physiology, the
radicle, or fibre of the root. (See Root.) This term is
used by Dillenius, in his Nova Genera, 121. t. 6, as a
generic name, for a set of plants referred by Linneas to
Sisymbrium. See that article.

Radii Pronator Quadratus, in Anatomy, a muscle of the
fore-arm. See PRONATOR.

Radii Pronator Teres. See PRONATOR.

Radii Supinator Brevis, 4 muscles of the fore-arm. See
Radii Supinator Longus, 1 Supinator.

Modinaeum, in Ichthyology, the little slender bones
supporting the membrane, forming the fins in fishes, and
called by Artedi officia radiata pinnatum, from their run-
ing from the base to the summit in the form of rays. See
FISH, and ANATOMY OF FISH.

Radium, in Geography. See RADUNP.OUR.

Radiolus, in Botany, so called by Dillenius, because
the cells of the ripe capsule spread like the rays of a little
wheel. The plant having been referred by Linneas to the
genus Linum, the above became its specific name; but it is
now restored to the rank of a genus by the late professor
Gmelin of Gottingen, as well as by the author of Flora
Sibth. v. 1. 110. Att. Hort. Kew. v. 1. 282.—Clas and
Caryophyllaceae, Juff.

Gen. Ch. Col. Perianth inferior, of one leaf, cut about
half down into four equal, permanent, wedge-shaped segments,
each of which is three-cleft. Cor. Petals four, obovate,
about the length of the calyx, alternate, with its principal
segments. Stam. Filaments four, oval-shaped, erect, the
length of the calyx; anthers roundish, of two lobes. Pet.
Germen superior, roundish, with four grooves; styles four,
terminal, very short; stigma capitate. Peric. Capsule
roundish, bluntly five-sided, of eight cells and eight valves.
Seeds solitary, elliptical, compressed, very smooth.

El. Ch. Calyx in many segments. Petals four. Cap-
ulus superior, with eight valves and eight cells. Seeds
solitary.

t. 893. (R vulgaris fernyphilosa; Dill. in Rari Syn. 345.
t. 15. f. 3. Jacob. Faverh. 92. Linnum Radiola; Linn.
Sp. Pl. 402. Fl. Dan. t. 178. Linnarcarpus Serpifolia, filo,
multicául, et multiovulórum; Mich. Gen. 23. t. 21. Mille-
greana minima; Rari Syn. ed. 2. 207. Ger. Em. 569.
Chamadileum vulgar; Vaill. Paris. t. 4. f. 6,)—Native
of sandy ground, overflowed by clean fresh water, throughout
Europe, flowering in July and August; not a very general
English plant. The root is annual, small, and
thick. Show an inch or two high, repeatedly forked,
corymbose, spreading, leafy, round, nearly smooth, many-
flowered, often reddish. Leaves opposite, pelliform, oval,
entire, smooth, nearly a quarter of an inch long.
Flowers small, white, on short, simple, solitary stalks from the
forks of the stem.—Gmelin has erred considerably in

the
the generic character and name, as well as in his reference to Linnaeus. The calyx is many-cleft, not composed of four distinct leaves; the plant has hardly any thing of the aspect of a Linum, and therefore cannot properly be called linsides; neither has it been published as a genus, under the name of Radiola, by Linnaeus, as Gmelin’s reference to the 12th edition of Syll. Nat. indicates.

**RADIOMETER**, a name which some writers give to the radius afronumicis, or Jacob’s staff. See *FORE-STAFF*.

**RADIIS, in Botany.** (See *Raphanus*.) The radish is much grown, according to the author of the Agricultural Survey of the County of Kent, on the belt rich loamy soils of the Isle of Thanet, and in East Kent, for the supply of the London feedmen. The roots usually cultivated for this use are, the early short top, the salmon, and the turnip-rooted radish.

The land for the growth of this sort of crop should be in a fine state of preparation, by being ploughed to a great depth in the early part of the winter, and broken well down by harrowing, so as to render it perfectly clean from weeds, being previously filled with well reduced manure. The ground being brought into this fine condition, the feed is down on furrows about ten inches apart, in a dry time in the month of March, about two or three gallons per acre. And as soon as the plants appear, every other row is cut up with a horse-hoe, leaving the rows twenty inches apart. When the plants get two or three rough leaves, they are hoed out in rows, and are then kept clean by repeated horse and hand-hoeing, when necessary, leaving the plants at about eighteen inches distance. It is added, in the above Report, that the crop is seldom fit to reap till October, and sometimes is out in the fields till Christmas, without receiving injury from wet weather; it being necessary that it should have much rain to rot the pods, that it may thrash well. In respect to the produce, it is from eight to twenty-four bushels per acre; and it is sold to the London feedmen, who feed it to all parts of the kingdom for retailing to the gardeners.

It is probable that this sort of crop might be grown in many other districts near the metropolis, or other large towns, with equal success, where the soil is of a rich loamy nature, as it is very cafe in its culture, and requires but little labour or trouble. As it is necessary for it to remain out such a length of time, however, it will be proper, especially in wet seasons, to keep the stems from falling over too much upon the ground, as they and the feed may be injured by being too much in contact with it. If kept up in this way, the stalks, feed-hulks, and other offal parts, may also form a good cut food for some sorts of live-flock, as is the case with some other similar sorts of crops.

**RADIIS, Horse.** See *COCHLILLARIA ARMENACIA*.

**RADIUS, in Anatomy,** that bone of the fore-arm which extends from the humerus to the wrist, in the line carried from the external condyle of the former bone to the thumb. See *EXTREMITIES*.

**RADIUS, Dislocations and Fractures of.** See *FRACTURE AND LuxATION*.

**RADIUS, in Botany and Vegetable Physiology,** means the aggregate marginal florets of compound flowers, each generally of an oblong form, and all spreading from the centre, or disk, like rays. Such are the white florets of the Daisy, and blue, purple or red ones, for the most part, of the *Aster*. The usual shape of the limb or border of such florets is ligulate; either linear, or elliptical; rarely, as in *Achillea*, short and roundish; the extremity having three or five teeth. In some compound flowers the radius consists of tubular florets, as in *Centaurea*; and those are matter, dislocate of organs of fructification. The ligulate radiant florets above-mentioned are either female, producing perfect seed; or they are abortive, with more or less imperfect traces of a pistil. Many of them have no sign of a stamen or stigma, but none is without so much of a germen, as serves for the basis, that supports the petal itself.

A radius is occasionally allured by some flowers, naturally delticute of one, as in the genus *Bidens*, each species of which, by such an acquisition, becomes a *Coreopsis*, and changes its order in the *Sympetra*, from *Polygama aquaticus*, to *P. Fupera*.* This is a change in an approach to a double flower, in that class; being a transformation of a certain number of the perfect, or united, florets into female ones. If such a transformation be total, and all the tubular florets become ligulate, the whole flower is double, and unproductive of feed, like the double Chamomile.

**RADIUS, Ray, in Geometry,** the semidiameter of a circle; or a right line drawn from the centre to the circumference.

The word is derived from the Greek ῥάβδος, rod. Fleta uses the word radius, for a furrow.

The radius is also called, especially in trigonometry, *radius tatus*; the whole fine.

It is implied in the definition of a circle, and it is apparent from its construction, that all the radii of the same circle are equal.

**RADIUS, in the Higher Geome try, Radius of the evolute, *Radius curvilineus, or Radius of the circle,* called also the radius of concavity and the radius of curvature, is a right line representing a thread, by whose evolution from off the curve on which it was wound, the curve is formed; or it is the radius of a curve that has the same curvature in a given point of a curve with that of the curve in that point. See *CURVATURE AND Evolute*, under which articles the method of finding this radius may be seen.

**RADIUS Afronumicis, an instrument usually called Jacob’s staff, the cross-staff, or fore-staff.**

**RADIUS, in Optics.** See *RAY*.

**RADIUS, in Mechanics,* is applied to the spokes of a wheel; because lifting like rays from its center.

**RADIUS Vector, is also used for a right line drawn from the centre of force in any curve in which a body is sup- posed to move by a centripetal force, to that point of the curve where the body is supposed to be. See *CENTRAL Force*.

**RADIUS, among the Romans, a name given to the iron rod with which the boys rolled the trochus.**

**RADIUS Articulatus, in Natural History,** a name given by Mellius, Gmelin, and some other authors, to a kind of figured foils, of which there are a great many very different species, some of which have been described by authors among the belemnites, under the names of alveolii belemnitarum. Mr. Gmelin, who has taken great pains to inform himself, as well of the nature and figure of these foils, from the subjects themselves, as of their history, and the various accounts of them from other authors, observes, that the place where they are most frequent is Sweden, and that there they are no where so common as in the isle of Oeland. Volkman figures some also which he found in Silesia, and Helwing others which he collected in Pruffia: he also found great numbers of them himself in Ruflia.

They are usually immersed in lime-kerne, and though at first sight they may all appear alike, yet, on a careful examination, they will be found to differ very greatly. The most obvious general distinction, established by Gmelin, is that some of them are straight, and others crooked. The straight ones may be divided into two genera. The first of these comprehends, according to this gentleman, two pecks; the first smooth, and with a converging alveolus. The
The regular and nice configuration of these bodies shews very plainly that they cannot be of mineral origin; but the several patellae of which each is composed, the fiphunculus of communication, obvious in several, and the shelly matter yet found remaining on many, prove them to have been once shell-fish of the univalve or tubular concamerated kind; the description of which, so far as it can be gathered from these remains, must have been this. The shell must have been either cylindric or conic in figure, of a smooth surface, and divided into several chambers or cells; but this for that the septa which form the concamerations are not continued and whole, but in some part of the periphery are cut in, in the shape of a crescent. Through these crescents, which, standing all together, make a continued canal, there has paled another shelly body of a cylindric or conic figure, also divided into concamerations, and that in such a manner, that the septa which form the cells are pierced with a small aperture on one side, which grows gradually smaller as the shell extends in length; and finally, through these apertures, in the concamerations, there pales another shell pointed at the end, and, like the rest, divided into its concamerations, and pierces along its middle with a fiphunculus.

Mem. Acad. Petrov. vol. iii. p. 263.

This shell is, therefore, a compage of three shelly bodies, enclosed one within another; and, it must be supposed, in order to carry an analogy with other shell-fish, these three shelly bodies have communication with one another, by means of certain flaps or perforations. The communication of these, one with another, seems all evident, from their being all found in their foffile state, filled with the same fomy matter; this, has, doubtless, been all received in at the fiphunculus of the inner shell, and thence has been thrown into the second, and from this into the third shell, so as to fill up all the concamerations of the outer, as well as of the inner parts. This must have been the case with these; and the several various species that are at this day found foffile, must have owed their origin to as many different species of the shells. The crooked and twisted, or wreathed kinds, which have the fiphunculus usually placed near the side, greatly approach in their structure to some of the corn ammon.

RADIX, in Botany and Vegetable Physiology. See Root.

RADIX, in Radical and Root.

RADIX, among Grammarians. See Radical, and Root. See Radical, and Root.

RADIX, in Mathematics, the same as root; but used in a different sense by different authors: we say the root of an equation, but the radix of a fyltem, the radix of a series, the radix of notation, &c. meaning in all these cases the fundamental quantity on which the fyltem is constructed, or that whence it has been derived, or that by means of which all other things of a like kind are compared.

RADIX of a System of Logarithms, is that number which is involved to the power denoted by the logarithm, is equal to that number. Thus, under the article Logarithms it is shown, that if \( r^a = a \), then \( x \) is the logarithm of \( a \), and \( r \) is called the radix of the fyltem. This radix in the common or Briggs's logarithms, is 10, and in the Neperian or hyperbolic logarithms, it is 2.71828128, &c. and generally the radix of any fyltem of logarithms, is that number whose logarithm in that fyltem is unity.

RADIX of a System of Notation, is that number which indicates the local value of the figures, and is in all fyltems represented by a unit and cipher (10), which is ten in the common fyltem, two in the binary fyltem, three in the ternary, twelve in the duodenary, and so on. See Notation.

RADIX of a Series is used, by some authors, as a term of comparison between any finite function, and its expansion or development: thus, the radix

\[
\text{of } 1 - r + r^2 - r^3 + r^4 \quad \&c. \text{ is } \frac{1}{1 + r} \\
\text{of } 1 - \frac{1}{2} + \frac{1}{4} - \frac{1}{8} + \frac{1}{16} \quad \&c. \text{ is } \frac{1}{1 + \frac{1}{2}} \\
\text{of } 1 - 1 + 1 - 1 + 1 \quad \&c. \text{ is } \frac{1}{1 + 1} \\
\text{of } 1 - 2 + 4 - 8 + 16 \quad \&c. \text{ is } \frac{1}{2 + 1} \\
\text{of } 1 + n + n^2 + n^3 + n^4 \quad \&c. \text{ is } \frac{1}{1 + n}
\]
RAD

of \(1 + 2x + 3x^3 + 4x^4 + 5x^5 \) &c. is \(\frac{1}{1-x}\)

of \(1 + \frac{x^3}{2} + \frac{3x^4}{8} + \frac{5x^5}{16} + \) &c. \(\sqrt{\frac{1}{1-x}}\)

See Dr. Hutton's Tracts, vol. i. p. 9. See also our article Series.

RAD-KNIGHTS. See REDMANS.

RADLER, in Geography, a mountain of Saxenburg.

RADLESTEIN, a town of the duchy of Carnol; six miles W. of Landihof.

RADLESTHAL, a town of Aftria; nine miles E. of Krottau.

RADMANS. See REDMANS.

RADMANSO, in Geography, a small island in the Baltic, near the coast of Sweden. N. lat. 59° 45'. E. long. 18° 44'.

RADNAGUR, a town of Bengal; 32 miles S. of Burdwan.

RADNITZ, a town of Bohemia, in the circle of Pilfen; 10 miles N. of Pilfen.

RADNOR, New, or Mass-y-Feid, a borough and market-town in the county of Radnor, South Wales, is situated near the river Somer-

gill, at the distance of seven miles N.W. from Kington, and 156 miles N.W. from London. In remote times, this town was

a place of great importance, as appears from its having given name to the county, but it has now dwindled into comparative

departure and insignificance. Caradog informs us, that about the year 990, Meredith ab Owain destroyed Radnor, in a ferocious

temple with his nephew, who had been afflicting the English to ravage South Wales. It recovered, however, from this disaster,

and continued to flourish till the union of Wales with England, when it began to decline, in consequence of its ceasing to be

fortified and garrisoned as a frontier town. Before that period, it was surrounded by a lofty wall, and a deep moat, some remains

of which are distinctly visible on the west and south sides. The walls, when standing, are traditionally said to have been of

great height. The area inclosed by them was an oblong square, containing about twenty-six acres of ground, laid out into three longitudinal

streets, which were intersected by five tranverse ones. Of these at present several have no buildings; and others are only foot paths. But though

thus decayed, Radnor still preserves its privileges as a borough. The corporation consists of a bailiff, twenty-five

capital burgesses, two aldermen, a recorder, a coroner, a town-clerk, and other inferior officers. The bailiff and

aldermen are chosen annually from among the capital burgesses, and are justices of the peace. The bailiff of the preceding

year is also a justice of the peace; and there are besides three additional persons nominated out of the capital burgesses, who are

invited with similar authority. The district over which they preside, and supercede the jurisdiction of the county magistrates, is considerable; comprehen

sively a circle round the town nearly ten miles in diameter. The bailiff's courts and the petty seions are regularly held every Monday, when the bailiff, aldermen, and town-clerk attend to transact business relating to the borough, and have power to determine all suits for sums under forty shillings. The quarter-seions for the borough are held on the Mondays after the county quarter-seions at Prestige; and the sheriff's county courts for the recovery of small debts, are

held every alternate month here, and at the town last mentioned. The representative for the borough is chosen by the burgesses of New Radnor, in conjunction with those of the boroughs of Knighton, Rhaiadar, Cefn Llys, and Cwncelas; the bailiff being the returning officer. As nothing but the circumstance of receiving parochial relief disqualifies any person from becoming a burgess, the number of voters is considerable; those of New Radnor are supposed to exceed 300, and the whole number, including those of the contributory boroughs, is estimated to be about 1500. To be a capital burgess of New Radnor, however, actual residence within the jurisdiction is essential, which is not the case as to the contributory boroughs: and if a capital burgess becomes non-resident he loses his privileges as such. A benefic society, established here in 1778, at present consists of above 100 members, who hold their annual meetings on the 6th of January.

Weekly markets were formerly held here on Tuesdays, but these are at present, only nominal, notwithstanding some late attempts to restore them. There are still, however, five annual fairs; and there is also an annual wake on the third Sunday in the month of August. The parish of Radnor is divided into three portions, of which the town of New Radnor is the principal, containing, according to the parliamentary returns of 1811, 75 houses, and 360 inhabitants. The public buildings here are the town-hall, the prison, and the church. The last consists of a nave, south aisle, and chancel, with a tower at the west end.

Radnor castle stood on an eminence commanding the town. Of this once majestic pile, a few fragments of walls only remain, but the entrenchments are still entire; the outer ward, called Baili-Glas, or the Green Court-Yard, is yet distinct from the inner one, or keep, and is nearly in its original form. In 1773, on digging within the area of this castle, fix or seven small "Gothic arches of good masonry were discovered," besides a variety of ancient inscriptions. The forest of Radnor extends several miles to the north of the town, covering the slope of a lofty eminence, from the summit of which are very extensive prospects. The principal seats in the vicinity are Downton-hall, the seat of Percival Lewis, esq.; and Harpton-court, a seat belonging to Thomas Frankland Lewis, esq. Both these mansions are surrounded by beautiful scenery, and are highly ornamental to this district. About two miles westward from the town is a celebrated water-fall, called Waters-break its-neck, seventy feet in perpendicular height; but it is extremely defective in water, except during the time of floods, when the effect produced is truly grand. At the western extremity of the parish is an intrenched dyke, which formerly extended across the whole vale of Radnor. War-closte, a field to the eastward of the town, is traditionally said to have been the scene of some military contests, but no particulars respecting it are preserved.

Old Radnor, or Pen-y-Graig, is a small village, situated about three miles to the south of New Radnor. Camden supposes it to have been the Magnos of Antoninus, which was garrisoned by the Phcenician regiment in the reign of Theodosius the younger; and there seems every reason to believe that it was a place of note in the Romo-British period. The Roman road passed cloote to the base of the hill upon which the village stands. The church here is a venerable old edifice of stone, with a massive square tower at one end. A curious screen, richly carved in wood, extends across the nave and side aisles. Here are various monuments to the memory of members of the Lewis family of Harpton. Carlile's Topographical Dictionary of Wales, 4to. 1813. Lipcomb's Tour through Wales.
RAD

RADNOR, a small pleasant town of America, in Delaware county, Pennsylvania. The place was originally called "Amstel" by the Dutch, who began to build here. The number of inhabitants is 925.

RADNOR, a town of South Carolina; 10 miles S.W. of Edmondbury.

RADNORSHIRE, an inland county of South Wales, is bounded on the north by the counties of Montgomery and Salop, on the east by the county of Hereford, and on the south and west by the counties of Brecknock and Cardigan. According to Mr. Clark, it contains 510 square miles, or 346,000 acres, and is politically divided into five hundreds, and fifty parishes; some of which are within the diocese of Hereford, and the remainder within that of St. David's. The parliamentary returns of 1811, state the number of its houses at 4,914, and of its inhabitants at 20,900. It sends two members to parliament; one for the county, and one for the borough of New Radnor, with its contributory boroughs. The face of the country is extremely mountainous and bleak in every part of it, but it is interlaced by several valleys, which are watered by the Wye, the Teme, the Lugg, the Teme, and the Eddow, and their respective fertile and arable tracts. These valleys afford a considerable extent both of meadow and arable land; especially the Vale of Wye-Side, and the Vale of Radnor, some portions of which are very fertile, and have a good soil and a congenial climate. In the other parts of the county, being a barren soil, and a chilly atmosphere, are the predominant characteristics. Nearly two-thirds of its whole extent being either in a state of commonage, or lying wholly waste, agriculture has hitherto made little comparative progress here. Cattle and sheep consequently constitute the chief produce of the county. The number of the latter is indeed very great. Hence Radnorshire is famed for its supply of wool; but notwithstanding this circumstance, singular to say, the manufacture of woolen goods is totally disregraded. The raw material is sold to the manufacturers of the north, by whom the inhabitants of this county are in return furnished with cloth.

Radnorshire contains three market-towns; Presteigne, Rhaiadar, and New-Radnor. The market at the last, however, is only nominal. The county courts are held at Presteigne, which is now the most important and flourishing town in the county. (See Presteigne.) The chief remain of antiquity within its limits is Offa's Dyke, which commencing at the river Wye, near Hay, skirts the counties of Radnor and Hereford, and falls into Montgomeryshire at Pwll-y-Pyd, a hamlet on the road between Bishops-castle and Newtown. The only religious house in the county was the abbey of Cwm Hir, founded in 1143, for monks of the Cistercian order, by Cadwathelain-ap-Madoc, who, at the dissolution, was valued at 28l. 17s. 4d. per annum. Of this monastery a considerable part of the buildings is yet standing, though in a very ruinous and dilapidated condition. Leland, in his itinerary, (vol. v. p. 141.) speaks of its church as the longest in Wales, and informs us, that it was "spoiled and defaced by Owen Glendower." The principal castles in Radnorshire were those of Colewine, Tynboni, Aberedow or Aber-Edwy, Ewennil, Radnor, Rhaiadar, and Pain's-castle. Several antiquaries, among whom are Camden, Gale, and Ward, place the Roman station Magns, or Magna, at Old Radnor, as it is mentioned above; but Baxter contends that it should be fixed at Ledbury, in Herefordshire, and Harris at Gaer, near Brecknock. In this county, particularly on the summit of Gwafoddin hill, are several of those collections of stones called in South Wales karnew, in North Wales, karnew, in Scotland, carius, and in Ireland, duine.

RAF

Radnor was erected into an earldom by Charles II., in the person of John Roberts, lord Roberts of Truro, but that title became extinct in 1757. It was revived, however, in 1705, in the person of William Bourerie, baron Longford, and viscount Folkestone, whose son Jacob, now earl of Radnor, enjoys his privileges. General View of the Agriculture of the County of Radnor, by John Clark, 4to. Skrine's Tours in Wales. Camden's Britannia. Pennant's Tour in Wales, 8vo.

RADNOTH, a town of Transylvania, on the river Maros; 32 miles W. of Szeberv.

RADOE, a small island in the North Sea, near the coast of Norway. N. lat. 65° 35'.

RADOFFIN, a town of Moravia, in the circle of Iglau; 21 miles E. of Iglau.

RADOLFZELL, or Radeszell, or Zell, a town of Germany, in Aultrian Swabia; situated on the Untersee, or lake of Lille; 10 miles N.W. of Constance.

RADOM, a town of Poland, in the palatinate of Sandomire; 30 miles N.W. of Sandomire.

RADISH, a town of Bohemia, in the circle of Prachatitz; founded by N. of Strakomitz.

RADOMISL, a town of Poland, in the palatinate of Lublin; 45 miles S. of Lublin.—Allo, a town of Poland, in the palatinate of Kiev; 36 miles N.W. of Kiev.

RADOMSK, or Radomski, a town of Poland, in the palatinate of Sisdia; 32 miles E. of Sirdia.

RADONITZ, a town of Bohemia, in the circle of Sätz; 13 miles W.S.W. of Sätz.

RADOSCHITSCH, a town of Poland, in the palatinate of Sandomire; 20 miles N.E. of Malogoz.

RADOS, a town of Prussia, in the palatinate of Culin; 10 miles W. of Lautenburg.

RADSTADT, a town of the archbishopric of Salzburg; 36 miles S.S.E. of Salzburg.

RÄDT vor dem Wald, a town of the duchy of Berg, where Roman Catholics, Lutherans, and Calvinists, have, each of them, a church; 25 miles E. of Daffeldorp.

RAJULA. See RASAIATORY.

RADUNPOUR, or Radimpoor, in Geography, a town of Hindooftan, in the county of Agimere, on the river Pudder, or Butlais; 171 miles N. of Surat. lat. 23° 58'.

RÄDZANOW, a town of the duchy of Warsaw; 30 miles N.E. of Ploceeko.

RÄDZIEZOW, a town of Poland, in the palatinate of Belez; 24 miles W. of Belez.

RÄDZIEJOW, or Ronschow, a town of Poland, in the palatinate of Breslum; 25 miles W. of Breslum.

RÄDZIVALNOW, a town of Lithuania; 50 miles E.N.E. of Minsk.

RÄDZIMIN, a town of the duchy of Warsaw; 12 miles N. of Warsaw.

RÄMSDORF, or Ramsdorff, a small but strong place of Brabant; three miles E. of Gertrudenberg.

RAEPOUR, a town of Hindooftan, in the circle of Goobud, on the Jumna; 38 miles E.N.E. of Lahaar.

RÄERDORP, a town of Holland; five miles N.E. of Amsterdum.

RÄTVIK, a calcareous mountain of Sweden, the height of which is estimated by Bergman at 6000 feet above the sea, observing also, as a singularity, that upon this mountain, and that of Rodberg, are found vast blocks of reddish felspar, mingled with quartz and brown mica.

RAFAEL, Cape, a cape on the E. coast of the island of Hifpaniola. N. lat. 19° 21'.

RAFAEL, St., a town of South America, in the province of
of Caraccas; 40 miles S. of Caraccas.—Also, a town of South America, in the province of Moxes; 210 miles E. of Santa Cruz de la Sierra la Nueva.—Also, a town of New Navarre; 105 miles S.W. of Cala Grande.

RAFH, a town of Egypt; 57 miles N.E. of Caiiec.

RAFALSO, a small island in the gulf of Finland. N. lat. 65° 29'. E. long. 26° 12'.

RAFAELLE DA URBINO, in Biography. See RAFFAELLE.

RAFFLING, a sort of game with three dice, in which he throws the greatest pair, or pair royal, in three casts; wins the prize or flake.

The word probably comes from the base Latin, risiflare, to risk, to hazard, take all away.

The raffle is properly the doublet or triplet; a raffle of aces, or duces, carries it against mere points.

RAFFLING is also used when a company of perfons club to the purchase of a commodity, or make small deposits, amounting in the whole to its full value; and he that throws the highest on three dice, or who has the highest number by means of balls thrown on a bagatelle or porto-bello table, takes it.

RAFICA, in Geography, a town of Asiatic Turkey, in the government of Diarbekir; three miles S. of Raca.

RAFLUNDA, a town of Sweden, in the province of Skone; 17 miles S. of Christianfadt.

RAFIA, in Botany, a genus of plants, separated from the Linnean Crotalaria and Liparia, augmented with several new species from the Cape, and named by its author, Professor Thunberg, in the second part of the preface to his Prodromus Plantarum Capetianum. De Theis is completely in the dark as to the person commemorated in this name, who can be no other than Mr. C. G. Rafin of Copenhagen, author of a Flora of Denmark and Holstein, in the Danish language, published in the years 1796 and 1800, in octavo, making two volumes, which include the first ten classes of the Linnean system. We know not whether any more has appeared. The name botanist has written a work on the physiology of plants; and several papers for the Academy of Sciences at Copenhagen. See Sims and König's Ann. of Bot. v. 1. 6.—Thunb. Prodr. 123. pref. n. 48. Willd. Sp. Pl. v. 3. 949. Ait. Hort. Kew. v. 4. 261.—Clas and order, Diadella Decandria. Nat. Ord. Papilionaceae, Linn. Leguminoseae, Jull.

Gen. Ch. Cal. Perianth inferior, of one leaf, bell-shaped, five-cleft, ringent; the upper lip in two broadish dilatant segments; lower divaricatet, in three acute ones, the middle one smalllet. Cor. Papilionaceous. Standard large, heart-shaped, acute, spreading, depressed at the base. Wings ovate, about half as long as the standard. Keel acute, the length of the wings. Stam. Filaments ten, all united into a linear tube, split along the base; five of them rather the throat; others simple. Pist. Germin filacted, linear; style simple, bent upwards at nearly a right angle; stigma obtuse. Peric. Legume filacted, oblong-lanceolate, compressed, of one cell and two valves. Seeds several, filacted, roundish-kidney-shaped.

Edl. Ch. Stamens all united. Calyx ringent; upper lip divided; lower divaricatet, in three segments, the middle one smalllet. Legume filacted, lanceolate, compressed.

1. R. amplexicaulis. Orbicular Rafina. Thunb. Prodr. 123. Willd. n. 2. (Crotalaria amplexicaulis; Linn. Sp. Pl. 1035. Genista perfusloata, orbiculatis folis; Schw. Theon. v. 1. t. 24. f. 5. Linn.)—Leaves reticulatet, orbicular, clasping the stem, alternate; the floral ones opposite, coloured.—Native of the Cape of Good Hope. A smooth, handsome, branched, racemose, clothed with entire leaves, from one to two inches across, finely reticulatet with innumerable veins; the upper ones, which accompany the flowers, smaller, and pale yellowish. Flowers solitary, nearly septic, smaller, than the floral leaves.

2. R. elliptica. Elliptical Rafina. Thunb. ibid. Willd. n. 3; excluding the reference to Andrews.—Leaves slightly veined, elliptic-ovate, acute, alternate; the floral ones opposite, not longer than the flowers.—Native of the Cape. Confounded by Linneus with the foregoing, from which it differs in having much smaller leaves, septic, not clasping the stem, quite different of reticulatet veins. Flowers of a deeper yellow, as long as the floral leaves.

4. R. triflora. Three-flowered Rafina. Thunb. ibid. Willd. n. 5; Ait. n. 1 Venten. Malm. t. 48. (Crotalaria triflora; Linn. Sp. Pl. 1004. Curt. Mag. t. 482. Borbonia cordata; Andr. Repof. t. 31, excluding the fynonym.)—Leaves ovate, smooth. Branches angular. Stalks single-flowered, three together.—Native of the Cape, where it was gathered by Sparrmann and Thunberg, and from whence its seeds were sent to King garden, in 1786, by Mr. Francis Maffon. The plant is biennial, requiring to be sheltered in winter, and flowering in June and July. Stem branched, about a yard high, most leafy in the upper part, smooth, and of a glaucous green, as well as the leaves, which are numerous, alternate, almost septic, more or less ovate, but varying in size and breadth. Flowers abundant at the summits of the branches, large, yellow, axillary, filacted, three together, the floral leaves smaller than the rest, and often tinged with purple.

5. R. opposita. Opposite-leaved Rafina. Thunb. ibid. Willd. n. 6. (Crotalaria opposita; Linn. Suppl. 322. Liparia opposita; Linn. Syll. Veg. ed. 13. 54. Spartium capenae; Sp. Pl. 995. Cytisus capenae; Berg. Cap. 217.)—Leaves elliptic-lanceolate; the upper ones mostly opposte. Flowers lateral, on short solitary stalks.—Native of the Cape, apparently unknown in our gardens. Linneus and his son confounded many different things under this species, some of which being marked in their herbarium as having been gathered by Thunberg, we presume to be among those to which he has defined; yet it is not possible to determine them all by his short characters, several of which unfortunately contradict the specific names. The stem of the present is described by the younger Linneus as simple, he considering as flower-stalks the copious, alternate, leafy branches, three or four inches long, on which one or two parts of the lower leaves are opoosite; the proper floral leaves, like those of the stem, being alternate; all the leaves are elliptic-lanceolate, or somewhat obovate, acute, entire, single-nerved, an inch or more in length. Flowers either lateral or axillary, among the uppermost leaves, solitary, each on a simple stalk about the length of its calyx. Corolla yellow, not half so large as the last species.

Leaves lanceolate, alternate or opposite. Flowers terminal."—This and all the following were gathered by prof. Thunberg, at the Cape. In the Linnaean herbarium is a specimen, by whom gathered does not appear, which seems to answer to the above character. (except the flowers being linear-lanceolate,) and which may perhaps explain the paradoxical contrariety between the specific name and character. In this specimen the flowers are really terminal, being foliatory at the ends of conspicuous, short, leafy, lateral branches, which are axillary. The whole plant has a Hytop-like aspect.

8. R. sphaerica. Spiked Rafnia. Thunb. ib. Wild. n. 9.—Leaves lanceolate, alternate. Flowers axillary, racemose."—Of this species alone, it seems, Wildenow had seen a dried specimen, and we regret that he did not give us some account of it.

The Linnaean herbarium contains two specimens, specifically different, which we presume belong to this and the last, but no human sagacity can appropriate them; except that one of them, with large and feebly purplish flowers, having rather the narrowest leaves, may be taken for filiformis. This is marked as gathered by Thunberg. The other has much smaller and yellow flowers. The stem is round in both.

11. R. retroflexa. Bent Rafnia. Thunb. ib. Wild. n. 12.—Leaves obovate. Branches reflexed backwards and forwards."—A specimen from Thunberg answers to the above name and character, except the leaves being rather linear-lanceolate than obovate. Their colour is somewhat glaucous. Flowers more or less terminal, on short stalks, with a wool-shaped trichia, or abortive leaf, at the base of each stalk.

All the species turn more or less black in drying. For Rafnia retusa of Venenat, Malmais. t. 53, see TEMPLETONIA hereafter, and Ait. Hort. Kew. v. 4. 269.

RAFSO, in Geography, a small island on the E. side of the gulf of Bothnia. N. lat. 61° 37'. E. long. 21° 12'.

RAFSUND, a town of Sweden, in the province of Jamptland; 28 miles S.E. of Trondhj.

RAFT, in Sea Language, a fort or float formed by an assemblage of various planks, or pieces of timber, fastened together side by side, so as to be conveyed more commodiously to any short distance in a harbour or road, than if they were separable. The timber and planks, with which merchant-ships are laden in the different parts of the Baltic sea, are attached together in this manner, in order to float them off to the shipping.

This means of conveying timber to navigable situations may be advantageously practised in many places. It is found of great utility in many of the northern parts of the island as well as others, near canals and rivers, where a cheap conveyance for such articles is required.

The balsa or catamaran used by the Indians and Spaniards in South America, is only a raft made of the trunks of the balsa; for an account of which, see the article BOAT.

They have one mast, on which is hoisted a large square sail; and a pair of oars, whose poles rest on each side the raft. When a fore-and-aft sail is set, a pair of oars is rigged forward. These rafts were the first conveyance by water, no doubt, long before vessels of a better construction were thought of; and what is still more surprising, they are made to float with foul winds, and steer, as well as any other kind of vessel, by means of an invention similar to, and perhaps the original of, that which is now called "a flying-keel." They have for this purpose planks about ten feet long, and fifteen to eighteen inches wide, which slide vertically in the spaces between the trunks which form the raft. It is only necessary to immerge them more or less, and put down a greater or lesser number at the fore or after part of the raft, to make it either luff-to, or fall-off from the wind, tack, veer, lie-to, and perform every necessary manoeuvre. The number of these planks is five or six, and if one of these planks be drawn up forward, the raft will keep away; and, if one is raised abaft, it will come to the wind. This sort of raft, from the simplicity of its construction, might perhaps be well adapted to many cases of emergency, after ship-wreck upon coasts, distinct of all other materials for ship-building.

RAFT-PORT, in a Ship, a square hole cut through the futtocks of some ships, immediately under the counter, to receive the planks or pieces of timber which are brought to lace her for transportation; and which, on account of their great length, could not be received aboard otherwise.

RAFTERING, in Agriculture, a provincial term used for a sort of ploughing in narrow ridges, or small ridges. It is useful for exposing a large surface of earth to the influence of the atmosphere.

RAFTERS, in Building, are pieces of timber, which, standing by pairs on the rafter-piece or rafting-piece, are laid in an angle at the top, and form the roof of a building.

It is a rule in architecture, that no rafters should stand farther than twelve inches from one another.

For the sizes or scantlings of rafters, it is provided by act of parliament, that principal rafters from 12 feet 6 inches to 14 feet 6 inches long, be 5 inches broad a-top, and 8 at the bottom, and 6 inches thick. Thse from 14, 6 to 18, 6 long, to be 9 inches broad at the foot, 7 a-top, and 7 thick. And those from 18, 6, to 21, 6, to 10 inches broad at the foot, 8 a-top, and 8 thick.

Single rafters, 6 feet 6 inches long, to be 4 and 3 inches in their square.

RAFTY, a provincial term signifying damp and muddy, as corn or hay in a wet season.

RAG, or RAK, among Hunters, denotes a company or herd of young colts.

RAG, or RAGG, ROWDY, in Mineralogy. See FERRITES.

RAG, a turn piece of cloth of any sort. See the next article.

RAGS, WEALLEN, as well as the clippings of pitch marks upon sheep, are good manure. The rags should be chopped small, about an inch or two square, and scattered on the earth at the second ploughing; for being thereby covered they will begin to rot by feed-time. They imbibe the moisture of dews and rain, retain it long, and, according to Dr. Home, keep loose dry soils in a moist state. They formerly coit about fourpence a bushel at London, from whence many loads were sent every year to Dunstable, which is thirty-three miles, where they are laid on even stiff lands, just after the fouling of the corn, allowing to the acre four sacks, of six bushels each; they are much higher now, at more than double
double this price, and no quantity of any great account to be procured. See MANURE, and Top-dressing.

The farmers in Oxfordshire make use of rags of this sort, procuring them from London and other places, at the rate of from eight to nine pounds the ton, which, with the carriage, laden them in upon the farms from nine pounds ten shillings to ten pounds. By some they are spread upon the clover lands, lays or layers for weeds, in the proportions of from three or four to fix hundred weight to the acre. Tried with dung in this way, in the quantity of seven hundred weight to the acre, the dung is found the better dressing. They are also applied for turnips, for which crop they are ploughed in before the winter, as soon as the wheatsowing is over; if ploughed in at the time of sowing turnips, they will not work for that crop. Some for this crop give half a coat of rags, and half a coat of chaff-fold. When applied on the clovers they seldom last longer than two years. Others think that half a coat of rags, and half a coat of dung, is the most beneficial method of applying this sort of manure. Some think rags are more durable than any other manure. Rags are occasionally brought from Whitney to this district, at from seven shillings and sixpence to eight shillings and sixpence the hundred weight, and five hundred weight spread upon the acre: they commonly last only one crop, but sometimes for two, and are found superior to any thing for wheat. They are ploughed in; and if the season be very dry, do not answer so well. They are supposed to do bale on a summer fallow for this crop.

In Suffolk rags are chiefly of service in the hop grounds, for which they are thought an excellent manure. Very great benefit is said to have been derived from the application of these rags, in contributing to preserve this sort of plantation in a state of constant moisture, and vegetation in the dry season, when grounds which have been manured with dung, have been dried up, and the hop crops have failed. Rags have likewise been found very useful on the moving grounds in some parts of Lancashire, when laid upon them in a pretty full proportion. When cut or chopped sufficiently small, they readily sink down upon the surface of the land, and do not afford any port of interruption to the fytch, while they absorb and keep in the moisture, which is of material benefit to such gross lands as are inclined to be dry.

RAG, in a Ship. See BOLTS.

RAGAL, in Geography, a town of Germany, in the county of Plundenz; 10 miles E. of Plundenz.

RAGALBUTO, a town of Sicily, in the valley of Demona; 23 miles S. of Cefalu.

RAGALMATO, a town of Sicily, in the valley of Mazzara; 8 miles N. of Naro.

RAGAMMEE, a town of Ceylon, near the W. coast; 58 miles S. of Columbo.

RAGANELLO, a river of Naples, which runs into the gulf of Tarento, near Civita Mandonia.

RAGAPILLY, a town of Hindostan, in Golconda, near the left bank of the Godavery; 5 miles S.E. of Badrachilum.

RAGATZ, a town of Switzerland, in the county of Sargans; 5 miles S.E. of Sargans.

RAGAY, a town on the S. coast of the island of Luzon. N. lat. 15° 35'. E. long. 123° 40'.

RAGGED, in Heraldry. See RAGULED.

RAGGED Heron, in Falconry, is a hawk that has its feathers broken.

Ragged Robin, in Botany. See Lycinis.

Ragged Harbour, in Geography, a bay on the E. coast of Newfoundland, being a part of Catalina bay; 2 leagues N. of Catalina harbour. N. lat. 49° 45'. W. long. 55° 40'.

Ragged Helmet, a small island in the Mergui Archipelago. N. lat. 10° 5'.

Ragged Island, a small island in the East Indies, near the island of Paraguay. N. lat. 11° 24'. E. long. 115° 50'.—Also, a small island among the Bahamas. N. lat. 22° 27'. W. long. 77° 18'.

Ragged Point, a cape on the E. coast of the island of Bermuda. S. lat. 2° 13'. E. long. 116° 40'.—Also, a cape on the N. coast of the island of St. Christopher. N. lat. 17° 30'. W. long. 62° 42'.

RAGGIIVOLO, a town of Italy, in the department of the Mincio; 19 miles S. of Mantua.

RAGHUS, in Hindu Mythology, is the name of the ancestor of Rama, one of their deified heroes, who is hence sometimes called Raghuva, or son of Raghu. Buddha, or Bouddha, another of the Indian deities, is said to have had a son also of this name.

RAGHUVA, a name of the Hindoo deified hero Rama, signifying a descendant of Raghu, a warlike character. All these names are still very common among Hindoos: whether confined to the sect who, as chiefly worshipping Rama, are called Ramanui, or more extensively given, we are not informed. See Rama.

RAGIAN, in Geography, a town of Peria, in the province of Fariflant; 130 miles N.W. of Schiras. N. lat. 30° 40'. E. long. 50° 8'.

RAGLAND, a small village of Monmouthshire, here mentioned on account of its castle, the ruins of which evincing its grandeur and magnificence, command the attention of travellers. During the rebellion it was held for the king, and defended to the last extremity by the marquis of Worcester; 8 miles W. of Monmouth.

RAGMAN'S Roll, or Ragman's Roll. See Roll.

RAGNIT, in Geography, a town of Prussian Lithuania, on the river Memel, endowed with the privileges of a town in the year 1722. Its ancient castle was famous even in the times of Paganism. The knights of the Teutonic order built it, with additional works, in 1255; but being destroyed in 1355, it was rebuilt a second time, and called Landeshuth; but afterwards it obtained the name of Ragnit from the river which passes by it; 36 miles E.N.E. of Königsberg. N. lat. 55° 5'. E. long. 22° 18'.

RAGOGNA, a town of Italy, in Friuli; 16 miles N.W. of Udina.

RAGOOGUR, a town of Hindostan, in the Malwa country, and circtr of Kitchwana; 116 miles N.E. of Oujen. N. lat. 24° 23'. E. long. 73° 30'.

RAGOTSKI, Francis, in Biography, the second of the name, prince of Transylvania, distinguished by his courage and patriotism, was born in 1676, at the castle of Bozlin, in Hungary. When he was only a year old he lost his father, prince Francis, and was left to the care of his mother, Helena Sereni, who afterwards married count Tekei. During his education he was carefully watched by the house of Auloria, and his correspondence with his mother, who had retired to Constantinople, was entirely broken off. He was now suffered to travel to most of the courts of Europe, and to contract a marriage with the princess of Helff Rohnfel. Zealously attached to the independence of his country, which was kept in a state of great degradation by the Imperialists, he secretly entered into a negociation with the French king, Lewis XIV., but being betrayed by one of his confidens, he was arrested, and a charge of treason was preferred against him. The sentence of guilty was soon pronounced, and he was committed to the custody of an officer,
officer, who, however, connived at his escape, and he arrived in a dragoon's habit at the frontiers of Poland. Here he received assurances of affiliation from France, and immediately published an eloquent manifesto, calling upon the nation to free itself from the Austrian yoke. Numbers joined him; being, however, but half armed, he was fearful of trusting his cause in their hands, and withdrew to the frontiers of Poland, where he was joined by fresh recruits. With these he ventured to make some progress; stormed several fortresses; and took a severe revenge upon the Imperialists, who had given no quarter to the Hungarian insurgents.

At this period the crown of Poland was vacant, through the deposition of Augustus by Charles XII. of Sweden, and the Polish chiefs were desirous of placing it upon the head of Ragotzki. But he had no such ambitious views: his great object was to liberate his country, and he refused to desert its cause for any other prospects. He accordingly pursued his successes, and by the reduction of Tokay, obtained the submission of almost the whole of Lower Hungary. So high was his reputation, that the diet of Alba Julia, in 1754, proclaimed him prince of Transylvania, with which dignity he was afterwards solemnly invested. He obtained likewise the title of protector of Hungary, and Lewis XIV. sent to him a public embassy. He soon began to feel the difficulty of supporting a popular insurrection against the arms and policy of a powerful sovereign, as well by the abandonment of some of his allies, as by the defection of his troops. He had another opportunity of giving a refusal to the crown of Poland, which was offered him by the czar Peter, weighing thereby his sincere attachment to the cause of his country, and he employed all the resources of valor and good conduct to support a declining cause. In 1751, a treaty was concluded between the Hungarian states and the emperor, into which he refused to enter, although the first article secured his life and property, with the title of prince of Transylvania. Mortified by the failure of his patriotic exertions, he withdrew to Turkey, renouncing his great estates, and preferring an honourable poverty to a splendid servitude. He afterwards passed some time in France, then returning to Turkey; he fixed his final residence at the castle of Rodolfo, on the sea of Marmona. There, says his biographer, "a Christian among Mahometans, and a philosopher among barbarians, he tranquilly closed his life in 1733, at the age of 61." He left "Memoirs of his Life," which were published in the "Revolutions de Hongrie," printed at Paris in 1739. In 1751 there appeared a work, entitled "Testament politique et moral du Prince Ragotzki," the authenticity of which is doubted. Moreci.

RAGOUT, or RAGUE, a sauce or flavoring, intended to increase or recover the appetite when languishing, or loft.

The term is French, but naturalized. It is also used for any high-flavored dish, prepared of flesh, fish, greens, or the like, by stewing them with the addition of bacon, salt, pepper, cloves, and the like highly-flavored ingredients.

We have ragoos of beef, of crav-fish, of giblets, of asparagus, of endive, of cocks-combs, of gammon, of celery, &c.

The ancients had a ragout, called garum.

RAG-PAVING. See PAVING.

RAG-STONE, a name given by our artificers to a kind of stone, which they use for setting an edge upon knives, chisels, and other tools. It is a greyish-colored stone, containing a large quantity of talc-like particles, and splits easily into thin flakes. It is a soft stone, and is used only for smoothing the setting an instrument after the edge has been prepared by grinding or rubbing the tool upon some other stone of a coarser texture. We have this from Newcastle and many other parts of the north of England, where there are very large rocks of it in the hills. This kind of stone is in some districts considerably blended and intermixed with the foul, rendering it of a more barren and unfertile quality.

RAGUENET, l'Abbé, in Biography. In 1702 the publication of a pamphlet, entitled "Parlele des Italiens et des Français en ce qui regarde la Musique et les Opéras," by this author, a man of taste and intelligence, who had redressed some time at Rome, gave birth to a long, but ineffec-
tual controversy, concerning the degrees of perfection, and superiority of French and Italian music. The book was licensed by Fontenelle, who said in his testimony, that he thought it would be very agreeable to the public, provided they were capable of equity." This declaration, however, did not prevent Frencu, the continuator of Bonet's "Histoire de la Musique," from attacking the author and Italian music in a most furious manner, treating both with equal contempt and obloquy.

The French, after this period, seem to have enjoyed their lyric fondness in great comfort and tranquility till 1732, when the performance of Pergolesi's "Serva Padrona" at Paris, by a company of burletta singers from Italy, set the musical republic in a flame which has not yet been extinguished.

There had, indeed, been a sensation excited, that was rather turbulent, and tending to a civil war, on the first appearance of Rameau as a dramatic composer in 1733, who, by new harmonies and accompaniments, had given offence to the true believers in the worship of Lully; but this soon subsided, and the nation not only heard his compositions with rapture, but reverenced him as "a theorist, to whom music was as much indebted as physics and philosophy to Newton."

This little work was published in English in 1709, and has been said to be translated by Galliard. If this worthy pros-
fessor was the translator, it was before he had made himself so completely master of the English language, as he appeared to be afterwards, in his translation of "Toi on florid Song."

The English of this parable is feeble and inaccurate; many of the notes, however, are good, and manifest a person who had been in Italy, and well knew the state of music in that country, as well as in England, at the beginning of the last century, during our first attempts at opera, before the arrival of Handel.

RAGUIER, Le, the name given by the French sailors to a wind peculiar to the gulf of Alexandretta or Scande-
room, which, rushing from the snowy summits of the mountains, frequently forces ships to drag their anchors several leagues.

RAGULED, or RAGGED, in Heraldry, is applied to an ordinary, or, gr. a crois, whose outlines are jagged or knotted.

Ragued differs from indented, as the latter is regular, and the former not.

The bearing is very ancient: Julius Cæsar gave for his badge, a boar's head, on a ragged taff.

Ragged is sometimes also used in the lene of truncated, or couped, and applied to a branch that is faved from the tree; or a fock fawed from its root.

RAGUN, in Geography, a town of Germany, in the principality of Anhalt-Dessau, on the Mulda; 9 miles S. of Dessau.

RAGUNDA, a river of Sweden, which rises in the lake
lake Storfo, and in the province of Medelpadia, changes its name to Indal.

RAGUSA, a small republic, situated on the eastern shore of the Adriatic, and nevertheless regarded as an Italian state. It has a population of about 56,000 persons, on an extent of 553 square miles. As this state is adjacent to the territory formerly belonging to the Venetians in Dalmatia, its government is regulated on the model of the Venetian aristocracy. Its religion is the Catholic, and its language the Slavonic, though most of the inhabitants speak Italian.

The fee is archiepiscopal, with six suffragans, and its commerce is considerable. The chief magistrate of the aristocracy in this island, called the "rektor," is changed every month. Here is also a council of ten, and a great council composed of all the nobles above twenty years of age, and these nominate the "Pregadi," a senate of sixty, which superintends all state affairs, receives and deputes ambassadors, and confers offices. The revenue of Ragusa was formerly estimated at a ton of gold, or about 100,000 florins. This small republic has found it necessary to engage the protection of the Turks, for which it pays a tribute of about 20,000 sequins; though the commerce is beneficial to the Ottomans, in supplying them with ammunition. Jealousy of their neighbours induces the Ragusans to shut the gates of their city, except for a few hours in the day. The capital is Ragusa; and it has been lately annexed, together with Dalmatia, to the kingdom of Italy. It now (1814) probably waits for a new allotment. The Ragusans have many country-loufes at Gravosa, another sea-port town. Stagno is another little town, subject to Ragusa. Of the Ragusan isles, the chief is Milet, or Melada, fertile in oranges, lemons, and good wine. On the north there is a tolerable haven, with a town of the same name. Three or four little isles in that neighbourhood also acknowledge the sovereignty of Ragusa.

RAGUSA, the capital of the above-mentioned island, is an ancient city, being the Ragnum of the Romans, and in the tenth century it became the metropolis of Dalmatia. In the 13th century it was conquered by the Venetians, and afterwards for a time subject to the crown of Hungary. It is a well-built city, and its commerce is not incon siderable. The harbour might be rendered capable of a firm defence; and the circumjacent isles are beautified by nature and art. Earthquakes, however, have been terrible; and that of 1667 destroyed 6000 persons; 243 miles N.W. of Saloniaki. N. lat. 42° 58'. E. long. 18° 18'.

Ragusa keeps accounts in ducats of 40 groffetti, each groffetto being divided into 6 foldi; but at the public offices accounts are mostly kept in perperi of 12 groffetti. Formerly the ducat represented a real coin struck at Ragusa, and had a fixed value; but since it has become a money of account, it is always equivalent to the Turkish piaster, and therefore liable to a change of value. At Ragusa no gold coin is struck; its silver are the old tallari, or dollars, commonly called Viliini or Ragunini, weighing 1 oz. 7 car. (Ragusa wt.), containing 17 parts of pure silver to 13 of alloy, and reckoned at 1/4 ducat, or 60 groffetti; but on account of the depreciation of the ducat, the value of the tallari has been proportionally raised in weight. The new tallari, called libertine, weighing 1 oz. 10 car. and containing 9 parts of pure silver to 6 of alloy, was valued at 80 groffetti. But since the year 1796, ducats have been coined of 40 groffetti, weighing 1/2 an ounce; also perperi of 12 groffetti, weighing 20 carats, and half perperi in proportion; these three coins, on the model of pure silver, and 11 of alloy. The groffetti, none of which have been lately coined, are still in circulation; they weigh the 60th part of an ounce, and bear the same value with the paras of Constantinople. The ducat of 1796 is worth 13½ florins, which is nearly the value of the Turkish piaster. The tallari, or Ragunini of 1759, is worre than the English standard 4 oz. 2 dwt.; its weight is 18 dwt. 7 1/2 gr., and its content in pure silver 256 gr., and its value in florins 21 1/2 d.

That of 1794 is worre 3 oz. 19 dwt., its weight 18 dwt. 1/2 gr.; its content in pure silver 256 gr., and its value in florins 18 1/2 d.

The ducat of 1797 worre 5 oz. 11 dwt.; its weight 8 dwt. 17 1/2 gr., content in pure silver 97 gr., and value in florins 15 d.

The pound of which gold and silver are weighed at Ragusa consists of 12 ounces; the ounce is divided into 6 faggii; the faggio into 22 carats, and the carat into 4 grains. But the pound of commercial weight is equal to 5607 English grains, or 12 oz. 13dr. avoirdupois; the former being 5062 English grains. The ell of Ragusa measures 27 1/2 French lines, or 20 1/4 English inches.

RAGWORT, in Botany. See OTHONIA, SENECIO, and SOLIDAGO.

RAGWORT, in Agriculture. A very pernicious plant of the weed kind, which is sometimes termed feagrin. It has a green stalk in its early state, but, as it advances in age, inclining to violet or purple, especially downwards. Its flowers are yellow, and thick-set, and composed each of a number of small pointed leaves. It runs to seed in the latter end of summer. The small, both of the stalk and leaves, which are jagged, as well as the flower itself, are so offensive to animals, as that hardly any will feed upon it, except when almost starved.

It has been proposed to destroy it by picking out the roots, and feeding the land clove with fpeck. It molly affects meadows and pasture lands when the soils are good.

RAHA, in Geography. See JERICO.

RAHABAH, or RABA, town of Arabia Debsert, near the Euphrates, on the road by which caravans travel from Syria to the Arabian Irak; 110 miles S.W. of Moful. N. lat. 35° 5'. E. long. 40° 21'.

RAHAH Malik Ben Tanz, a town of Alatic Turkey, in the province of Dirbexir, on the Euphrates; 50 miles S. of Kerkieh.

RAHAB, a town of the desert of Syria, containing about five or six thousand inhabitants, situated on a plain, surrounded with date-trees; 70 miles N. of Meghild Ali.

RAHANPOUR, a town of Bengal; 42 miles N.W. of Nattore.

RAHAPA, a small island in the East Indian seas, near the E. coast of Borneo. N. lat. 4° 58'. E. long. 114° 4'.

RAHAS, in Ichthyology, a name given by some authors to the torpedo, or cramp-fish.

RÄHEINA, in Geography, a bay on the W. coast of Mowwee, one of the Sandwich islands. N. lat. 20° 50'. E. long. 205° 19'.

RAHMAPAT, a large lake in the Arabian Irak, 90 miles in circuit, near Meghild Ali.

RAHENSTEIN, a town of Bohemia, in the circle of Saatz; 19 miles S.W. of Saatz.

RAHMANIE, a town, or rather village, of Egypt, built
built on the W. bank, at the entrance of the canal of Damankour, which is navigable only at the rise of the Nile; 9 miles S. of Faouz; which fec.

RAHMETABAD, a town of Persia, in the province of Irak; 20 miles N.E. of Confar.

RAHNIS, or RAHIS, a town of Saxony, in the circle of Neutadt; 10 miles S.W. of Neutadt. N. lat. 50° 33'. E. long. 11° 46'.

RAHNY, a town of Bengal; 25 miles N.W. of Dinagepore.

RAHON, a town of France, in the department of the Jura; 6 miles S. of Dôle.

RAHOOH, a town of Hindoofooan, in the subah of Lahore; 198 miles S.E. of Lahore. N. lat. 31° 7'. E. long. 75° 42'.

RAHU, in Astronomy, is the Hindoo name of the planet of the ascending node, or dragon's head. Ketu is the name of the other node; and a fable, in the usual style of mythological allusion, is given under that article, of their origin and mithap. The malignant Rahu was decapitated, and Ketu was his head. In one painting of the Hindoo zodiac, the headless Rahu is represented of a black colour, in red clothing, mounted on an owl, and holding a flos in his hand: in another, he holds a spear, and flonds on a tortoise. In the fable given under Ketu it is related that Vithu was the decapitator of Rahu; other accounts assign that office to Narayana. Among the Hindoos, as we have had occasion to remark in several articles, their sciences, as well as their history and religion, are enveloped in a mafs of mythological allegory: a farther instance of which, connected with the subject of this article, is seen under Eclipse (Note. A reference being made from the article Ketu to this, we take the opportunity of correcting two typographical errors in that article. In its early part, for Kanyapâ, read Ka-nyapa; and in the fourth line of the second column, for or read a.)

RAHWA Y, in Geography. See RAWA.

RAI, or RAH, an ancient town of Persia, in the province of Irak, before Itipahan the capital of Persia. This was once a grand and proud city; and its ruins still cover a great extent of country. It holds a distinguished place in the annals of Persia: it is mentioned by Arrian and Diocletianus Siculan, as the capital of the province of Rhages, so called from the calamities brought upon this part of the empire by the earthquakes to which it formerly was, and is still subject. It is frequently mentioned in the wars of the renowned Haroun al Raâfîd; it was the capital of this part of Persia, in the reign of Alp-Arslân, and continued to flourish until it was sacked by the generals of Jenghis Khan. Its ruins are situated five miles S. of Tahraan, the present capital of Persia; and in the centre of them is a village, called Sheik Abdul Azzeem, from a son of the seventh Imam, to whose memory a noble mosque and mausoleum have been erected.

RAJA, denoting king, an appellation given in Hindoofooan, or the empire of the Moguls, to princes descended from those that ruled there before the conquest of the Moguls; who exercized all rights of sovereignty, only paying a tribute to the Great Mogul, and observing the treaties by which their ancestors recognized his superiority.

There are some rajahs who still retain a more independent sovereignty in the mountains: the Indians call them rai; the Persians, plurally, raijan: our travellers rajahs, or rajas. These have under their command foldours, called raja-san or persons descended from rajahs, who are a robust brave people, and who enter into the service of those who will pay them. The Great Mogul has several of these rajahs in his service.

'The chief lords of the Moguls, viz., the vice-roys, governors of provinces, and chief ministers of state, F. Crawf observes, are called ambas; and the idolatrous rajahs, or Indian lords who governed petty states before the conquest of their country, held the same rank at court with the ombras.

All the difference was, that the children of the rajahs succeeded their fathers in the show of the sovereignty left them; whereas the children of the Mahometan lords lose all in losing their fathers.

The Indians account four ages from the beginning of the world: and in the second, which lasted 1,256,000 years, they hold the rajas or kachstras had their rise; a noble caste, though inferior to the Brahms. Vice then, they say, began to creep into the world; men only lived to 300 years, and their stature was reduced, &c.

RAIA, the Ray, in Ichthyology, a genus of fishes of the order Chondropterygii, of which the generic character is, that it has five oblique spiracles on each side, placed beneath the neck; the head is small, pointed, and not distinct from the body; the mouth is beneath transverse, toothed; the body is broad, thin, and flat.

The individuals of this genus are all inhabitants of the sea only: they keep at the bottom, and in winter cover themselves with sand and mud: they feed on tectaceous animals, fish, or any animal substances which they may happen to meet with. They grow to a large size, sometimes exceeding 200lbs. in weight. The females are the larger, and produce their young alive, only one at a time, which, like the shark tribe, are inclosed in a quadrangular, black,orny shell, the corners of which end in slender incurved points, but not extending into long filaments, like those of the shark: the eyes are half covered with a thin membrane, oblong, placed on the upper part of the head: above these, in the place of nostrils, is a broad fulcus or groove, divided by a reticulate membrane, confining of creased folds, and closed with a valve: behind this fulcus are two small familiar orifices: the tongue is very broad, short, and smooth. The ventral fins are covered with a thick skin, and surrounding the body: the ventral at the base are connected with the anal; the fifth is generally ealuable, the liver is large, and producing a great quantity of pure oil.

Of this genus there are nineteen species, divided into three sections: viz. A. comprising the electric ray, or torpedo and skate; these have sharp teeth. B, including the king-ray and thornbacks, having obtuse teeth. And C, which are denominated uncertain, comprising five species, which inhabit the Red sea, or about the Cape of Good Hope, but which have not yet been sufficiently examined.

Section A. — With sharp Teeth.

Species.

* Torpedo; Electric Ray. The body of this fish is entirely smooth and flat. The species inhabits the Mediterranean, and grows to a large size: some have been taken that have weighed from 60 to 80lbs. each, but the average weight is less than 20lbs. It is of a dirty chalyf colour; the head and body are round, and but indistinctly separated. The body is extremely thin; behind the eyes are two wide foramina, which have been supposed to be intended by nature for conveying food; they are befit with six cutaneous fingers on their inner circumference, and communicate with the mouth. The torpedo can live about twenty-four hours out of the sea, and a short time longer, if put into fresh water;
It inhabits those places where the bottom is sandy, and buries itself superficially by flinging the sand over its back with a sort of vibration, which it gives to its extremities. It is in this situation that the torpedo sows its eggs, and the unwaried passenger, who inadvertently treads upon it, by the exertion of its electrical or benumbing faculty. This power is servicable to the animal in two important respects: as a means of defence against voracious fishes, and as a method by which it is enabled to procure its subsistence from among the smaller tribes; for the former, when electrified, is deprived of all possibility of seizing their prey; and the latter, after having unwarily approached the torpedo, and received the shock, are incapable of making their escape. (See Torpedo.) The food of the torpedo is furmullers and plaice; the former are so swift, that it is impossible for the torpedo to take them by pursuit, and as this fish has been found in its stomach, it is presumed that it was taken by means of the electrical shock. The torpedo has been taken off Pembroke, at Torbay, and near Waterford in Ireland. It is caught like other flat fishes, with the trawl, and is commonly found in water forty fathoms deep, in company with other species of this genus.

* Batesi; the Skate. This species is varied; the middle of the back is smooth; the tail is beft with a single row of spines. It inhabits the European ocean, and is thought to be the largest flat fish of the genus: the body above is cincereous, sometimes with a few black lines, beneath white, with waved lines of black dots; round the eyes are numerous small, hooked spines; in the males the fins are full of spines. Of all the larger fishes, the skates are the most numerous, and their numbers are in a great measure owing to their size, and to the protection afforded them by those frightful spines which nature has afforded them. There is not one of the rabidious tribes, excepting, perhaps, the cachalot and white shark, that has a swallow sufficiently large to receive them, and even these are probably deterred from their purposes of destruction by the armour with which their prey is covered. Of some the size is such as to defy all powers of destruction which even the shark himself possest. In England some of the species have been taken, weighing upwards of two hundred weight, but even this is far inferior to their enormous bulk in other parts of the world. Near the island Guadaloupe, a ray was killed more than twenty-five feet long, and almost fourteen broad. After all, the fishes of this tribe probably attain a much larger size than that of any individual which has ever yet been examined. It is only the smallest of the kind that approach the shores; the largest continue for ever prowling at the bottom in the unfathomable caverns of the ocean, where they continue perhaps to grow for a century.

The fishes are said to be found in March and April, at which time they swim near the surface of the water, several males pursuing one female. The females cast their young, as they are called, in May, and continue to produce till September: they are very prolific, not less than three hundred eggs having been found in the body of a single female. The rays generally frequent those parts of the sea where the bottom is black and muddy, where they devour every thing indiscriminately, but they are more delicate with regard to a baited hook. They devour any putrid substances whatever, but if the bait has been taken up and suffered to lie for any time in the open air, they will not touch it; they appear to receive the line, and to dread it; but the impulse of hunger overcomes their caution, and even though they perceive the danger, if thoroughly hungry, they devour the bait, as if regardless of the consequences. See Skate.

* Oxyrinchus; Sharp-nosed Raia. Varied; middle of the back with ten spiny tubercles. This is similar in shape to the skate, but with a longer and sharper snout; the colour of the whole upper part is cincereous, with several pale or whitish spots, intermixed with a few dark dusky streaks or variegations; beneath it is white, with dusky or blueish streaks; down the back and tail runs a single row of spines, and a few others are placed about the region of the eyes: the sides of the tail are also sometimes furnished with a row of smaller or weaker spines than those on the upper part; the eyes are large, as is also the mouth. This species, like the skate, sometimes, but not often, is taken of a very confiderable size. It is a native of the Mediterranean and Northern seas.

* Muraena. This species has a smooth belly and back: it has spines near the eyes, and a single row of them on the tail. It inhabits the Mediterranean; the body above is marked with an oblong spot.

* Fullonica; the Fuller Ray. The back is covered with spines; the eyes with a single row; pectoral fins and tail with a triple row. It inhabits the European seas; grows to a large size; the body above is cincereous, with numerous black spots; beneath it is white. The snout of this fish is short and pointed; the milican memrane is fringed; the teeth are small and sharp; and the tail is slender. It has been thought by some authors that this is only a variety of the next species.

* Rutilus; Rough Ray. The back of this species has a single spine; and the tail is beft with a triple row of spines. This is greatly allied to the thornback, but covered with more numerous spines, every part of the skin on the upper surface being variegated with dark curved aculei of different sizes; of these, one row of the largest runs down the middle of the back, and three, or sometimes five, along the tail; others are disposed about the eyes, and the fringes of the pectoral fins: the general colour is yellowish or whitish-grey, sometimes variegated with dusky or brownish clouds and streaks; the under side is white, and beft with very numerous scattered spines, but less strong than those on the upper side. It is about the size of a thornback. Mr. Pennant mentions one that measured nearly three feet from the nose to the tip of the tail. It is a native of the Mediterranean and other seas.

B. — Teeth obtusus.

Species.

Seaphen. Body nearly round; tail twice as long as the body, winged beneath, and with two long spines above, forked on each side. It inhabits the Red Sea, and in sometimes so large, as to reach three yards across; body above brown, with three rows of large hemispherical tubercles down the middle of the back; beneath it is quite flat and smooth, and it is of a reddish-white. It is from the skin of this species that a beautiful substance called Galalbat is prepared by the French, and which, being coloured with blue, green, or red, according to the fancy of the article, and afterwards polished, is so frequently used for various kinds of cafes, telescope tubes, &c. For this purpose the smaller or younger specimens are preferred; the tubercles in the more advanced or full-grown animals being too large.

There is a variety of this species: the length of the specimen described by Dr. Ruffell was about 9½ inches; the tail is about two feet nine inches long; the colour of the whole animal is a dull leaden above, with a deep blue tail; beneath it is dusky white; on the middle of the back there are only two pearl-formed tubercles instead of three; the tail is furnished with a sharp spine and a fin beneath. It is a native of the Indian seas.
RAIA.

AQUILA. The body is smooth; the tail is pinnate, with a long ferrate spine. This species is of a rhomboidal shape, but with a considerable dilatation: the pectoral fins approach to a subulate form; the colour is cinnereous above; pale or whitish beneath: the head is rather large, and the snout produced: the eyes are large and prominent, with yellow irides: the tail is long, slender, sharp-pointed, and furnished about the middle with a spine similar to that of the fling-ray. This species grows to a very great size, sometimes measuring ten, twelve, or even fifteen feet in length, and weighing upwards of three hundred pounds. It is found in the Mediterranean, Atlantic, and Indian seas, and is said to swim in a flower manner than most other rays; its prey on smaller fishes, and is said to try to strike and kill, or at least disable its prey with the caudal spine: when taken, it is observed to vibrate the tail with great strength and rapidity in all directions. It is not reckoned among the edible fishes; but the liver, which is very large, is said sometimes to be eaten, though it is more frequently used for the purpose of preparing from it a clear oil, which it affords in great plenty.

ASTINACUS; Sting ray. The body of this species is smooth; its tail has a long sharp spine, ferrate on the fore part, and another on the back; there are two other varieties of which the one has a smooth body; the back is beft with two spines, ferrate on the fore part; the body of the other is covered with spots.

This species is described as having a body somewhat approaching the ovate, the pectoral fins less pointed than in some other species of this division. The snout is pointed; the body more convex than usual; the colour of the whole animal above of a yellowish-olive, but the back is sometimes found to approach to a blue-brown; beneath it is whitish; the tail is of a considerable length, and without a fin, very thick at the base, and gradually tapering to the extremity, which is very slender: near the middle it is armed, on the upper part, with a very long, flattened, and sharp-pointed bone or spine, finely ferrated in a reversed direction on both sides: with this the animal is capable of inflicting very severe wounds on such as incautiously attempt to handle it; and it answers the purpose both of an offensive and defensive weapon. This weapon is annually cast, and as it frequently happens that the new spine has arrived at a considerable size before the old one has been cast, the animal is occasionally found with two, in which state it has been sometimes erroneously considered as a distinct species. This fish is said not to grow to a very large size. It is found in the Mediterranean, Atlantic, and Indian seas, and is numbered among the edible rays. On account of the danger attending the wounds inflicted by the spine, it is usual with the fishermen to cut off the tail as soon as the fish is taken. In some countries it is said to be illegal to sell the fish with the tail adhering to it.

It was formerly thought that the spine of the fish possessed a venomous quality, by infusing into a wound made by it some very active poison; this is now proved to be completely erroneous, and the effects sometimes produced by it arise entirely from the depth of the puncture and laceration, which, if taking place in a tendinous part, or among the larger nerves and blood-vessels, have often proved fatal. It may not be amiss to observe, that some ancient writers have debated upon the effects of this animal's powerful weapon in terms of considerable luxuriance; it was supposed to be not only poisonous in the living animal, but to preserve its poison when taken from the fish, and affixed to the head of an arrow or a spear; it was said even to destroy the most healthy and flourishing plant by its touch, and even to cause trees to die by striking the bark with its point. It formed the head of the fatal spear presented by Circe to her son Telephus, by which he was rendered superior to his enemies, and with which he, at length, unconfidently, flew his father Ulysses. The general habits of this species are similar to those of the rest of the genus, often lying flat, and in ambuscade on the soft mud at the bottom of the shores which it frequents, and feizing its prey by surprise; at other times it will pursue it through the depths of the ocean.

*CLAVATA; Thornback. The body of this species is fpinous; the teeth tuberculate; across the belly is a strong semilunar cartilage. This species grows to a very considerable size, though rarely equal in magnitude to the skate already described; in its general appearance it resembes that fish, but is somewhat broader in proportion, and is readily distinguished from the skate by the very strong, curved spines with which its upper surface is covered; these are more conspicuous down the middle and on each side of the back, where four or six, of much larger size than the rest, are generally seen; the remaining parts being furnished with many scattered spines of a smaller size, interspersed with still more minute ones, and the whole skin is of a rough, or thargue-like surface; the back is marked with an uncertain number of pale or whitish round spots of different sizes, and which are commonly surrounded with a blackish or dark coloured edge; these spots are said to be caused by the shedding of the spines at different intervals; along the middle of the back runs a single row of strong spines, continued to the tip of the tail; the colour of the skin is a brownish-grey, with irregular blackish or dusky variegations; the under part is white, with a light cast of flesh-colour, and about the middle of the body, as well as on the fins, are disposed several spines similar to those on the upper side, but less strong. The thornback is an inhabitant of the Mediterranean and other seas, and is held in some esteem as food, though not considered equal to the skate in goodness.

RHINOBATOS. Body long, tapering; snout lengthened. This is reckoned a very remarkable species, and is thought to connect in some degree the genera of raia and fquals, the body being much longer than in the preceding kinds of ray; the snout is lengthened, but not very sharp; and the body, which is moderately convex above, and flat beneath, gradually tapers from the shoulder to the tail, which is furnished above with two fins, of an oblong shape, and situated at a considerable distance from each other: the tip of the tail is also dilated into an oblong fin. The colour of the whole fin is of a dull earthy brown, paler beneath, and the skin is everywhere roughened by minute tubercles. This fish is said to grow to the length of about four feet, and is a native of the European seas. It is very frequently seen about the coasts of Naples.

DIJNDESTIS. Tail-fin two-lobed; spines in a triple row at the beginning of the back, and afterwards in a single row; the first dorsal fin is above the ventral. It inhabits the Red sea, and is about two yards long. The body is a little rough, and of a pale ash colour; above it is varied with whitish spots; beneath it is whitish; behind the vent are a few brown and white spines.

LUMMA. Body oval, smooth, tesselaceous, with blue spots; pinnate tail with a single spine. It inhabits the Red sea, and is hardly a foot long; the spots oval, unequal, beneath whitish. It is much allied to the eagle-ray, and is of a reddish-brown colour above; the tail is somewhat longer than the body, marked above, for half its length, with two longitudinal blue stripes, and is furnished about the middle with one, and sometimes with two, large and ferrated spines, which
which are covered at their base by a blueish-brown skin; the under part of the body is pale or whitish.

**Arnak.** Body orbicular, silvery; tail round, without a fin, and furnished with two spines. It inhabits the Red sea; the teeth are granulate.

**C. Uncertain.**

**Ommeneschrit.** Tail round and spotted. It inhabits the Red sea, and very much resembles the R. paffinaca.

**Tajara.** Tail round; body beneath snowy. It inhabits the Red sea. When just taken, it beats violently with its fins.

**Schoukie.** Body with a few remote spines. It inhabits the Red sea, and approaches the shores by night. The spine on its tail inflicts a dangerous wound.

**Rajensia.** Back with a single fin; the tail is short, pinnate at the end; the body is smooth and unarmed; and the snout is a little obtrude. It inhabits near the Cape of Good Hope, is shaped something like the torpedo, except that it has a fin on the back. The body is small and orbicular; above it is convex, beneath flat.

**Rajabarry, in Geography,** a town of Bengal; 10 miles S. of Dacca. N. lat. 23° 24′; E. long. 96° 36′.

**Rajacotty,** a town of Thibet; 60 miles N.W. of Sirinagur.

**Rajagunge,** a town of Assam; 16 miles S. of Gentiah.

**Rajagur,** a town of Hindooftan, in Bahar; 35 miles W.S.W. of Gayah.—Allo, a town of Hindooftan, in Guzerat; 10 miles N.E. of Champahee.

**Rajahun,** a town of Hindooftan, in the circuit of Ciccaco; 12 miles W. of Ciccaco.

**Rajakeria,** a town of Hindooftan, in the province of Agra.

**Rajamundry,** a circar of Hindooftan, bounded on the N. by the circar of Ciccaco and Golconda, on the E. by the bay of Bengal, on the S. by the circar of Ellore, and on the W. by Golconda. It is crossed by the Bain Gonga from N. to S.—Allo, the capital of the abovementioned circar, situated between Ellore and Ciccaco, on the Godavery. Its principal riches consist of forests of teak-wood. N. lat. 17° 10′; E. long. 81° 57′.

**Rajanagur,** a town of Bengal; 25 miles S. of Dacca.—Allo, a town of Hindooftan, in the circar of Rajamundry; 7 miles N.E. of Rajamundry.

**Rajania, in Botany,** so called in honour of our immortal naturalist, the Rev. John Ray, the most accurate in observation, the most philosophical in contemplation, and the most faithful in description, amongst all the botanists of his own, or perhaps any other, time. His life will be given hereafter, in its proper place. Plummer, who established this genus, finding the name *Raia* preoccupied by zoologists, contrived to call the plant *Jan-Raia*; which Linnaeus turned about into Rajania, still retaining the idea of the Christian name, combined with the other. But such an idea is ludicrous to English ears, and is happily not, in general, perceived. We presume to alter the orthography in one letter, writing the word as it is always pronounced, and deducting it regularly from the Latin *Raia*, by which name the perfom commemorated is known all over the literary world.—Plum. Gen. 33. t. 20. Linn. Gen. 525. Schreb. 692. Willd. Sp. Pl. v. 4. 788. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 391. Jaff. 43. Lamarck Illust. t. 818. Garin. t. 14.—Clans and order,

Female, Cal. Perianth superior, of one leaf, bell-shaped, in six deep segments, permanent, withering. Cor. none. Pfil. Germum inferior, compressed, with a prominent border at one side, three-celled; styles three, the length of the calyx; stigmas obtuse. Peric. Capsule membranous, of three cells, without valves, crowned by the calyx; two of the cells barren, almost obliterated, without wings; the third fertile, compressed, extended into a very large, half-ovate, membranous wing. Seed solitary, nearly elliptical, compressed.

Section 1. Leaves simple.

1. *R. bafata.* Halberd-leaved Raiania. Linn. Sp. Pl. 1461. (Jan-Raia scandens, folio oblongo, anugo et auriculato; Plum. Gen. 33. Bryonia rufctu alato, folis auriculatis; Plum. Amer. 84. t. 98.)—Leaves oblongate; somewhat heart-shaped at the base.—Gathered by Plummer, about Port-de-paix in the island of Hifpaniola. Root perennial, sometimes large and ovate; sometimes four or five inches long, and two thick, round at each end, like a fawage. Its substance resembles that of a radish, without any internal fibres; the bark thin, ash-coloured, a little rugged and warty; the flesh very white, tainting like a bean. This root throws up only one very slender, long, climbing, smooth, knotty *flem*, thickest at the base, where it is accompanied by several fibrous radicles. We presume it to be annual. Leaves scattered, spreading, on short flanks, smooth and membranous, about three inches long; heart-shaped, dilated, abrupt, and seven-ribbed at the base; then suddenly elongated into a nearly linear, entire, central, three-ribbed lobe, blunth, with a small point; the under side paler, and rather downy. Stipulas in pairs, awl-shaped, minute. Flowers small, whitish, in simple, axillary, drooping clusters. *Bracteae* minute, ovate, acute, solitary at the base of each partial flake. *Fruit,* as Plummer says, like half that of a maple-tree, of a silvery hue when young, but afterwards tawny.

2. *R. cordata.* Heart-leaved Raiania. Linn. Sp. Pl. 1461. Ait. n. 1. (Jan-Raia scandens, folis tami; Plum. Lc. 148. t. 155. f. 1.)—Leaves ovate; somewhat heart-shaped at the base; seven-ribbed.—Native of the West Indies, from whence it was sent to Kew garden, in 1786, by Mr. Alexander Anderson. It flowers in the flower in July, and we cannot but with some accurate botanist would publish a good figure and description of the plant, of perfect to its name. Plummer represents the habit of the root, *flem,* &c. much like the foregoing; but the leaves are regularly ovate, pointed, more or less heart-shaped at their base, and furnished with seven ribs continued from that part to the point. These ribs are connected by numerous transverse veins. *Inflorescence, flowers, and fruit,* much as in *R. bafata,* but having seen no specimen, we can say nothing respecting the *fipulas or bracteae,* none of which are noticed in the plate.

Quiqualis. Narrow-leaved Rainia. Swartz 

Leaves linear-lanceolate; rounded at the base, three-ribbed. Native of extremely dry bushy places, in the west part of Hifpaniola, where it climbs upon high trees, flowering in May. Root annual. Stem thread-shaped, round, twining, flaccid, subdivided. Leaves nearly a span long, entire, three-ribbed, veiny, smooth. Flowers small, rounded, red, under the flowers. On some plants the latter are entirely male, with six nearly sessile anthers; on others all hermaphrodite, with six perfect flowers, a triangular oblique stem, no style, but three minute stigmas. Campana as in the rest of the species. Swartz.

5. R. quinquifolia. Five-leaved Cluttered Rainia. Linn. Sp. Pl. 1462. (Jan-رایاراجیا quinquifolia; Plum. t. 149. f. 2.).—Leaves five together at each joint, elliptic-oblong. Clusters lateral, between the joints. Native of the Weel Indies, but hitherto observed by Plumier only. This seems to have the habit of all the foregoing, except that the stem has tumid joints, at each of which stand five elliptic-oblong, obtuse, entire, three-ribbed leaves, about three inches long, on short footstalks. The clusters are represented not axillary, as in the others, but lateral and alternately, from the spaces of the stem between the joints.

Section 2. Leaves compound.

6. R. quinata. Five-leaved Umbellate Rainia. Thumb. Jap. 148. Mart. n. 6.—Leaves five on a common stalk, emarginate. Umbels axillary.—Observed by Thunberg about Nagasaki and in Kofu, in Japan, flowering in April and May. The Japanese call this plant Fagi Kusa, and Akki. Stem twining, round, smooth, ash-coloured, branched. Leaves several together, axillary, falcate, smooth, of five separately falcate, umbellate, ovate, entire leaflets, each from three-quarters of an inch to an inch and a half long, emarginate with a point. Common footstalks thread-shaped, smooth, two inches or more in length; partial half as long as the finger nail. Flowers in umbels, from the same buds as the leaves, on slender stalks as long as the footstalks; partial stalks capillary, the length of the nail. This species differs from the hall in having compound leaves, and umbellate flowers. Thunberg.

7. R. breviflora. Six-leaved Cluttered Rainia. Thumb. Jap. 149. Mart. n. 7.—Leaves five on a common stalk, oblong, acute. Flowers racemose. Native of the country of Fakona, in Japan, among bushes, flowering in April. Its vernacular names are Akki, Mhe Kusa, and Tzu So. The stem is round, falcate, smooth, climbing. Leaves alternate, smooth, fix on a stalk, umbellate, on slender partial stalks, oblong, acute, entire, veiny, two inches long; pale at the back. Common footstalks round, bent, three or four inches long, swelling at each extremity. Flowers in axillary clusters, snow-white. Differs from R. quinata in having mostly six leaflets on a stalk, which are acute, reticulated with veins at the back, and larger than in that species. The flowers moreover grow in clusters, not umbels.
a town of Hindoostan; 20 miles E.S.E. of Allahbad. N. lat. 24° 40'. E. long. 80° 17'.

RAJEGUDAR, a town of Hindoostan, in Lahore; 35 miles E.N.E. of Behnbur.

RAJEHAUT, a town of Bengal; 16 miles N.W. of Biffimpour. N. lat. 23° 13'. E. long. 86° 40'.

RAJEHAR, a catarc of Bengal, bounded on the N. by Purneac, on the E. by Purneac, Maulida, Dinapour, and Raujeely, on the S. by Sultanabad, and on the W. by Hindoea and Boghpoor.—Also, the capital of the above catarc, lying on the W. bank of the Ganges, nearly in the parallel of Maulida, and about 20 miles from it; at the foot of the chain of hills which projects into the river at Sielyguly and Ternagully. It is in a ruinous state, although not above 14 centuries ago the residence of the viceroy; and has hardly the population of an ordinary market-town at present. Its situation is romantic, but not pleasant; for in Hindoostan, the hills and catarcs being always covered with wood, that beautiful swelling of the ground, which is so justly admired in European landscapes, is loit; and the fancy is presented at beet with nothing beyond a wild scene; which can only be relished by being contrasted with soft and beautiful ones. It is more than thirty miles above the head of the delta of the Ganges, and therefore M. d'Anville placed it erroneously by assigning its situation at this place. N. lat. 25° 21'. E. long. 87° 56'.

RAJEMAL, a town of Hindoostan, in Vifapour; 37 miles N.W. of Poonah.

RAJEMUNGALAM, a town of Hindoostan; 16 miles S. of Tinevelly.

RAJTEA, one of the South-eea islands, named also Uliteta; which fee.

RAJETPOUR, a town of Bengal; 15 miles S. of Rogonatpour.

RAJEWICE, a town of Lithuania; 42 miles S.S.E. of Brzece.

RAIGIRI, a town of Hindoostan, in Golconda; 10 miles S.E. of Beder.

RAIGUR, a town of Hindoostan, in the catarc of Sumbulpour; 15 miles N. of Sumbulpour.

RAJIK, a town of Syria, on the Euphrates; 18 miles S. of Bembig.

RAIL, in Architecture, is applied variously; particularly to those pieces of timber which lie horizontally between the pannels of wainscot, and over and under them. The word is also applied to those pieces of timber which lie over and under balusters in balconies, itairacles, &c. Also, to the pieces of timber that lie horizontally from post to post in fences, with pales or without. See Fence. Gaills, in a Shps, are long narrow pieces of fir, or oak, with mouldings of regular members of architecture stuck on them, which are fastened, or sometimes wrought from the solid plank, as ornaments to the shps' sides. The former are now discontinued in the navy, as they were found to rot the sides very much; the latter, wrought from the solid plank, are used in merchant ships. The rails of the head and ftern are pieces of oak timber handiomed wrought with mouldings. The lower rail along the fide is named the noafll-rail, and the next above it the fnee-rail, which are generally placed parallel to the top timber line, the fnee-rail with the top of the fide amidships, and the wail-rail about twenty inches below it; the rails next above and parallel to the fnee-rail are called drift-rails, and the rails above the plank-flee, if any, the fite-rails. The rails of the head are distinguished by the upper or main-rail, the middle and the lower-rail; and the rails of the ftern take their names from the parts to which they are fixed, as the fack-rail, lower counter-rail, upper counter-rail, foot space-rail, brace-rail, taffarel-rail, and taffarel fite-rail. (See Plate 1. Ship-building.) To these may be added the thwarship pieces of the framing of the great cabin bulk-heads.

Raills of the head are certain curved pieces of timber, extending from the bows on each side to the continuation of the ship's item, to support the knee of the head, and the ornamental figure fixed upon it.

Rail, or Water-Rail, in Ornithology, the name of the rallus aquaticus of authors, which is a bird of a long fnder body, with short concave wings. The bill is fnder, slightly incurvated, and one inch three quarters long; the upper mandible black, edged with red, the lower orange-coloured; the irides red; the head, lind-part of the neck, the back and covert of the wings and tail are black, edged with an olive-brown; the fale of the wing is white; the quill-feathers and secondaries fdlty; the throat, breast, and upper part of the belly, are afh-coloured; the fides under the wings, as far as the rump, fdlly varied with black and white bars; the tail is very fhort, conflifting of twelve black feathers; the ends of the two middle fipt with rail colour; the feathers immediately beneath the tail white; the legs are placed far behind, and are of a dully fhck colour; the toes very long, and divided to their origin. The bill is beakshaped, with the fides not webbed, it takes the water, will swim on it with much efue, but is often observed to run along the surface. It delights flesh in flying than in running, which it does very fwtily along the edges of brooks covered with rushes. When it runs, it every now and then lifts up its tail, and in flying hangs down its legs. Pennant.

This bird, fays Mr. Pennant, is properly fui generis, agreeing with no other, but forming a feparate tribe; though M. Briffon and Linneaus place it with the land-rail, and Mr. Ray with the water-hens. It is a well-tailed bird.

Rail, Land, the rallus crex of Linneaus, is a migrating bird, with a fhort, ftrong, thick bill; always found among corn, grafs, broom, or fucre. It leaves this kingdom before winter. They have long legs, and a fingular note, reembling the word crex, often repeated. The feathers on the crown of the head, hind part of the neck, and the back, are black edged with gray colour; the covert of the wings of the fame colour, but not spotted; the tail is fhort and of a deep bay, the belly white, and the legs afh-coloured. They are in great fteent in Anglesea, where they appear about the 2oth of April, fupposed to pafs over from Ireland, where they abound. They are found in molt of the Hebrides, and the Orkneys. Pennant.

Railling, in Rural Economy, a fort of fence conftructed with pefts and rails. It is often made use of in protecting young hedge fences, from the cropping of cattle or other animals. Any fort of coarse timber does very wel for this lat purpose, luch as outside pefts, and the boughs or loppings of timber plantations. See Fence.

Railery, as Dr. Johnson hath defined it, denotes flight fattire, or fatical merriement; and a beautiful writer compares it to a light which dazzles, and which does not burn. It is sometimes, what it aways ought to be, innocent and pleasant, but it is too frequently offensive. Railery is of various kinds; ferior, severe, and good-humoured; there is a kind which perplexes, a kind which offends, and a kind which pleases.

It has been fully obferved, that in order to rally well, kindnefs should prevail in every thing that is faid, as the characfer of a friend fhould be maintained to warrant freedom with a perfon who is addrefed, especially in this way. Al- lulions to past follies, and hints that tend to revive what a perfon wishes for ever to forget, fhould never be introduced as
as subjects of railery. It is below the character of persons of humanity and good breeding, to indulge mirth, while any one in the company is suffering, as the effect of that mirth, pain and mortification.

**RAILWAY, Tram or Dram-road, or Wagon-way, in Rural Economy.** A track constructed of iron, stone, timber, or other material, upon the level surface of an inclined plane, or other situation, for the purpose of diminishing friction, and thus serving for the easy conveyance of heavy loads of any kind of articles. See Plate IV. Canals, figs. 31 to 35. See also CANAL.

It has been remarked, that railways have hitherto been confined, almost exclusively, to coal-works, and other mines; and that inventions, wholly on recommendations are simplicity and usefulness, are often suffered to lie long in a state of public neglect; while others, perhaps, of no real utility, but of more imposing aspect, and being perniciously blazoned forth by interested or blinded partisans, are readily adopted; and bas'd, for a while, in the sunshine of public favour. The time has, however, at length arrived, when carriages moving on level surfaces, or on gently inclining planes, with little friction, and without obstructions, are fast spreading over the face of the country. It has been observed that there may be many line-works, as well as other forts, from which railways may be laid, in different directions, with great benefit to their proprietors and the surrounding neighbourhoods in general.

With the view of diminishing horse labour, it has been suggested by Dr. Anderson, in his Recreations in Agriculture, that where internal canals cannot be established, this may be effected, and intercoure facilitated, by means of railways, which have not yet been introduced into general practice. It is further stated, that they were first solely employed for transporting coals to a moderate distance from the pits, to the places where they could be shipped, being universally made of wood. And long, says he, had they been applied to this use, without any idea having been entertained that they could be employed for more general purposes. By degrees they were, however, carried to a farther extent; the icarity of wood, and the expense of their repairs, suggested the idea of employing iron for the purpose of improving these roads. At the first, flat rods of bar-iron were nailed upon the original wooden rails, or as they were technically called, *fleeperis*; and this, though an expensive process, was found to be a great improvement. But the wood upon which these relied being liable to rot and give way, some imperfect attempts were made to make them of cast iron, but these were found to be liable to many objections, until the buffers was taken in hand by Mr. Outram, engineer, at Butterly Hall, Derbyshire, who contrived at the same time, so far to diminish the expense, and improve the strength of the road, as to bring them to a degree of perfection, that no one who has not seen them can easily conceive could have been done. And it is added, that this having been carried into execution in a few cafes, and found to anwer, has been improved upon and simplified by practice, till it is now brought to such a state of perfection as to have given proofs, that it admits of being carried much beyond the limits of what was for many years conceived to be possible, and to afford demonstrative evidence, that it may in future employed to a wider extent still, to which no limits can be at present assigned or foreseen.

There are a great number of railways in Derbyshire, Shropshire, Lancashire, and many other parts of the country. In the first of the above counties, there are railways of very different lengths; one of five miles in length, leading from the town of Derby to the collieries in the vicinity; another, from the lime-stone rocks on the Cranford canal, called the Crick railway, which is about one mile and a half in length; a third from the Beggarlee colliery to the same canal, denominated Barber and Walker's railway, of similar length; a fourth from the lime-works in the neighbourhood of Bolton, to the canal near Whaley bridge, termed the Peak-forest railway, which is about six miles in length; a fifth called the Marple railway, of about one mile and a half long, on the Peak-forest canal; &c. A railway over Blifworth-hill near Nottingham, on the Grand Junction canal, which are three miles and a half in length, and constructed in a double manner; a seventh, which has the name of the Ashby de la Zouch railway, has four miles of double and eight miles of single rails. Some of these railways are formed in a very complete manner, especially those which have been made since the various improvements of them were introduced. They have been of prodigious utility and advantage to the county, both in regard to its agricultural improvements and its manufacturing interests and concerns.

These forts of railway roads have likewise been introduced into many parts of the county of Salop, with vast benefit and success to the different interests of the district. They have here had a new application, in being employed for the purpose of conveying heavy weights from different levels on canals.

Speaking of the great utility of canals in the carriage of various articles in this county, it is observed by Mr. Telford, an able engineer, that another mode of conveyance has frequently been adopted to a considerable extent; which is that of forming roads by means of iron rails laid along them, upon which materials are carried in waggons, which contain from fix to thirty hundred weight; experience, he thinks, has now convinced us, that in countries the surfaces of which are rugged, or where it is difficult to obtain water for lockage, where the weight of the articles of the produce is great in comparison with their bulk, and where they are mostly to be conveyed from a higher to a lower level, that in those cases, iron railways are in general preferable to canal navigation.

It is supposed, that on a railway well constructed, and laid with a declivity of fifty-five feet in a mile, one horse will readily take down waggons containing from twelve to fifteen tons, and bring back the same waggons with four tons in them. This declivity, therefore, suits well, when the imports are only one-fourth part of what is to be exported. If the empty waggons only are to be brought back, the declivity may be made greater; or an additional horse applied on the returning journey will balance the increase of declivity. If the length of the railway were to be considered, it may, it is supposed, without much inconvenience, be varied from being level to a declivity of one inch in a yard, and by dividing the whole distance into separate flages, and providing the number of horses suitable for each portion of railway, according to the distance and degree of declivity, the whole operation may be carried on with regularity and dispatch.

It is upon the whole believed, that this useful contrivance may be varied so as to suit the surface of many different countries, at a comparatively moderate expense. It may be constructed in a much more expeditious manner than navigable canals; it may be introduced into many districts where canals are wholly inapplicable; and in case of any change in the working of mines, pits, or manufactories, the rails may be taken up and laid down again in new situations, at no very great expense or trouble.

It is also further noticed, that some parts of this and the neighbouring counties, in which canals had once been intended
intended to be formed, have since been looked over and examined with the view of having iron railways instead of navigable cuts; and in many cases this may be the most advisable and proper, particularly in all situations where difficulties arise in the constructing of navigable canals, or other forts of works for water carriage.

The county of Lancaster, too, has a great many of these iron railways for the convenience, accommodation, and advantage of the different collieries, manufactories, and other works, where heavy loads are to be transported. The coal works near St. Helens, in the vicinity of Liverpool, has a double railway some miles in length; and at the iron-works of lord Belcarra, near Wigan, as well as his canal coal pits near the same place, there are double railways of very considerable length. To the south of the town of Preston, at a small distance from Bambrigg bridge, there is likewise one communicating with the Lancaster and Kendal canal, which is also double and of great length; serving to convey the coals from the southern parts of the county to that canal, in order to their distribution in the northern parts, and the adjoining districts.

On the east side of the same county they also prevail in many places, and are found of the greatest use, being the means of dispatching much business in a ready manner and without much expense of labour.

The utility of these railways has been found to be extremely great in other coal-works and canals, where they are at present very extensively employed; and it has been suggested, that they may be applicable in other cases, as for shortening the team labour of a farm so as to bring it within one day's journey, where more than one were formerly necessary, by which a great saving in labour and expense may be made. Also, in rendering the business of lime works more easy and expeditious in different instances. It has likewise been hinted by Mr. Beatfon, in the first volume of Communications to the Board of Agriculture, that they might be had recourse to on roads where there are unavoidable rises or falls, for taking up or letting down heavy loaded waggons or other carriages. It is observed, that near Colebrough Dale there is one at a small distance from the iron bridge, upon which loaded boats are drawn up to a canal, two hundred and twenty feet above the level of the river Severn, and let down in a similar manner into it, by which means twenty-two locks are saved, and the work executed in an expeditious manner. It is supposed, that this is the greatest inclined plane in Europe, or perhaps in the world, for though they are much used in China in the place of locks, has he never heard of any of them being equal in height to this. The rails are best made of iron. It is added, that they have been found useful in improving soft, molly, boggy lands, on which horses cannot travel; a rail road of this fort having been formed through a peat moss near Manchester by Mr. Wakefield, while it was under improvement, at the expense only of about three hundred pounds a mile, on which a single horse was capable of drawing the greatest facility seven wagons at once, each being loaded with about seven hundred weight of marle, bearing in the whole forty-nine hundred weight, and with the weight of the wagons upwards of three tons. This was performed, it is observed, over a place where a few months before a dog could hardly venture without the danger of being drowned. On the Ketley and other canals in the county of Shropshire, vast advantages have been derived from laying railways upon inclined planes, and letting down and drawing up the different articles by means of machinery, as may be seen in the very able Agricultural Report of that district, where excellent representations of them are given.

Besides these different cases of railways, another has been suggested by the writer of the Annals of Agriculture, which is that of having them laid from the stack-yards to the threshing machines, by which the grain may be conveyed to them at any time with ease and convenience, as well as any particular stack that may be wanted.

It is further stated by the ingenious Dr. Anderson, that the best idea he can give of the benefit that may result to the community from the use of this kind of railways, will be from stating some facts respecting them, which were lately communicated to the Society of Arts by Mr. Wilkes, of Measham, near Loughborough, in Leicestershire; a spirited and judicious agriculturalist. He had a railway of this fort made, which was about five miles in extent, leading from a coal-mine to a market. He found it so fully to answer his expectations after it was finished, that he communicated to the above society an account of some trials he had made of it, requesting that such of the members of that respectable institution as were foreigners of information on that head, would do him the honour to witness some experiments that he wished to make upon it, for the information of the public. A committee of the members was accordingly appointed for that purpose, and before them he shewed that a moderate sized horse, of about twenty pounds value, could draw upon it with ease down hill (the descent being one foot in a hundred) thirty-two tons, and without much difficulty forty-three, and seven tons up hill, independent of the carriages. The doctor concludes from these facts, that upon a perfect level a horse could draw with ease from ten to twenty tons. It is observed, that Mr. Wilkes's railway, on which the experiments were made, was, from local circumstances, laid upon wooden sleepers, and is not fo perfect as those done upon stone. But it is added, that twenty tons are the load which such a horse could draw with ease, travelling at the usual waggon rate, in boats upon a canal; so that the number of horses required in this way will not be much, if at all, greater than on a canal.

Certain advantages attach to this mode of conveyance, which do not so well apply to a canal, and more perfect; but it is not his intention to draw a parallel between these two modes of conveyance. Nobody can entertain any doubt, he thinks, about the utility of canals where they are easily practicable. He only wishes to point out this as an eligible mode of conveyance where canals cannot be conveniently adopted.

It is further remarked, that it was customary at the first, to put the whole load to be drawn by one horse upon railways into one waggon; but now, when the load is 100, much augmented, it has been found eligible to divide it into many parts, so that no one waggon shall carry more than one or two tons; by this method the weight is so divided, that the pressure is never so great upon one point as to be in danger of too much crushing the road; the carriages can be made much more limber and light in all their parts, and they are much more easily moved, and more manageable in all respects than they otherwise would have been. And another advantage of this arrangement, which defers to be particularly adverted to, is, that it admits of shifting the carriages so as to leave a load, as it were, in parcels at different places where they may be required, without trouble or expense. This, when it comes to be fully understood and carried into practice, will, he thinks, be a convenience of invaluable value, a thing that has been always wanted, and never yet has been found though it has been diligently sought for. The able writer has here endeavoured to illustrate its importance and utility in transporting goods from the wet docks now forming on the Isle of Dogs to London, and in carrying roads to different distant parts of the country; in which cafes,
RAILWAY.

eas, and in all where there is much business to be done, they would require to be double, one for going, and the other for coming upon, to prevent interruption and interference.

And he afterwards offers a few remarks, tending to shew the practicability of the measure, and to guard against setting out upon a bad plan, which might, he supposes, in time to come, frustrate the good that might have resulted from the undertaking; merely premising, that he propos'd these railways solely for the purpose of conveying weighty loads, leaving the roads, as at present, open for coaches and light carriages.

Also with a view to discover how far it may be practicable to introduce these iron railways into general use, he has made some inquiries respecting the expense of making them; and although this must vary according to the abundance and goodness of materials, and other circumstances, the following statement may serve to give some general notions on that head. In the most eligible situations, where materials are abundant and good, and circumstances favourable, the lowest expenditure at which a single railway of this kind can be made, will be about one thousand pounds a mile. But as a single railway must be liable to great inconveniences, unless under very particular circumstances, double railways ought to be considered as the only useful fort. These, for public purposes, according to the opinion of the inventor, should be very substantially made. The metal used should be of the finest sort, and of substance enough, not merely to carry the weights proposed, but to be equal to bear almost any blow or shock that they may be likely to experience; and, thus made, what they will lose by rust or wear, will be long ere it materially weakens them. Made after such a manner, in favourabe situations in the country, a double railway may, he thinks, cost about two thousand pounds a mile, but in the neighbourhood of London, where the charge of everything is high, and where they should be of the strongest fort, we should suppose they might cost nearly three thousand pounds a mile. It is bad economy, he thinks, to fave on articles of this fort at the first; for the little expense thus laid out then will be much in repairs: how small these repairs are, may be imagined from this circumstance, that when a road is thus made, the undertaker does not scruple to supply all that are broken, free of charge, for the first three years. Say then that such a road cost three thousand pounds a mile, this would bring a charge upon the turnpike of 150l. a-year, say 50l. more for annual repairs; this is, in all, 200l. per annum. Compare this with the expense of keeping the present roads in repair. It has been suggested to him, that there is annually laid out in repairs upon the road from Hyde Park Corner to Hounslow, considerably above one thousand pounds a mile; so that the difference of expense is, even at the beginning, very much in favour of railways: and were the money thus at first expended to be gradually paid off, the tolls might thus be lowered almost to nothing. And, he thinks, that a turnpike road cannot be made in almost any situation for less, as he is told, than 1000l. per mile; but where it is of considerable width, as near great towns, it will run from 1500l. to 2000l. per mile; and in annual repairs, including the purchase price of materials, carting them on the road, spreading, raking off, and carting away, again, from 100l. to 1000l. a mile. Say 1500l. prime cost, the interest is 35l. and 150l. for repairs, the annual charge of such road would be 225l. This is an expense of 100l. 5s. 4d. more than the other. But for the present, let us suppose that they will be equal, the extra charge for purchasing ground for a new waggonway, &c. being equal to that surplus; let us now see what would be the difference of charge to the employers of these waggon to the same amount pafs each day, carrying fix tons each, drawn by eight horses; these, at one shilling each waggon for toll (or two-pence a ton), would produce 5l. a day, or 185l. a year; which, at the rate of eight miles for each turnpike, would be 228l. per mile, the farplus being produced by road horses and light carriages. The charge to the employer, for this stage, must be 182l. and the keep of 800 horses, besides servants, incidental charges, and owner's profits for the transport of 660 tons of goods a day. Say that the same horses travel two stages a day, the turnpike money would be doubled; that is, 365l. per annum; the keep of 800 horses, at 2l. each per diem, is 20,000l. These sums added make 32,850l.; owner's profit and incidental charges, say 10 per cent., 3285l.; in all 36,135l., or, on 219,000l., being 600 tons a day, about one-fourth per ton. And supposing the fame quantity of goods carried on the railway, and the same turnpike money paid, and that each horse drew only fifteen tons, this would require only, he thinks, forty horses; the keep of which, at 2l. a day, would be 1460l.; add the toll, 1825l. is 3285l. per annum. Owner's profit, &c. upon this sum 10 per cent. as above, 3285l.; in all 36135l., or about four-pence a ton, just one-tenth part of the charge in the other case. He thinks, that when the object comes to be considered in this point of view, few measures that can be proposed will hold forth such an important national improvement as this would be. Considered with regard to the consumption of the produce of the earth (an object at present deferring the fullest attention, as this improvement can be applied to almost every part of the country), it would, he supposes, reduce the number of heavy road horses to one-eighth part of what they are at present, and of course augment the number of cattle or other consumable provisions in a proportionate degree, so as greatly to lower the price of the necessaries of life. It would, in the next place, lower the price of the carriage of goods of all kinds to an amazing extent; and lastly, as a consequence of that, it would give such encouragement to agriculture, as no other measure that can be contrived could ever effect, and that without confining such a thriving expense to any one individual, or to the state. On the contrary, by inducing cheapness of provision, and affording such efficacious encouragement to manufacturers and to agriculture, it would produce a general prosperity, which, by augmenting the consumption of taxable commodities, would augment the public revenue; while, at the same time, every individual would feel himself relieved from the prelude of many taxes that prove distressful to him at present. After justly reproving every sort of gambling speculations by moneyed men in undertakings of this nature, and shewing the numerous evils that attend them, he advises it, as highly necessary to prevent these railways from ever becoming private property, on any account, to keep them open and patent alike, to all who shall choose to employ them as a king's highway, under such regulations as it shall be found necessary to subject them to by law. In short, they should, he thinks, be put upon the same footing, in all respects, as public roads are at present, only under the direction of a distinct set of commissioners, who should have the superintendence of everything that concerns this species of roads only. These commissioners should be vested with authority under an act of parliament, to erect turnpikes upon them, to levy certain stipulated tolls, and to mortgage the produce of these tolls for the purpose of raising money to be applied in the necessary purchases of land, and making the roads. In the act it should
should be expressly stipulated, that the produce of these tolls should be applied solely to keeping the road in repair, paying the interest of sums borrowed, and clearing off the principal as fast as the collections would admit; and when the whole money borrowed was thus paid off, the tolls should be so lowered as only to produce money sufficient to keep the roads in a state of continually good repair. This would be the expense of transporting goods be annually diminishing, and the prosperity of the country be thereby augmenting from day to day. He adds, that he is particularly earnest in this business, as he has not been an uncounseled observer of the effects that have resulted from the establishment of turnpike roads in Scotland, which were begun within his recollection; and these effects have been such as no man who had not seen it would have believed could ever have taken place. Distance may be said to be thus diminished from place to place; lands that were originally far beyond the influence of the town as a market for any thing else than live-stock, are thus brought, as it were, close to its gates; and the value of the produce of many articles is thus to them augmented fourfold, while they are at the same time diminished to the public. Not only is the value of produce raised, but the quantity also of that produce is augmented exceedingly by means of manures which become then accessible. Foulle manures, such as chalk, lime, and marle, which were formerly confined to a narrow spot, expand themselves as if it were by a magical power, and by that expanisible influence diffuse around fertility, riches, and plenty.

Coal's and other weighty articles that may be useful in arts or manufactures of various kinds, which never were, nor ever could have been of any value to the owners of them, so long as the expense of transportation exceeded a certain sum, find a ready market to any extent as soon as the price falls below that rate, thus contributing not only towards the enriching of the owners, but to the furnishing of employment to the various persons who must be engaged in preparing or transporting them to market, and the universal accommodation of the whole. Around every market you may suppose a number of concentric circles drawn, within each of which certain articles become marketable which were not so before, and thus become the source of wealth and prosperity to many individuals. Diminish the expense of carriage but one farthing, and you widen the circle; you form, as it were, a new creation, not only of itones, and earth, and trees, and plants, but of men also, and what is more, of industry, of happiness, and joy. It is added, that by making these roads the property of the public, and free to every person to bring his own waggons upon them where he pleased, farmers, when near them, would make by roads of the fame fort leading into these from their respective premises; the inhabitants of villages and country districts would join together, and at one common expense make roads of the same fort leading to a greater distance inwards, as they now make bye roads for themselves. Thus would all be accommodated; those who had business enough to furnish a sufficient load for one horse might go to market with it when they pleased: those who had dealings on a smaller scale could have one, two, or more waggons of their own conjoined with those of others to make up a load for one horse: and those of still smaller means could have one wagggon loaded with the joint articles belonging to two, three, or more. A ton weight might then be pushed before a man to market for many miles, as a wheelbarrow is now. It is scarcely possible, he supposes, to contemplate an infitution from which would result a greater quantum of harmony, peace, and comfort, to persons living in the country, than would naturally result from this arrangement. In fact, he says, no one measure, that would tend to effectually to lower the price of the necessaries of life, and restore abundance.

In what regards the method of forming and constructing these railways, it is observed by the same writer, that the following has been given by the inventor as the most improved plan: first, that the best line the country affords should be traced out, having regard to the direction of the carriage of articles or trade to be expected; and if such trade be both ways in nearly equal quantities, a line as nearly horizontally as possible should be chosen. If the trade is all in one direction, as is generally the case between mines and navigation, then the most desirable line is one with a gentle gradual declent, such as should make it not greater labour for the horses employed to draw the loaded wagons down, than the empty ones back; and this will be found to be the case on a railway defending about one foot vertical in one hundred feet horizontal. Or, if the railway and carriages are of the very best construction, the defcent vertical may be to the length horizontal as 1 to 50, where there is little or no upgate loading. In cafes between mines and navigations the defcents will often be found greater than could be wished. On a railway on the improved plan, where the defcent is more than 1 to 50, fix or eight waggons, loaded with thirty or forty hundred weight each, will have such a tendency to run downwards, as would require great labour of one horse to check and regulate, unless that tendency was checked by lodging some of the wheels. On such, and steeper roads, iron flippers are applied, one or more to a gang of waggons, as occasion may require. Each flipper being chained to the side of one of the waggons, and, being put under the wheel, forms a fledge. Where the defcent is very great, steep inclined planes, with machinery, may, it is observed, be adopted, so as to render the other parts of the railway easy. On such inclined planes the defending loaded waggons being applied to raise the ascending empty; or partly loaded ones, the necellity of flegding the wheels is avoided; and the labour of the horse greatly reduced and lessened.

In order to obtain the desired levels, gentle declents, or steep inclined planes, and to avoid sharp turns, and circuitous tracks, it will often be found prudent to crofs valleys by bridges and embankments; to cut through ridges of land; and in very rugged countries short tunnels may, he thinks, sometimes be necessary. The line of railway being fixed, and the plans and sections by which the frame is to be executed and settled, the ground for the whole must be formed and effectually drained. The breadth of the bed for a single railway, should be, in general, four yards; and for a double one six yards, exclusive of the fences, fide drains, and ramparts.

That the bed of the road being so formed to the proper inclination, and the embankments and works thereof made firm, the surface must be covered with a bed of itones broken small, or good gravel, six inches in thicknes beyond. On this bed must be laid the sleepers, or blocks to balance the rails upon. These should be of stone in one place where it can be obtained in blocks of sufficient size. They should not be less than eight, nor more than twelve inches in thicknes; and of such breadth (circular, square, or triangular,) as shall make them 150lbs. or 200lbs. weight each. Their shape is not material, so as they have a flat bottom to rett upon, and a small portion of their upper surface level, to form a firm bed for the end of the rails. In the centre of each block should be drilled a hole, an inch and a half diameter, and six inches in depth, to receive an octagonal plug of dry oak, five inches in length; for it should not reach the bottom of the hole; nor should it be larger than the nice to put in easily.
cally, and without much driving; for if too tight fitted it
might when wet burl the stone. These plugs are each to
receive an iron spike or large nail, with a flat point and long
head, adapted to fit the counter-funk notches in the ends of
two rails, and thereby to fasten them down in the proper
position, or situation in which they are to lie.

With regard to the rails, they should be of the round
iron, one yard in length each, formed with a flange on
the inner edge, about two inches and a half high at the ends,
and three and a half in the centre; and shaped in the bell
manner to give strength to the rails, and keep the wheels in
their track. The sides of the rails, for general purposes,
should not, he thinks, be less than four inches broad; and
the thickness proportioned to the work they are intended
for. On railways for heavy burdens, great use, and long
duration, the rails should be very stout, weighing 40 lbs.,
or, in some cases, nearly half an hundred weight each. For
railways of less consequence, less weight of metal will do;
but it will not be prudent to use them of less than 30 lbs.
weight each, in any situation exposed to breakage above
ground. But it is observed that in mines, and other works
under ground, where very small carriages only can be em-
ployed, very light rails are used, forming what are called
train roads, on a system introduced by Mr. Carr; and these
kinds of light railways have been much used above ground
in Shropshire, and other counties where coals and other
minerals are obtained.

It is added, that in fixing the blocks and rails great atten-
tion is required to make them firm. No earth or soft ma-
terials should be used between the blocks and the bed of small
stones or gravel, on which the rails must all be fixed by an
iron gage, to keep the fides at a regular distance, or parallel
to each other. The belt width of road for general purposes
is four feet two inches between the flanches of the rails; the
wheels of the carriages running in tracks about four feet five
inches acnder. Rails of particular forms are necessary
where roads branch out from or intersect each other; and
where carriage roads cross the railways; and, at turnings of
the railways, great care is required to make them perfectly
easy. The rails of the fide forming the inner part of the
curve should be fixed a little lower than the other; and
the rails should be let a little under the gage, so as to
bring the fides nearer together than in the straight parts;
these deviations in level and width to be in proportion to the
sharpness of the curve. The blocks and rails being fixed and
spiked fast, nothing more remains to be done than to fill the
hoie-path, or space between the blocks, with good gravel,
or other proper materials; a little of which must also be put
on the outside of the blocks to keep them in their proper
places. This gravel should always be kept below the sur-
face of the rails on which the wheels are to run, to keep the
tracks of the wheels free from dirt and obstructions. The
form of the rails must be such as will free them from dirt if
the graveling is kept below their level.

And in the constructing of the carriages great attention to
avoid friction is necessary, particularly in the formation
of the wheels and axles, which must be adapted to the form
of railways and kind of loading; but for which general direc-
tions cannot be given in a narrow compass. It is prob-
able that this valuable invention may also be applicable to
many other purporses in agriculture or manufactures, as it
becomes more generally known, and the facilities which it af-

fords are better known. See Canal.

RAIMALPOUR, in Geography, a town of Hindostan, in
Rohilcund; 30 miles S. of Berilly.

RAIN, a town of Hindostan, in Guzerat, on the gulf
of Cutch; 45 miles W. of Noanagur.—Alfo, a town of
Bavaria; 16 miles N. of Augsburg. Lat. 43° 37'. E.
long. 10° 52'.

RAIN, or Old Rain, a town of Scotland, in Aberdeens-
shire, near which are the remains of a palace of the former
bishops of Aberdeen; eight miles S. E. of Inverary.

RAIN, the dissipation of water which descends from the
atmosphere in drops of various sizes. By this circumstance
rain is distinguished from dew or fog; in the former of
which the drops are so small, that they are quite invisible;
and in the latter, though they are of a larger size, they
seem to have little more specific gravity than the atmos-
phere itself, and may therefore be reckoned hollow spherules
rather than drops.

Rain is, apparently, a precipitated cloud; as clouds are
nothing but vapours raised from moisture, waters, &c.

And vapours are demonstratively nothing else but little
bubbles or vesicle detached from the surface of the ter-
restrial globe by the power of the solar or subterraneous heat,
or some other cause. These vesicle, being specifically
lighter than the atmosphere, are buoyed up by it, until they
arrive at a region where the air is in a state of balance with
them; and here they float, till by some new agent they are con-
verted into clouds, and thence either into rain, snow, hail,
mist, or the like.

But the agent in this formation of the clouds into rain,
and the vapours into clouds, has been much controverted.
Some philosophers have supposed that the cold, which con-
stantly occupies the superior regions of the air, chills and conden-
ses the vesicle, at their arrival from a warmer quarter; con-
gregates them together, and occasions several of them to coa-
dele into little malfes: and by these means their quantity of
matter increasing in a greater proportion than their sur-
face, they become an overbalance to the thin air, and ac-
cordingly descend in rain.

Dr. Derham accounts for the precipitation thus: that the
vesicle being full of air, when they meet with a colder
air than that they contain, this internal air is contracted into
a less space; and consequently the wettery shell, or case,
is rendered thicker, so as to become heavier than the
air, &c.

It has, however, been objected to this hypothesis, that
rain often happens in very warm weather; and though it be
allowed, that the condenfation may be owing to the cold
of the upper regions, yet the drops acquire a considerable
increase of size as they descend. E. G. On the summit of
a hill they are small and occasion only a drizzling shower;
but in descending the hill it becomes more considerable, and
at the bottom of the hill the drops are much larger, and the

RAI
the rain is impetuous. Hence it appears that the vapours are condensed when the atmosphere is warm as well as when it is cold.

Others only allow the cold a part in the action, and ascribe a share of it to the winds, alleging, that a wind blowing against a cloud will drive its vesture upon one another, by which means several of them, coalescing as before, will be enabled to descend; and the effect will be still more considerable, if two opposite winds blow together toward the same place. To which they add, that clouds already formed, happening to be augmented by fresh accretions of vapour, continually ascending, may on this account be enabled to descend.

Against the above stated hypotheses of Derham, it has been objected that the vesture of vapour, if they be such, are filled, not with air, but fire or heat in a latent state, and till they part with this heat, the vapour cannot be condensed. Cold is not always sufficient to produce this effect; for in the most severe frosts the air is rare, and parts with little or none of its vapours, for a considerable time. It is also alleged, that the winds have no considerable agency, since blowing upon vapour is so far from condensing it, that it unites more closely with the air; and wind is known very much to promote evaporation. See VAPOUR.

Yet the grand cause, according to Rohault, still remains: that author conceives it to be the heat of the air, which after continuing for some time near the earth, is at length carried up on high by a wind, and there thawing the snowvilli, or flocks of the half-frozen velicula; reduces them into drops; which coalesce, descend, and have their dilatation perfected in their progress through the lower and warmer flages of the atmosphere. Others, as Dr. Clarke, &c. ascribe this descent of the clouds rather to an alteration of the atmosphere than of the velicula; and suppose it to arise from a diminution of the spring, or chalybea force of the air.

This elasticity, which, as they say, depends chiefly or wholly on the dry terrene exhalations, being weakened, the atmosphere sinks under its burden, and the clouds fall, on the common principle of precipitation.

Now, the little vesture, by any or all these means, being once upon the deficient, will pervert therein. notwithstanding the increafe of resistance they every moment meet with in their progress through flill denser and denser parts of the atmosphere. For, as they all tend toward the equal point, viz. the centre of the earth, the farther they fall, the more cohesion will they make; and the more cohesion, the more matter will there be under the same surface; the surface only increasing as the squares; but the solidity as the cubes; and the more matter under the same surface, the less friction or resistance there will be to the same matter.

Thus if the cold, the wind, &c. happen to act early enough to precipitate the ascending vesture, before they are arrived at any considerable height, the coalescences being few in fo short a descent, the drops will be proportionably small; and thus is formed what we call DEW. See DEW.

If the vapours prove more copious, and rise a little higher, we have a MIST or FOG; which see respectively.

A little higher still, and they produce a small rain, &c. If they neither meet with cold, nor wind enough to condense or dissipate them, they form a heavy, thick, dark flky; which lasts sometimes several weeks. This hypothesis of the diminution of the atmosphere's elasticity, requires a more satisfactory explanation of the cause of this diminution. By ascribing it to terrene exhalations, we only solve one difficulty by introducing another; for we are totally unacquainted with the nature and operation of these exhalations. But let the cause be what may be supposed, if it act equally, and at once, upon all the vapour in the air, all that vapour must be at once precipitated; and the consequence must be, that instead of gentle showers continuing for a considerable time, we must have copious water-spouts, lasting only for a few minutes or seconds, which, instead of refreshing the earth, would drown and lay it waste.

Those who assign both of the above hypotheses, account for many of the phenomena of the weather; e.g. why a cold is always a wet summer, and a warm a dry one; because the principle of precipitation obtains in the one case, and is wanting in the other. Why we have ordinarily most rain about the equinoxs; because the vapours arise more plentifully than ordinary in the spring, as the earth becomes loosened from the brumal constrictions; and because, as the fun recedes from us in autumn, the cold increasing, the vapours that had lingered above during the summer heats, are now dispatched down, &c. Why a settled, thick, close sky fiercely ever rains till it has been first clear; because the equally diffused vapours must first be condensed, and congregated into separate clouds, to lay the foundation of rain; by which means the reft of the face of heaven is left open, and pervious to the rays of the sun, &c.

For other phenomena of rain, as they relate to the weather-glass, see BAROMETER, and WEATHER. It cannot be doubted, that there is a connection between the deficit of the barometer and the fall of rain; but no satisfactory reason has yet been assigned for the circumstance; nor is it possible to foretell with certainty that rain will follow any changes in the height of the barometer that have been observed. The immediate dependence of rain, or of any other atmospheric phenomena, on the influence of the moon, appears to be rendered highly improbable, not only by mathematical calculations of the effects of the moon's attraction, but also by the irregularity of the observations which have been adduced in favour of such a connection. (See Influence of the Moon.) But however uncertain the ultimate causes of rain may be in general, their effects in some places are sufficiently constant, to be attributed to permanent local circumstances, and in particular to the periodical recurrence of similar winds.

For a more particular account of other theories, for explaining the ascent of vapours, the formation of clouds, and the fall of rain, see VAPOUR.

Besides the causes of rain, mentioned above, Desaguliers thinks it owing to the loss of electricity in the vapours of which they were formed.

Other writers, in the progress of this part of philosophical science, have considered rain as an electrical phenomenon; or at least they have supposed, that the powers of electricity may concur with other causes in producing it. Sienior Beccaria, whose observations on the general state of electricity in the atmosphere have been more extensive and accurate than those of any other person, reckons rain, hail, and snow, among the effects of a moderate electricity in the atmosphere. Clouds that bring rain, he thought, were produced in the same manner as thunder clouds, only by a moderate electricity. He describes them at large, and the resemblance which all their phenomena have to those of thunder-clouds is very striking. He notes several circumstances attending rain without lightning, which render it probable, that it is produced by the same cause as when it is accompanied with lightning. Light has been seen among the clouds by night in rainy weather; and even by day rainy clouds are sometimes seen to have a brightnes evidently independent of the sun. The uniformity with which
which the clouds are spread, and with which the rain falls, he thought, were evidences of an uniform cause like that of electricity. The intensity also of electricity in his apparatus generally corresponded very nearly to the quantity of rain that fell in the same time. Sometimes all the phenomena of thunder, lightning, hail, rain, snow, and wind have been observed at one time; which shows the connection they all have with some common cause. Signior Beccaria, therefore, supposes, that, previous to rain, a quantity of electric matter escapes out of the earth, in some place where there was a redundancy of it; and in its ascent to the higher regions of the air, collects and conducts into its path a great quantity of vapours. The same cause that collects, will condense them more and more; till, in the places of the nearest intervals, they come almost into contact, so as to form small drops; which, uniting with others as they fall, come down in rain. The rain will be heavier in proportion as the elafficity is more vigorous, and the cloud approaches more nearly to a thunder-cloud. He imitated the appearance of clouds that bring rain, by inflating himself between the rubber and conductor of his electrical machine; and with one hand dropping collophonia into a spoon fastened to the conductor, and holding a burning coal, while his other hand communicated with the rubber. In these circumstances the smoke spread along his arm, and, by degrees, all over his body, till it came to the other hand that communicated with the rubber. The lower surface of this smoke was every where parallel to his clothes, and the upper surface was swelled and arched like clouds replete with thunder and rain. In this manner, he supposes, the clouds that bring rain diffuse themselves from over those parts of the earth which abound with electric fire, to those parts that are exhausted of it; and by letting fall their rain, restore the equilibrium between them. Signior Beccaria also thought, that the electricity communicated to the air, which both receives and parts with it slowly, would account for the retention of vapours in a clear sky; for small disjointed clouds, not diffused into rain; for the smaller and lighter clouds in the higher regions of the air, which are but little affected by electricity; and also for the darker, heavy, and sluggish clouds in the lower regions, which retain more of it. He even imagined that some alteration in the weight of the air might be made by this electricity of it: the phenomena of rain, he thought, favoured the supposition, that the electric matter in the air did, in some measure, leffen its pressure: for when the electric matter is actually in the air, collecting and condensing the vapours, the barometer is low. When the communication is made between the earth and the clouds by the rain, the quicksilver begins to rise; the electric matter, which supported part of the pressure, being discharged. Lettre deI' Elecfricino. Priestley's Hist. &c. of Electricity, vol. i. p. 427, &c. 8vo.

Dr. James Hutton's theory of rain is stated and simply illustrated in the 1st volume of the Edinburgh Transactions, p. 47, &c. It is well known that atmospheric air is capable, with a certain degree of heat, of dissolving a given quantity of water. (See VAPOUR.) Dr. Hutton ascertains the ratio of the dissolving power of air, in relation to water, with different degrees of heat; and thus, by mixing a portion of transparent humid warm air with a portion of cold air, the mixture becomes opaque, and part of the water will be precipitated; or, in other words, the vapour will be condensed into rain. Hence he observes, that since the capacity of air for moisture increases faster than the temperature, there must be a depotation of moisture when two saturated portions of air at different temperatures are mixed. Dr. Hutton supposes that heat and solution do not increase by equal increments; but that, in reality, if heat be suppos'd to increase by equal increments along a straight line, solution will be exprest by ordinates to a curve, whose convex side is turned towards that line. That the power of solution is not increased in the same ratio with heat is, however, hypothetical, except when we rise pretty high in the scale, when its proportionate increase is some-what doubtful; nor has our author supported it by experiment. The condensation of the breath in air is not to the purpose, unless we suppos'e the air to be already fattened with vapour. In any view, it can only amount to this, that to render it visible, the heat must be diminished in a greater proportion than can be compensated by the power of solution in the body of air, in which the portion expired is at first immersed. In order to explain the origin of rain from this cause, we must always suppos'e a constant diminution of heat to take place at the moment of the condensation of the vapour; but we actually find, that the change from a state of vapour to the fluid state is attended with heat; so that rain must at once oppose its own cause, and continued rains would be impossible without the aid of other causes.

Dr. Hutton endeavours, from his own system, to explain the regular and irregular leasons of rain, with regard to either the generality of its appearance, or the regularity of its return. And to obviate the apparent exceptions of the theory, from the generality of rain, he explains the proportional quantities of rain, and adds a comparative effimate of climates, in relation to rain with the meteorological observations made in our own climate. As our limits will not allow our doing full justice to our author's reasoning, we must refer to his own paper on the subject. Mr. Dalton, in his "Meteorological Essays," (Eff. vi.) expresses his approbation of Dr. Hutton's theory in general; to this purpose, he says, "the principles of none appear to me to be more plausible and consistent with facts." Dr. Hutton, as we have above shown, considers the varieties of heat and cold, affecting the soluble power of the atmosphere, as the sole causes of rain; and Mr. Dalton observes, when we consider that evaporation and the precipitation of vapour are diametrically opposite, it is reasonable to suppos'e that they should be promoted by opposite causes: and as heat and dry air are favourable to evaporation, so cold, operating upon air replete with vapour, promotes its precipitation. Dr. Hutton, however, seems to consider water as chemically combined with the atmosphere, and that cold produces precipitation in a manner similar to what it does in water saturated with salt, or in other chemical processses; whereas Mr. Dalton suppos'es, that a portion of the vapour, consider'd as a distinct and peculiar fluid, is condensed into water by cold; but the effects resulting from the two theories will be the same. See METEOROLOGY, and VAPOUR.

M. de Luc, in the 2d volume of his "Thoughts on Meteorology," has directed particular attention to the various circumstances that attend rain. He has also examined the several hypotheses of different authors, and concludes, that they are altogether insufficient to account for the formation of it. In this inquiry the grand question under discussion is, what becomes of the water that rises in vapour into the atmosphere? or what is the state in which it subsists there, between the time of its evaporation, and its falling down in rain? If it continues in the state of water, as vapour, or such as is the immediate product of evaporation, it must possess the distinctive characters essential to that fluid; it must make
make the hygrometer move towards humidity, in proportion as the vapour is more or less abundant in the air: on a diminution of heat, the humidity, as shown by the hygrometer, must increase; and on an increase of the heat, the humidity must diminish; and the introduction of other hygroscopic substances, drier than the air, must have the same effect as an augmentation of heat. These are the properties of vapour, on every hypothesis of evaporation; and, therefore, all the water that exists in the atmosphere, without poffefling these properties, is no longer vapour, but must have changed its nature. M. de Luc fhews, that the water which forms rain, though it has ever been confidered and reafoned upon as producing humidity, does not poffefs this property, and must, therefore, have palled into another state. As he thinks that the vapour paffes into an invisible state in the interval between evaporation and its falling again in rain, and that in this state it is not fensitive to the hygrometer, he confiders the laws of hydrology as insufficient for explaining the formation of rain; but he does not pretend to have difcover'd the immediate caufe of the formation of clouds and rain. If it is not in the immediate product of evaporation that rain has its fource; if the vapours change their nature in the atmofphere, fo as no longer to be fensitive to the hygrometer, or to the eye; if they do not become vapour again till clouds appear; and if, when the clouds are formed, no alteration is perceived in the quality of the air; we muft acknowledge it to be very probable, that the intermediate state of vapour is no other than air, and that the clouds do not proceed from any distinct fluid contained in the atmofphere, but from a decomposition of a part of the air itself, perfectly similar to the reft. For other observations on the acfen and nature of vapour, and the subsequent formation of rain, we refer to the articles Meteorology, and Vapour.

As to the general quantity of rain that falls, and its proportion in several places at the fame time, and in the fame place at several times, we have many obfervations, journals, &c. in the Memoirs of the French Academy, the Philof. Tranf. and many other publications; from which we shall make the following extracts.

Upon measuring the rain falling yearly, its depth, at a medium, is found as in the following table.

The whole quantity of rain at London, in each of the years specified below, was as follows: viz.

Half Year 36.76 19.24 32.66

As rain-gages have been fixed of late years in almost every part of the kingdom, we are enabled to determine, with considerable exactness, the depth of water which the rain yields in any given place. It may be observed, however, that inland counties have less rain than maritime ones, especially those which border on the western seas. But still a greater difference seems to take place between a mountainous country, and a champagne or flat country. In the former there often falls double or triple the quantity of rain in a year that there does in the latter, and never less than an equal quantity. It is also observed, that those winds bring most rain that blow from the quarter in which is the most and nearest sea; as are west and south-west winds. The rain-gage also shews, that more rain is collected in the instrument, as it is placed nearer the ground; without any appearance of a difference, between two places, on account of their difference of level above the sea, provided that the instrument is as far from the ground at the one place, as it is at the other. These effects are noticed in the Phil. Tranf. for 1769 and 1771, the former by Dr. Heberden, and the latter by Mr. Daines Barrington. Dr. Heberden says, "A comparison having been made between the quantity of rain which fell in two places in London, about a mile distant from one another, it was found that the rain in one of them constantly exceeded that in the other, not only every month, but almost every time that it rained. The apparatus used in each of them was very exact, and both made by the same artifit; and upon examining every probable cause, this unexpected variation did not appear to be owing to
to any mistake, but to the constant effect of some circumstance which, not being supposed to be of any moment, had never been attended to. The rain-gage in one of these places was fixed so high, as to rise above all the neighboring chimneys; the other was considerably below them; and there appeared reason to believe, that the difference in the quantity of rain in these two places was owing to this difference in the placing of the vellum in which it was received.

A funnel was, therefore, placed above the highest chimneys, and another upon the ground of the garden belonging to the same house, and there was found the same difference between these two, though placed so near one another, which had been between them, when placed at similar heights in different parts of the town. After this fact was sufficiently ascertained, it was thought proper to try whether the difference would be greater at a much greater height; and a rain-gage was therefore placed upon the square part of the roof of Westminster Abbey. Here the quantity of rain was observed for a twelvemonth, the rain being measured at the end of every month, and being taken that none should evaporate by passing a very long tube of the funnel into a bottle through a cork, to which it was exactly fitted. The tube went down very near to the bottom of the bottle, and therefore the rain which fell into it would soon rise above the end of the tube, so that the water was no where open to the air except for the small space of the area of the tube; and by trial it was found that there was no sensible evaporation through the tube thus fitted up.

The following table shews the result of these observations.

From July the 7th, 1766, to July the 7th, 1767, there fell in a Rain-gage, fixed

<table>

</tbody>
</table>

By this table it appears, that there fell below the top of a house above a fifth part more rain than what fell in the same space above the top of the same house; and that there fell upon Westminster Abbey not much above one-half of what was found to fall in the same space below the tops of the houses. This experiment has been repeated in other cases with the same result. What may be the cause of this extraordinary difference, has not yet been discovered; but it may be useful to give notice of it, in order to prevent that error, which would frequently be committed in comparing the rain of two places without attending to this circumstance.

Such were the observations of Dr. Heberden on first announcing this circumstance, viz. of different quantities of rain falling at different heights above the ground. Two years afterward, Daines Barrington, esq. made the following experiments and observations, to shew that this effect, with respect to different places, respected only the several heights of the instruments above the ground at those places, without regard to any real difference of level in the ground at those places.

Mr. Barrington caused two other rain-gages, exactly like those of Dr. Heberden, to be placed, the one upon mount Renning, in Wales, and the other on the plane below, at about half a mile's distance, the perpendicular height of the mountain being 450 yards, or 1350 feet; each gage being at the same height above the surface of the ground at the two stations.

The results of the experiment are as below:

<table>
<thead>

</tr>
</tbody>
</table>

"The inference to be drawn from these experiments, Mr. Barrington observes, seems to be, that the increase of the quantity of rain depends upon its nearer approximation to the earth, and scarcely at all upon the height of places, provided the rain-gages are fixed at about the same distance from the ground." It may not be improper to subjoin to the foregoing account, that, in places where it was first observed, a different quantity of rain would be collected, according as the rain-gages were placed above or below the tops of the neighbouring buildings; the rain-gage below the top of the house into which the greater quantity of rain had for several years been found to fall, was above fifteen feet above the level of the other rain-gage, which, in another part of London, was placed above the top of the house, and into which the lesser quantity always fell. This difference, therefore, does not, as Mr. Barrington justly remarks, depend upon the greater quantity of atmosphere through which the rain descends: though this has been supposed by some, who have hence concluded that this appearance might readily be solved by the accumulation of more drops, in a dense through a great depth of atmosphere."

In the examination of the results from meteorological tables, it should be observed, that several years' account of the rain at any place is required, before a medium yearly quantity can be obtained with sufficient accuracy. The following table, formed by Mr. Dalton, and published in the first part of the fifth volume of Manchester Memoirs, gives us the largest collection of accounts of rain fallen in different places in England that has to our knowledge hitherto appeared. They are chiefly taken from the Transactions of the Royal Society, and of other societies.

General mean 35.2

The general mean of 35.2 inches is, as our author apprehends, a little above the medium for England and Wales, as the greater number of places are those where much rain falls. If we take up a mean for each of the above-mentioned counties, (where more than one place in a county is given,) and then a general mean from the counties, the result is a reduced mean of 31.3. Even then it may be objected, that the greater part of the counties are maritime; but it must be observed, that there is no account of rain in Wales; and we may safely conclude, that the rain in Wales would exceed the last-mentioned mean as much as the inland counties of England, not in the above list, would fall short; because Wales is both a mountainous country, and exposed to the sea.

We will, therefore, conclude, that the mean annual depth of rain in England and Wales, deduced from these twenty counties, is 31 inches; a quantity which suffices for observations, our author is confident, will diminish, and probably not increase much.

The editors of the Encyclopedia, under the article Weather, from 16 places of observation, make the annual mean for Great Britain 32.53 inches; and M. Cotte, in the Journal de Physique for 1791, gives a mean derived from 147 places, in different parts of the world, equal to 34.7 inches.

If we take the dew (see Dew) at 5 inches annually, we shall have 56 inches of water at a medium annually, on the surface of the earth, in England and Wales, reckoning 31 for rain and 5 for dew. Admitting the computation of Guthrie, the area of England and Wales is 46,450,000 square miles. This, reduced to square feet, gives 1,378,520,869,000; which, multiplied by 3 feet, the annual depth of rain and dew, gives 4,135,720,859,000 cubic feet of water, = 153,176,320,000 cubic yards, or 12 cubic miles = 115,000 millions of tons in weight, nearly. This immense mass of water is disposed of partly by the supply of rivulets, and the foaming into the earth a small way, so as to break out again in lower ground in the form of springs, and then make its way to some rivers, by which it is conveyed to the sea; and partly being carried into the atmosphere in the process of evaporation. The decomposition of water by vegetables is not noticed, because it is precluded, that in the course of nature the principles are combined, and water formed again. See River, Spring, Evaporation, and Vapour.

As to the use of rain, we may observe that it moistens and softens the earth, and thus fits it for affording nourishment to plants; by falling on high mountains, it carries down, with many particles of loose earth, which serve to fertilize the surrounding vallies, and purifies the air from noxious exhalations, which tend in their return to the earth to meliorate the soil; it moderates the heat of the air; and is one means of supplying fountains and rivers. However, vehement rains in many countries are found to be attended with barrenness and poornefs of the lands, and miscarriage of the crops in the succeeding year; and the reason is plain; for these excessive storms wash away the fine mould into the rivers, which carry it into the sea, and it is a long time before the land recovers itself again. The remedy to the famine, which some countries are subject to from this fort of mischief, is the planting large orchards and groves of such trees as bear effulent fruit; for it is an old observation, that in years, when grain succeeds worth, these trees produce mott fruit of all. It may partly be owing to the thorough moistening of the earth, as deep as their roots go, by these rains, and partly to their trunks flopping part of the light mould carried down by the rains, and by this means furnishing themselves with a coat of new earth. Phil. Trans. N° 90.

The water afforded by rain is found highly refreshing to almost all sorts of vegetable crops, and to promote their growth in a rapid manner, when not produced in too great abundance at a time. This effect, which may often be perceived to take place in a sudden manner, after warm showers in the early spring months, is probably caused by the large proportion of oxygen that is contained in rain-water, as well as from the necessary moisture being afforded to the fibres of the roots of the plants. Too much rain may be injurious, however, by lessening the necessary cohesion and compactness of the soil, by which they may not afford proper support to the roots of growing vegetables. And another injury may be produced by the too frequent occurrence of heavy showers, by which a large proportion of the decomposing vegetable and animal materials of lands, which are soluble or diffusible in water, may be conveyed away into the ditches, rivers, and ultimately into the sea, and of course prove the cause of infertility. In hilly situations, this effect may arise from even light showers; on which account, they have been advised to be plunged in a planting direction, as by that means the rains may be more perfectly detained in the soil. And it has been suggested by Dr. Darwin, that as the foliage or buds of plants require more moisture for their vigorous growth than their flowers, in this climate, continued rains may be liable not only to wash off the farina from
from the burbling anthers, and in that way prevent the impregnation of the pistillate, but also delay the ripening of the seeds or fruit, from the want of a due evaporation of their perspirable matter, as well as from the last solar light in cloudy seasons. On this account it is, he supposes, that in the north of Scotland the oats are sowed seldom to ripen till the frosts commences, with the dry season which accompanies it.

Thus, as the effects of rain are so very considerable on vegetation, it would be highly useful to ascertain the quantity or depth of rain that falls annually in different districts, and the difference in the effects which are produced by it. See Water and Weather.

The vast quantities of rain which fall in some districts, from the peculiar nature of their situations, especially where they are of the grazing or pasture kind, as those of Cheshire, Lancashire, and others, are often highly beneficial to their general fertility; the natural grass pastures of which districts, though frequently of inferior qualities to those in many other places, are, in consequence of this circumstance, rendered superior in their abundance of grass, the strength of its vegetation, and the richness of its quality. The former of the above counties may indeed, without any impropriety, be reckoned one of the most productive grassland districts in the kingdom, as is fully evinced by the great abundance and superiority of its dairy products. The grass lands in this tract of country mostly retain their full verdure during the most sultry and parching seasons, except where they are of a sandy or gravelly nature in their under strata. Where they are near to the sea, however, in this as well as other parts, they are liable to become mossy, or be covered with the mors plant, either in consequence of so much of the spray from it falling in the manner of light rain, or some other cause of that kind.

The quantity of rain falling upon land has much influence upon its temperature, or state of heat, and, of course, great effect on vegetation in that way; and the nature of its mixture with it, or the manner in which it is distributed through its parts, or combined with its different carthy materials, is another means by which it becomes of great importance, as it relates to the supply of nourishment and support to vegetables as crops.

Rain falling in large quantities, on particular sorts of retentive soils, is a frequent cause of that kind of injurious wetness, which lands so much in need of surface-draining to remove it. See Surface-draining.

The nature and effects of flowers and rain are extremely curious and interesting in several different points of view, both to the agriculturist and the philosophical inquirer.

Rains, Preternatural. We have numerous accounts in historians of preternatural rains, such as the raining of stones, of dust, of blood, of mud, and of live animals, as young frogs, and the like. We are not to doubt the truth of what those who are authors of veracity and credit relate to us of this kind, so far as to suppose that the falling of stones (which see) and dust never happened; the whole mistake (if it be so with regard to the first instance) is the supposing them to have fallen from the clouds; but as to the blood and frogs, it is very certain that they never fall at all, but the opinion has been a mere deception of the senses. Men are extremely fond of the marvellous in their relations; but the judicious reader is to examine strictly whatever is reported of this kind, and is not to suffer himself to be deceived.

There are two natural methods by which quantities of stones and dust may fall in certain places, without their having been generated in the clouds, or fallen as rain. The one is by means of hurricanes: the wind which we frequently see tearing off the tiles of houses, and carrying them to considerable distances, being equally able to take up a quantity of stones, and drop them again at some other place. But the other, which is much the most powerful, and probably the most usual way, is for the eruptions of volcanoes, and burning mountains, to toss up, as they frequently do, a vast quantity of stones, ashes, and cinders, to an immense height in the air; and these being hurled away by the hurricanes and impetuous winds, which usually accompany those eruptions, and being in themselves much lighter than common stones, as being half calcined, may easily be thus carried to vast distances, and their falling in places where the inhabitants know nothing of the occasion, they cannot but be supposed by the vulgar to fall on them from the clouds. It is well known, that in the great eruptions of Etna and Vesuvius, showers of ashes, dust, and small cinders, have been seen to obscure the air, and spread the surface of the sea for a great way, and cover the decks of ships; and this at such a distance, as it should appear (conceivable) that they should have been carried to; and probably, if the accounts of all those showers of these substan ces mentioned by authors be collected, they will all be found to have fallen within such distances of volcanoes; and if compared, as to the time of their falling, will be found to correspond in that also with the eruptions of those mountains. We have known instances of the ashes from Vesuvius having been carried thirty, nay forty leagues, and peculiar accidents may have carried them yet farther.

The raining of blood has been ever accounted a more terrible sight, and a more fatal omen, than the other preternatural rains already mentioned. It is very certain that nature forms blood no where but in the vessels of animals, and therefore showers of it from the clouds is by no means to be credited. Those who suppose that what has been taken for blood, has been actually seen falling through the air, have had recourse to flying insects for its origin, and suppose it the eggs or dung of certain butterflies discharged from them as they were high up in the air. But this seems a very wild conjecture, as we know of no butterfly whose excrements, or eggs, are of such a colour, or whole abode, as is so high, or their flocks so numerous, as to be the occasion of this.

It is most probable that these bloody waters were never seen falling, but the people seeing the standing waters blood-coloured, were alarmed, from their not knowing how it should else happen, that it had rained blood into them. A very memorable instance of this there was at the Hague in the year 1679. Swammerdam, who relates it, tells us, that one morning the whole town was in an uproar, on finding their lakes and ditches full of blood, as they thought, and having been certainly full of water the night before, they agreed it must have rained blood in the night; but a certain physician went down to one of the canals, and taking home a quantity of this blood-coloured water, he examined it by the microscope, and found that the water was water still, and had not at all changed its colour, but that it was full of prodigious swarms of small red animals, all alive, and very nimble in their motions, whose colour and prodigious number gave a red tinge to the whole body of the water they lived in, on a lens accurate inspection. The certainty that this was the case, did not however persuade the Hollanders to part with the miracle; they prudently concluded, that the sudden appearance of such a number of animals was as great a prodigy as the raining of blood would have been; and are assured at this day, that this portent foretold the scene of war and devastation which Lewis XIV. afterwards brought into that country, which had before enjoyed forty years uninterrupted peace.
The animals, which thus colour the water of lakes and ponds, are the pulces arborescentes of Smawderam, or the water-fleas with branched horns. These creatures are of a reddish-yellow, or flame colour; they live about the sides of ditches, near weeds, and among the mud, and are therefore less visible, except at a certain time, which is in the end of May or beginning of June: it is at this time that these little animals leave their reccefs to float loose about the water, to meet for the propagation of their species, and by that means become visible in the colour they give the water. This is visible, more or less, in one part or other of almost all standing waters at this season; and it is always at this season that the bloody waters have alarmed the ignorant.

The raining of frogs is a thing not less wonderful in the accounts of authors who love the marvellous, than those of blood, or of stones; and this is supposed to happen so often, that there are multitudes who pretend to have seen eye-witnesses of it. These rains of frogs always happen after very dry seasons, and are much more frequent in the hotter countries than the cold ones. In Italy they are very frequent; and it is not uncommon to see the streets of Rome swarming both with young frogs and toads in an instant, in a flower of rain; they hopping every where between the people’s legs, as they walk, though there was not the least appearance of them before. Now they have been seen to fall through the air down upon the pavements. This seems a strong circumstance in favour of their being rain’d down from the clouds, but when strictly examined, it comes to nothing; for these frogs, that are seen to fall, are always found dead, lamed, or bruised by the fall, and never hop about as the rest; and they are never seen to fall, except close under the walls of houses, from the roofs and gutters of which they have accidentally slipped down.

To the raining of frogs we ought to add the raining of grass-hoppers and locusts, which have sometimes appeared in prodigious numbers, and devoured the fruits of the earth. There has not been the least pretence for supposing that these animals descended from the clouds, but that they appeared on a sudden in prodigious numbers. The naturalist, who knows the many accidents attending the eggs of these, and other like animals, cannot but know that some genera will prove particularly favourable to the hatching of them, and the prodigious number of eggs that many insects lay, could not but every year bring us such abundance of the young, were they not liable to many accidents, and had not provident nature taken care, as in many plants, to continue the species by a very numerous flock of seeds, of which perhaps not one in five hundred need take root, in order to continue an equal number of plants.

The raining of fishes has been a prodigy also much talked of in France, where the streets of a town at some distance from Paris, after a terrible hurricane in the night, which tore up trees, blew down houses, &c. were found in a manner covered with fishes of various sizes. Nobody here made any doubt of these having fallen from the clouds; nor did the absurdity of fish, of five or six inches long, being generated in the air, at all stirle the people; or make their belief in the miracle, till they found upon inquiry that a very well-flocked fish-pond, which flood on an eminence in the neighbourhood, had been blown dry by the hurricane, and only the great fish left at the bottom of it, all the smaller fry having been tolled into their streets.

Upon the whole, all the supposed marvellous rains have been owing to substances naturally produced on the earth, and either never having been in the air at all, or only carried thither by accident.

Vol. XXIX.

RAIN. Freezing. See Freezing.
RAINF, Bird, in Ornithology. See Cuculus Pluvialis.
RAIN-FOWL, an English name given by many to the common green woodpecker, or picus viridis, from an observation that it is always seen clamorous when rainy weather is coming on. The Latins have, for the same reason, called it the pluvialis avis. See Picus.
RAIN-GAGE, called also Ombrometer and Pitometer, an instrument for measuring the quantity of rain that falls. That which is mentioned under the article Ombrometer, consists of a tin funnel d (Plate XXIV. Miscellany, fig. 2.), whose surface is an inch square, a flat board a, and a glass tube b, let into the middle of it in a groove, and an index with divisions e, f; the board and tube being of any length at pleasure. The bore of the tube is about half an inch, which, says Mr. Pickering, the inventor, is the best size. This machine is fixed in some free and open place, as the top of the house, &c.

The rain-gage employed in the house of the Royal Society, is described by Mr. Cavendish in the Phil. Trans. for 1776, p. 384. The vessel which receives the rain is a conical funnel, strengthened at the top by a brass ring, twelve inches in diameter. The sides of the funnel, and inner lip of the brass ring, are inclined to the horizon, at an angle of above 65°, and the outer lip at an angle of above 55°, which is such a degree of steepness, that there seems to be no probability either that any rain which falls within the funnel, or on the inner lip of the ring, should dash out, or that any which falls on the outer lip should dash into the funnel. A vertical section of the funnel appears in Plate XXIV. Miscellany, fig. 3; A B C and a b c being the brass ring, B A and b a the inner lip, and B C and b c the outer. This vessel is placed on some flat leads, on the top of the society’s house. It can hardly be screened from any rain by the chimneys, as none of them are elevated above it in an angle of more than 25°, and as it is raised ¾ feet above the roof, there seems no danger of any rain dashing into it by rebounding from the lead.

In fixing rain-gages care should be taken that the rain may have free access to them, without being impeded or obstructed by buildings, &c. and therefore the tops of houses are to be preferred. Also, when the quantities of rain collected in them, at different places, are compared together, the instruments ought to be fixed at the same height above the ground at both places; because at different heights the quantities are always different, even in the same place. And hence also, any register or account of rain in the gage ought to be accompanied with a note of the height at which the instrument is placed above the ground. Dalton found the rain of a gage 50 yards high, in summer two-thirds, and in winter one-half as much as that of a gage below. Mr. Dalton observes, that a strong funnel, made of sheet iron, tinned and painted, with a perpendicular rim, two or three inches high, fixed horizontally in a convenient frame, with a bottle under it to receive the rain, is sufficient for this purpose.

The rain-gage is an invention which should be in the possession of every correct farmer in every part of the kingdom, and which would thereby have much tendency to the improvement of agriculture as contributing to the knowledge of the degree of moisture which prevails in the soils, after showers or heavy rains, with greater accuracy and certainty than has been hitherto the case.

It is noticed by Mr. Nairn, in his Agricultural Survey of Clydesdale, that professor Anderson, of the university of Glasgow, has invented, perhaps, the most ingenious and accurate rain-gage of any that has yet been known. It receives
the rain at a little more than one hundred feet above the level of the sea; accounts which have been regularly kept since the year 1781; but previously to that period the rain was measured by an old rain-gage. It is to be regretted, however, that the exact nature of this invention is not more fully explained; and that other cheap plain inventions of this nature are not better known to the farmer.

**RAIN.** See Water.

**Rains,** in the Sea Language, denote all that tract of sea to the northward of the equator, between four and ten degrees of latitude; and lying between the meridian of Cape Verde and that of the eastermost islands of the Lame

Rain it takes its name from the almost continual calms, constant rains, and thunder and lightning, to a great degree, always found there. The winds, when they do blow, are only small uncertain gusts, and shift about all round the compass; so that ships are sometimes detained here a long while, and can make but very little way.

**RAINBOW.** Iris, or, simply, the bow, a meteor in form of a parti-coloured arch, or semicircle, exhibited in a rainy sky, opposite to the fun, by the refraction of his rays in the drops of falling rain.

There is an in secondary, or fainter bow, usually seen inclining the former at some distance. Among naturalists, we also read of lunar rainbows, marine rainbows, &c.

The rainbow, sir Isaac Newton observes, never appears but where it rains in the fun-shine; and it may be represented artificially by contriving water to fall in little drops, like rain, through which the fun shining, exhibits a bow to a spectator placed between the fun and the drops; especially if a dark body, e. g. a black cloth, be disposed beyond the drops.

That the rainbow is opposite to the fun, has always been observed. It was, therefore, natural to imagine, that the colours of it were produced by some kind of reflection of the rays of light from drops of rain or vapour. The regular order of the clouds was another circumstance that could not have escaped the notice of any person. But though more reflection had in no other case been observed to produce colours, and it could not but have been observed that reflection is frequently attended with that phenomenon, so that some of the ancients, as we learn from Aristotle's tract on meteors, knew that the rainbow was caused by the refraction of the sun's light in drops of falling rain; yet no person seems to have thought of having recourse to a proper refraction in this case before one Fletcher of Breflau, who, in a treatise which he published in 1571, endeavoured to account for the colours of the rainbow by means of a double refraction, and one reflection. But he imagined that a ray of light, after entering a drop of rain, and suffering a refraction, both at its entrance and exit, was afterwards reflected from another drop, before it reached the eye of the spectator. He seems to have overlooked the refraction at the farther side of the drop, or to have imagined that all the bendings of the light within the drop would not make a sufficient curvature, to bring the ray of the fun to the eye of the spectator. Antonio de Dominis, bishop of Spalato, whose treatise, "De Radiis Volus et Lucis," was published by I. Bartolius, in 1611, was the first person who advanced, that the double refraction of Fletcher, with an intervening refraction, was sufficient to produce the colours of the rainbow, and also to bring the rays that formed them to the eye of the spectator, without any subsequent refraction. He distinctly describes the progress of a ray of light entering the upper part of the drop, where it suffers one refraction, and after being thereby thrown upon the back part of the inner surface, is from thence reflected to the lower part of the drop; at which place undergoing a second refraction, it is thereby bent so as to come directly to the eye. To verify this hypothesis, he procured a small globe of fluid glass, and viewing it when it was exposed to the rays of the fun, in the same manner in which he had supposed that the drops of rain were situated with respect to them, he actually observed the same colours which he had seen in the true rainbow, and in the same order. The theory of A. de Dominis was adopted, and in some degree improved, by Descartes. Philosophers were, however, for a long time at a loss when they endeavoured to assign reasons for all the particular colours, and for the order of them. Indeed, nothing but the doctrine of the different refrangibility of the rays of light, which was a discovery reserved for the great Sir Isaac Newton, could furnish a complete solution of this difficulty.

Dr. Barrow, in his "Lecciones Opticas," (Lect. 12. n. 14.) says, that a friend of his, meaning Mr. Newton, communicated to him a method of determining the angle of the rainbow, which was hinted to Newton by Slusius, without making a table of the refractions, as Descartes did. The doctor shows the method, with other curious particulars. But the subject was given more perfectly by Newton afterwards, in his "Optics," prop. 9; where he makes the breadth of the interior bow to be nearly 22° 15', that of the exterior 34° 40', their distance 8° 25', the greatest semidiameter of the interior bow 42° 17', and the least of the exterior 50° 42', when their colours appear strong and perfect.

**Rainbow, Theory of the.** To conceive the origin of the rainbow, let us consider what will befall rays of light coming from a very remote body, e. g. the sun, and falling on a globe of water, such as we know a drop of rain to be.

Suppose, then, A D K N (Plate XVIII. Optics. fig. 1.) to be a drop of rain, and the lines E F, B A, O N, to be rays of light coming from the centre of the fun; which, on account of the immense dilution of the fun, we conceive to be parallel.

Now the ray B A being the only one that falls perpendicularly on the surface of the water, and all the rest obliquely, it is easily inferred, that all the other rays will be refracted towards the perpendicular. (See Refraction.)

Thus the ray E F, and others accompanying it, will not go on straight to G; but as they arrive at H I, they will deflect from F to K; where some of them, probably, escaping into the air, the rest are reflected upon the line K N, so as to make the angles of incidence and refraction equal.

Farther, as the ray K N, and those accompanying it, fall obliquely upon the surface of the globe, they cannot pass out into the air, without being refracted, so as to recede from the perpendicular L M; and, therefore, they will not proceed straight to Y, but will deflect to P.

It may be here observed, that some of the rays, arriving at N, do not pass out into the air, but are again reflected to Q; where being refracted, like the rest, they do not proceed right to Z; but, declining from the perpendicular T V, are carried to R; but since we here only regard the rays as they may affect the eye placed a little below the drop, e. g. at P, those which deflect from N to Q, we let aside, as useless, because they never come to the eye. On the contrary, it is to be observed, that there are other rays,
rays, as \(2 \frac{3}{4}\), and the like; which, being refracted from 3 to 4, and reflected to 5, and from 5 to 6, may at length, by refraction at 6, arrive at the eye \(\gamma\), placed beneath the drop.

Thus much is obvious; but to determine precisely the quantities of refraction of each ray, there must be a calculation; by such calculation it appears, that the rays which fall on the quadrant A D, are continued in lines, like those here drawn in the drop A D K N; whereas there are three things very considerable: first, that the two refractions of the rays, in their ingress and egress, are both the same way; so that the latter does not destroy the effect of the former. Secondly, that all of the rays passing out of A N, N P, and those adjoining to it, are the only ones capable of affecting the eye, as being sufficiently close and contiguous, and because they come out parallel; whereas the rest are diverging, and dispersed too far to have any sensible effect, at least to produce any thing so vivid as the colours of the bow. Thirdly, that the ray N P has shade or darkness under it; for, since there is no ray comes out of the surface N 4, it is the same thing as if the part were covered with an opaque body. We might add that the same ray N P has darkness above it; since the rays that are above it are inefficient, and signify no more than if there were none at all.

Add to this, that all the effectual rays have the same point of reflection, i.e. the parallel and contiguous rays, which alone are effectual after refraction, will all meet in the same point of the circumference, and be reflected thence to the eyes.

Farther, it appears, that the angle O N P, included between the ray N P, and the line O N drawn from the centre of the bow, is the angle by which the rainbow is distant from the opposite point of the sun, and which makes the semi-diameter of the bow. The method of determining it will be seen in the sequel of the article. But since, besides those rays coming from the centre of the sun to the drop of water, there are many more from the several points of its surface; there are a great many other effectual rays to be considered, especially that from the uppermost, and that from the lowest part of the sun's body.

Since, then, the apparent semi-diameter of the sun is about 16 minutes, it follows, that an effectual ray from the upper part of the sun will fall higher than the ray E F by 16 minutes; thus does the ray G H (fig. 2.) which, being refracted as much as E F, deferts to I, thence to L, and at length emerging equally refracted with the ray N P, proceeds to M; and makes an angle O N M with the line O N. In the like manner, the effectual ray Q R coming from the lowest part of the sun, falls on the point R, 16 minutes lower than the point F on which the ray E F falls; and this, being refracted, declines to S; whence it is reflected to T; where, emerging into the air, it proceeds to V; so that the line T V, and the ray O T, contain an angle whose magnitude will be ascertained. Again, upon computing the deflections of the rays, which like that 2 (fig. 1.) coming from the centre of the sun, and being received into the lower part of the drop, we have supposed to be twice reflected, and twice refracted, and to enter the eye by lines like that 67 (fig. 3.) we find that which may be accounted effectual, as 67 with the line 86 drawn from the centre of the sun, contains an angle 867; whence it follows, that the effectual ray from the highest part of the sun to the eye in F, the angle 86 F becomes of a certain magnitude ascertained below. In like manner, since G H I K L M is the way of an effectual ray from the lowest part of the sun to the eye, the angle 86 M becomes greater than the former by 16 minutes.

Since, then, we admit several rays to be effectual, besides those from the centre of the sun, what we have said of the shade will need some alteration; for of the three rays described (figs. 2 and 3.), only the two extreme ones will have a shadow joined to them, and that only on the outer side. Hence it is evident, that these rays are perfectly dispersed to exhibit all the colours of the prism.

For the great quantity of dense or intense light, i.e. the bundle of rays collected together in a certain point, e.g. in the point of reflection of the effectual rays, may be accounted as a lucid or radiant body, terminated all around by shade. But the several rays, thus emitted to the eye, are both of different colours; that is, they are fitted to excite in us the ideas of different colours; and are differently refracted out of the water into the air, notwithstanding their falling alike upon the refracting surface.

Hence it follows, that the different or heterogeneous rays will be separated from one another, and will tend separate ways; and the homogeneous rays will be collected, and tend the same way; and, therefore, this lucid point of the drop in which the refraction is effectual, will appear fringed or bordered with several colours; that is, red, green, and blue colours will arife from the extremes of the red, green, and blue rays of the sun, transmitted to the eye from several drops, one higher than another, after the fame manner as is done in viewing lucid or other bodies through a prism.

Thus, adds Sir Isaac Newton, the rays that differ in refrangibility, will emerge at different angles; and, consequently, according to their different degrees of refrangibility, emerging most copiously at different angles, they will exhibit different colours in different places.

A great number, then, of these little globules being difpand in the air, will fill the whole space with these different colours; provided they be so dispersed as that effectual rays may come from them to the eye; and thus will the rainbow, at length, arife.

Now, to determine what that disposition must be, suppose a right line drawn from the centre of the sun through the eye of the spectator, as the line V X (fig. 2.) called the line of sight, or axis of vision; being drawn from to remote a point, it may be eliemed parallel to all other lines drawn from the same point; but a right line, falling on two parallels, makes the alternate angles equal.

If, then, an indefinite number of lines be imagined drawn from the spectator's eye to a part opposite to the sun where it rains; which lines make different angles with the line of sight, equal to the angles of refraction of the differently refrangible rays, these lines, as rays, on drops of rain illumined by the sun, will make angles of the same magnitude with rays drawn from the centre of the sun to the same drops. And, therefore, the lines thus drawn from the eye will represent the effectual rays that occasion the sensation of any colour.

Now it is known, that the eye, being placed in the vertex of a cone, sees objects upon its surface, as if they were in a circle; and the eye of our spectator is here in the common vertex of several cones, formed by the several kinds of effectual rays, with the line of sight. Now in the surface of that whole angle at the vertex, or eye, is the greatest, and in which the others are included, are those drops, or parts of
of drops, which appear red; and in the surface of that cone whose angle is least, are the purple drops; and in the intermediate cones, are the green, blue, &c. drops. Hence, then, several kinds of the drops must appear as if disposed into so many circular coloured facets, or arches, as we see in the rainbow. (Rohault's Sytem of Nat. Phil. vol. ii. part iii. cap. 17.) This part of the solution for Isaac Newton expresses more precisely, thus: suppose O (fig. 4.) the eye, and OP a line parallel to the sun's rays; and let POE, POF, be angles of 40° 17', and 42° 2'. And suppose the angles to turn about their common side OP, with their other sides OE and OF, they will describe the bounds, or verges, of the rainbow.

For if E, F be drops placed anywhere in the conical surface described by OE, OF, and be illuminated by the sun's rays SE, SF; the angle SEO being equal to the angle POE, or 40° 17', shall be the greatest angle in which the most refrangible rays can, after reflection, be refracted to the eye; and, therefore, all the drops in the line OE shall send the most refrangible rays most copiously to the eye, and therefore strike the facets with the deepest violet colour in that region.

And in like manner the angle SFO being = to the angle POF = 42° 2', shall be the greatest in which the least refrangible rays after one reflection can emerge out of the drops; and these rays shall come most copiously to the eye from the drops in the line OF, and strike the facets with the deepest red colour in that region.

And, by the same argument, the rays which have intermediate degrees of refrangibility, shall come most copiously from drops between E and F, and so strike the facets with the intermediate colours, in the order which their degrees of refrangibility require; that is, in the progress from E to F, or from the inside of the bow to the outside, in this order: violet, indigo, blue, green, yellow, orange, red; though the violet, by the mixture of the white light of the clouds, will appear faint, and incline to a purple.

Here it may be observed, that all the rays but the violet in the line SE will emerge from E in a greater angle than SEO made by the violet, and consequently will pass below the eye; and all the rays but the red in the line SF will emerge from F in a less angle than SFO made by the red, and consequently will pass above the eye; by which means only red will appear in the line SF, and only violet in the line SE.

And, since the lines OE, OF, may be situated any where in the above-mentioned conical surface; what is said of the drops and colours of the same lines, is to be understood of the drops and colours throughout the whole superficies. Thus is the primary or inner bow formed.

RAINBOW, Secondary, or Outer. As to the secondary, or fainter bow, usually surrounding the former, in affording what drops would appear coloured, we excluded such as lines drawn from the eye, making angles a little greater than 42° 2', shall fall upon, but not such as should contain angles much greater.

For, if an indefinite number of such lines be drawn from the spectator's eye, some of which make angles of 50° 57', with the line of ascent, e. gr. OG; other angles, of 54° 7', e. gr. OH; these drops on which these lines fall must of necessity exhibit colours; particularly those of 50° 57'.

E. gr. The drop G will appear red; the line GO being the fame with an effeetual ray; which, after two reflections, and two refractions, exhibits a red colour. Again, those drops which receive lines of 54° 7', e. gr. the drop H, will appear purple; the line OH being the fame with an effeetual ray; which, after two reflections and two refractions, exhibits purple.

Now there being a sufficient number of these drops, it is evident there must be a second rainbow, formed after the like manner as the first.

Thus, according to sir Isaac Newton, in the least refrangible rays, the least angle at which a drop can send effeetual rays after two reflections, is found by computation to be 50° 57'; and in the most refrangible, the least angle is found 54° 7'.

Suppose, then, O the place of the eye, as before, and POG, POH, to be angles of 50° 57', and 54° 7'; and these angles to be turned about their common side OP; with their other sides OG, OH, they will describe the verges, or borders, of the rainbow C H D G.

For, if G, H be drops placed anywhere in the conical superficies described by OG, OH, and be illuminated by the sun's rays, the angle SG O, being equal to the angle POG, or 50° 57', shall be the least angle in which the least refrangible rays can, after two reflections, emerge out of the drops; and, therefore, the least refrangible rays shall come most copiously to the eye from the drops in the line OG, and strike the facets with the deepest red in that region.

And the angle SHO being equal to P OH, 54° 7', shall be the least angle in which the most refrangible rays, after two reflections, can emerge out of the drops; and, therefore, those rays shall come most copiously to the eye from the drops in the line OH, and so strike the facets with the deepest violet in that region.

And, by the same argument, the drops in the region, between G and H, shall strike the facets with the intermediate colours, in the order which their degrees of refrangibility require; that is, in the progress from G to H, or from the inside of the bow to the outer, in this order: red, orange, yellow, green, blue, indigo, violet.

And since the lines OG, OH, may be situated anywhere in the conical superficies; what is said of the drops and colours in these lines is to be understood of the drops and colours every where in this superficies.

Thus are formed two rainbows, an interior and stronger, by one reflection; and an exterior and fainter, by two; the light becoming weaker and weaker by every reflection.

Their colours will lie in a contrary order to one another; the first having the red without, and the purple within; and the second, the purple without, and red within; and so of the rest.

RAINBOW, Artificial. This doctrine of the rainbow is confirmed by an easy experiment: for upon hanging up a glass globe, full of water, in the sun-shine, and viewing it in such a posture as that which the rays, which come from the globe to the eye, may, with the sun's rays, include an angle either of 42°, or 50°; if, e. gr. the angle be about 42°, the spectator, supposing at O, will see a full red colour in that side of the globe opposite to the sun, as at F. And if that angle be made a little less, supposing by depressing the globe to E, the other colours, yellow, green, and blue, will appear successively, in the same side of the globe, also exceedingly bright.

But if the angle be made about 50°, supposing by raising the globe to G, there will appear a red colour in that side of the globe towards the sun, though somewhat faint; and if the angle be made greater, supposing by raising the globe to H, this red will change successively to the other colours, yellow, green, and blue.

The same thing is observed in letting the globe revolve, and raising or depressing the eye so as to make the angle of a jilt magnitude.
RAINFALL.

Newton's Optics, part ii. prop. 9. prob. 4. p. 147. ed. 3.

RAINFALL. Dimension of the.—Descartes first determined its diameter by a tentative and indirect method; laying it down, that the magnitude of the bow depends on the degree of refraction of the fluid; and assuming the ratio of the sine of incidence to that of refraction to be in water as 250 to 187.

But Dr. Halley has, in the Philosophical Transactions, N° 267, given us a simple direct method of determining the diameter of the rainbow from the ratio of refraction of the fluid being given; or, vice versa, the diameter of the rainbow being given, to determine the refractive power of the fluid.

The principles of Dr. Halley's construction for this purpose, illustrated and facilitated by Dr. Morgan, bishop of Ely, will be understood from the following view of them.

Let SN, Sn, (Plate XVIII. Optics, fig. 5.) be two of the efficacious rays incident upon a drop of rain; these, when refracted to the same point F, and thence reflected to G, g, will have the parts within the drop on one side NF, nF, equal to those on the other side FG, Fg, from the nature of the circle, and because the angles of incidence CFN, CFN, are equal to the angles of reflection CFG, Cfg. And since the parts within the drop are equal and alike situated, they will be similarly situated with regard to the drop itself; and, consequently, as the incident rays SN, Sn, are supposed to be parallel, the emergent rays GR, gr, will be also parallel. From C, the centre, draw the radii CN, Cn, CF, then will CNF = CFN be the angle of refraction, and the small arc Nn is the nafcent increment of the angle of incidence BCN; and as it measures the angle at the centre Cn, it is double the angle at the circumference upon the same arc, viz. NFn, which is the nafcent increment of the angle of refraction NFC.

Further, let the ray SN (fig. 6.) enter the lower part of the drop, and be twice reflected within the drop at F and G; then is the ray NF equal to the ray FG, and the arc NF = the arc FG. Draw Fg parallel to FG, and it will be the reflected part of some ray Sn, whose obliquity to the drop makes it cross the ray NF in its refraction; then will the part nf = Fg, and the arc nf = Fg, and the small arc Ff = Gg. Therefore, 2Ff = (Ff + Gg = the arc FG - Fg = NF - nf =) Nn - Ff; consequently Nn = 3Ff, i.e. the nafcent increment of the angle of incidence is equal to three times that of the angle of refraction. After a like manner it may be shown, that after three, four, four, &c. reflections, the increment of the angle of incidence will be four, five, six, &c. times greater than that of the angle of refraction. Hence, in order to find the angle of incidence of an efficacious ray, after any given number of reflections, we are to find an angle whose nafcent increment has the same ratio to the increment of its corresponding angle of refraction, generated in the same time, as the given number of reflections (n) increased by unity has to unity; i.e. as n + 1 to 1. But these increments are as the tangents of the respective angles directly.

For let ACD, ABD (fig. 7.) be the angles of incidence and refraction proposed; and if we suppose the line AC to move about the point A in the plane of those angles, the extremity of it, C, will describe the circle AC; and when AC is arrived at the situation A, the line BD will be thereby removed into the situation B. Draw CD, then is the angle ACD = A BC + C A B, and the angle A cd = C B A + e A B; therefore the excess of A cd above ACD, or the increment of ACD, is equal to both the angles C B e and C A e. But since the angle A e C differs infinitely little

from a right one, a circle described on the diameter A C shall pass through the points D and e; and, therefore, the angles C A e, C D e, (infilling on the same arc C e of the said circle) will be equal; and, therefore, the increment of the angle A CD is equal to C B e + C D e = C d e. But the nafcent angles D c e and D B e are as their sines, that is, as their opposite sides BD and D c = D e, the angle C D e being infinitely small; but BD : CD :: DE : DA (the line DE being parallel to AC) :: tangent of the angle EBD = ACD : tangent of the angle ABD. Therefore the increment D d e of the angle ACD is to the increment C B e of the angle ABD (generated in the same time) as the tangent of the former to the tangent of the latter directly. Hence the praxis is as follows:

First, The ratio of the sine of incidence, to the sine of refraction, being given; to find the angles of incidence, and refraction of a ray, which becomes efficacious after any given number (n) of reflections.—Suppose any given line, as A C (fig. 8.) which divide in D; so that A C : A D :: I : R; and again divide it in E, so that A C may be to AE as the given number of reflections, increased by unity, is to unity; i.e. as n + 1 : 1. Upon the diameter C E describe a semicircle C E B, and from the centre C, with the radius A D, describe an arc DB intersecting the semicircle in B; then drawing A B, C B, and letting fall the perpendicular A F on C B produced; A B C, or its complement to two right angles, A B F, will be the angle of incidence; and A C B the angle of refraction required. For, drawing B E parallel to A F, the triangles A C E and E C B are similar. Now, the sine of the angle A B C, or A B F, is to the sine of A C B as A C to A B = A D = I. to R; therefore if A B F be the angle of incidence, A C F will be the angle of refraction. Moreover, the nafcent increment of A B F is to that of A C B (generated in the same time) as C F : B F :: A C : A E, on account of the similar triangles; i.e. as n + 1 to 1, by construction. The ratio, therefore, of the nafcent increment of the angle of incidence A B F to that of the angle of refraction A C B, is that which is required in the angles of incidence and refraction of an efficacious ray, after a given number of reflections; consequently the angles A B F and A C F are those required. From this construction we may easily deduce Sir Isaac Newton's rule for finding the angle of incidence A B F. See his Optics, p. 148, 149.

For A C : A B :: I : R; whence A C = \( \frac{I}{R} \times A B \); and C F : B F :: n + 1 : 1; therefore C F = n + 1 \times B F; or (putting n + 1 = m) C F = m \times B F; and, on account of the right angle at F, A C² = C F² = A B² - B F², i.e. \( \frac{I}{R} \) A B - m B F = A B - B F²; and, therefore, m B F² - B F² = \( \frac{I}{R} \) A B - A B²; and, conseqently, B F = \( \sqrt{\frac{I}{I - R R}} \) A B = \( \sqrt{\frac{I}{I - R R}} \). Hence, because in the first bow, the ray emerges after one reflection, we have \( n = 1, m = 2, m' = 4 \), and \( m - 1 = 3 \); therefore \( \sqrt{3 R R} : \sqrt{I - R R} :: A B : B F \); therefore the radius of the angle of incidence. In the second bow, where there are two reflections, \( m' = 1 = 8 \); whence \( \sqrt{8 R R} : \sqrt{I - R R} :: A B : B F \). In the third bow, after three reflections, \( m'' = 1 = 15 \); and \( \sqrt{15 R R} : \sqrt{I - R R} :: A B \).
To the coine of the angle of incidence,

\[ \frac{BAF}{F} = 30^\circ 37' \]

Hence the angle of incidence A B F is 59° 23' in the red rays.

Secondly, Having given the angle of incidence, and the ratio of I to R, or of refraction; to find the angle which a ray of light emerging out of a refracting sphere, after a given number of refractions, makes with the axis of vision, or an incident ray, and consequently, to find the diameter of the rainbow.

The angle of incidence, and the ratio of refraction, being given, the angle of refraction is given; which angle being multiplied by double the number of refractions increased by 2, and double the angle of incidence subtracted from the product, the angle remaining is the angle sought.

In order to find the angle of refraction, say

\[ \text{As } \frac{I}{R} = 108, \text{ with logarithm is } - 2.033424 \]

\[ \text{Is to } R = 81 \]

\[ \text{So is the fine of incidence } 59^\circ 23' = 9.934708 \]

To the fine of the angle of refraction 40° 12' 9.809859

Then, making the angle CNF (fig. 9.) = 40° 12', NF will be the refracted ray, which at F is reflected into FG, and at G emerges in GR. Produce the incident and emergent rays SN and RG, till they intersect each other at X, and as CF bisects the angle N FG, it will, if produced, bisect the angle SX R. Then CFN = C X N + FN X; but FN X = C N X - C N F; therefore CFN = C X N + C N X - C N F; that is, 2 C F N - C N X = C X N; or 3° 24' - 59° 23' = 21° 51' = C X N; therefore 2 C X N = S X R = 42° 2'; which is the measure of the angle that the incident and emergent rays, which are the least refrangible, contain with each other. \[ \text{If instead of the ratio 108 to 81, we take that of } 109 \text{ to } 81, \text{ we shall find the values of } \sqrt{3} R \text{, and } \sqrt{1} = R, \text{ such as will give the angle of incidence B C N, and the arc } B N = 58^\circ 40', \text{ and the angle } S X R = 40^\circ 17', \text{ for the most refrangible, or extreme violet rays.} \]

If the ray be twice reflected, viz., at F and G, as in the production of the extreme bow, and emerges at H in the direction HA, intercepting the incident ray SN in Y, we may find the angle A Y S thus: produce A H till it meets G X, produced in R; then in the triangle H G R, the external angle H G X = H R G + H G R. But because of equal angles of reflection at F and G, H G R = F G X; therefore H G X = FG X = H G F + H R G = 2 C G F, or C N F. But S X R = 4 C N F - 2 C N X; therefore in the triangle Y X R we have the two internal angles \[ \text{R X } = 6 \text{ C N F} - 2 \text{ C N X} = \text{the external angle at } Y, \text{ viz. A Y N. In this case, to find the angles of incidence and refraction, we have } \sqrt{8} R = ; \sqrt{1} = R; \text{ radius; } \text{coine of the angle of incidence; whence the said angle will be found } 71^\circ 50' = \text{C N X. And as 108; } 81 = \text{fine of } 71^\circ 50'; \text{ fine of } 45^\circ 27' = \text{C N F, the angle of refraction; therefore } 6 \times 45^\circ 27' - 2 \times 71^\circ 50 = 120^\circ 3' = \text{AYN; and, therefore, its complement } A Y S = 50^\circ 57', \text{ the angle required for the least refrangible rays. But for the most refrangible, where } I: R = 109:81, \text{ we have the angle of incidence } 71^\circ 26', \text{ and the angle of refraction } 44^\circ 47'; \text{ and, therefore, the angle } A Y S = 54^\circ 7'. \text{ In the same manner the same angles are calculated after three or four refractions.} \]

From the preceding problems we obtain the following results, viz.,

I. Rainbow, \{ Red 42° 2' \} The spectator's back being turned

II. Rainbow, \{ Red 50° 57' \} to the fun.

If the angle made by a ray, after three or four refractions, were required, and therefore the diameters of the third and fourth rainbow (which are scarcely ever seen, on account of the great dimunition of the rays, by so many repeated refractions) they will be found, III. Rainbow, \{ Red 41° 37' \} The spectator being turned to wards the fun.

IV. Rainbow, \{ Red 43° 52' \} The spectator being turned to wards the fun.

Dr. Morgan's Dissertation upon the Rainbow, among the notes upon Rohault's Systém of Philosophy, part iii. chap. xvii.

Hence, the breadth of the rainbows is easily found: for the greatest semi-diameter of the first crown, i.e. from red to red, being 42° 2'; and the least, viz. from violet to violet, 40° 17'; the breadth of the fæcia or bow, measured across from red to violet, will be 1° 43'; and the greatest diameter of the second bow being 54° 2', and the least 50° 57', the breadth of the fæcia will be 32° 10'. And hence the difference between the two will be found 8° 54'.

In thefe measures the fun is only esteemed a point; wherefore, as his diameter is really about 30', or 32', so much must be added to the breadth of each fæcia or bow, from red to violet, and so much must be subtracted from the difference between them.

This will leave the breadth of the primary bow, 2° 15'; that of the secondary bow, 5° 30'; and the interval between the bows, 8° 25'; which dimensions, deduced by calculation, Ibn Isaac Newton affirms us from his own observations, agree very exactly with those found by actual measurement in the heavens. Optics, p. 153. ed. 3.

Rainbow, Particular Phemomena of the. From this theory of the rainbow, all the particular phenomena of it are easily deduced: hence we see why the iris is always of the same breadth; because the intermediate degrees of refrangibility of the rays between red and violet, which are its extreme colours, are always the same. See Apparent Magnitude.

Secondly, Why it is more diffinitely terminated on the side of the red than on that of the violet? there being no efficacious rays in the space adjoining to the red drops, i.e. to the space between the bows, whence it terminates abruptly; whereas, in the space on the side of the violet ones, there are some rays emitted to the eye, which, though too feeble to affect it strongly, yet have this effect, that they soften the violet edge insensibly, so that it is difficult to determine precisely where it terminates.

Thirdly, Why the bow shifts its situation as the eye does; and, as the popular phrase has it, flies from those who follow it; and follows those that fly from it? the coloured drops being disposed under a certain angle about the axis of vision, which
is different in different places: whence also it follows, that every different spectator sees a different bow.

Fourthly, Why the bow is sometimes a larger portion of a circle, sometimes a leaf? its magnitude depending on the greater or less part of the surface of the cone, above the surface of the earth, at the time of its appearance; and that part being greater or less, as the line of aspect, or axis of vision, is more inclined or oblique to the surface of the earth; which inclination, or obliquity, is greater as the sun is higher: whence, also, the higher the sun, always the less the rainbow.

Fifthly, Why the bow never appears when the sun is above a certain altitude? the surface of the cone, in which it should be seen, being lost in the ground, at a little distance from the eye, when the sun is above 42° high.

Sixthly, Why the bow never appears greater than a semi-circle, on a plane? since the bow is never so low, and even in the horizon, the centre of the bow is still in the line of aspect; which, in this case, runs along the earth, and is not at all raised above the surface.

Indeed, if the spectator be placed on a very considerable eminence, and the sun in the horizon, the line of aspect, wherein the centre of the bow is, will be notably raised above the horizon (considering the magnitude of the circle whereof the bow ufe is to be a part). Nay, if the eminence be very high, and the rain near, it is possible the bow may be an entire circle.

Seventhy, How the bow may chance to appear inverted, i.e. the concave side be turned upwards? viz. a cloud happening to intercept the rays, and prevent their shining on the upper part of the arch: in which case, only the lower part appearing, the bow will foem as if turned upside down; which, probably, has been the case in several prodigies of this kind, related by authors.

Indeed the bow may appear inverted from another cause: for, if when the sun is 41° 46' high, his rays fall upon the smooth surface of some spacious lake, in the middle of which a spectator is placed; and if, at the same time, there be rain falling, to which the rays may be reflected from the lake, it will be the same as if the sun should shine below the horizon, and the line of view be extended upwards: thus the surface of the cone, wherein the coloured drops are to be placed, will be wholly above the surface of the earth.

But since the upper part will fall among the unbroken clouds, and only the lower part be found among the drops of rain, the arch will be inverted.

Eightly, Why the bow sometimes appears inclined? the accurate roundness of the bow depending on its great distance, which prevents us from judging of it exactly; if the rain, which exhibits it, chance to be much nearer, we shall see its irregularities; and if the wind, in that case, drive the rain so that the higher part be farther from the eye than the lower, the bow will appear inclined.

Ninhtly, Why the legs of the rainbow sometimes appear unequally distant? if the rain terminate on the side of the spectator, in a plane so inclined to the line of aspect as to make an acute angle on the left hand, and an obtuse angle on the right, the surface of the cone, which determines what drops will appear, will fall upon them in such manner as that those on the left hand will appear farther from the eye than those on the right. For the line of aspect being perpendicular to the plane of the bow, if you suppose two rectangular triangles, a right and left, the cathetus of each to be the line of view, and the base of the semi-diameter of the bow, inclined as above; it is evident, since those angles of the triangles, next the eye, must always be the same (viz. 43° in the inner bow), the bases of the right-hand triangle will, in this case, appear much longer than that of the left.

Dr. Langwith, in the Phil. Tranf. N.577, describes a remarkable rainbow, in which he observed several series of colours, which increased the bow to a breadth far exceeding what had been determined by calculation. The colours of the primary rainbow, he says, were, as usual; under this was an arch of green, and then alternately two arches of reddish-purple, and two of green, and under all a faint appearance of another arch of purple. The order of the colours was, 1. Red, orange, yellow, green, light blue, deep blue, and purple. 2. Light green, dark green, and purple. 3. Green and purple. 4. Green, and faint vanishing purple.

M. Bouguer frequently saw a phenomenon of this kind, when he was upon the mountains of Peru, where the sky is often extremely serene. Similar appearances have been also observed by others. Dr. Pemberton has attempted to explain them by means of the Newtonian doctrine of fits of easy reflection and transmission; but he goes upon the supposition that the differently-coloured rays have their separate fits, on their arrival at the surface of any medium, without any regard to the thickness of it; whereas it is plain, that, in such a case, all kinds of rays are reflected or transmitted promiscuously. It is most probable that these colours are formed in very minute drops of water or vapour, intermixed with the larger drops, that their formation depends upon the same principle with the colours of thin plates, and that they are similar to those of several kinds of halos. Dr. Pemberton himself observes, that it is most likely that these additional rings of colours are formed in the vapour of the cloud, which the air, being put in motion by the fall of the rain, may carry down along with the large drops. This, he says, may be the reason why these colours appear under the upper part of the bow only, this vapour not defending very low. As a farther confirmation of this, those colours, he observes, are seen strongest when the rain falls from very black clouds, which cause the fiercest rains; by the fall of which the air will be most agitated. Phl. Tranf. abr. vol. vii. p. 140. Priestley on Light and Colours, p. 593.

It has been a subject of controversy among biblical critics, whether the antediluvian atmosphere presented any such phenomenon as a rainbow. The occasion of this debate is a passage in Genesis, ch. ix. 12—17. Mr. Whitehurst, in his "Inquiry into the original State and Formation of the Earth, &c." attempts to establish the probability that the antediluvian atmosphere was so uniformly temperate, as to be subject to no forms, tempests, or rain. The opinion is by no means probable, nor does the above-cited passage warrant any such conclusion. The rainbow was then made the sign or token of God's covenant with Noah, that no such calamity should again take place. unnable denotes a sign or token, and in this sense it is used in the case of Cain, Gen. iv. 15. The mark set upon Cain was, as Shuckford conceives, a sign or token (s) given to him, that he should be preferred from the evil which he deprecated.

Rainbow, Lunar. The moon sometimes also exhibits the phenomenon of an iris, or bow, by the refraction of her rays in the drops of rain in the night-time.

Aristotle says, he was the first that ever observed it; and adds, that it never happens, i.e. is never visible, but at the time of the full moon; her light, at other times, being too faint to affect the sight after two refractions, and one reflection.

The lunar iris has all the colours of the solar, very distinct and pleasant; only faint, in comparison of the other; both
both from the different intensity of the rays, and the different disposition of the medium.

In that mentioned, Philosophical Transactions, N° 331, Mr. Thoreby observes, the largeness of the arch was not so much less than that of the sun, as the different dimensions of their bodies, and their dilations from the earth, should seem to require; but as to its extremities, and the beauty of its colour, it was admirable. This continued about ten minutes before the interposition of a cloud hindered its observation.

RAINBOW, Marine. The marine or sea-bow is a phenomenon sometimes observed in such a highly excited sea; when the wind, sweeping ports of the tops of the waves, carries them aloft; so that the sun's rays, falling upon them, are refracted, &c., as in a common flower, and paint the colours of the bow.

F. Bours, in the Philosophical Transactions, observes, that the colours of the marine rainbow are less lively, less diminutive, and of less duration, than those of the common bow; that there are fears above two colours distinguishable, a dark yellow on the side next the sun, and a pale green on the opposite side.

But these bows exceed as to number, twenty or thirty being sometimes seen together; they appear at noon-day, and in a position opposite to that of the common bow, i.e. the concave side is turned upwards, as indeed it is necessary it should be, from what we have seen in accounting for the phenomena of the solar bow. A coloured bow is always to be seen in the scattered water of a jet, a broken cascade, and the like, when the fun and the spectator are in proper situations. To this class of bows may be referred a kind of white or colourless rainbows, which Mentzelius, and others, affirm to have been seen at noon-day. M. Mariotte, in his fourth Essay de Physique, says, these bows are formed in mists, as the others are in flowers; and adds, that he has seen several, both after fun-rising, and in the night.

The want of colours he attributes to the smallness of the vapours which compose the mist; but we should rather account for it from the exceeding tenueity of the little vulee of the vapour; which being, in effect, only little watery pellicles bated with air, the rays of light undergo but little refraction in passing out of air into them; too little to separate the differently-coloured rays, &c.

Hence, the rays are reflected from them, compounded as they came, that is, white.

Rohault mentions coloured rainbows on the grafs, formed by the refractions of the sun's rays in the morning dew. Tair. de Physt.

Rainbows have been also produced by the reflection of the sun from a river; and in the Philosophical Transactions, vol. i. p. 294, we have an account of a rainbow, which must have been formed by the exhalations from the city of London, when the sun had been wet twenty minutes, and consequently the centre of the bow was above the horizon. The colours were the same as in the common rainbow, but fainter.

The best way of forming a resemblance of a rainbow is to fasten a number of small glass balls, or a number of small glass bubbles full of water, upon a dark board, and to present the board thus furnished to the sun at a proper inclination, which experience easily finds, whilst you turn your back to the sun, and look at the board.

RAINFELDEN, in Geography, a town of Aufrria; 2 miles W. of Rainfelden.

RAINHAM, a township of Norfolk county, in Upper Canada; being the seat township frostng on lake Erie, well of the grand river Lands.

RAINSBRON, a town of Germany, in the margraviate of Anspach; 3 miles N. of Creglingen.

RAINIE LAKE. See Le Plee.

RAJ, a town of Hindoostan, in Malwa; 30 miles S. of Malh.

RAJOOLA, a town of Hindoostan, in Dowlatabad; 18 miles W.N.W. of Konkur.—Also, a town of Bengal; 63 miles N. of Dacca.

RAJOUR, a town of Hindoostan, in Lahore; 36 miles N.W. of Jumma.

RAJOWLY, a town of Hindoostan, in Bahar; 30 miles S. of Bahar.

RAJPOOTANA, a country of the Rajpoots, generally denoting Agimere (which see), and the original country of the founder of the Mahratta state, whose rulers, about half a century ago, aspired at universal empire in Hindostan; but these have been reduced to their present low state, by the depredations of Mahratta detachments, which being composed of light horse, and accustomed to separate into small parties, have, by their defultory movements, at once spread desolation, and eluded the attacks of the inhabitants. This is the fact with regard to the open parts of Rajpootana; the mountainous parts remaining free from their incursions.

Rajpootana was divided into three great principalities, under the names of Oudipour, Joodpur, and Amber (or Amere), now better known by that of Jining, or Jyeqgur. (See each respectively.) In Achar's division of the empire, these principalities were classed as belonging to the foubah of Agimere, sometimes called Marwar. It is not easy to assign the precise limits and dimensions of these principalities, which occupy the space between the western confines of Agra and the north-east part of Guzerat, and between the sandy desert (or Registan) and Malwa; that is, an extent of 320 British miles from N.E. to S.W., and 200 broad in the widest part. Jyingur or Jyeqgur lies to the N.E., Oudipour to the S.W., and Joodpur to the N.W., bordering angularly on the other. Pere Wendell's MS., cited by Rennell, states the revenues of Oudipour at 10 lacks of rupees, Marwar at 40, and Jyingur at 40, per annum, in the year 1779. The whole revenue of the foubah of Agimere, in the time of Achar, appears to have been only about 75 lacks. Aurungzebe is said to have doubled the land-tax on the Rajpoots, and accordingly in Mr. Frazer's account, Agimere is stated at 163 lacks of rupees. The two former, viz. Oudipour and Marwar, are very mountainous, with a sandy soil in the valleys; the latter is the most fertile, and was, about the middle of the last century, in a high state of improvement, under the government of the celebrated rajah Jyingur, or Jefing, who founded the new capital of Jyeqgur, whence the name of the province was changed to that of the capital. Jyeqgur was a place of great wealth and commerce in 1779, being the entrepots of the principal part of the goods that are brought from every quarter of India. The rajah built an observatory in his capital; but the confusions that have for long prevailed in this province, must have greatly reduced the wealth and importance of the capital. Sindia, as Rennell informs us, received the tribute of all the three Rajpoot provinces, and converted it to his use; and he also made considerable conquests in them, particularly in Jyingur. In early times the whole Rajpootana probably constituted one entire kingdom, or empire, under the rana or prince of Oudipour, the head of the Rajpoot states; the antiquity of whose house may be inferred from the name.
RAI

Rhaunae appearing in Ptolemy, nearly in its proper position, as a province. See Oudipour.

The province of Agimere in general (see Agimere) has ever been the country of the Rajpoos; that is, the warrior tribe among the Hindoos, and which are noticed in Arrian and Diodorus; and Chitnore, or Oudipour, (considered by Rennell as synonymous,) is, in his opinion, reckoned the first among the Rajpoits. (See Chitore.) From the Ayin Acbaree we derive some new ideas respecting the division of the foubah of Agimere. It confided at that time of three grand divisions, Marwar, Meywar, and Hadowty, (or Nagore); and these contained seven circars or subdivisions, Agimere, Chitore, Rantamour, Joudypour, Siroyw, Nagore, and Beykeener (or Bacaner). Marwar, as including the circars and fubdivisions of Agimere, has become almost synonymous with Agimere, in commonacceptation. The extent of this province, as given by the fame book, is 168 coffes, or about 320 British miles, from E. to W.; and 150 coffes, or 285 British miles, from N. to S. Such is the province of the Rajpoits. From the indulgence granted to this tribe throughout India, viz., that of feeding on goats' flesh, it may be inferred, fays Rennell, that the custom originated in this mountainous country. The grain cultivated there is chiefly of the dry kind. The taxes amounted, in the time of Achar, to no more than a seventh or eighth of the produce of the harvest. Rennell's Memoir.

RAJPOOTS, the inhabitants of Rajpoottana; which see. They were not confined entirely to the foubah of Agimere; as some inferior tribes of them are settled in Bundelcund, and in Gurry-Mundella. Others, according to Thevenot, are settled in Moultan; and indeed he represents Moultan as the original country of the Kutties, from whom the Rajpoits sprang.

The Kutties or Catries, who formed a particular feet of Hindoos at Moultan, were the Cathets of Diodorus, and the Cateel of Arrian, with whom Alexander carried on war, on the borders of the Mali. The Rajpoits are ordinarily divided into two tribes or chaffes, viz., those of Rathore, and Chohan or Sceofoda. Marwar, or the N.W. division of Agimere, is the proper country of the former; and Meywar, or Oudipour, of the latter. The Rathore tribe were originally the most numerous of the two; and it has been said by colonel Dow, among others, that the Mahratta chiefs had their origin from the Rathore tribe; and in proof of this it has been alleged, that the etymology of the name Mahratta has been deduced from Rathore, prefixing to it "maha,” or great. (See MAHARRATTA.) The Rajpoits are represented by Thavenot as having spread from Moul- tan, their proper country, over all the Indies. Diodorus Siculus distinguishes them by the custom of their women burning themselves alive, on the funeral piles of their husbands; which is indeed a custom among them, as well as some other Hindoos, at this day. Rennell.

RAIPUR, a town of Bengal, on the bank of the Ganges; 10 miles N.E. of Curnockdaugh.

RAISE, in the Mange, is used for working. See Raising.

Raiser is likewise used for placing a horse's head right, and making him carry well, and hindering him to carry low, or to arm himself.

Vol. xxix.

RAISEN, in Geography, a town of Hindostan, in Malwa; 15 miles S. of Bilph. N. lat. 23° 16'. E. long. 77° 49'.

RAISER, in Building, a board set on edge under the foreside of a step, a slat, &c. See STAIR, &c.

RAISIN, in Geography, a river of America, which runs into lake Michigan, N. lat. 43° 12'. W. long. 85° 42'. —Also, a river of America, which runs into lake Erie, N. lat. 43° 20'. W. long. 82° 55'.

RAISIN Island, a small island in lake St. Francis. N. lat. 43° 5'. W. long. 74° 27'.

RAISIN, or Raifen, Market, a small market-town in the east division of the wapentake of Wallcroft, parts of Lindsey, and county of Lincoln, England, is situated on the banks of the river Raifen, whence it derives its name, at the distance of 15 miles N.E. from Lincoln, and 149 miles N.W. from London. According to the population returns of 1811, it contains 164 houses, and 964 inhabitants. Here is a weekly market on Thursday, and there are fairs every alternate Tuesday, after Palm Sunday, and on the 29th of September. The church is an ancient structure, and is remarkable for the peculiar form of the upper windows in its embattled tower. These have a pointed arch, divided into two pointed lights, and a quatrefoil head. Up the centre runs a strong mullion, crofled by a tranfom, terminating at the impostas, as happens in the church of Yarborough, near Louth, which renders it probable that both edifices were erected by the same architect. The living is a vicarage in the gift of the crown; and by the endowment the vicar is entitled to the usual tythe of ale. Besides the church, there are in Raifin a Roman Catholic chapel, and a Methodiff's meeting-houfe; also a free-school, and an hospital for poor old men.

At a short distance from Market-Raifen, are the villages of Middle and Well Raifen. Middle Raifen was formerly divided into two parishes, called Drax and Tufpholm, but these are now united. At Tufpholm stood an abbey of Premontritenian canons, which was founded in the reign of Henry II., by Alan de Neville, and his brother Gilbert. Previous to the dissolution, it was inhabited by nine monks, whose annual income, according to Speed, amounted to £92. 18s. 6d. The church is a small, but ancient building, consisting of a nave and chancel, which are separated by elegant screen work, beneath a pointed arch, supported by circular columns. The nave appears to have had tide-niles, as the pillars and pointed arches kand in relief from the present wall.

The principal feats in this vicinity are Willingham-houfe, a feat of the Boucherett family; and Thurgundy, the property of Lord Middleton. The latter anciently belonged to the Willoughbys. The house is situated on an eminence, commanding an extensive view over the vale to Swinhope, and is surrounded by pleasure-grounds, finely varied by wood and lawn. Beauties of England and Wales, vol. ix. by John Britton, 1827.

RAISING, in the Mange, one of the three actions of a horse's legs; the other two being the fay, and the tred. The raising or lifting up of his legs in caprioles, curves, &c. is esteemed good, if he perform it hardly, and with ease; not crossing his legs, nor carrying his feet too much out or in; yet bending his knees as much as is needful.

RAISING the LAND, in Sea Language. See Laying the Land.

Raising a Purchase, denotes the act of disposing of certain instruments or machines in such a manner, as that, by their mutual efforts, they may produce a mechanical force sufficient...
cient to overcome the weight, or restistance, of the object to which the machinery is applied.

Raising-Pieces, or Reafon-pieces, in Architecture, are pieces that lie under the beams, and over the pofts or puncheons: thefe lying on the brick-work are called plate-bands.

RAISINS, grapes prepared by drying them in the fun, or in the air; to fit them for keeping, and for some medicinal purpofes.

Of thefe there are various kinds: as, raisins of Damafeus, thus called from the capital city of Syria, in the neighbourhoud of which they are cultivated. They are much used in the composition of fpirits, together with jujubes and dates; they are brought flat, and feeded, of the fize of the thumb; whence it is easy judging of the extraordinary bulk of the grape, when feen. Travellers tell us of bunches weighing twenty-five pounds. Their fhape is faffifht and difagreeable.

Raisins of the fun are a kind of raisins brought from Spain, of a reddifh or blueifh colour, feened, and very agreeable to eat. There are various other forts, denominated either from the place where they grow, or the kind of grape, &c. as raisins of Calabria, Nufcadine raisins, &c.

The finest and best raisins are thofe called in fome places Damafeus and jube raisins. These are the fruit of the raisin Damafcena, and are diftinguifhable from the others by their bargenefts and figure; they are flat, and wrinkled on the surface; soft and juicy within, near an inch long, and fempellelucid, when held againft a good light; they have a feent, agreeable, and vinous fhape; and when feen, and growing on the bunch, are of the fize and fhape of the large olive.

The common raisins are the fruit of feveral species of grape, which are better or worfe, according as they have been more or lefs carefully cured. The raisins of the fun, or jar-raffins, fo called, because they are imported in jars, are all dried by the heat of the fun; and thofe are the forts used in medicine.

The common way for drying grapes for raisins is to tie two or three bunches of them firmly together, while yet on the vine, and dip them into a hot lircium of wood-afhes, with a little olive oil in it. This difpoafs them to fhrink and wrinkle; and after this they are lef left on the vine three or four days, separated on ficks in an horizontal situation, and then dried in the fun at leisure, after being cut from the tree. Some raisins are dried by the heat of an oven; and the difference between thefe and fuch as are dried in the fun, is obfvious; the latter are fweet and pleafant, but the former have a latent aciditie with the fweetnefs, that renders them much lefs agreeable. See Currents.

All the kinds of raisins have much the fame virtues; they are nutritive and bafmifc, but they are very fubjeft to fermentation with juices of any kind; and hence, when eaten immoderately, they often bring on colics. They are allowed to be attenuant, and are given in cafes where the humours are too thick and vivid, and they are faid to be very good in nephritic complaints; they are, however, too familiar in our foods, to be much regarded at prefent as a medicine. They are an ingredient, indeed, in our pectoral decoctions, and in fome other medicines of that intention; in which cafes, as also in others where altrigeny is not required of them, they fould have the ifones carefully taken out. The are used in fome compositions rather with an intent of taking off the nauseous taste of other ingredients, and for obtufing their acrimony, than of doing any extraordinary service themselves

RAISIN-Brandy, a name given by our fpirituals to a very clean and pure fpirit, procured from raffins fermented only with water. Thus treated, they yield a fpirit, fcarce at all diftinguifhable from fome of the wine-fpirits; for there are as many kinds of wine-fpirits as there are of grapes. The caufes of the operation of dilifling is performed in this cafe, the nearer will be the refeimblance of the wine-fpirit; that is, there will be more of this flavour in the fpirit, when as much as can be of the oil is thrown up with a gellong heat.

The diliflers are very fond of the wine-fpirit, with which they hide and difguife the fhape of their rauolous malt, and other fpirits; and in defeft of that fpirit, this of raffins, made in this caufe mofterly, will go aloft as far. It is indeed surprizing how extensive the ufe of these flavouring fpirits is, ten gallons of raffin-fpirit, or fomewhat lefs of the wine-fpirit, being often fimilar for a whole pipe of malt-fpirit, to take off its native flavour, and give it an agreeable visinility. It is no wonder, therefore, that the diliflers, and ordinary rectifiers, are fo fond of this, as it is a good cloak for their defefts, and the imperfection of their procесes.

When raffin-brandy is intended for common ufe, the fire should be kept fluorer and more regular in the diliflation; and the fpirit, though it hath lefs of the high flavour of the grape, will be more pleafant and more pure.

RAISIN-Wine. See Wine.

RAIT, in Rural Economy, a term used to signify the procès or operation of diliflating the fap of vegetables, by exposure to moisturer, or the impaflion of the atmosphere. It is moftly applied to hemp, f lax, or fome fimilar fubftances, and fometimes to hay, when it has been much ex- posed to alternations of wet and dry weather.

When the procès is performed by means of water, as is moftly the caufe with hemp, frequently but not always with flax, and occasionally with other articles of the fame nature, it is ufually denominated water-raifing, and the article is faid to be water-raifed; but where it is effed by ex-pofure to the air, upon the ground, when spread out, it is generally called ground-raifing, and the fubftance is faid to be ground-raifed. In the performance of these operations or procèses with hemp, flax, and fuch like fubftances, there is great necefly and attention required to fee that they are carried to a fufficient length, without going too far, fo as to injure the textures of the fubftances in their cortical parts. This may probably be accomplished with the greateft certainty by the frequent examination of the materials themselves; keeping them perfectly under the water in the former cafe, and frequently turned with new surfaces to the atmosphere in the latter, never having the graffy furface on which they are spread out of too great a length. The effects of heavy rains, when long continued, might likewise be carefully attended to in this latter infance. See Flax, Hemp, and Water-raifing.

RAITAPOUR, in Geography, a town of Hindooftan, in the circar of Rajamundry; 12 miles N. of Rajamundry.

RAITCH, in Rural Economy, a term signifying a line or fift of white, down the face of a horse. It is a very common mark in the faces of horses.

RAITENBACH, in Geography, a town of Germany, in the principality of Culmbach; 8 miles E.N.E. of Wonfiedel. Also, a town of Bavaria, in the bishopric of Aich- fladt; 8 miles N. of Aichfladt.

RAITENBURG, a town of the duchy of Carniola; 3 miles N. of Rudolfswehr.

RAITING, GROUND, in Rural Economy, that method of rafing or accomplishing the separation of the barks or coverings of the fleins of flax, hemp, and other fimilar plants,
RAK

by means of spreading them out in a thin manner upon close
grassy surfaces, instead of putting them into ponds or pools of
flagrant water, in order that they may be expelled to the
atmosphere. It is occasionally employed for flax and other
small flaked plants, but seldom or never for hemp and those
which have large ones. It is a practice which stands in need of
considerable attention and management. See Rait.

RAJUAPUR, in Geography, a town of Mocum-
pour; 18 miles S. of Bargao.

RAIVATA, in Hindoo Mythological History, one of the
saints or fages included in the denomination of Menus. Rai-
vata is said to have been the son of Agni, the regent of fire,
also called Pawaqa, (which bee), and Menu.

RAJYA, in Geography, a town of Hindoostan, in Ba-
har; 20 miles E.S.E. of Bahar.

RAKAPORAH, a town of Hindooftan, in the circar
of Juffpour; 10 miles N.E. of Odeypour.

RAKAS, a town of Transylvania, on the Alaut; 16
miles N.W. of Cronstadt.

RAKE, in Agriculture, a tool of the toothed kind, made
use of for many purposes of husbandry, as for collecting to-
gether hay, corn, flubble, roots, leaves, and other fimilar
forts of materials. It is a very useful and convenient kind
of tool in all fuch intentions. There are many defcriptions
of this fort of implement.

RAKE, Bean-Stubble, a tool of the rake kind, constructed
for the purpose of clearing bean-stubbles. It is employed on
some farms in Essex, as by Mr. Ketcher, at Burnham,
where it is found to be well-adapted to this use, and to do
its work in a perfect manner. The head, which is seven
feet eight inches in length, is formed with a very flight
curve, having teeth fef in it in rather a clofe manner, which
are one foot and a half in length, bending or curving a little
forwards at the points. It is attached by a frame to the
axle of the wheels, which is three feet two inches long; and
the wheels are two feet fix inches in their diameter. The
hooks and shafts for the horfe are four feet in length. This
is a very fimple contraction of this nature, and one which
is capable of eafy application. The teeth fhould be made
ftrong, whether they are of wood or iron. This is an im-
plement which wants to be better known in other districts.

RAKE, Corn, a large frong rake, made fef of in dif-
ferent districts for bringing together the moving grain crops.
It is sometimes constructed with wooden teeth, but a better
mode is to have them of iron, being a little bent forward,
having the length of seven or eight inches. As it requires
much exertion to perform the work with them, they fhould
always be made as light as possible, fo as to have fufficient
power to perform the work. It has been ftrated by Mr.
Somerville, in his Agricultural Survey of the District of
East Lothian, that though the common hay-rake is mostly
used there, a different kind for grain has been partially tried,
and found to answer the purpofe much better. In this, the
length of the head is from ten to fifteen feet, the handle
about seven feet, with a piece of wood across the end of it,
by which it is drawn by two men. The teeth are of wood
or iron; the left are the bell, as well as the moft durable,
and are a little bent forward at the point, which gives them
the power of retaining and carrying the ears along with
them, much better than they would otherwife do. To
make clean work, efpecially if the ridges are gathered, the
field is raked across: in that way, every thing is taken up.
But when it is preferred to draw the rake in the direction
of the ridges, it may be considerably improved, by cutting
the head into two or three leaths, and joining them with
hinges, which will allow it to bend and accommodate itself
to the curvature of the ridges. The advantage of this kind
of rake has been found considerable, even in cafes where
every possible attention has been paid to the cutting of the
crop; but it frequently happens, that, owing to the damp-
ness, greenness of the straw, or a foul grasy bottom, it is
necessary to leave the crop unbound for a day or two, during
which, if it be overtaken by a high wind, much of it will
be scattered and loft, unless considerable pains are taken to
gather it by hand-raking, or otherwife. Where the long
rake is used for that purpofe, the expence will in no in-
stance, he thinks, exceed four-pence fterling per acre. An
experiment made on a field of 30 acres, will convey some
idea of the benefit that may be derived from the use of that
instrument. The field was in barley, and the rakings, when
threshed, yielded

Threshing - - - 0 7 6

Total expence 11 10

Which deducted from 14l. 5s., leaves a profit of 13l. 2s. 2d.
fterling. It is neceffary to obferve, that about ten acres of
the field were left unbound, and a good deal disorderd by
a high wind; but as confiderable pains were taken in the
binding, the proportion obtained from the ten acres did
not greatly exceed what was got from the ref of the field,
the whole of which was cut with a great deal of care.

But though this mode of working the rake affords con-
siderable profit and advantage, they would be a great deal
more, by having recourse to horfes in the draught of them.
One horfe in each would do as much labour as several
men in a given time; and by having shafts and low wheels fef-
d to the tool, it could be readily adapted to this method of
being wrought.

RAKE, Couching, a large fort of strong horfe-rake, with
long round fomes or teeth, crooked or bent forward in a
gentle manner, and placed about two inches diliant from
each other; and a small beam in the middle, with fide
pieces, and an apparatus for attaching the horfe to it. It
is found very useful in bringing together the roots of couch,
and other wefts, in order to their being burnt, or carried
off the land, and in other ways destroyed. See Couch-
Rake, Quick-Rake, and Rake-Twist.

RAKE, Dew, a fort of large rake, or hand drag, so
named from being used before the dew is off the ground, or
other fort of harvest work can be begun. It is a powerful
convenient fort of implement for harvest work.

RAKE, Garden, a well-known fort of tool for raking
the ground, as well as for putting in seeds, &c. In
order to fuit every kind of gardening work with rakes,
there should be three or four different fizes, from about fix
to eighteen inches long in the head, having handles from fix
to eight feet in length, and the heads toothed with iron teeth
two or three inches long, being placed from one to two
inches afunder, according to their refpective fizes. The
first or largest rake fhould have the head about fifteen to
eighteen inches long, the teeth three inches, and placed two
inches afunder, which is proper for raking flubborn or
rough dug ground, and for putting in large kinds of feeds,
raking off large weeds after hoeing, and many other pur-
poses.
poses in large gardens. The next size should have the head twelve inches long, the teeth three inches, being placed one inch and half afender, which is proper for all common raking in ordinary light ground, and for raking in most kinds of small feeds, as well as other purposes. A third fort of small rake should have the head about nine inches long, the teeth two and a half, being placed one inch afunder; proper for fine raking beds, borders, &c. and raking in some particular fine feeds; as well as between rows, &c. of certain plants occasionally, where larger rakes cannot be introduced. And the smallest fort should have the head fix inches long, the teeth two and a half, and placed one inch afunder; being very useful for raking between small plants in beds and borders, and other small parts, where the plants stand close, as well as several other purposes of that kind.

It may be noticed, that all these forts of rakes are constructed both with wooden heads and iron teeth, and with the heads and teeth wholly of iron in both; of which the teeth are generally flattened, the back edge rounded off, and narrowing gradually to the point; the other straight, and placed on the heads edgeways acros, with the back edge outward, and with the points all inclining very moderately inward, in a regular manner: the wooden-headed rakes having each end of the head hooped with a thin flat iron ring, to secure it from splitting. It is very seldom that wooden teeth are employed in this way, or for these uses.

Those of the first fort are generally the lightest and cheapest, being proper for any kind of garden raking; but the latter, or iron-headed rakes, when made neat and as light as possible, with the teeth well set, in a proper position, and firmly fastened, are equally proper, and in some cases preferable, as in some wetthift or moist soils, as not being liable to clog so much as wooden rakes, and at the same time more durable. They are, however, more proper for middling and small rakes than for large ones; as, in strong raking, the teeth are more liable to get hoof than in the wooden-headed rakes.

Both the forts, in their different sizes, are sold at the principal ironmongers' shops, both with and without handles.

And rakes having the heads, teeth, and handles, wholly of wood, may sometimes be used for particular purposes; such as raking in light kinds of kitchen-garden feeds in light ground, and taking off large hood-up weeds in wide clear spaces, raking up swaths of mowed short grasses before the sweepers, &c. fallen leaves of trees in autumn, and clipings of hedges, &c. as well as several other uses about the pleasure-garden.

Rake, Hay, a well-known tool, with short teeth and a long handle, made use of in making hay. It is usually made of willow, or some other similar wood, in order that it may be light and handy. The teeth should not be too long, as, when that is the case, they are apt to hang and pull among the stubs of the grasses in raking with them, and thereby retard the operation, as well as cause much fatigue to the labourer.

Different improvements have been made on this implement. A late useful alteration is the making the teeth to screw into the head, and fasten with screw nuts, by which the inconvenience of their dropping out in dry grass is obviated. It has been observed, that with the stop-teeth rake, the operator is capable of performing much more work than by the common one. They are likewise capable of being conveniently made use of both for hay and corn. They were originally made and sold by Mr. Corot, of Leiceter.

Another improvement is mentioned in Young's Agricultural Report of Norfolk, which is the addition of wheels. It is flatted, that the "hand wheel-rake" of Pleg is an excellent implement for both hay and corn: it is to answer the purpose of the common hay-rake, and is about four feet long in the rake; and the two wheels, of nine inches diameter, so fixed, that the teeth are kept in any posture, at the will of the holder.

In some parts of Lancashire, they make use of a large horse-rake for collecting the hay together, and raking it up from the ground, which is found to be highly convenient and beneficial; as one horse, in one of these rakes, will perform as much labour as a great number of men, in a certain space of time; and besides the expedition, the work is considerably better done, in consequence of the greater weight of the implement.

The head of the rake has something of a large easy half circular form, into which two strong pieces of wood are fastened, which constitute the shafts for the horse. There are two low wheels behind, and the head has long teeth, curving a little forward, fixed into it at two or three inches from one another. The teeth may be made either of wood or iron, and should have considerable strength. The whole has no great weight, though it must obviously be considerably heavier than the common rake; which is found of much advantage in its working, as has been hinted at above.

Rake, Horse Stubble, an implement used in Norfolk and Suffolk, on the large and middling-sized farms, and, from its great utility, extending itself to other districts. It is employed for barley and oat crops, being drawn by a horse. And it has been flated by Mr. Young, that one man and a horse, driven by means of a line or rein, are capable of clearing from twenty to thirty acres, in a moderate day's work; the grain being deposited in regular rows or lines across the field, by simply lifting up the tool, and dropping it from the teeth, without the horse being flopped. It cools from four to five pounds.

Figures of it may be seen in the above Agricultural Reports. Horses have now been employed for working other forts of rakes, and found of great advantage, as has been already seen.

Rake, Horse-rake, a large heavy kind of horse-rake, having strong iron teeth, fourteen or fifteen inches in length, placed at five or six inches from each other, and a beam four inches square, and eight or ten feet in length. In drawing it, two horses are mostly made use of, by which it is capable of clearing a considerable quantity of stubble in a short time. Tools of this fort are highly useful on corn farms, for collecting this useful material, and should be much more frequently employed than they are at present.

Rake, Twitch, a large horse-rake, employed in certain cafes for clearing lands from the roots of couch, twitch, or quitch-grasfs, as well as those of other forts. It is constructed in different ways, as with one or two rows of teeth; but the latter is probably the best method, as by placing one row opposite the intervals of the other, it must be rendered a very efficient tool.

Rake of a Ship, is to much over her hull as overhangs at both ends of her keel.

That part of it which was before, is called the rake forward-on; and that part which is at the setting on of the stern-post, is called her rake-off, or afterward-on.

When a ship hath but a small rake forward-on, but is built with her stern too straight up, she is called huff boiler.

Rake of the Rudder, is the hindermost part of it.

Rake, among Hunters. See Rag.

Rake, in the Mange. A horse rakes, when being shouldered-ploaid, or having strained his fore-quarter, he goes to lame, that he drags one of his fore-legs in a semicircle; which
which is more apparent when he trots, than when he
paces.

RAKE, or Vein, in Geology, the most common repository of
metallic ores. These veins intersect mountains nearly
vertically, or more or less inclined from the perpendicular.
They are filled with ores, intermixed with the peculiar
minerals accompanying each kind of metal. They vary
from a few inches to some feet or yards in width, and ex-
tend to a very considerable depth and distance. The upper
side of the vein is provisionally called the hanger, and the
lower side the ledger; and the inclination from the perpen-
dicular is called the hade of the vein. For a particular ac-
count of the structure and formation of veins, see Veins,
Metallic.

RAKEL, in Geography, a town of Dobruzzi Tartary,
on the Danube; 15 miles W. of Iakski.

RAKESBURG, or Rakelsburg, a town of the duchy of
Sturia, situated on an island in the Muhich; the inhabitants
of which carry on a considerable trade with Hungary and
Croatia; 36 miles S.E. of Gratz. Lat. 46° 45'. E.
long. 15° 36'.

Raking signifies sloping or winding, as when a wall
is not built up right or slanting.

Raking, in Agriculture, the operation of performing
work with a rake. It is a sort of work that requires little
art or trouble in its execution; but whether performed with
the common or horse-rakes, it should always be done in an
effectual manner. In the business of hay-making, clean
raking not only affords a neatness in the appearance, but,
over a great extent of surface, a considerable saving of hay.

In raking hay lands, where horses are employed, some
degree of care is necessary in directing the work, and driving
the animals, in order that no inconvenience of delay may be
experienced, and that every part of the land may be gone
over in the most regular manner. Small boys may serve to
direct the horses by riding upon them, and some faving be
made in that way.

In raking cut corn crops with horse-rakes, especially
those of oats and barley, it is sometimes the best method to
proceed in a cross direction of the ridges, drawing up the
produce into long rows at suitable distances; the horses
being driven by the men, who know the management of the
handles of the rakes, by means of whip reins brought from
the horses to the flits of the implements. It seldom hap-
ens that so good work can be made in going the length-
ways of the lands, particularly where they are much
rounded, and of a small fize in breadth, as the tools will
not fit well to their rounded form, unless where they are
constructed in separate parts in their heads, so as to admit
of motion by means of joints. In this mode of raking, the
corn may sometimes be readily tied up into sheaves.

But in the raking of flutters, it is more useful to pass in the
direction of the ridges, though the contrary method is
not unfrequently had recourse to. In those cases, as well
as in the others, the flauy grains or flutters are always
brought together into lines or rows, in order to be more
readily taken up by the carts either bound or unbound.

In the raking of the roots of weeds together upon lands,
it is constantly the best practice to perform the work in
both directions; as, by such means, the whole of them may
be laid hold of in a more complete and effectual manner than
could otherwise be done. See Rake.

Raking, in Gardening, a necessary operation in the gar-
den, to break the surface of the soil small, and render it
fine for the reception of particular sorts of small seeds and
plants, previous to sowing and planting; as well as to render
it neat and even to the eye. It is also employed in raking in
seeds, as being an expeditious mode of covering them in.
In all kinds of small seeds, or hardy plants, the ground
being dug, &c. and the surface remaining rough after the
spade, the seed is sown, and then raked in with an even
hand, once or twice in a place, as a back and a fore stroke,
or more as may be necessary.

And this operation is useful also among growing plants,
that stand distant enough to admit the rake, particularly
where the surface is inclinable to bind, or where numerous
small seed-weeds appear, as it loosen the soil, and retards
the growth of the weeds, and promotes the growth of the
young plants. It is also good culture at particular feasons,
to annoy flags, especially in kitchen-gardens, to rake be-
tween the rows of small plants in autumn and winter, &c.
The raking of the beds, borders, and other compartments
of pleasure-grounds, now and then, smooth and even, like-
wise gives an air of culture and neatness to the whole.

It may be observed, that this sort of work should gen-
erally be performed in dry weather, and when the ground is
also moderately dry; as when done in rainy weather, or
when the ground is very moist and cloggy, the surface is
apt to cake and bind hard. This should be well attended to
in sowing seeds. Rough ground does not rake well,
when it is become very dry at top, especially if it was dug
wet, and suffered to lie till the clods have become very dry
and hard; in which case it will not rake well, until mello-
rowed or pulverized by a shower of rain. But common
light garden ground generally rakes best when fresh dug,
perhaps the same day, or day after the farthe, before
dried too much by the sun and wind, or rendered wet by
rain, &c. The operation should, however, be performed
when the ground is in such order as the clods will readily
break and fall to pieces under the rake, without clogging
much to it, or the mould become even without running into
lumps.

Raking of a Horse, is the drawing his ordure with the
hand out of the fundament, when he is coltive, and cannot
dung. In order to do this, the hand must be anointed with
fellad-oil, or butter.

Raking a Ship, is the act of cannonading a ship on the
stem or head, so that the halls shall ficur the whole length
of her decks, which is one of the most dangerous inciden-
ties that can happen in a naval action, so much so, that the
men are ordered to lie down at their quarters. This is fre-
nently called raking fore and aft, being the fame with what is
called enflagging by engineers. See Enfilade.

Raking Knees. See Knees.

Raking Table, or Raked Table, among Architect, a mem-
ber hollowed in the square of a pedetalf, or elsewhere. See
Cavetto, and Scotia.

Rakokie, in Geography. See Raci-koke.

Rakonitz, or Rakownitz, a town of Bohemia,
and capital of a circle of the same name, which is moun-
tainous and covered with forests, but fertile in corn,
and affording some excellent horses. It was made a royal
town in 1586. It is celebrated for its beer, which is the prin-
cipal article of its commerce; 22 miles W. of Prague. N.
lat. 50° 5'. E. long. 13° 57'.

Rakora, a town of European Turkey, in Bulgaria;
40 miles S.S.E. of Viddin.

Rakow, or Racow, a town of Aulrian Poland,
in the palatinate of Sandomirz, formerly populous; the Soci-
arians had a college and printing-house here, but were ex-
peled in 1643; 40 miles W. of Sandomirz. See Racow.

Rakoweena, a harbour on the coast of Kamih-
chatka, in Asian bay, three miles long, and one and a
half
half broad, with water from thirteen to three fathoms, and a bar at its entrance: it runs at first in a south-eaft and afterwards in a southerly direction; three miles S. of St. Peter and St. Paul.

RAKSHA, in Hindu Mythology, a species of malignant demon, of whom great ufe is made in their epic machinery and popular tales. They are of various flapes and colours, and suppeded to be animated by the souls of bad men of earlier existence, receiving punishment in these forms as enemies to the gods, and obstructors of their beneficent intentions towards mankind. Another clafs of these evil genii comprehend those called Yaksha. Rakshasa and Yakshas are the plurals, and Rakshni and Yakshni the feminine; for these evil doings are not confined to sex. Ravana, the giant king of Lanka, or Ceylon, who opposed Rama, aided by the gods in the invasion of his kingdom, is sometimes called the lord of Raksha. See Ravena.

RAKULSKOI, in Geography, a town of Russia, in the province of Ufling, on the Dvina; 20 miles N. of Krafneobors.

RALEIGH, Sir Walter, in Biography, a distinguished character in the reigns of queen Elizabeth and James I., was second son of a gentleman of an ancient family in Devonshire. Few names, says Sir Walter’s biographer, Mr. Cayley, vary so much in the manner of writing it. By Sir Robert Naunton and Lord Bacon it is written Raleigh; in some old deeds the orthography is Rale or Raleigh; while king James, Hooker, and other respectable writers, adopt the mode of spelling which is still common in this country, viz. Raleigh; but the original letters of Sir Walter himself, wherever the signature is preferred, have Raleigh, and on that account we choose to adopt it in this work. Sir Walter, of whom we are treating, was born at a farm called Hayes, in that part of Devonshire that borders on the sea, in the year 1552. By his mother he was related to those famous knights, Sir John, Sir Humphrey, and Sir Adrian Gilbert. After he had received the usual school education, he was sent to Oriel college, Oxford, where he distinguished himself by a proficiency in learning far beyond his age; but the active disposition and martial ardour with which he was endowed, soon put an end to his learned career. About the year 1569, he, in company with many young gentlemen of the best families in the country, went into France, as well to instruct themselves in the art of warfare, as to assist the Protestants in that kingdom, who were then grievously oppressed. In this school he was employed five or six years, but by what means he escaped the horrible massacre of Paris, and the provinces, on the famous St. Bartholomew’s day, we have no knowledge. He returned to England in 1575, and it should seem he immediately became a refident in the Middle Temple, whence a commendatory poem of his, prefixed to a work of George Gafcoigne’s, is dated in 1576. That he was not a student in the law, at this time, he has himself declared, and he shortly after passed into the Netherlands, where he served some time against the Spaniards. In this, and other transactions of the same kind, he followed the fashion of the times. France and the Netherlands were in those days the schools of Mars; to which all were obliged to resort who meant to pursue the fortune of arms. Many young men returned to their native country ruined in their fortunes, their constitution, and morals; but Raleigh had made a good use of his time, gained a large flock of useful knowledge, and was so completely polished in his manner of address, that he was now considered as one of the best bred and most accomplished gentlemen in England.

On his return in 1578, he found his half-brother, Sir Humphrey Gilbert, engaged in a design of making diffic-

versies in North America, for which he had obtained a patent, and for the furtherance of which he had procured the affil-

iance of many friends. Raleigh was delighted with the design, and embarked in it cordially. This project proved very unfortunate to the adventurers, but it gave young Raleigh an introduction to the sea service, in which he afterwards so much distinguis hed himself. From this unlucky adventure, Mr. Raleigh arrived safe in England in the spring of the year 1579, and very soon after he appears to have offered his services to the queen to go to Ireland, to the inhabitants of which, pope Gregory VIII., and the Spaniards had sent men, money, and other assistance, to enable them to take arms against the established government. He obtained a captain’s commission, and served in Munster under the earl of Ormond. In this petty warfare he displayed so much good conduct, vigour, and courage, that he was afterwards made governor of Cork; and as a reward for his services, he received from the crown the grant of a considerable estate in Ireland. A misunderstanding with the lord-deputy Grey put a stop to his farther rife in the army; he returned to England, and was quickly introduced to the queen’s notice, and by his own merits attained a large share in her favour. As he was forward to distinguish himself in all public services, so on the return of the duke of Anjou into the Netherlands, he was one of those who accompanied him out of England, by the express command of queen Elizabeth, and on his coming to England in 1582, he brought over the prince of Orange’s letters to her majesty. Some months after this he refided at court, and was honoured with the favour and protection even of contending families, who were proud of showing the true judgment which they had of real merit, by becoming patrons to Raleigh. In 1584 he was married in his brother Gilbert’s second attempt, and though he did not venture in person, yet he built a new ship, called the bark Raleigh, and furnished it completely for the voyage; “the unsuccessful end of which,” says Campbell, “it seemed to predict, by its untimely return in 48s than a week to Plymouth, through a contagious distemper which feized on the ship’s crew.”

While at home Raleigh was not negligent of putting his fortune as a courtier. “He had a good perfon and address, made an elegant appearance, and put on that air of gallantry which was so meritorious in the eyes of Elizabeth. It is said, that he was once attending the queen in a walk, when she came to a spot, that by its site obstructed her course; he immediately took off his rich cloak, and spread it on the ground for her to walk on. Pleased with this attention, it is observed, that the facrifice of a cloak obtained for him many a good fuit.” The enterprising spirit of Raleigh was fhewn in the year 1584, in a scheme which he formed of making discoveries and settlements in those parts of North America which had not been subjected to any European power. His interest at court, and his ability in flating and letting forth his plans to the, best advantage, obtained for him an extenfive patent for executing his purpose; and, in confequence, with the help of a society of his friends, he fitted out ships under the command of captains Amadas and Barlow, which failed from Plymouth in that year, and took poftilion of an isle near the mouth of Albemarle river, in what is now called North Carolina. From the terms of the patent, it appears, that the great object of these adventurers, as it was of all others in that reign, was the search after mines of the precious metals. Raleigh was not himself in this expedition: the ships returned in the autumn with some commodities which sold so well, that the company was encouraged to fit out a fleet of seven vessels for the following year, of which the command was given to
On his return from his Portugal voyage he visited his Irish estates, and there either formed or renewed his acquaintance with the poet Spencer, who celebrates him under the title of the "Shepherd of the Ocean," and acknowledges the obligation of having first made him known to the queen. To his Fairy Queen he likewise prefixed a letter to Raleigh, explanatory of its plan and design. The patronage of literature was one of the best traits in the public characters of an age, in which means was singularly mixed with heroism. The naval enterprises of the reign of Elizabeth were for the most part predatory expeditions, and often on foot by individuals for their private benefit, and encouraged, though not feebly aided, by the crown. In 1592 Sir Walter Raleigh engaged in a considerable undertaking of this kind, with a view of attacking Panama, and intercepting the Spanish Plate fleet. He fitted out thirteen ships, by himself and his associates, which were joined by two of the queen's men of war, and he was appointed general of the whole fleet. Scarcely had he set sail when he was recalled by his sovereign; proceeding, however, to Cape Finisterre, he divided his fleet into two squadrons, with cruizing for orders, and then returned. One of the squadrons fell in with a rich wreck, the capture of which was the only instance of success which attended the expedition. His ardour for war was shown by his support in parliament of a motion, that certain subsidies granted to the crown should be for the express purpose of carrying on a war offensive and defensive against Spain. To undermine his credit with the queen, Parsons, a Jesuit, published a libel against him, charging him with Atheism: the queen is said to have imbibed some prejudice against him on this account, but he incurred her heavy displeasure by an intrigue with one of her maids of honour, the daughter of Sir Nicholas Throgmorton. The consequences of this amour brought a fœcadula upon the court of the virgin queen; and though he made the best repayment in his power, by marrying the lady, his offence was punished by an imprisonment in the Tower of some months, and a subsequent banishment from the queen's presence.

During his imprisonment he projected an expedition for the discovery of the empire of Guiana, which had already been visited by the Spaniards, and the extent and opulence of which had been the subject of many marvellous tales. Having obtained some preliminary information, from an old navigator whom he dispatched for the purpose, he embarked in person, in the month of February 1595, with a squadron of ships fitted out at a great expense, and failed to the island of Trinidad, where he made himself master of the town of St. Joseph; he then proceeded up the great river Oronoko, but was obliged by the heat of the weather, and the difficulties of the navigation, to return, with doing nothing more than merely taking possession of the country in her majesty's name. Unwilling to return without appearing to have done something, he published a work, entitled "Discovery of the large, rich, and beautiful Empire of Guiana," which was evidently the refult of a fertile imagination rather than of real observation, and which Hume rigidizes as a production "full of the groffest and most palpable lies that were attempted to be imposed on the credulity of mankind."

Sir Walter had so far regained the good opinion of the queen, that he had a naval command in the expedition against Cadiz, in 1596, under the earl of Essex and Lord Ellingham. In the attack he was one of the leaders of the van, and by his valour and prudence contributed a full share to the success of the glorious action. In the following year he sailed as rear-admiral in the expedition of which Essex was commander-in-chief, and the purpose of which was to intercept the Spanish West India fleet. Arriving first with
Ralegh.

It is said that even Coke, the attorney-general, who treated Ralegh on his trial with all the abuse that belonged to his character, and was thought authorized by his office, expressed surprise at the sentence, and declared that he had charged him with no more than misprision of treason. Three were executed for this plot, two were pardoned, and Ralegh was only reprieved and committed to the Tower. His wife, at her own earnest solicitation, was permitted to become his fellow-prisoner, and his youngest son was born in the Tower.

In Mr. Cayley's life of Sir Walter Ralegh, published in London in 1806, we have a curious letter of Lord Cecil, then secretary of state, to Sir Thomas Parry, the English ambassador in France, in which he gives an account of the conspiracy just referred to, and of the motives which led the different persons to take a part in it. Sir Walter was indicted for conspiring to deprive the king of his government, to raise up faction within the realm, to alter the religion and bring in the Roman superstition, and to procure foreign enemies to invade the kingdom. The principal overt act in the indictment was, that Sir Walter had a conference with Lord Cobham, as to the best means of advancing Arabella Stuart to the crown and throne of this kingdom, and that they should apply to the king of Spain to procure his assistance in this cause. Sir Walter made an able stand in his trial against the legality of conviction upon the evidence of a single witness, but the judge, rendered infamous by his conduct on the trial, overruled the objections.

The active mind of Sir Walter Ralegh was now left to exert itself within the walls of a prison, and its employment conducted more to his honour than his liberty perhaps would have done. Here he composed the greater part of his works, especially his "History of the World." Prince Henry, a youth of most amiable qualities, and as unlike his father as possible, contracted a generous admiration for the splendid talents of Ralegh, and cherished him in his solitary confinement by his friendship and correspondence. "No king," said the royal youth, "but my father would keep such a bird in a cage." Henry, however, died, and with him the hopes of deliverance vanished from the mind of the state prisoner. 

At length, however, after twelve years' confinement, Sir Walter obtained his liberation, but probably not without the use of bribes, applied to the new favourite Villiers. For the purpose of repairing his fortunes, he planned a new expedition to Guinea, and his report of a rich gold mine existing in that country was a sufficient inducement for a number of adventurers to engage in the scheme. He obtained a patent under the great seal from the king, for making a settlement in Guinea. James, however, in order to retain his hold upon him, did not grant him a pardon of the treasons of which he had been convicted. There is no doubt but Sir Walter might have purchased a pardon, and, at one time, had thoughts of doing so. He even consulted Sir Francis Bacon, whether it would not be advisable for him to give a round sum of money for a pardon in common form; to which the learned lawyer answered, "Sir, the knee timber of your voyage is money; spare your purse in this particular, for, upon my life, you have sufficient pardon for all that is past already, the king having under his broad seal made you admiral of your fleet, and given you power of the martial law over your officers and soldiers." Ralegh having employed all his resources in fitting out the expedition, failed for Guinea with twelve armed vessels in July 1617. He had not even long before he was obliged to put into the harbour of Cork, by frows of weather, where he remained till the 10th of August. In November he arrived at Angola.
Guiana, where he was received with the utmost joy by the Indians, who not only rendered him all the service in their power, but endeavoured to persuade him to end all his labours there, and take upon himself the sovereignty of the country, which, however, he readily refused. A violent and long continued sickness prevented him from undertaking the discovery of the mine in perfon. This important affair he entrusted to one of his captains, Keynes: the scheme, however, proved abortive, the Spaniards having been before hand with him in the search of gold. Hume, for the purpose of elucidating James, endeavours to show that the real intention of Sir Walter Raleigh was to plunder the Spanish settlements, and neither to colonize, nor to work the mines. He assumes that Raleigh was a wilful deceiver in the expectations he had raised of vast subterraneous riches; but considering his character, it is surely more reasonable to believe that he was carried away by some vague ideas of this kind, and Hume admits that the Spaniards were at the very time working some mines. It will be readily admitted, that James did not imagine he was giving Raleigh a commission of holilities against Spain, yet he must have known that the exclusive claims of that crown in South America rendered every interference with its dominion hostile in its eyes. The fact seems to be, that the expedition was undertaken with an intention to make the most of it, by any means within the power of the armament, and that the commander trusted to its success for justification before a court where bribery to favourites was omnipotent.

In this expedition Raleigh's elder son lost his life, of which, and of the unfortunate issue of Keynes's undertaking, he reproached his captain very severely, who, without hesitation, put an end to his own life. Raleigh, with a heavy heart, fled to homelands. In July 1618 he arrived at Plymouth, and in his journey to London he was arrested, and carried back to Plymouth. Twice he attempted to escape, but was secured and committed a prisoner to the Tower. James was exasperated at the injury which had been inflicted on Spain, a power then in amity with England, and which had been complained of by the Spanish court in very strong terms. He was, moreover, about to enter into a more intimate connection with that court, and therefore, without hesitation, determined to sacrifice Raleigh to its resentment. Though his death had been determined on, it was difficult to take away his life. His conduct in the late expedition, though the want of success had rendered it criminal in the eyes of the court, was far from being in the sight of the nation; and though judges might have been found who would pronounce it treason, yet even in those days it was not easy to find a jury who would, without evidence, have found him guilty. The commissioners therefore, who had been appointed to inquire into the matter, and who had frequently examined him, finally reported, that no ground of legal judgment could be drawn from what had passed in the expedition. Upon this, it was resolved to call him down to judgment upon his former sentence, which, says Campbell, was done, with all the circumstances of iniquity and brutality that can well be conceived. Being brought before the court of king's bench, his plea of an implied pardon, by his having acted under the king's commission since sentence had been pronounced, was overruled, and he was not permitted to enter into a vindication of his conduct in the late voyage. Execution was accordingly awarded, and the king's warrant for it produced, which had been signed and sealed before-hand.

"That this judgment was illegal," observes Dr. Campbell, "and that Sir Walter was really murdered, has often been said, and, I believe, seldom doubted; but I think it has not been made so plain as it might be, and, therefore, in respect to his memory, I will attempt it, by shewing that the judgment was absolutely illegal, as well as manifestly iniquitous.

"It is a maxim in our law that the king can do no wrong; and most certain it is, that no king can do legal wrong, that is to say, can employ the law to unjust purposes. Sir Walter Raleigh, after his conviction, was dead in law, and, therefore, if king James's commission to him had not the virtue of a pardon, what was it? Did it empower a dead man to act, and not only to act, but to have a power over the lives and estates of the living? It either conveyed authority, or it did not. If it did convey authority, then Sir Walter was capable of receiving it; that is, he was no longer dead in law: or, in other words, he was pardoned. If it conveyed no authority, then this was an act of legal wrong. I cannot help the blunder; the absurdity is in the thing, and not in my expression. A commission under the privy seal, if not under the great seal, granted by the king, with the advice of his council, to a dead man; or, to put it otherwise, a lawful commission given to a man dead in law, is nonsense not to be endured; and, therefore, to avoid this, we must conceive, as Sir Francis Bacon, and every other lawyer did, that the commission included, or rather conveyed, a pardon. Indeed, the same thing may be made out in much fewer words. Grace is not too strong a mark of royal favour as trust; and, therefore, where the latter appears, the law ought, and, indeed, does, presume the former. This judgment, therefore, did not only murder Sir Walter Raleigh, but, in this instance, subverted the constitution, and ought to be looked upon, not only as an act of the basest prostitution, but as the most flagrant violation of justice that ever was committed."

The sentence of death was pronounced on him one day, and put in execution on the following, Oct. 29, 1618, in Old Palace Yard. His behaviour on the scaffold was calm and manly. He addressed the people at some length; he said he never feared death, and much less at that time; that as to the manner of it, though to others it might seem grievous, yet for himself, he had rather die in this way than in a burning fire. He desired to see the axe, and feeling the edge of it, said to the sheriff, "this is a sharp medicine, but a sure remedy for all evils." Being asked which way he chose to place himself on the block, he replied, "to the heart be right, it is no matter which way the head lies," and giving the signal, he received the stroke with the most perfect composure. Such was the end of the illustrious Sir Walter Raleigh, in the 66th year of his age, by a sentence which was regarded as one of the most dishonourable measures of an odious administration. The panegyrick upon his character by Dr. Campbell is much too highly coloured: Sir Walter Raleigh was not faultless, though in extent of capacity and vigour of mind he had few equals in an age that abounded with great men. His imprisonment was the occasion of his obtaining a high reputation as an author. His writings were on various topics, and are classed as poetical, geographical, political, philosophical, and historical. They are now but little known. His "History of the World," though not much read, is regarded with respect, as one of the best speciments of the English language of that time; the style is pure, nervous, and without pedantry. It is the style of a man of business as well as of a scholar. It has been many times reprinted, but the best edition is that of Oldys, in 1736. He brought down his history no farther than the overthrow of the Macedonian empire. Of his miscellaneous works, a collection in two volumes 8vo. was printed in 1748. Biol. Brit. Hume. Campbell. Cayley.
and parish in the hundred of Rochford, and county of Essex, England, is situated at the distance of 14 miles S.E. by S. from Chelmsford, and 34 miles E. by N. from London. This place appears to have been anciently of considerable note. It was the head of the barony of Swene, and had a castle adjoining to it, of which some fragments and earth-works still remain. These consist of a mount, with an oval-shaped bate, surrounded by a double ditch and rampart, and several outworks, particularly on the east side. The summit of the mount is divided; the western division being of a circular form, and 100 feet high; and the eastern one of an oval form, and lower: the principal ditch varies in width from 36 to 50 feet, and the interior vallum is 50 feet high. The church here is an acent edifice, and contains an old tomb, greatly mutilated, but displaying the remains of very beautiful workmanship in the pointed style. The parson whose memory it was intended to preserve is now unknown; the upper part, to which the inscription was probably affixed, being totally destroyed. The market at Raleigh is held on Saturday, weekly; and there is an annual fair on Trinity Monday. Hearne, in his edition of Leland's Itinerary (vol. iii. p. 8.), informs us that a custom-courthas been kept here, yearly, the Wednesday next after Michaelmas day. "The court," says that author, "is kept in the night, and without light, but as the eye gives, at a little hill without the town, called the King's hill, where the fieward writes out the fines, with coats, and not with inche; and many men and manors of great hold worth of the same; and do sit unto this strange court, where the fieward calls them with as low a voice as possible he may; giving no notice when he goes to the hill to keep the fame court; and he that attends not is deeply aperiod, if the fieward will. "Tis commonly called Lawley-Court." Weaver, in his "Funeral Monuments," adds, respecting this custom, that he was informed, "that this vile attendance was imposed at the first upon certain tenants of divers manors hereabouts, for conspiring in this place, at such an unfeasible time, to raise a commotion." According to the parliamentary returns of 1811, Raleigh parish contains 162 houses, and 1131 inhabitants.

Raleigh, a township of Essex county, in Upper Canada, W. of Harwich, bounded on the N. by the Thames, and S. by lake Erie.

Raleigh, a town of America, in Wake county, North Carolina, the present seat of government, about ten miles from Wake court-house. The general assembly of the state in December 1791, appropriated 10,000l. towards erecting public buildings, and named it after the celebrated sir Walter Raleigh, under whose direction the first settlement in North America was made at Roanoke Isle and in Albemarle Sound. The state-house is a large handsome building, and called Gebäuden. The plan of the town is regular; the streets intersecting each other at right angles. It is, however, subject to the disadvantage of being remote from navigation; 61 miles N.E. of Fayetteville, 167 from Petersburg in Virginia, and 448 S.W. of Philadelphia.

RALEMO, a river of Chili, which runs into the Pacific ocean, S. lat. 37° 56',

RALENDORF, a town of the duchy of Carinthia; 12 miles S. of Sarengen.

RALESTEDE, a town of the duchy of Holstein; 8 miles E. of Hamburg.

RALICOTT, a town of Hindoostan, in Vindapour; 31 miles N. of Amalfagar.

RALENTANDO, Ital., a musical term of late invention, for relaxing the measure at particular parts of a composition, which, when done by a great master, manifests feeling and intelligence; but when attempted by mean performers, it has no other effect upon an audience than that of breaking time; and we think that this refinement is often abused. It has been chiefly practised in France, andfavours of affectation, and that overcharged tenderness which renders the national airs tendres so disagreeable, or fo ridiculous, to the natives of all other countries.

RALLUS, the Rail, in Ornithology, a genus of birds of the order Grallae; the generic character is, that the bill is thickish at the base, attenuated on the back towards the tip, compressed, a little incurved, pointed; the tongue is rough at the tip; the body is compressed; the tail is short; the feet have four cleft toes. There are seventeen species.

*CAEN; land rail, crake, corn crake, daker hen, &c. Of this species the wings are of a rusty red; the bill and legs of a brownish-grey; the irides are of a hazel colour; the feathers of the body are of a reddish-brown; the upper ones are black in the middle; the chin is very pale, and the belly is of a whitish-yellow. It is about nine or ten inches long, and inhabits the sedgy parts of Europe and Asia. From the circumstance of its appearing at the same time with the quail, and frequenting the same places, it has been denominated the king of the quails. Its well-known cry is first heard as soon as the grats becomes long enough to shelter it, and continues till the grats is cut. The bird, however, is seldom seen, as it skulks in the thickest parts of the herbage, and runs so nimbly through it, winding and doubling in every direction, that it is difficult to come near it. When it is hard pushed by the dogs, it sometimes stops short and quats down, by which means its too eager pursuer overthrows the spot and loses the trace. It seldom springs but when driven to extremities, and generally flies with its legs hanging down, but never to a great distance. As soon as it alights, it runs off, and before the Fowler has reached the spot, the bird is at a considerable distance. It emigrates, appearing with us about the latter end of April, and departing in October. On its first appearance, and till the female begins to fit, the male is frequently heard to make a fingular kind of noise, much resembing that of a comb when the finger is drawn along the teeth of it, and which has been used as a decoy. When they first arrive, they are very lean, but before their departure, they become exeeffively fat, and are much sought after for the delicacy of their flesh. They lay from twelve to sixteen eggs in the grats, of a dirty whith colour, with a few yellow spots: the flesh is excellent. There are two varieties, thus described: 1. Rufous brown, beneath paler; wings and tail deeper; the chin and vent are white; the legs are dusky red. This is found in the island of Jamaica. The bill is larger and black. 2. Reddish-grey beneath, and wing-coverts rusty brown. This species inhabits China: the legs are of a dusky colour.

AQUATIC; Water Rail. Wings grey spotted with brown; flanks spotted with white; bill orange beneath, but black and reddish at the base; the irides are red; the feathers of the upper part of the body are of an olive-brown, and black in the middle; the lower ones are cinereous; those of the lower part of the belly and vent are edged with rufous; quill-feathers dusky; the lower tail-coverts are white; the tail-feathers are short and black; the two middle ones at the tip, and the others, are edged with ferruginous; the legs are of a dusky red. It is about twelve inches long, but does not weigh more than four ounces. It is found in the watery places in Europe and Asia. It is sometimes, but not in any
any great numbers, met with in various parts of Great Britain, in low situations, about watercourses and rivulets, where it seeks shelter among fedge, rushes, and reeds, and is seldom put to flight, depending on its legs for safety. When aroused it flies only to small distances, and in a heavy and very awkward manner, with its legs hanging down. It runs nimbly, and frequently flips up its tail. The neck is made of fedge and coarse grals, among the thickest aquatic plants, or in willow beds. The female lays six or more eggs, rather larger than those of a blackbird, of a pure white colour. This bird continues with us all the year, and by many it is erroneously believed to be the land rail metamorphosed in the autumn; but the different bills which the two birds have constitute an essential distinction.

* Porzana; spotted gallinule, or spotted water hen.

This species has the middle tail-feathers edged with white; the bill and legs are of a pale olive. It inhabits Europe and North America, and is generally found on the shores of small streams, hiding itself among the rushes; it is nine inches long. This bird is describably as having a greenish-yellow bill; its irides are hazel, and head brown, spotted with black. The line over the eyes is of a pale grey; the neck above and flanks are of a brown-ash, with small white spots; the back and wing-coverts are olive, with black stripes, and near the edges of the feathers with white spots, the greater with white stripes and lines; the cheeks, chin, and throat, are of a pale grey, with brown spots; the breast is brown, with white spots; the belly is variegated with cinereous and white; the vent is of an ochre-yellow. This bird is extremely timid and sanguine, and is seldom seen in Great Britain, eluding observation by its perpetual vigilance and lurking habits. Its neck is formed, with singular care, of matted rushes, and materials which will float on the water, on which it remains tied, by some filaments, to the flanks of reeds, by which it is prevented from being carried away by the tide or current. The bird is in great esteem for the table.

**Crepitans; Clapper Rallus.** Bill and legs brown; body above olive, the feathers ash at the edges; chin white, throat and breast yellowish-brown. This species inhabits New York, and is from fourteen to sixteen inches long.

* Fuscus; Brown Rallus.*** This is brown, as its specific name imports; its vent is waved with white; the legs are yellow. It inhabits the Philippine isles, and is seven inches long. The body beneath is light chestnut, on the belly it is inclining to grey; the tail is barred with white and black.

**Striatus; Streaked Rallus.** Blackish, waved with white; chin reddish. The bill of this species is of a horn colour; the crown is varied with dusky and bay; the nape is bay; neck, back, shoulders, and rump, brown, with whitish spots; the wing-coverts are marked with a few tranverse whitish streaks; the chin is of a reddish-white; the cheeks, throat, breast, and upper part of the belly, cinereous, with a tinge of olive; the lower part is barred with dusky and white; quill-feathers brown, the outer bands reddish-white, the inner are white; the tail is brown with white lines; the legs are of a greyish-brown. It inhabits the Philippine islands, is eight inches long, and is probably a variety of the philippensis.

**Torquatus; Banded Rallus.** Brown, beneath waved with white; it has a white line below the eyes. This also is found in the Philippine isles, and is twelve inches long. The bill and legs are grey-brown; cheeks and chin black. The body beneath is tranversely streaked with black and white; the collar is of a bay colour; the quill-feathers on the outer edge paler; bands within on the first three white, the next reddish-bay.

**Philippensis; Philippine Rallus.** The specific character of this bird is brown, but beneath it is barred with grey; the eye-brows are white, and the neck beneath has a reddish cast. There are three other varieties, thus described: 1. Red-brown, spotted and streaked with black and white; head chestnut; body beneath and eye-brows cinereous; this, notwithstanding its name, is found at Otaheite. 2. Brown, spotted and streaked with white, beneath white; eye-brows grey; the tail is barred with brown and white; this inhabits Tongataboo. 3. Above brown, beneath ash; back and wings lined with white spots; the belly beneath is white, with blackish bars. This is about eleven inches long, and is found in the Philippine islands.

**Ecaudatus; Tailless Rallus.** Olive; beneath blueish; body tranversely waved with black; eye-brows white. It inhabits Otaheite. The bill is blackish, and the upper part of the head is of a pale brown; the orbits are black; over the eyes, on each side the head, it has a broad white line; the body above is of a deep glossy olive, with a tinge of olive on the shoulders; the vent is of a pale yellow; the tail is so short as to be scarcely perceptible; the coverts are of a pale blue.

**Carolinus; Soree.** This bird is brown; the frontlet is black; the breast is of a lead colour; the bill is yellow; the legs are greenish. It inhabits Virginia, and is from seven to eight inches long; this is a capital bird for the table. The irides of this bird are red; the crown and body above are brown, marked with black spots; the face and chin are black; but the rest of the neck, temples, and breast, are of a blueish-ash; the belly and outer edge of the wings are white; the wings and tail are brown.

**Pheniculus; Red-tailed Rallus.** This species is black but beneath it is white; the bill and legs are greenish; the front is naked and of a flesh colour; the vent and tail of a rufly red. It is found in the island of Ceylon, and is about nine inches long. The bill and legs are tinged with red; the crown and cheeks are pure white; the quill-feathers are spotted with blue. There are two varieties.

**Above cinereous, beneath white; the belly and vent are red.** This is an inhabitant of China, and is fifteen inches long. 2. The front of this is white; the vent is red, and the legs are yellow. It is found in Madagascar, and is longer than the last.

**Virginianus; Virginian Rallus.** Brown, without spots; the bill and legs are brown. It inhabits Virginia, and is probably a variety of the R. aquatilis.

**Ferrugineus; Red-breasted Rallus.** This bird is dusky above, and cinereous beneath; the neck and breast are ferruginous; the bill is pale, and the legs yellow. It is nine inches long; the eye-brows are pale; the flanks are marked with tranverse, narrow, white lines.

**Capeensis; Cape Rallus.** This species is of a ferruginous colour; but the lower part of the breast, belly, vent, wings, and tail, are waved with black and white; the bill is black, and the legs are of a blood-red. It inhabits the Cape of Good Hope and Ceylon, and is of the size of the R. crex. The two middle tail-feathers are ferruginous.

**Ceruleus; Blue-necked Rallus.** This is of a bay colour above, but blueish beneath; the bill and legs are red; the vent is white, and the belly is marked with transverse black streaks. It inhabits the Cape of Good Hope; it is seven and a half inches long.

**Zeylanicus; Ceylon Rallus.** The head of this bird is dusky; the body above is ferruginous, beneath it is reddish, waved with brown; the first quill-feathers are black; the
bill and legs are red. It is found, as its name imports, at Ceylon; it is larger than the R. aquaticus, and has a long tail.

AUSTRALIS; Trogloidyte Rallus. Ruddy ah; wings and tail-brown; the feathers are barred with black. It inhabits New Zealand, and is seventeen inches long. The bill and legs are yellowish; the body above is of a rufly brown, beneath rufly ah; quill and tail-feathers are waved with black.

PACIFICUS; Pacificus Rallus. Black, speckled with white; wings barred; the head is brown, the breast is of a blueish-ah. It is found in Otaheite, and the neighbouring isles. Bill red, the legs are of a flesh colour; the chin and eye-brows are white; the neck of the ruin is rufly.

TABUENSIS; Tabuan Rallus. Brownish-black; beneath it is of a dully colour; the bill is black, and the legs are bay. A variety has its vent streaked with black and white; the legs are red. It inhabits the South-sea islands, and is six inches and a half long. The eye-lids and irides are red.

NIGER; Black Rallus. Black; bill red at the base, brown at the tip; the legs are brown or red. This is an African bird, and is nine inches long.

SANDECUENCIS; Sandwich Rallus. This is of a pale ferruginous colour; but the bill is of a dusky ah; the legs are of a dull flesh colour. A variety has a yellowish bill and legs. It inhabits the Sandwich isles; and another variety is very small, and found in the Tanna isles.

TAITIENSIS; Otaheite Rallus. Cineous; body above red-brown; the bill, rounded tail, and claws, are black. This inhabits Otaheite and the Friendly isles, and is about six inches long. The quill-feathers are dusky and edged with white; the legs are yellow.

OCCIDENTALIS; Dusky Rallus. This is brown streaked with black, beneath it is of a rufly brown; the bill is black, and the legs are of a red-brown. It inhabits the Sandwich isles, and is six inches long; the edge of the mandibles is yellowish.

LONGIROSTRIS; Long-billed Rallus. The upper part of this species is cinereous, spotted with brown, beneath it is rufly white; the flanks are transversely waved with white, the bill is long and of a ferruginous colour. It inhabits Cayenne, and is from nine to twelve inches long. The bill is tipt with brown; the legs are yellowish, and the chin whitish.

VARIEGATUS; Variegated Rallus. This bird is streaked and spotted with white and black; the hind-head is dusky; the bill is yellowish; the chin is white; and the legs are yellow. It inhabits Cayenne, and is eleven inches long. The wings are brown, the covert is spotted with white; some of the middle tail-feathers are edged with white.

CAVENNNIS; Cayenne Rallus. The crown of this bird is rufous; the body above is of an olive-brown; beneath it is rufous; the ocular hand is blackish; the quill-feathers are black; the bill is brown, and the legs bay. There is a variety having its crown bay; chin and vent reddish-white. It inhabits Cayenne and Guiana; it is eight inches long; in the evening it is noisy and gregarious, by day it is solitary; it builds in the forkt branch of a shrub, near the ground. The vent is pale.

JAMAICENSIS; Jamaica Rallus. Above reddish-brown with black streaks; the bill and chin are black; the throat and breast are of a blueish-ah; the belly is marked with white and brown lines. It, in its name imports, inhabits Jamaica, and is five inches long. The bill is reddish at the base; wing-coverts brown, spotted with white; the quill-feathers are of a reddish-brown, with black lines, the secondaries and tail-feathers are spotted with white, and the legs brown.

MITRUS; the Little Rallus. This is brown, but beneath it is yellowish; eye-brows, streaks on the back, and spots on the wing-coverts, white; tail barred black and white. A variety has the middle of the neck above rufous; the belly and vent are waved with black and white. It inhabits Cayenne and Jamaica, and is five inches long. The bill is brown; the wing-coverts are black; the chin is whitish, and the legs are yellow.

PUILLUS; Dwarf Rallus. Striped with ferruginous and black; the body beneath is blackish, with narrow white bands; the throat and breast are blueish. This is found near salt lakes of Dauria, and is of the size of a lark. The face, neck beneath, and middle of the breast longitudinally, are blueish; the middle of the chin is whitish; the longitudinal band through the eyes of a pale rufly colour; the back is scattered with white longitudinal lines; the legs are greenish.

BARBARICUS; Barbary Rallus. This is of a ferruginous colour; the bill is black; the wings are spotted with white; the rump is streaked above with white and black, and beneath with white; the legs are of a dusky brown. This, as its name imports, is an inhabitant of Barbary, and is the size of a plover.

DUBUS; Doubtful Rallus. Striped with brown and ferruginous; the belly is white; the flanks are barred with brown and rufly ah; the first quill-feathers without are longitudinally white. It is the size of the common gallinule. The face is of a pale rufly colour; the chin is of a dirty white, surounded with a broad brown collar; the fides are brown; the bill and legs greenish-black.

RALLYING, or War, the reassembling, or calling together of troops, being confuted, and put to flight.

RALPH, James, in Biography, a miscellaneous writer, defended probably from mean parentage, was the intimate friend of Dr. Franklin, who speaks of him as ingenious and shrewd, gented in his address, and extremely eloquent. Franklin knew him in America, and though he does not mention what Ralph's situation then was, yet as he wrote a fine hand, and was well versed in accounts, it is imagined he was a schoolmaster. In 1725 Ralph accompanied Franklin to England, with a resolution of not returning to America, where he left his wife, with whom, and with whose family, he had lived on ill terms. In London he was, for a considerable time, supported by his friend Franklin, till their intimacy was dissolved, when Ralph considered the quarrel as a complete discharge of the debt which he owed his benefactor. Ralph changed his name to that of Franklin, which he thought necessary, having formed a new female connexion, and settled as a schoolmaster in a village in Berkshire. From this time there is no regular narrative of his life, which was probably passed as a hired party writer. He is spoken of with much-contempt in the Dun-grad, as the author of a poem called Night: —

"Silence, ye wolves! while Ralph to Cynthia howls, And makes night hideous—Anfwer him, ye owls."

In a note, it is said he wrote a fawing piece, entitled "Sawney," very abusive of Swift, Gay, and Pope; that he panegyrised his own works in the journals, was wholly illiterate, wrote plays, and was employed in a political newspaper. The late Pope must be taken with much limitation, it being inspired by party motives: Ralph having recommended himself to persons in power at the beginning of George II.'s reign, would for that reason be obnoxious to Pope and his friends. He became an able writer.
RAM

writer in prose, and was author of many political pamphlets, which were much applauded in their time; but his chief work was "The History of England during the Reigns of William, Anne, and George I.," with an introductory Review of the Reigns of the Brothers Charles II. and James II., in which are to be found the Seeds of the Revolution. By a Lover of Truth and Liberty," 2 vols. fol. 1774—6. This work obtained the plaudits of Mr. Fox, who, in his posthumous historical fragment, speaks of the author as "the historian of great acuteness as well as diligence. The last publication of this author was entitled "The Cate of Authors by Profeffion or Trade, stated with regard to Booksellers, the Stage, and the Public," which is laid to contain much good sense and lively fatire. Mr. Ralph died at Chiswick, in the year 1762. Gen. Biog.

RAM, in Geography, a town of European Turkey, in Servia, on the S. side of the Danube; 10 miles E. of Paffarowitz.

RAM, in Agriculture, the male of the sheep kind. It may be observed, that the rams of different breeds of sheep vary greatly in their forms, woods, and fleeces, and other properties; but the following description by that excellent flock-farmer, Mr. Culley, defcures the attention of the breeder and grazier. According to him, his head should be fine and small, his nostrils wide and expanded, his eyes prominent, and rather bold or daring, ears thin, his collar full from his breast and shoulders, but tapering gradually all the way to where the neck and head join, which should be very fine and graceful, being perfectly free from any coarse leather hanging down; the shoulders broad and full, which mutt at the same time join so easy to the collar forward, and chine backward, as to leave not the leaf hollow in either place; the mutton upon his arm or fore-thigh must come quite to the knee; his legs upright, with a clean fine bone, being equally clear from superfluouf skin and coarse hairy wool from the knee and hough downwards; the breast broad and well forward, which will keep his fore-legs at a proper widenefs; his girth or cleft full and deep, and in- stead of a hollow behind the shoulders, that part by some called the fore-fflank should be quite full; the back and loins broad, flat, and straight, from which the rum-mand rife with a fine circular arch; his belly straight, the quarters long and full, with the mutton quite down to the hough, which should neither fland in nor out; his twill, or junction of the infide of the thighs, deep, wide, and full, which, with the broad breast, will keep his fore-legs open and upright; the whole body covered with a thin pelt, and that with fine, bright, loof wool. It is observed, that the nearer any breed of sheep comes up to the above defcription, the nearer they approach towards excellence of form.

But though this is a very correct, appropriate, and admir-able description of a finely-formed ram, objections have been made by fome to a few of the properties which are laid down. Width and expansion of the nostrils in sheep, it is suppos'd, are liable to caufe the lower parts of the nofes to be too thick and large; while in naturally good and improved forms, the lower parts of the nofes and mouths are for the most part small. Nor is the pro- minent and bold daring eye held in more estimation, as it is thought not to fiew a good difposition; but, on the contrary, to displa'y too much quicknefs and activity, or wildnefs of nature in the animal. Opinions, however, differ much on this point among sheep-farmers; and a lively quick eye is almoft always considered as favourable to a good difposition.

Rams naturally poifefs more boldnefs and courage than either wethers or ewes; and they are very apt, unless great care is taken, to acquire mischievous habits of attack- ing perfo ns or animals that may by accident approach them.

In some sheep-diftrics the breeders are greatly in favour of large rams, but in others fome of a fmalier fize are prefer-red; the choice of the fize of the rams fhould, however, in every inftance, be regulated by the nature and abundance of the keep, or the quality of the lands, as it is utterly im- poifible that the inferior forts of pastures can keep sheep flock of the large fize, as in thole of the better kinds; and it would be highly disadvantageous in the beft riche forts to have a small-sized flock when they could support a large one in an equally perfect manner. Middle-sized rams are, upon the whole, the moft fuitable and proper for lands in general, and for all the purpofe of the breeder.

The growth and conftitutions of young rams should never be fuffered to be endangered by their having too great a number of ewes, as is too frequently the practice with sheep-breeders.

It is a very improper custom, but one which prevails with the graziers in fome sheep-diftrics, to keep all their rams, perhaps to the amount of from twenty to fifty or more of all kinds, in one field or pature; as their contentions are often fo violent, especially about the riding time, as to caufe the fols of one or two rams to each in all fuch cafes. This practice is the moft common in the sheep-diftricts to- wards the southern part of the island, being feldom met with in thole of the midland or more northern parts. It ought to be every where done away with.

The old rams are now almoft always got quit of by being fattened as rams, and fold at the neighboring markets, or to butchers, at a very inferior price, there being often much competition for this fort of low-priced meat in fome situations. It was formerly, however, the custom in fome places to knit them before they were fattened and fold to the butchers or otherways, but much injury and lots being found to be foltrained by that method, it has been left off; it being now concluded, on the whole, that the lots by knitting the rams is greater than that which is fuffered in the re- duction of the price of ram mutton.

The practice of letting out rams in the midland diftricts for the purpose of improving the breeds of sheep, having produced fuch beneficial effects, the rife, nature, and pro- grefs of it may deferve the attention of the flock-farmer. It has been ably and accurately delineated, in the following manner, by Mr. Marlhall, in his Rural Economy of that part of the kingdom.

It is flated, that in this diftrict, in general, the manage- ment respecting rams is fimilar to that of other parts of the island; the breeders rearing or purchafing them. But that it is observa ble, however, that the advocates of the old breeds, though they will not adopt the modern flock, have fallen, in some degree, into the modern practice of letting by the fefon. But that the rams of the modern breed are never fold; but are palled from breeder to breeder, by the fefon only. And that for the purpose of promoting this inter- course, each principal breeder has his float of rams; commencing, by common confeft, the 8th of June, and lafiting until Michaelmas, or until the fefon of letting be palled. That during a few weeks after the shows commences, every ram-breeder may be faid to keep open house. Breeders and others, from all quarters of the kingdom, as well as the promoters of the breed who reside in the neighbourhood, attend these shows; going, in parties, from one to another; fome to take, others to fee and pafs their judgment. And that these private exhibitions clofe with a public show, at Leicester, the roth of October; when rams of every defcription, but moftly an inferior fort of the improved
proved breed, are collected; being brought in wagons; many of them from a considerable distance; some to be field, but chiefly to be let for the season. That this show has been held, he believes, time immemorial; not, however, for the purpose of letting, but for that of sale. But the letting of rams by the season, has long, he understands, been a practice in Lincolnshire. However, the origin, in the midland districts, may be traced—to a ram let by Mr. Bakewell, at Leicester fair, about forty years ago, at the low price of sixteen shillings. But humble, however, as was this beginning, it proved, Mr. Marshall says, to be the first stone of the foundation of a department of rural busines, that has already risen to an astonishing height, and may, for some length of time, continue to bring in a copious source of wealth to the country. In the management of this busine, the principal ram-breeder fave annually, twenty, thirty, or perhaps forty ram-lambs; castration being seldom applied, in the first instance, to the produce of a valuable ram. For, in the choice of these lambs, they are led more by blood, or parentage, than by form; on which, at an early age, little dependance can be placed. He adds, that their treatment, from the time they are weaned, in July or August, until the time of shearing, the first week in June, confonts in giving them every indulgence of keep; in order to push them forward for the show: it being the common practice to let such as are fit to be let the first season, while they are yet yearlings—provincially fiarhogs. Their first pasturage, after weaning, is pretty generally, he believes, clover that has been mown early, and has got a second time into head: the heads of clover being confidered as a most forcing food for sheep. After this goes off, turnips, cabbages, colewort, with hay, and report fays, with corn. But the use of this the breeders feverally deny, though, collectively, they may be liable to the charge. However this may be, something confiderable depends on the art of making up—not lambs only, but rams of all ages. Fat, like charity, covers a multitude of faults; and, beside, is the bell evidence their owners can produce, of their fattig quality, —their natural propensity to a state of fatness; while in the fates of the fiarhogs is feen their degree of inclination to fat at an early age. And that the fattig quality being the one thing needed in grazing flocks, and being found, in some confiderable degree at birth, to be hereditary,—the fatter rams are of course the left; though other attachments, well or ill placed, as to form, or fashionable points, will perhaps have equal or greater weight in the minds of some men, even in this enlightened age and diftrict. And the shearings, which will not make up sufficiently, as to form and fatness, are either kept on to another year, to give them a fair chance, or are castrated, or butchered, while fiarhogs.

With regard to the flowing, it is remarked, that the shows of the principal breeders confift, by common confent, of forty rams each, moftly from one to five years old, they being seldom found efficient after that age; some, however, will continue in vigour to the fifth or seventh year. And that, during the show, they are moftly kept in small inclosures, of two, three, or four acres; with three, four, or more rams in each, according to their ages, and the advancement of the fason. And in a corner, or other convenient part of each paddock, a small pen, made with hurdles, is placed; for the purpose of handling them. Into these pens they go, through custom, as tractably as worked oxen to their stalls. Indeed, the old rams, from the unwieldines of their frame, and the load of fat they have to carry at this fason, as well as from habit, will suffer themselves to be handled abroad; and even appear to take pleasure in the respect with which they have been treated. But it is observed, that of late a new method of flowing has been tried out by the leading breeder, and adopted by one at least of his followers. Instead of flowing them abroad, and driving three or four of them up together in a pen, they are shut up in bowls, and brought out separately, being never seen together. He thinks, that among accurate judges, this mode of flowing may be well enough; but to those who have had less experience it gives offence, as it deprives them of their best guide, comparison; and he can see no fair advantage accruing from it to the latter.

It is remarked, that though the defirable points of a ram are such as have been noticed, the choice of the hirer is determined, in some measure, by the intention for which he is about to hire: as whether it be that of getting wedders, or mere grazing flock: or rams for the purpose of letting. Hence the grazier and the ram-breeder choose different sheep, so as to suit their different purposes. He adds, that the characteristic difference between what is termed a ram-getter, and a wedder-getter, or a good grazier’s sheep, is that of the former being every where cleaner and finer, the head small, the bone and offal light, the flesh good, and the form beautiful. The mere grazier likes a ram no worse for having a strength of frame, and is less scrupulous about his form than the ram-breeder, whose great object is fineness: his ewes, and the natural tendency of the breed, serve to give his offspring size and substance when it is wanted.

In respect to the practice of letting, it is observed, that a novel circumstance has likewise taken place lately in the busines of letting. The traditional custom of letting a price was exploded, at least by the late Mr. Bakewell, and one of his disciples; whose customers were left to make their own valuations, and bid what they pleased. But this, as well as flowing them separately, it is observed, gives great offence, especially to strangers, who cannot brook the idea of being both buyers and sellers. The latter, however, has more than one advantage in referring the price, provided he do not thereby drive away his customers: he is, in effect, letting to the best bidder.Besides, he is, through this means, enabled to regulate his prices to his customers, without giving any of them pointed offence: for as the principal breeders are, in the main, of their busines, competitors, it is no more than common good policy, in the leader at least, to advance himself, and keep back those who press upon him closely. It is, therefore, good management, Mr. Marshall thinks, in him to let a superior ram to an inferior breeder, whose ewes are yet of bafe blood, at a lower price than to one who is farther advanced, and whose ewes perhaps are nearly equal to his own: for if the hirer may not thereby be able to get the lead from him, he may run away with part of the best prices; and the only line the leader has to tread is, either to refuse him, or to make him pay in the first instance. And again: sometimes two or three capital breeders will join in the hiring of one superior ram; and, in this case, the blood being more widely dispersed, the price ought to be, and always is advanced, in proportion to the number of partners there may be in the busines. Hence, in the leader, a refervation of price may be allowable, especially in the letting of first-rate rams.

He observes, in regard to the conditions of letting, that notwithstanding the number of years the letting of rams has now been in use, and the extraordinary height to which the prices have risen, the transaction does not appear to have yet received any settled form; nor to have been rendered legally binding, by any written articles, or conditions of letting; much being still left to the bonour of the parties. It is, however, generally understood, that the price agreed upon...
RAM.

upon shall not be paid, unless the ram in contract, or another as good, impregnate the stipulated number of ewes. If, through accident or inability, part only be impregnated, a proportional part of the price is abated. If he die while at ride, the los falls on the latter, whether his death happens through accident or neglect; no cates, he understands, having yet been otherwise determined. It is likewise under- flood, that the herdsman shall not suffer him to serve any other than his own ewes; and of these, no more than a stipulated number, which is proportioned to the age or ability of the ram, and the mode of using him. And further, that if a grazier hire a valuable ram, at a wedder-getter's price, (which is not unusual at the wane of a season, when valuable rams happen to be unlet,) it is under-flood, or rather agreed, that he shall not fear rams from him; a condition which may frequently be advantageous to both parties. The letter pockets five or ten guineas, which otherwise he might not have had; and the herdsman, by suffering himself to be "tied down," as it is termed, gets a greater improvement in his stock than otherwise he could have got for the same money. He adds, that the time of paying the money is, he understands, unfixed; feldom, he believes, until after the ewes have brought proofs of the ram's efficiency, or after the lambing season.

It is observed, that with regard to the prices for letting rams by the season, that from the first letting to the year 1780, the prices kept gradually rising from sixteen shillings to a guinea, and from one guinea to ten. In 1780, Mr. Bakewell let several at ten guineas each; and what is rather inexplicable, Mr. Parkin of Quarendon let one, the same year, for twenty-five guineas, a price which then astonished the whole country. That from that time to 1786, Mr. Bakewell's stock rose rapidly, from ten to a hundred guineas; and that year he let two-thirds of one ram (referring one-third of the usual number of ewes to himself) to two principal breeders, for an hundred guineas each; the entire services of the ram being rated at three hundred guineas. This excellent breeder making that year, by letting twenty rams only, more than a thousand pounds! and that, since that time, the prices have been still rising. Four hundred guineas have been repeatedly given. The above breeder, this year (1789), makes, he understands, twelve hundred guineas by three rams, (brothers he believes,) two thousand of seven, and of his whole letting full three thousand guineas! And that he now lets nothing under twenty guineas; a well-judged regulation, which Mr. Marshall thinks will probably be beneficial both to himself and his customers.

It is added, that, beside this extraordinary sum made by Mr. Bakewell, there are fix or seven other breeders who make from five hundred to a thousand guineas each. The whole amount of monies produced this year, in the midland counties, by letting rams of the modern breed for one season only, is estimated, by those who are adequate to the subject, Mr. Marshall thinks, at the almost incredible sum of ten thousand pounds. He knows that it is a popular idea, especially of those who, living at a distance, have only heard of these extraordinary things, without having an opportunity of coming at facts, that the extravagant prices which are talked of are merely nominal; the principal part of the money being returned, the actual prices given being small, in proportion to those held out. This, however, is, he believes, and on the best authority, an erroneous idea. At the first setting out of the high prices, there might be some transfigurations of that nature; but if ever they existed, they have ceased long ago. Mr. Bakewell at present has the name, at least, of being parimonious, even to the shepherds of the flocks on which his rams are employed. His highest present, he understands, is five shillings; if the price be under fifty guineas, only half-a-crown. But the enormousness of these prices may be explained, he thinks, on other grounds. The high prices are not given, he says, by graziers, for the purpose of getting wedders as grazing flock; but by ram-breeders, for the purpose of getting rams, to be let to graziers; the highest being given by the principal breeders only, not for the purpose of getting rams to let to graziers as wedder-getters, but for that of getting rams, to be let out again to inferior tup-men, as ram-getters.

It is further stated, that the graziers' prices run, even now, from one to ten guineas. He has not heard of more than ten guineas being given, by a mere grazier, for a ram, for the sole purpose of getting grazing flock: five or six guineas is the common price. And supposing he gives the highest price, ten guineas, and that the ram serves a hundred ewes, (some single, some double,) the expense of getting amounts to no more than two shillings a head; which is incomparable, compared with the difference between a well and an ill grazing sheep, between a sheep that will get as fat at two years old as another will at three; or, in other words, which will, at two years and a half old, fetch ten or fifteen shillings more than his comrades of another breed, but of the same natural size, and going in the same partures, or feeding on the same sort of food. In respect to the middle prices, as those from twenty to fifty guineas, they are, under the present circumstances, equally reconcilable, he thinks, to common sense. If a breeder, who gives fifty guineas, rear ten tolerable rams fit for the grazier's use, and let them at five guineas each, he brings himself home, even the first season of letting, besides having the rams fit for another season and another flock, and besides a general improvement in his stock for the future. And those who give the higher prices, as one to two hundred guineas, have, or ought to have, proper bales to build upon, sufficient flocks of well-bred ewes; in which case, they have a fair chance of producing ram-getters, worth, while the present spirit of improvement lasts, twenty to fifty guineas a season. And that with respect to the very high prices, they are given by a few first-rate breeders, who are playing a high game, running a hard race, for the pride and profit of being a leader, when Mr. Bakewell is not; a contention which may last as long as Mr. Bakewell, and be at once an honour to his genius, and a reward of his services.

In respect to the treatment of rams after letting, it is remarked that the breeders of rams, as well as of bulls, find it expedient to reduce them to the eumorphous state in which they are shown, previously to the season of employment; the old rams, in particular, being frequently returned upon their hand, non-efficient. Hence, as they are let, they are transferred to private partures, and moderate keep; it being a pretty general rule not to show a ram after he is let, or contracted for to a person.

In the feeding out on let rams, the usual time of beginning is the middle of September: the means of conveyance, carriages of two wheels with springs, or hung in sholts; some of them being large enough to hold four rams. In these they travel from twenty to thirty miles a day; being sometimes sent, in this way, two or three hundred miles, and sometimes more.

It has been observed by the same writer, that the manner of using these rams has lately received a very great improvement. Instead of turning them loose among the ewes at large, as heretofore, and agreeably to the universal practice of the island, they are kept apart, in a separate paddock or small
small inclosure, with a couple of ewes only each, to make them roll quietly; having the ewes of the flock brought to them singly, and leaping each only once. He thinks, by this judicious and accurate regulation, a ram is enabled to impregnate near twice the number of ewes he would do, if turned loose among them, especially a young ram. And he adds, that, in the old practice, fifty or eighty ewes were esteemed the full number for a ram; in the new, from a hundred to a hundred and twenty are allowed. Seven score have been served by one ram in a season: this, however, much too great a number.

And while at ride, the treatment of the ram is merely that of keeping him well, and free from disorders; suffering him to serve no other than the hirer's own ewes, and of these the limited number only, and to return him safe when he has done; generally the beginning of December: or, if the hirer has met him on the road, (which is customary,) the latter, in return, meets him on his journey home. And the after treatment consists in stirring, by every devious means, to reload his carcase, and make him fat and handsome for the ensuing show, in order that he may be let again with advantage.

This is the whole of the plan that was pursued in that district, which has led the way to so much improvement in the breeding of sheep, and from which the country has derived such vast benefits, and such a number of advantages. But though the above practices have not been lately carried on to their former extent, they are still very considerable. See Sheep.

It is remarked, that the practice of hiring rams in Romney Marsh is not carried on with the same degree of spirit as it is in Leicestershire, and that rams were of more value for the hiring feason some time ago than they are at present, especially when the crofs of the above county took place, as then from twenty to one hundred guineas were frequently given. One graizer some time since let rams to the amount of twelve hundred guineas; but the rage is now over, the people not being so foolish as to be duped out of their money, without the prospect of being repaid. It is here the practice with some to ride their ram lambs; but they are paid always to be injured in their growth, if not in their constitutions and dispositions, by it. When a ram dies while at ride, the losfs falls on the owner, and, before, he is not paid for the riding. The time of paying is when the rams are removed from the ewes. This is done by carrying them away in carts, or leading them by ropes. The ram lambs are here now mostly selected and fattened, in such numbers as are proper for the hirers.

Some time before the riding season, the graizers call and agree for the hiring or purchasing of rams, the general price usually from three to five guineas; but a superior one will bring ten in particular cases, though many good useful ones let at three guineas. Some purchase them to ride, and immediately afterwards sell them in the markets. The rams, which are to be hired, are here flown all together in pasture fields, which is a disadvantagous method.

In Suffolk, until lately, ten guineas were the highest price that was heard of for the sale of any ram. Now some let many of their three-years old rams for fifty; and inferior ones at thirty, twenty, and ten guineas. Some have even been let to high as one hundred guineas.

RAM is also a term used to signify any thing which has a strong smell or taint.

RAM, in Astronomy. See Aries.

RAM of M. Montgolfier, Hydraulics, in Mechanic, a machine for raising water to any given height, which has lately attracted much attention in France. The first person who employed this method was Mr. Whitehurst, and it was afterwards improved by Mr. Boulton. Its construction and use may be sufficiently understood by the following statement. It serves to raise water by means of the momentum of a stream of water flowing through a long pipe. The passage of the pipe being flopped by a valve, which is raised by means of a bar, as soon as the water begins to move sufficiently, the whole column of fluid must necessarily concentre its action almost instantaneously on the valve, and in this manner it leaves the characteristic property of the water, and acts as if it were a single solid; so that, supposing the pipe to be perfectly elastic and inextensible, the impulsive motion overcome any prejudice, however great, that might be opposed to it; and if the valve open into a pipe leading to an air-receptacle, a certain quantity of the water will be forced in, so as to condense the air, more or less, rapidly, to the degree that may be required, for raising a portion of the water contained in it to any given height. Young's Course of Lectures on Nat. Philos. vol. i.

RAM, in Mythology, the name of the highest god among the Gentoos. When a widow offered herself to be burnt on the funeral pile of her husband, she was encouraged by the presence of a number of attendants, who formed a circle around her, and offered her fresh betel, entreating that, as she would in a short time appear with her husband in the presence of Ram, or their highest god, she would supplicate for various favours for them; and above all, that she would salute their decafe friends, whom she might meet in the celestial abodes, in their names.

RAM, Battering. See Aries.

RAM's Horns, in Fortification, a name given by M. Belidor to the tenailles.

RAM-Head, on board a Ship, the name of a great block belonging to the fore and main halliards. It hath in it three shivers, into which the halliards are put, and at its head the eyes are reeved into a hole made there for that purpose.

RAM-Head, in Geography, a cape on the S. coast of Ireland, and county of Waterford; four miles E. of Youghal bay. N. lat. 51° 50'. W. long. 7° 44'.—Alfo, a cape on the S. E. coast of New Holland. S. lat. 36° 56'. E. long. 119° 35'.—Alfo, a cape of England, on the S. coast of Cornwall, in the English Channel, between Whitehead bay and Plymouth found. N. lat. 50° 19'. W. long. 4° 2'.

RAM-Hornuz, a town of Persia, in Chufitan; 65 miles S.E. of Susser or Shuffer.—Alfo, one of the most romantic valleys in Persia, which has been lately placed under the beglerbeg of Behaban. It is fifteen furlongs in length (the furlung being estimated at 32 English miles), and from six to eight miles in breadth. The river Jeraci, entering at the eafen extremity, eows through the centre of it, when meeting the Kkoorkhankeende, which descends from the mountains five miles E. of the town of Ram-Hornuz, they together force a passage through a low ridge of hills, which skirt the valley to the fourth. This fertile spot is, at present, in the hands of five native chief's; the firft of whom is an Arab, who resides in a mean village, situated at the W. end of the valley, and built amidst the ruins of the ancient city of Ram-Hornuz. The remaining four are Persians, and brothers, who have each a castle, or fortified village; from which they make frequent raids, and carry off the corn of cattle of their rivals. A great battle was fought in this valley, between Artaxerxes Babegan, and Ahabanes, in which the former was victorious, and first aliumed the title of "Shah en Shah," or king of kings. Kinneir's Peri. Emp. 1813.

RAM's Island, an Island in lough Neagh, Ireland, about two miles from the shore, and containing about six acres.
acres. It is in the western part of the lough, in what is called Sandy bay, and is the only island. One of the round towers, so frequent in Ireland, is found here, and renders it an interesting object from the neighbouring grounds. Dubourdieu's Antrim.

RAM or RAMLA, a town of Palestine, which was formerly large, and defended with strong walls; celebrated as the place where St. Paul cured Æneas. The Mussulman reverence here the tomb of Locman the wife, and the sepulchres of seventy prophets, said to have been buried here. The church of St. George is the only object now worthy of notice. The place has a kind of market for gall-nuts, fena, and gum arabic, which the Arabs bring hither for sale; 20 miles N.W. of Jerusalem.

Rama, a town of Dalmatia; 20 miles S.W. of Moitar.

Rama, or Ramab, signifying an eminence, in Scripture Geography, a town of Judea, in the tribe of Benjamin, according to the book of Joshua, ch. xviii. v. 20. It was situated towards the mountain of Ephraim, between Gaba and Babel, about seven miles from Jerusalem, according to St. Jerom. This city lay on the road from Samaria to Jerusalem; for which reason Baasha, king of Israel, caused it to be fortified, to obstruct the passage from the land of Judah into that of Israel. This is the Ramatha, or Ramathaim-Zophim, the country of the prophet Samuel. (1 Sam. i. 19. and ii. 11. &c.) It was on the frontiers of Ephraim and Benjamin; and frontier cities were inhabited by both tribes. Jeremiah probably speaks of this Ramah. Jer. xi. 1, 2, 3. See also ch. xxxi. 15, 16, 17.

Rama, a city of Naphthali (Josh. xix. 35.), on the frontier of Apher (Josh. xix. 20.)

Rama, in Hindo Mythology, is the name of a distinguished mortal, in whom their deity Vishnu was incarnated for the purpose of relieving mankind from the tyranny and oppression of Ravana, the malignant king of Lanka, or Ceylon. This incarnation is one of the ten avatars, or defences of Vishnu, and is, in its supposed importance, second only to that of Krishna. It is similarly a popular history, and allusive to it perpetually occurs in the writings and conversation of the Hindoos. The invasion and conquest of Lanka is the subject of one of their finest poems, entitled the Ramayana; it furnishes subjects for the drama, for itinerant bards; and for every purpose of poetry, being replete with magnificent imagery, and abounding in striking incidents. (See Ramayana.) The mortal parents of this divine hero were Raja Dafaratha, king of Ayodisha (Oude), and his first wife Kahunislya. Hence this Rama is sometimes styled Dafar Rama, to distinguish him from other heroic Ramas; and sometimes Rama Chandra, meaning of lunar descent.

There are three persons of the name of Rama, recorded as incarnations of Vishnu. One is Bala Rama, the elder brother, by the same parents, of Krishna; the second, Para Rama; and the third, Rama Chandra, the subject more immediately of this article. But it has been made a question, whether they be not three representations of one person, or three different ways of relating the same history; and whether any or all of them mean Rama the son of Cushi, for W. Jones (A. Ref. vol. i.) says he leaves others to determine. He deems Rama to be the same as the Grecian Dionysos, who is said to have conquered India with an army of fayrs, commanded by Pan; and Rama was also a mighty conqueror, and had an army of large monkeys or fayrs, commanded by Maruty, son of Pavan. (See Maruty.) Rama is also found, in other points, to resemble the Indian Bucephus: he is, notwithstanding his lunar appellation above noticed, fabled to be a descendant of the sun, his wife's name is Sita; and it is very remarkable that the Peruvians, whose Incas boasted of the same descent, riled their great festival Ramasoa.

In a charge delivered by Dr. Watson, afterwards bishop of Landaff, to the clergy of the archdeaconry of Ely in May 1780, are many curious and shrewd observations on oriental usages. He notices a "string of curts deeply with the same amongst people so far removed from each other as the Egyptians and Peruvians. The Egyptian women, be fays, made sacred cakes of flour, which they offered to the queen of heaven, at their principal solar festivals called Raymni and Ctinna: the Peruvian women did the same." Almost all the customs described as common to these diflant people, the Egyptians and Peruvians, as well as that quoted, are Hindoo curts, ancient and existing.

All the Ramas are famed as great warriors and as youths of perfect beauty. In the Gita, an epic of the Mahabarat, Krishna, describing himself to Arjun as pre-eminent among all things and persons, says, "Among those who carry arms, I am Rama." It is Rama Chandra, however, and his lovely Sita, who are the favourite subjects of heroic and amatory poetists: he is described in the Ramayana of ample shoulders; brawny arms, extending to the knee; neck shell-formed; chest circular and full, with auspicious marks; body hyacinthine; with eyes and lips of fangine hue; the lord of the world; a moiety of Vishnu himself; the source of joy to Ikhwakwus's race." He is suitably mated in his faithful Sita, one of the most interesting females in Hindoo poetry. (See under her name for some account of her, and a description of her person.) Rama is also called Raghub, or son of Raghu, (see these articles,) like Ikhwaku, one of his mortal ancestry. Kaka-paksha-dara, or crow-winged, is an epithet given to the Ramas, and to other warriors, from a certain mode of holding the head, leaving the hair over the ears only, rendering crow's wings, as is fancied. Shyamula, or blue-bodied, is an appellation of Rama, as well as of Krishna, and of their common prototype, Vishnu; all being represented of hyacinthine hue. It may be here remarked, that several incidents in the Sri-Bhagavat, (a history of Krishna,) and in the Ramayana, told similarly of their several heroes, seem to mix or approximate, though perhaps scarcely to identify, the characters of Krishna and Rama. Each was a wife by bending an unyielding bow; not very unlike the story of Ulysses. Each is described as over-coming the demon, Kumbakarna, and others. Krishna descended into hell; so did Sita, the fakti, or energy of Rama. Both have adventures with the bear Jamba. See Jamba, &c.

All sects and tribes, who, under the denomination of Vaijnavas (which see,) worship Vishnu, (bating such deistical philosophers as sceptically deny the personal existence of inferior deities, attributes, or avatars, of whom fee under JAINA,) agree in placing, that, with the exception of Krishna, the potentiality of the preferring power was never exhibited in such plenteous as in the avatara of Rama. In popularity, and in dramatic, historico, and poetic shapes, it rivals that of Krishna. And as one or more feasts adore Krishna as the deity himself, and draw rules for their religious and moral conduct from the Sri-Bhagavat; so the feast called Ramany similarly clothe Rama in almighty attributes, and deem the Ramayana a complete body of ethics and morality. See RAMANY.

In the series of incarnations of Vishnu, called das-avatars, or the ten defences, to distinguish them from others of less importance, the avatars of Para Rama and Rama Chandra are usually placed sixth and seventh, as given under VISINU. Sometimes Krishna is altogether omitted; in which case,
Bala Rama ranks as the eighth. Muyala is a name of the third Rama, under which word some notice is taken of him. And of Parufes or Paruflha Rama, see under that article. The name of Rama, or perhaps more correctly of Rami, is one of the many names of Parvati, conort of Siva. The name is also used, beyond the pale of his own sectaries, in supplication and praise. Ram-Ram is a usual salutation, like our good morrow, between friends at meeting or parting, and is used by both Vaishnavas and Saivas; and it is reverently reiterated in times, and in aid, of ablation (see JAP); and under the operation of feelings of enthusiasm or diffidence.

The history of the Ramas mixes itself with that of so many others of Hindoo mythological personages, that in many of our accounts of such personages, &c. particulars occur respecting them. Thole deifics of further notice of the Ramas are, therefore, referred, in addition, to the following articles: Ceylon, Jaya, Rajahnslya, Lakhinmax, Lanka, Maruty, Ravena, Ramayana, Ruseka, Sita, &c. from which other references point to articles on subjects connected herewith.

RAMADA, or Nem Salamanca, in Geography, a town of South America, in the province of St. Martha; 90 miles E. of St. Martha. N. lat. 11° 10'. W. long. 72° 20'.

RAMADAN, a port of bent observed by the Mahometans, in obedience to the express command of the Koran, during which they fast the whole day, from the time the new moon first appears, till the appearance of the next new moon, with such extreme superition, that they not only abstain from eating, drinking, &c. but, dare not wash their mouth, nor even swallow their spittle, from day-break till night, or sun-set.

The men, indeed, are allowed to bathe themselves; but it is on condition they do not plunge the head under water, lest some drops enter by the mouth or ears, &c. But as for the women they are strictly forbidden bathing. Some are so cautious, that they will not open their mouth, to speak, lest they should breathe the air too freely. The fast is also deemed void if they kiss or touch a woman. To make amends, they feast all night till day-break; though the more rigid begin the feast again at midnight; and usually spend more in this month than in six others.

The Ramadan happens at different seasons of the year; and when it is in the summer it is very hard on the labourers. This month once in thirty-three years is in every feast of the year, the Turkish month being lunar, and they beginning at the day they can see the moon; whereas the Jews begin their account from the day the moon makes, which is a day before the Turks.

The reason given why the month of Ramadan was fixed upon for this purpose is, that on this month the Koran was sent down from heaven. From this fall of Ramadan none are excused, except travellers and sick persons, under which latter denomination are included all those whose whole health would be manifestly injured by keeping the fast; but then they are obliged, so soon as the impediment is removed, to fast an equal number of other days; and breaking of the fast is ordered to be expiated by giving alms to the poor.

RAMAG, a word used by some of the chemical writers to express alkali.

RAMAGE, a term used for the boughs or branches of trees. Hence, Ramage-fluo, or Falcon, one that is wild and coy, as having been long among the boughs, preying for itself. All falcons retain this name till they have left the nery; being so called in May, June, July, and August. These are very rarely reclaimed. See Brancher, Falcon, and Hawking.

RAMAGE Velvet. See Velvet.

RAMAGURRY, in Geography, a town of Hindooftan; 30 miles W. of Triticinopoly.

RAMAH, a town of Arabia, in the province of Neds-jed; 120 miles N.W. of Jarama.

RAMAH, or Ramalla, Ramoola, Ramola, Ramba, Ruma, or Remphis, a city W. of Jerusalem, between Lydda and Joppa, according to St. Jerome; or between Joppa and Jerusalem, as modern travellers describe it. This is the place which Enfebus and St. Jerome took for Armenia, the country of Joseph. Matt. xxvii. 57.

RAMAI, in Ichthyology, a species of Sciana; which see.

RAMALINGA, in Geography, a town of Hindooftan, in Coimatore; 16 miles S.S.W. of Erroad.

RAMALIS VASA, a name given by some anatomical authors to the vena porta.

RAMANUJ, the name of a religious sect of Hindoos, of the great subdivision of Vaishnava, who worship Vishnu, the perfonification of the preferring power of the deity, in his incarnation of Rama. Of this sect some worship Rama only, some his spouse Sita, and some both Rama and Sita conjointly. (See Rama.) Among the Ramanuj none are addicted to the indecent, or left-handed, mode of worship noticed under the article RADIA as deserving her votaries. (See farther under SAKTA, and Sects of Hindoos.) The different sects of Hindoos are distinguishable by a variety of marks on their foreheads; of which a great many are represented in the second plate, with copious explanations in page 424, of the Hindu Pantheon. The sect of Ramanuy are known by a double upright white line on the forehead, with a red line between, or sometimes a circle or dot. Sometimes the lines are red and the circle black.

RAMAS, Cape, in Geography, a cape on the W. coast of Hindooftan; 21 miles S. of Goa.

RAMASSERAM, a town of Hindooftan, in thecir- care of Rajamundry; 35 miles S.S.E. of Rajamundry.

RAMAYANA, the title of a poem in the Sanserit language, of great celebrity in India, and regarded as sacred by some sects of Hindoos, and greatly venerated by all. Its subject is the exploits of three personages named Rama; but more especially the wars conducted by one of them, named Rama Chandra, for the conquest of Lanka or Cey- lon, from its powerful sovereign Ravena, or rather, indeed, for the rescue of his wife from the hands of that tyrant. It is comprised in seven kandas, or books, containing 24,000 shlokas, or metrical stanzas; named thus: 1. Adi-kanda, containing 64 seftions, and 2850 flanzas; 2. Aoydhyakanda, 80 seftions, and 47 10 flanzas; 3. Aranyaka-kanda, 114 seftions, and 4150 flanzas; 4. Kesikenda-kanda, 64 seftions, 2925 flanzas; 5. Sundara-kanda, 43 seftions, 2045 flanzas; 6. Yugda-kanda, 105 seftions, 4500 flanzas; 7. Uttara-kanda, 90 seftions, 3360 flanzas. The Ra- mayana may be called an epic poem, as it is on one continued, interesting, and heroic action. It is second in celebrity only to the Mahabarat, and perhaps superior to it in reputation for holiness. (See Mahabarat.) We have the auth- ority of Sir William Jones for saying, that this great epic poem, in unity of action, magnificance of imagery, and elegance of diction, far surpasses the elaborate work of Nonnus, in forty-eight books, entitled Dionysiaca; and for believing that the heroes of the poems Rama (patronymically distinguished by the name of Dafrat Rama) and Dionyse are the same.

A curious
A curious parallel might be drawn between the manners and customs described in the two works, the Dionysiac and Ramayana. The processions and rites detailed in the former seem descriptive, with a little licence for poetical embellishment, of those in usage to this day in India. Some of these Bacchic orgies are noticed under our articles Dionysia and Nonius; which see. A keen etymologist would find innumerable lingual coincidences; and, in truth, many of the names of perfons, Bacchus and Dionysos, and of places, as well as original perfons, seem febrerly traceable to the sacred language and rites of the Brahman.

So highly is the Ramayana venerated, that the fourth class of Hindoos, the Sudra, is not permitted to read it. At the end of the first book, a promise is made of great benefit to any individual of the three first classes or tribes who shall duly read it. “A Brahman, reading it, acquires learning and eloquence; a Kshetriya will become a monarch; a Vaitya will obtain vast commercial profits; and a Sudra, hearing it, will become great.” Of these distinctions of tribes or classes, the reader will find due notice under Sects of Hindoos. Under Rama we have stated that his name reiterated is used by several sects as a term of abhorrence, or benediction. The author of the Ramayana, in the vinity of playful edictum, which, from its frequency with oriental poets, has ceased to seem blaming, calls on his readers to “salute Valmiki, the cukoo, who, mounted on the branch of poetry, founds the delightful note of Ram-Ram.”

It has been furnished that the Ramayana, like the Mahabharat, is allegorical, so far as relates to personal adventures; which, in both cafes, are mere machinery for the introduction of a concealed sylem of philosophy and ethics: in the first instance the allegory is physical, in the latter moral. Under the article Mahabharat the allegorical nature of that extraordinary poem is sufficiently shown. The Kuras and Pandus, the heroes of that poem (see Kuru and Pandu), are personifications of virtues and vices. The Ramayana and the Dionysiac relate how their respective Indian conquerors led armies of fayrs. (See hereon under Maruty and Rama.) These fayrs, or monkies, we apprehend to be personifications of winds, or gaseous metaphors. In the Ramayana we find the machinery to confit of the sun and planets, fire, the firmament, wind, water, &c. personified in the gods or regents of those bodies, elements, &c. It has been further furnished that whenever these two extraordinary poems, the Mahabharat and Ramayana, shall appear in English, and their allegories be more fully examined, it may possibly be found, that not only the three Ramas will melt into one, but that all will amalgamate with Kirlihna. Some objections to the identity of the Ramas have been offered of a chronologial nature. Parafa Rama, it is contended, reigned or flourished eight generations before Rama Chandra. Their poetical identity, however, is sufficiently established; and one can scarcely bring such a twofold of allegory, incarnations, and whimsical adventures, to the test of sober historical and chronological accuracy. Personifications of these names may have reigned or flourished at any given period, for they have always been very common, and are fo still.

The Ramayana is so replete with incident, that it is scarcely possible to give any analysis of its subject with sufficient brevity for this work. Unity of action is, however, its characteristic, namely, the recovery of Sita from the hands of her ravisher Ravana, the gigantic tyrant of Ceylon. It may be noticed in passing, that the Ramayana, like the Iliad, is founded on a rape, and that Sita is the Helen of the Hindoo epic. (See Sita.) So inextricably intermixed are the varied subjects of the Hindoo mythological history, that the discussion of one necessarily brings another under notice. This is the cause of such frequent references to and from the articles under which we have endeavoured to give a succinct account of such a number of subjects of that description, distinct apparently, but in reality connected, and often confounded with each other. On the subject of this article, the Ramayana, or for quotations from it, we may therefore refer to the following, among others: Ceylon, Lakshmi, Lanka, Mantra, Parasu Rama, Menaka, Ravana, Hemha, in addition to those pointed to in earlier passages of this article, and in those articles just named.

What precedes, referring to the poem bearing the title of this article, is offered respecting the Ramayana of Valmiki. There are many other poems of the same name in Sanscrit, Prakrit, Hindvi, and many other Hindoo dialects; as well as in Arabic, Persian, Malayon, and others derived from the like source. These are of course of unequal celebrity and merit; and acknowledged to be greatly distant from Valmiki’s divine poem. Even of this it may be said, that the style is frequently flat and diffuse, deficient in ornament, and abundant in repetitions. As well as Valmiki’s work, several others, under the same title, are usually considered with more respect than mere profane poems. One is ascribed to Vyasa, the reputed author or compiler of the Vedas and Puranas. (See those articles.) A considerable portion of several of the latter mythological romances is occupied by the same subject, viz., the adventures of Rama; but in the Vedas no mention is made of this perfon, except, indeed, in some detached parts, reasonably refuted to have been interpolated by zealous fectaries. The titles even of the philosophical and profane poems, commentaries, &c. that in divers languages owe their origin to the Ramayana, would require a catalogue of no incalculable extent to contain them. Among these are included many dramatic works. The quotations from, and allusions to its mythological perfonages and fables, in the works of the minor poets, are incessant; and upon the whole, there is no subject, perhaps, in the whole range of Hindoo mythology, or history, so often in the minds and mouths of that race of all ranks and fefts, as the story of the Ramayana in some of its bearings. That of Krihna rivals it in popularity. Both are chanted by itinerant bards, who illustrate their subjects by exhibiting a series of pictures from the Ramayana and Mahabarat. Women’s fingers frequently accompany the eastern troubadours who are commonly met with in every city, camp, and town of India.

RAMAZZINI, Bernardi, in Biography, an Italian physician of distinction, was born at Carpi, near Modena, in 1633, where his father was a respectable citizen. Having received a classical education from the Jesuits at his native town, he went to Parma for the study of philosophy at the age of 19, undecided what profession to adopt: at the end of three years he selected that of physic, and received the degree of doctor at Parma in the beginning of 1659. He then repaired to Rome for the completion of his studies, and settled in practice in the duchy of Cafora. He was soon obliged by ill health, however, to return to his native air; and, on his recovery, he married, and purfued his profession at Carpi. Finding his reputation increasing, he removed to Modena, at the solicitation of some friends, in 1671, where he met with merited success, and excited the jealousies of his brethren. In 1682 he was appointed professor of the theory of medicine in the university, which had been recently established at Modena, by duke Francis II.; and he continued to fill this office for eighteen years, attending at the same time to practice, and not neglecting the cultivation of polite literature, to which he was particularly partial. The
elegance of his Latin style in his writings, evinces the suc-
cess with which he pursued the study of the classics. In
1720 he was invited to a professorship at the more distin-
guished university of Padua, and removed thither. Though
somewhat advanced in age, he fulfilled the duties of his
chair with an air of importance, not to be surpassed by his junior col-
leagues, for the space of three years, when he was attacked
with a disease of the eyes, which threatened to destroy his
vision, and which, in fact, did ultimately deprive him of
that faculty. Having lost the pleasure of reading, which
was the only source of his regret, he supplied that amufe-
ment by the assistance of his grand-children, who read to
him, and acted as his amanuenses. In 1728, however, the
senate of Venice appointed him president of the college
of physicians of that capital, and in the following year raised
him to the first professorship of the practice of medicine.
He continued to perform the duties of those honourable
posts, at the earnest solicitation of his constituents and pu-
pils, with great diligence, to the end of his life, and died
on his birth-day, November 5th, 1744, in consequence of
an attack of apoplexy, which seized him while he was pre-
paring for his lectures, at the age of 81.

Ramazzini was a member of several of the academies of
science established in Germany, Berlin, &c., and left several
works; the principal of which, and one which will ever
be held in estimation, is his treatise on the diseases of arti-
fts and manufacturers, entitled "De Morbis Artificum Dia-
triba," first published in 1721, and frequently reprinted.
He also published some tracts relative to certain epidemics,
both among men and cattle; some "Ephemerides Baromet-
trice_; a work on the abuse of Peruvian bark; and several
orations delivered in his professorial capacity. All his
works have been collected and published together at Padua,
Genoa, Vienna, and Naples; the edition of London is the

Rambang, in Geography, See Renbang.
Ramberville, or Remberville, a town of
France, in the department of the Vosges, and chief place of
a canton, in the district of Epinal; 19 miles E. of Mer-
court. The place contains 4926, and the canton 14,014
inhabitants, on a territory of 317½ square kilometres, in 28 con-
nunues. N. lat. 43° 21'. E. long. 6° 43'.
Rambin, a town of Anterior Pomerania; 10 miles
W.S.W. of Bergen.
Ramble, a town of Spain, in the province of Cor-
dova; seven miles N.W. of Montelana.—Alfo, a town on the
W. coast of the island of Tenerife; three miles W. of La-
guna.
Rambouillet, a town of France, in the depart-
ment of the Seine and Oise, and chief place of a canton, in
the district of Verfailles, the seat of a tribunal, and of a
national farm, where the sheep are much celebrated for the
fineness of their wool; 27 miles S.W. of Paris. The
place contains 2586, and the canton 9652 inhabitants, on a
territory of 305 square kilometres, in 17 communes. N. lat.
48° 39'. E. long. 1° 54'.
Rambure, a town of France, in the depart-
ment of the Somme; 8 miles S. of Oise.
Ramburelles, a town of France, in the depart-
ment of the Somme; 9 miles S. of Abbeville.
Ramchund-pour, a town of Bengal; 30 miles
N.E. of Calcutta.
Ramchundra, a town of Hindoostan, in the cir-
car of Mahurhurbe; 23 miles S.S.E. of Harripour.
Ramchunpore, a town of Bengal; 60 miles N.
of Dacca.

Rameau, John Philip, in Biography, chevalier de
St. Michel, composer to the king of France, and to l'Aca-
demie Royale de la Musique, or serious opera at Paris, was
born at Dijon in 1683. He went early in his life to Italy,
and at his return was appointed organist at Clermont en
Auvergne, where his "Traité de la Musique" was written,
in 1722. He was afterwards elected organist of St. Croix
of the Bretonnerie at Paris. Here his time was chiefly
employed in teaching; however, he published harpsichord lec-
tons, and several other theoretical works, without distin-
guishing himself much as a vocal composer, till the year
1735, when, at fifty years of age, he produced his first
opera of "Hippolite et Aricie." The music of this
drama excited professional envy and national discord.
Party rage was now as violent between the admirers of Lulli and
Rameau, as in England between the friends of Bononcini
and Handel, or, in modern times, at Paris, between the
Gluckists and the Piccinists.

When the French, during the last century, were so con-
tented with the music of Lulli, it was nearly as good as that
of other countries, and better patronized and supported
by the most splendid prince in Europe. But this nation, fo
frequently accused of more volatilty and caprice than their
neighbours, have manifested a steady perseverance in pro-
curing in their music, which the strongest ridicule and contempt
of other nations could never vanquish.

Rameau only answered his antagonists by new produc-
tions, which were still more successful; and, at length, he was
acknowledged by his countrymen to be not only superior to
all competition at Paris, but sole monarch of the musical
world. From 1733 to 1760 he composed twenty-one operas,
of which the names and dates are annually published in the
"Specècles de Paris," and in many other periodical works.
Rameau's style of composition, which continued in favour
almost un molested for upwards of forty years, though formed
upon that of Lulli, is more rich in harmony, and varied in
melody. The genre, however pleasing to all ears but thofe of France, which had been nutured in it, was carried
by the learning and genius of Rameau to its acme of per-
fec tion; and when that is achieved in any style, it becomes
the buffet of subsequent composers to invent or adopt
another, in which something is still left to be done, besides
servile imitation.

The opera of "Cafior and Pollux" having been long regar-
ded in France as the matter-piece of this composer, we
shall here insert a few remarks upon it, that have been made
on a recent examination.

The overture is the best of this author, upon Lulli's plan.
The opening symphony is beautiful; but why the same
melody was not applied, in the same measure, to the poetry,
we know not, unless the verification required a change of
time; but, in that case, why write the symphony on a sub-
ject that would not suit the words? But those eternal
changes in the measure, which tease and disappunt the ear
of all that are used to other music, is general in serious
French operas, and frequently much to the fault of the poet as
musician. It is, however, wonderful, that this defect was not
sooner discovered. The overcharged tendernes of Ramea-
u's music appears in all his flow movements, which are in
one style, and generally in triple time. This matter perpetu-
ally
tually discovers himself to be a great harmonist; but incurred to a bad taste and style of composition, as well as to bad singing, he has only augmented the defects of his predecessors, and rendered what was rude and clumsy in Lulli still more offensive, by endeavours at sweetness and high f easoning. The appoggiaturas, or leaning notes, being so frequently incorporated in the harmony, renders it crude, and the hanging on every note, as if unwilling to relinquish it, checks and impedes the motion of the air, and gives it a slow and languid effect, however lively the theme on which it is composed. Every passage in such melody resembles a French heroic verse:

"Each is an Alexandria through the song,
That, like a wounded snake, drags its slow length along."

The opening of the second act, "Que tout gemisse," is very fine, and the pathos well applied; but the subsequent air, which is call in an admirable mould, is spoiled by frequent and unnecessary changes of measure; and yet in spite of these defects, and the vocal outrages of mademoiselle Arnould, we were more pleased and affected by this scene, than any other we ever heard at the French serious opera. The march, which has few appoggiaturas in it, is like other Christian music.

The prelude tendre, at the opening of the third act, abounds with too many of these drags, which being equally harsh to the ear and injurious to pulsatixs, seem to prevent the performer from ever falling on his feet; and bar eleventh, the chord of the superfluous fifth, which makes all nature shudder, except our Gallic neighbours, is here continued so long, that it distorts the countenance of every other hearer, like hiera pieta. The minor minuet, page 121, after so long and tiresome a minority, is rich in harmony and graceful in melody. The voice is worie used by the composer than the most insignificant instrument. For after several symphonies that are extremely promising, and the ear has been made to expect a continuance of the preatory strain, nothing is given to the vocal part but broken accents and dislocated measures. In the chaceone, which is admirable, the measure is well marked and well accented. This must long have preceded Jomelli's favourite chaceone, and have served as a model to him, Thobler, and others, in composing this species of dance. More genius and invention appear in the dances of Rameau than elsewhere, because in them, there is a necessity for motion, measure, and symmetry of phrase. And it may with truth be said, that nothing in Lulli's operas was imitated or adopted by the rest of Europe, but the figure of his overtures, or in Rameau's, but the dances.

But though the several merits of this musician have been too much magnified by partizans and patriots in France, and too much depreciated by the abettors of other systèmes and other styles, as well as patriots of other countries, yet Rameau was a great man; nor can the profeffor of any art or science mount to the summit of fame, and be elected by his countrymen supreme dictator in his particular faculty, without a large portion of genius and abilities.

The successful revival of his opera of "Caïtor and Pol-lux" in 1754, after the victory obtained by his friends over the Italian burletta fingers who had raised such disturbance by their performance of Pergolesi's intermezzo, the "Serva Padrona," was regarded as the most glorious event of his life. The partizans for the national honour could never hear it often enough. "This beautiful opera," says M. de la Borde, "without any diminution in the applause or pleasure of the audience, supported a hundred representations, charming at once the soul, heart, mind, eyes, ears, and imagination of all Paris."

From this era to the time of his death, in 1767, at eighty-four years of age, Rameau's glory was complete. The Royal Academy of Music, who all regarded themselves as his children, performed a solemn service in the church of the Oratory, at his funeral. And M. Philidor had a mas performed at the church of the Carmelites, in honour of a man whose talents he so much revered. See Base, Base Fondamentale, and Countermelodic.

RAMEL, a name given by some chemical writers to rhubarb.

RAMEDEGA, in Geography, a town of Hindostan, in the circuit of Gangpour; 15 miles S.W. of Pada.

RAMEE, a town of Bengal; 50 miles S. of Ila

RAMEEAPATAM, a town of Hindostan, in the Carnatic; 30 miles S. of Ongole.

RAMEEPUR, a town of Hindostan, in Allaha-bad; 35 miles E.N.E. of Gazipour.

RAMELLI, Agostino, in Biography, a celebrated Italian mechanist and engineer, was born, in 1530, at Ma-fanzana, in the diocese of Milan. Having entered the army, he rendered a considerable time under the marquis de Marignano, a general of Charles V. After this, he served under the duke of Anjou as captain, or engineer, at the siege of Rochelle, in 1573, where he was dangerously wounded, and taken prisoner. When that prince, afterwards Henry III., was called to the crown of Poland, he was the friend of Ramelli, and he nominated him his engineer when on the throne of France. In 1588 he published a work in Italian and French, entitled "Le Diverle et Artificieuse Machine del Capitono Agolino Ramelli," &c. with nearly 200 figures, describing a great number of machines for various purposes, most of his own invention, and which exhibit much ingenious contrivance. The work is very scarce, and is much prized by the curious.

RAMELSCHACH, in Geography, a town of Austria; 5 miles S.E. of Meillai.

RAMELTON, or Rathmelton, a small port-town of the county of Donegal, Ireland, situated on a bay at the bottom of Lough Swilly. It is 117 miles N.W. by N. from Dublin.

RAMENAPILLY, a town of Hindostan, in the cir-
cor of Rajampur; 42 miles E. of Rajampur.

RAMENTUM, in Botany, a form of pubescence in
plants, which, as the name signifies, has the appearance of a hair, being flat, membraneous, mostly irregular in size and shape, quite unlike the uniform hairs or bristles of which the clothing of moss plants consists. (See Pubescent.)

The above term was first used, if we recollect rightly, by L'Heritier, and occurs in some species of Begonia. The fealnees of Ferns is of a similar nature.

RAMERUP, in Geography, a town of France, in the department of the Aube, and chief place of a canton, in the district of Arcis-sur-Aube; 6 miles E. of Arcis-sur-Aube. The place contains 123, and the canton 8870 inhabitants, on a territory of 440 kilometres, in 29 communes.

RAMESAN, an oriental term for a month of fasting, very religiously observed among the Turks, and otherwise called Ramadan; which see.

RAMESERAM, in Geography, a town of Hindostan, in the circuit of Cuddapa; 6 miles E. of Gandicotta.

RAMETTA, a town of Sicily, in the valley of De-
mona; 6 miles W. of Meffina.
RAMEX. (ramus, a branch,) in Surgery, a rupture, or hernia. See HERMIA.

RAMEX Feminae See Circumcision.

RAMGAD. in Geography, a town of Hindoostan, in Bahar : 10 miles W. of Bahar.

RAMGARY, a town of Hindoostan, in the country of the Notts : 15 miles W.N.W. of Palauchererry.

RAMGAUT, a town of Hindoostan, in the subah of Delhi : 57 miles S.E. of Secundra.

RAM-GETTER, in Rural Economy, a term applied by the medlaad breeders to such rams as are proper for getting ram-flock, in contradistinction to such as are fit only for getting wether-flock. See RAM.

RAMGONGA, in Geography, a river of Asia, which rises in Tibet, and runs into the Ganges, 10 miles N. of Canogg.

RAMGUR, a circuit of Bengal, bounded on the N. by Bahar, on the N.E. by Curneedkagh, on the S.E. by Pachera, on the S. by Nagpur, and on the W. by Koonda and Toree : about 90 miles long, and 60 broad. — Also, the capital of this circuit : 135 miles W.N.W. of Calcutta. N. lat. 23° 20'. E. long. 85° 41'. — Also, a town of Hindoostan, in Dowlatbad : 55 miles S. of Neemul. N. lat. 18° 3'. E. long. 79° 15'. — Also, a town of Hindoostan, in Malwa : 8 miles S. of Rargoopour. — Also, a town of Hindoostan, in the subah of Delhi : 5 miles N. of Coel. — Also, a town of Hindoostan, in Guzerat : 50 miles E.S.E. of Surat. — Also, a town of Bengall : 15 miles N.W. of Madnapour.

RAMGUR. See SERNAH.

RAMGURRA, a town of Hindoostan, in the Mylore, captured by the English in 1791 : 42 miles N.E. of Serunga-patam.

RAMHYTTE, a town of Sweden, in Westmanland ; 36 miles from Stockholm.

RAMI, in Hindu Mythology, one of the many names of the goddes, Parvati; which see. Under this name she is said to be worshipped at the splendid temple on the island called Ramiferum, between Ceylon and the cape named by us Comorin, but which should be called cape Kaimarn, or Kumarn, another of the names of this goddess, and meaning the virgin. (On this point see LANKA and PARVATTI.) Sami is the name of a tree or wood Sacred to Parvati, and is sometimes called Sami Ram. Rami is the term that is here employed to express the origin of the Seminarii of the Greeks. (See hereon Af. Rep. vol. iv. p. 282. vol. vii. p. 246. Svo, ed.) A description of the celebrated temple of Ramiferum will be found under that article. See also SAMI.

RAMI-AVENPOUR, in Geography, a fort of Bengal : 27 miles S.S.W. of Budwang.

RAMIFICATION, the production of branches or branches, or of figures resembling braches.

RAMIFICATIONS, in Anatomy, are the divisions of the arteries, veins, and nerves, arising from some common trunk.

RAMIGRI, a word used by some writers as a name for colophony.

RAMILLIES, in Geography, a village of France, in the department of the Somme and Maine, at the source of the river Gere, worthy of being recorded on account of a battle fought here in the year 1562, between the allies commanded by the duke of Marlborough, and the French under marquis Villeroy. The confederates took the whole of the enemy's baggage and artillery, and about 120 standards, 600 officers, and 6000 private soldiers: about 800 were killed or wounded. The loss of the allies did not exceed 3000 men : 13 miles N. of Namur.

RAMING, a town of Austria : 11 miles S. of Steyr. — Also, a town of Persia, in the province of Irak : 40 miles E. of Coorar.

RAMINGAM, a town of Hindoostan, in Dowlatbad : 10 miles N. of Oadigher.

RAMINGSDORF, a town of Austria : two miles E. of Steyr.

RAMINGUE, in the Mangi. A hodie gets this name that is seditive, and refits its leaves to the spurs; that is, defends himself with malice against the spurs; sometimes doubles the reins, and frequently yorks to favour his disobedience. See TIECKELIS and DOUBLE.

RAMIS, BARTOLOMEO, in Biography, a Spaniard, the first modern who flattened the necessity of a temperament in musical instruments, of which the tones are fixed. He was contemporary with Francisco, and in 1462 published a work, entitled "De Musica, Tractatus, five Musica practica."

He seems to have converted Pietro Aaron to his opinions: as that theorist manifestly exalts the quality of Ramis on all occasions at the expense of Francisco.

The Spaniard was attacked in a rough manner by Nicholas Burtius, for differing from Guido in his division of the monochord, in a tract entitled " Musices Opusculum cum Defens. Guidonis Artini adversus quendam Hiptanum veritas praevinctor." Bemun. 1487. This tract, printed in black letter, is in the Ashmol. Collect. among the books of Art, Wood.

Burtius imagined the honour of Guido to be injured by the Spaniard, as Guido used the Pythagorean proportions, and had never thought of a temperament. Burtius, in his turn, was handled very roughly by Spataro, the disciple of Ramis (Joannes Spadarius Bononiensis, Musices ac Bartolomi Rami Paulo ejus Preceptoris honesta Defensor in Nicol. Burtij Parment. Opusc. Bolognae, 1491.): and the venerable Francisco, finding himself very rudely handled in the dispute by the sufferers of temperament, in 1522, when he was upwards of seventy years of age, took up the defence of Pythagoras, as Fontenelle, at near a hundred, did of Des Cartes. After this, the war became general, and continued to rage with great violence for more than a century, between the friends of tempered scales, and the adherents to ancient proportions and equal harmonies.

RAMISERAM, in Geography, an island in the Indian sea, between the island of Ceylon and the coast of Coromandel; to which there is a passage of about 12 or 14 leagues from the island of Manar, on the coast of Ceylon. But the advantages that might be derived from this speedy communication are in a great measure prevented by the numberless shallows and sand-banks, which every where interrupt the passage, and which are so high, that many of them are dry except during the monsoons. There is in particular a line of sand-banks, which runs quite across from Manar to Ramiferam, denominated Adam's bridge, and also Ram's bridge, because God is said to have come by this way into Ceylon. (See Adam's Bridge and MANAR.) From Ram, Ramiferam takes its name, and it has a large temple dedicated to him. The shortness of the passage from Ramiferam to Manar is particularly useful on account of the speedy conveyance it affords to people on business, and the communication of intelligence. The messengers who usually go from Culein to Manar, a distance of 160 miles, in three days, take boat here, and cross over by Adam's bridge to Ramiferam; and then proceed along the Coromandel coast to Madras. An express
express in favourable weather will run from Columbo to Madras in eight days, and the journey has been accomplished once in seven days. (See Manka.) The isle of Ramiseram, which is the limit of the Hindoo religion in more modern times, and of the conquests of the Mussulman princes, is, as we have said, separated from Ceylon by Adam's bridge. The island is low, sandy, and uncultivated, except with a few scattered Palmira and cocoa-trees. The pagodas, for which it is so famous, lie on the Ceylon side, near the sea, and are the resort of innumerable multitudes of different sects of religion in India, during the feason of certain festivals. The numerous pagodas are constructed in the same style with those on the Coromandel coast; and they are surrounded with the houses of the Brahmins, priests, and other religious persons, whose zeal leads them to attend on their temples; among whom, in particular, may be seen the descendants of the Tamuls, Telingas, Canarians, Mahtrattas, and Orias, who compose a great body of the original inhabitants of the southern peninsula. Their houses are built of the cocoa-tree, in small figures and streets, where their families are seen reclining on the little mud terraces, and under the payals or virandals. They do not allow Europeans to enter these temples; but they are known to revere those of the coast in their crowded ornaments, spires of brickwork, long porches in front, and viias, at the extreme end of which are placed the deities, in an obscure position, surrounded by lamps burning day and night. The same reverence for strangers subsists among all the southern Brahmins. The Brahmins allow no labour or cultivation to be carried on in the island of Ramiseram, considering it altogether as sacred. The contributions of those who visit it are sufficient for the support of the temples. Several of the neighbouring Poligar chiefs contribute largely, and some of these rajahs have statues erected to them for their gifts. The chief pagoda has several of these statues in its different figures. Low as the land lies in this island, good water is easily procured; for on scooping it up, the water collects immediately in the holes; but this is not the case in Manka and the wet coast of Ceylon.

The guardianship of this sacred isle belongs to a family of devotees, called "Byrageses," the chief of whom is always doomed to celibacy: the succession being carried on by the fathers or the collateral branch, who are permitted to marry. This institution is similar to that of the sovereignty of the Travancorians and Nairs of the Malabar coast. The clothes and turbans of the devotees are of a tawny red colour, decorated with large black beads, of a particular kind of wood. From the pagodas just mentioned there runs out a long narrow piece of sand, terminating in a point, within a mile of which is a choultry at Tuna Goody. This is a square of houses with a court inclosed for the accommodation of pilgrims, who come to the farthest point of the island to perform their ablutions in the sea, the most sacred and the purest of their ceremonies. A Brahmin takes care of this choultry, and a pole with a light is fixed at the end of the point to direct the pilgrim. N. lat. 9° 18'. E. long. 79° 22'. Percival's Ceylon.

Of the temple in this island we shall give some account, extracted from a publication of Mr. Cordiner, who visited it. The external appearance is not remarkably grand, and at a distance, no idea is excited of the minute ornaments and labour of workmanship which strike the eye on a nearer inspection. All the architecture seen without doors is insignificant, compared with the magnificence of the interior. After an examination of the whole structure, which is entirely of hewn stone, Mr. C. deemed the extent of masonic labour in its erection, most have been equal to that of any of the most splendid cathedrals of Europe. "On entering it we were," he says, "completely astonished at the grandeur of the workmanship, and extent of the dimenions, which far surpassed any idea that we had formed of Indian magnificence." From the west gate a low gallery, 144 feet in length, with three rows of pillars on each side, leads down to the centre of the building; where it branches off, in galleries similarly constructed, to the right and left, each extending 150 feet, then running from west to east 520 feet, and enclosing an oblong rectangular space. The gallery runs also along the centre of the temple 788 feet, and a similar gallery runs across from north to south, where are like entrances, intersecting the former in the centre of the rectangular space. All the galleries have on each side triple rows of mafy stone pillars, of highly laboured workmanship. Those in the front line are the largest and most superb, having a huge lion, with the mouth wide open, sculptured in bas relief, above three distinct capitals, over which are a scroll, and a richly ornamented cornice. Statues of the size of life are attached to many of the pillars, representing gods and deified persons. The pillars stand on a continued basement, forming the floor of the galleries, raised three feet, with steps to ascend by, all of stone. The roofs of all the galleries are flat, formed of stones reaching across, from the projection of one cornice to that of the other. The galleries are eighteen feet wide, and in the centre thirty feet high from the floor. The number of pillars within the temple amounts to 2625. The edifice is inclosed by a heavy stone wall, 20 feet high, 830 feet from east to west, and 625 from north to south. Large as these dimensions may appear, they are dwarfed to be but small compared with those of temples on the continent of India, one of which covers a square mile of ground. The covered gallery, fronting the south gate, which seems unfinished, strikingly resembles the entrance of the Elephant cave, near Bombay. Solid pyramidal erections surmount the western and eastern entrances, composed externally of a grand number of small pillars, and two, in the form of window frames or gateways, riving one above another, in seven different stories. That over the western, which is the principal entrance, appears to be 150 feet high; the eastern seems lower and unfinished. The north and south gates are less majestic than the others; but their completion is said to be intended, when they will be similarly surmounted and ornamented as the western portal. Privileged persons, among whom were women carrying water-pitchers, appeared constantly passing and re-passing about the interior of the temple.

Two hundred Brahmins are attached to this temple, and supported in ease and luxury by its endowments. It is dedicated to Siva, the destroying power, called by the vulgar Rama Lingam. It contains likewise, Mr. Cordiner says, images of Vishnu the preserver, and of all the subordinate divinities. Of Brahma, the creator, he states, the Hindoos never dare to form any likeness. This is a common error, that is explained and corrected in the article IDEOLATRY of this work.

A broad street runs parallel to each side of the temple composed of comfortable houses, and large chouchies for the accommodation of pilgrims and travellers, of stone, with flat roofs supported in front by pillars; the fronts being open. In one of these Mr. Cordiner observed two ivory palankeens inlaid with gold, the property of officers belonging to the sanctuary. In others he noticed five cairiages, called by the English Smancy coaches, used for the purposes of carrying the idols in procession: the use to which the ivory palankeens are, we apprehend, also applied.
These carriages are described as solid masses of wood, of a pyramidal shape, intended to symbolize the Linga. (See Linga.) The exterior of their coaches are covered with grotesquely obscene carving.

At the external corners of the temple, and in the streets of the town, there are smaller temples in honour of different deities, and containing images. In some of the streets spreading trees, among them the ficus religiosa and tamarind, are surrounded with square stone terraces, on which are placed little images of Poller or Ganea, (see Pollear) the Linga, two serpents entwined, and other emblems of Hindoo mythology. These terraces are used for contemplation, or more active religious duties, as noticed under the article Pradakshina. Rows of fruit-trees, among them the cocoa-nut, plantain, and pomegranate, stand in gardens beyond the north and south walls of the temple.

On the opposite side of the island, near the sea, distant about eight miles from the temple, is the ancient fort and choultry of Pombom. The road between is very splendidly paved with smooth stones, each six feet by four; and the greater part of the road is nobly shaded by the most beautiful and majestic trees. The larger trees of this superb avenue are surrounded by smooth-raked terraces of masonry, on which travellers rest in comfort, completely shaded. About half way between the grand temple and Pombom is a very elegant small temple, built on the same general plan with the larger, having two maffy towers raised in the centre of the oblong area, and a covered walk, with three rows of pillars on each side, all round. The outside of the towers is completely covered with flutes in miniature, representing all the variety of their mythological divinities. The choultry, for the accommodation of pilgrims and travellers at Pombom, has two fronts, and three inclosed squares; and is surrounded by piazzas levelled several feet, with square pillars and terraced roofs. Contiguous is a small temple, the door of which was open, displaying an image of Ganea or Poller, in the usual form, elephant-headed and pot-bellied, ornamented with necklaces of flowers.

There are several other elegant temples on this interesting island, which is entirely dedicated to the purposes of religion. No plough is allowed to break the soil, and no animal, wild or tame, is ever killed on it.

Dancing girls, mountebanks, and beggars, abound here, as in other reftorts of the idle and wealthy.

The small remains of antiquity still extant on Ceylon, sufficiently prove that similar religious institutions did once exist there, and that chooltries and temples were erected at the different places, all the way from Manar through the island, 200 miles, to Dondra, its southern extremity, and the extreme extent of Hindoo pilgrimage. At the latter place, the ruins of a temple dedicated to Siva are still to be recognized; but only one row of scattered pillars, and a few remnants of broken images have survived the fanatic fury of the early European invaders. Rama's peaceful island falling under the protection of a more liberal and enlightened government, fortunately escaped those religious tempests, which spread devastation round the coasts of Ceylon.

Lord Valentine has more recently visited this interesting scene, and Mr. Salt, who accompanied his lordship, has published a very elegant view of the temple. The entrance is described to be through a gateway, about 100 feet high, covered with carved work to the summit. The door is 40 feet high, composed of single stones placed perpendicularly, with others crossing. This massive workmanship reminded lord Valenta of the ruins of Egyptian architecture. He describes the quadrangle to be about 600 feet each side, and says that, on the whole, this temple is the finest piece of architecture that he had seen in the east. Words, he says, cannot describe its magnificence. The concourse of pilgrims is very great, and brings in a large sum; each paying according to his rank. The raja of Tanjore has been accustomed to the year before, but could not afford it; as in presents and various expences, it was estimated that his highness could not have performed this act of devotion under 60,000 pagodas, about 25,000l. sterling. His whole family would of course have expected to participate in the happiness and benefits of the pilgrimage. The idol uses no water but what is brought from the Ganges by fakirs; with this it is bathed every morning; and this holy water, thus acquiring additional sanctity, is fought and purchased by the devout for fin-expelling purposes.

RAMISTS, in the History of Learning, the disciples of Peter Ramus, who was born in a small village in Picardy, in 1515, and from being a servent in the college of Navarre at Paris, became, by his talents, industry, and perseverance, one of the most famous professors of the sixteenth century. By attacking the authority of Aristotle, and attempting to substitute in the place of his logic a method of reasoning better adapted to the uses of rhetoric and improvement of eloquence, he excited a terrible uproar in the Gallic schools; so that the two first books he published, viz. "Institutions Dialecticae," and "Aristotelicon Animadversiones," were prohibited through the kingdom of France, and the author prohibited from any more teaching philosophy. His enemies persected him with lampoons and satires, and even held him up to public ridicule on the flage. However, Ramus afterwards recovered his credit, so that he obtained the royal professorship of philosophy and eloquence, and afterwards of mathematics, at Paris, in 1547. But his enemies were inveterate in their persecution of him, and as soon as it was known that he favoured the party of the Hugonots, he was obliged once again to withdraw himself from the effects of their resentment. In the intervals of peace, he returned to his flation; but in 1568, when the civil war was a third time renewed, he resolved to leave France, and make a tour through Germany. After spending three years in visiting the principal German universities, and receiving many tokens of respect, he resolved, fatally for himself, in 1571, to return to his own country. Accordingly he settled at Paris, where he perished in the massacre on St. Bartholomew's day. On the tumult of this execrable day, Charpentaire, professor of mathematics, who had been eclipsed by the superior talents of Ramus, seized the opportunity of being revenged upon his rival, and, under the pretence of religion, employed assassins to murder him. His body was afterwards thrown into the street to the enraged pupils of Charpentaire, who dragged it ignominiously along the streets, and then cast it into the Seine.

The Disciples of Ramus, such was the astonishing influence of their master's learning and character, prevailed so far as to banish the Peripatetic philosophy from several cabinets of learning, and to substitute in its place the syllogism of their master, which was of a more practical kind, and better adapted to the purposes of life. Although he had considerable merit in exposing the defects and inconveniences of the Aristotelian philosophy, he did not seem to have been equally successful in his attempt to establish a new logical institute. The general outline of his plan is as follows: Considering dialectics as the art of deducing conclusions from premises, he endeavours to improve this art, by uniting it with that of rhetoric. Of the several branches of rhetoric he considers invention and disposition...
position as belonging equally to logic. Following chiefly
the example of Ciceron, he divides his treatise on Dialectics
into two parts; the first of which treats of the invention of
arguments, the second of judgments. Arguments he de-
rects not only from what the Aristotelians call middle terms,
but from any kind of propositions, which, connected with
another, may serve to prove any affirmation. Of these he
counters various kinds. Judgments he divides into
axioms, or self-evident propositions, and “dianoës,” or
deductions by means of a series of arguments. Both these
he divides into various classes; and illustrates the whole by
examples from the ancient orators and poets.

In the logic of Ramus, many things are borrowed from
Aristotle, and only appear under new names; and many
others are derived from other Grecian sources, and particu-
larly from the dialogues of Plato, and the logic of the
Stoics. Whillest the author has the merit of turning the art
of reasoning from the futile speculations of the schools to
forensic and common use, his plan is defective in confining
the whole dialectic art to the simple object of disputation,
and in omitting many things which respect the general con-
ture of the understanding, and the investigation of truth.
Defective as the system of Ramus is, lord Bacon (Augm.
Se. i. vi. c. 2.) has passed too severe a censure upon him,
and others have concurred in it: for he is unquestionably
entitled to great commendation for having, at the period in
which he lived and wrote, with so much firmness and
perseverance, asserted the natural freedom of the human un-
derstanding. The logic of Ramus obtained great authority in
the schools of Germany, Great Britain, Holland, and
France; and science derived ultimate advantages from the
treatises which were written between the followers of
Ramus and those of the Stagyrite. But the fame of Ramus
vanished before that of Des Cartes. Brucker’s Phil. by
Enfield, vol. ii.

RAMLA, in Geography, the original Arimathea, a town of
Palestine, distant one-third of a league from the village of
Loudd, or the ancient Lydda and Diospolis. This town is
almost in as ruinous a state as Loudd itself. Within its
boundaries nothing is found but rubbish; nevertheless, the
agriculture of Gaza refines here in a feral, the floors and walls
which are tumbling down. He maintains about 100 house-
men, and as many Barbary soldiers, who are lodged in an
old Christian church, the nave of which is used as a stable,
and in an ancient kan, which is disused with them by the
founders. The adjacent country is planted with lofty olive
trees, disfigured in quinences. Amidst these plantations,
which are decaying, are found dry wells, cisterns fallen in,
and vault vaulted reservoirs, which prove that, in ancient
times, this town must have been upwards of 1/2 league in
circumference. At present it feerely contains 200 fa-
milies. The little land, which is cultivated by a few of
them, belongs to the mufti, and two or three of his relations.
The rent content themselves with spinning cotton, which is
called purchased by two French houses established there.
At Ramla there is also a soap manufactory, the produce of
which is almost wholly sent to Egypt. In 1784 the aga
built here a wind-mill, which, says Volney, is the only one
I have seen in Syria or Egypt, though they are said to have
been invented in these countries. The only remarkable an-
tiquity at Ramla is the minaret of a ruined mosque on the
road to Yafa. By an Arabic inscription, it appears to have
been built by Saïd-el-din, sultan of Egypt. From the
summit, for it is very lofty, the eye discerns the whole chain
of mountains, which begins at Nablous, and skirting the
plain, levels itself toward the south. Volney’s Travels in
Egypt and Syria, vol. ii.

VOL. XXIX.

RAMLEAH, a mountain of Arabia, in the province of
Nedsed, extending from S.W. to N.E. about 250 miles;
the S.W. extremity being 80 miles E. of Kalaat el
Moilah.

RAMLER, Charles-William, in Biography, a cele-
brated German poet and professor of belles lettres at Berlin,
was born at Colberg in the year 1725. He was distin-
guished at a very early period by his poetical genius; and
in 1754 he published a poem, entitled “The Game of Chefs,”
which displayed a considerabe share of genius. In 1758 he
translated the abbé Batteaux’s Treatise on the Belles
Lettres, which he adapted to the genius of his native lan-
guage, and added some dissertations on the German style
and verification. In the following year he published, in
conjunction with Leffing, the epigrams of Logan, an
author who, notwithstanding his great merit, had been suf-
fered to remain in obscurity. In 1760 he published “Sacred
Cantatas,” which were followed, during the next 20 years,
by a great number of other publications, chiefly poetical,
of which a list is given in the General Biography. In the
year 1780 Ramler turned his attention to several of the old
German poets, and published at Leipzig the Epigrams of
Wernicke, Opitz, Ticherman, Andrew Gryphius, and
Adam Olearius. He was so successful in polishing the
works of others, and gave such proofs of his taste and cri-
tical talents, that Göse, one of the most distinguished Ger-
aman amatory poets, allowed him full liberty in his last will
to retain or reject such parts of his poems as he might think
proper. In 1782-3 he published at Berlin a translation of
the poetical pieces in the different volumes of the Spectator,
which he followed, in the subsequent ten years, by a variety
of other works on different subjects; among which may be
mentioned “A Short Introduction to Mythology, in two
Parts.” Ramler has been styled the German Horace; and
his biographer says, that though his verses disfay perhaps
less boldness and simplicity than those of the Roman, they
equal them in sublimity, and surpass them in harmony. It
has been remarked to the honour of Ramler, that he at-
tached to him Frederic the Great, and his successor, by his
poetical talents; from the latter he had a considerabe pen-
sion paid him during the closing years of his life. Ramler
was one of the directors of the national theatre at Berlin,
and professor of the belles lettres in the school of the corps
of cadets; but the latter office he resigned in 1790. Gen.
Biog.

RAMME, in Geography, a river of the duchy of Bremen,
which joins the Ouche, near its source.

RAMMED Earth Buildings, in Rural Economy, are
such as are raised with some sort of earthy material. This
mode of building with earthy materials is supposéd by some
to have been known at a very early period, and has been
long practised with success in the southern parts of France,
especially about Lyons, though little understood in any
other part of Europe until lately. This method has, how-
ever, appeared to have so many advantages, that it was
made trial of in different places in this country; and the re-
result has been so favourable, that the practice seems to de-
fer the attention of the proprietors of land, in all situa-
tions where buildings are to be erected on a cheap and
economical plan. In order to facilitate the knowledge of
the art, Mr. Holland has presented the public with the
method of performing the buildings, in a paper, translated
from a French work on the subject, inserted in the first
volume of Communications to the Board of Agriculture, in
which he says that the French writer, M. Francois Coin-
teraux, remarks, that the possibility of raising the walls of
houses two or even three stories high, with earth only,
which will sustain floors loaded with the heaviest weights, and of building the largest manufactories in this manner, may oftenon every one who has not become an eye-witnes of such things. It is a method, which in the above district of France is known by the term forge; but as it is accomplished by the ramming or compelling earth, or earthy substances, in moulds or cafs, the above term has also been applied to it. See Forge, Building in.

RAMMEKENS, in Geography, a sea-port town of Holland, in the Isle of Walcheren, formerly one of the best harbours in Zeeland. This town, which was constructed as a fortress in the year 1547, and called "Zeebourg," was one of the towns pledged to queen Elizabeth by the states general for the succours the lent them against Spain in the year 1585; three miles E. of Flushing.

RAMMER, in Agriculture, a term applied to a substance which forms a part of the subsoil or sublittara of particular districts. It is usually covered with a thin weak earth or mould in some places. It is penetrable by the roots of some plants, but not without that is, very unfriendly to the vegetation of plants in general. It is frequently met with in Chehure and other counties. See Soil.

The term signifies a composition of various kinds of clay, white sand, and gravel, which is intimately intermixed with a small portion of oysid of iron. It is for the most part found under a weak brown or grey earth which is rarely more than four or five inches in depth in the above district, lying in strata of from eighteen to thirty inches in thickness, upon a white or red sand or clayey marle, the latter often partaking of its nature for the depth of some feet. Rammer or ramelly soils are therefore constantly of a barren and unproductive avature.

RAMMELBERG, in Geography, a large and lofty mountain in Westphalia, celebrated for its mines. These mine-works yield lead, copper, silver, fome gold, borax, lapis calaminaris, zinc, sulphur, jet, vitriol, and yellow ochre. It lies near Goslarn.— Alto, a town of Westphalia, in the county of Mansfeld; three miles S.E. of Wippra.

RAMMELLY, in Agriculture, a word used to signify such crops as are tall or rank, as beans, &c.

RAMMER, a well-known implement formed of wood in different ways, according to the purpose for which it is to be used. These implements are very necessary in putting poles into the ground, in inclining land, in order to clothe the earth firmly about them, as well as for laying down turf or sods, in order to render it smooth and even. See Beetle.

Rammer of a Gun, the gun-flick; a rod or staff used in charging a gun, to drive home the powder to the breech, as also the shot, and the wad, which keeps the shot from rolling out.

The rammer of a great gun is a cylinder of wood, whose diameter and length are each equal to the diameter of the shot, with a handle fixed to it. See Spung.

RAMNA, in Geography, a mountain of Bosnia; 16 miles N. of Orach.

RAMNAGUR, a town of Hindoostan, in Bahar; 42 miles N.E. of Durbungah.— Alto, a town of Bengal; 10 miles N.E. of Kilhergera.— Alto, a town of Hindooostan, in Oude; 27 miles N.E. of Lucknow.

RAMONCHAMP, a town of France, in the department of the Volguys, and chief place of a canton, in the district of Remiremont. The place contains 2385, and the canton 11,325 inhabitants, on a territory of 245 kilometres, in 6 communes.

RAMONDON, Lewis, in Biography, an English finger, who first appeared on the stage of Drury-lane in 1706. But he sung in Arinoc, and Pyrhus and Demetrius, when these operas were performed at the Queen's theatre in the Haymarket. He appears no more as a public singer after this period, but his name occurs as a composer in a collection of songs called the "Merry Musick," 1715; and as the editor of the opus, or "the song tunes in the opera of Camilla, contrived and fitted to the harpichord or spinet," in the title of which it is said, "that the lefions being placed on five lines render them proper for a violin and a lute." Almost all organ and harpichord music was till this time written and printed on five lines.

RAMOOI, in Geography, a town of Arakan; 60 miles N.N.W. of Arakan.

RAMOR, LAUGH, a lake of Ireland, in the southern part of the county of Cavan, which contains several islands, on which are held the runs of some ancient castles. These were formerly adorned with wood, but are now bleak and desolate. The river Blackwater, which issues from it, joins the Boyne at Ravan. Lough Ramor is about 15 miles S. from Cavan.

RAMOS, or LAMOS, a river of Africa, which runs into the Atlantic, 60 miles N.N.W. of Cape Formosa. N. lat. 5° 45'.

RAMS, D investigated in the river of the Amazons, about 70 miles long, and from 10 to 20 broad; 60 miles above Pausix.

RAMOSE LEAF, in Botany. See Leaf.

RAMOTH, in Scripture Geography, a famous city of Pallene, in the mountains of Gilead, and hence called Ramoth-Gilead. This city belonged to the tribe of Gad. It was affixed to the Levites, and was one of the cities of refuge beyond Jordan. According to Ezechias, it was 15 miles E. from Philadelphia, but St. Jerom places it in the vicinity of Jabok, and consequently N. of Philadelphia.

RAMOUCCI, in Geography, a river of Abissi, which runs into the Dews, N. lat. 50° 20'.

RAMOURY, a town of Hindoostan, in the circular of Hindostan; 20 miles E. of Hurdah.

RAMPAH, a town of Hindoostan, in the circular of Rajamundry; 40 miles N. of Rajamundry.

RAMPANT, in Heraldry, is applied to a lion, bear, leopard, or other beast, in posture of climbing, or standing upright upon his hind-legs, and rearing up his fore-feet; shewing only half of his face, as one eye, and one ear.

The term is French; and signifies, literally, creeping. It is different from soluant, which denotes a posture less creft, or somewhat flowing forwards, as if making a saul.

This posture is to be specified, in blazoning, in all animals, except in the lion and griffon; it being their natural situation.

RAMPARA, in Geography, a town of Hindoostan, in Concan; 20 miles N. of Gheria.

RAMPART, or RAMPH, in Fortification, a wall, bank, or elevation of earth about the body of a place, to cover it from the direct fire of the enemy, and of sufficient thickness to resist the efforts of the cannon for many days; and formed into bastions, curtains, &c.

The word is formed from the Spanish amparo, defense, or covering.

Upon the rampart the soldiers continually keep guard, and pieces of artillery are planted there for the defence of the place. Hence, to shelter the guard from the enemy's shot, the outside of the rampart is built higher than the inside, i.e. a parapet is raised upon it with a platform. Hence, also, earth not being capable to be raised perpendicularly, like stone, the rampart is built with a talus or slope, both on the inner and outer side.
The rampart is sometimes lined, i.e. fortified with a stone wall within, otherwise it hath a berme. It is encompassed also with a moat or ditch, out of which the earth that forms the rampart is dug.

The height of the rampart should not exceed three fathoms, this being sufficient to cover the houses from the battery of the cannon: neither ought its thickness to be above ten or twelve, unless more earth be taken out of the ditch than can be otherwise hallowed. See Construction, according to M. Vauban's first Method.

The ramparts of half-moons are the better for being low, that the small fire of the defendants may the better reach the bottom of the ditch; but yet they must be so high as not to be commanded by the covert-way.

Rampart is also used in Civil Architecture, for the space left void between the wall of a city and the next houses. This is what the Romans call pomarium, in which it was forbid to build, and where they planted rows of trees, for the people to walk and amuse themselves under.

Ramparts, in Geography, a town of Bengal; 8 miles S.E. of Rungpore.

Rampeting, or sodding, denotes the process of building sod or turf walls, or banks.

Rampfersgrube, in Geography, a town of Germany, in the country of Heneberg; six miles W. of Meinungen.

Ramphastos, the Toucan, in Ornithology, a genus of birds of the order Picæ, of which the generic character is as follows: Bill very large, light, hollow, convex, serrate at the edges; each mandible incurvate at the tip; nostrils behind the base of the bill, long, narrow; the tongue is feathered at the edges, the foot motley climbers.

The birds of this genus first became known to naturalists on the discovery of South America, and to the warmer regions they appear, in general, to be confined. Like the hornbills, they are distinguished by the size of their beaks, which, in some species, is nearly equal to that of the whole body. It is, however, of a very light substance, and, in the living bird, it is compressible between the fingers. Both mandibles are serrated in an outward direction; the tongue is of a highly singular form, representing the appearance of a very narrow lanceolate feather, being of a somewhat horn or cartilaginous nature, and divided on each side into innumerable short and close-set fibres; in consequence of which it was described by some early writers on natural history as a real feather, supplying the place of a tongue.

The orbits of the eyes are generally bare. The toucans are supposed to feed on fruits, but in a state of captivity they will eat animal food. They deposit their eggs, which are usually two in number, in the hollows of trees, on the surface of the decayed wood. These birds have been as yet met with only in South America, and there merely between the tropics, being totally incapable of sustaining the cold. They are easily tamed and familiarized, and several species have been brought to England, where fruits, fish, and flesh have been promiscuously devoured by them with considerable voracity. Whatever was received by the bill was thrown into the air, and on its return caught, and, without the slightest mastication, instantly devoured. There are seventeen species enumerated by Gmelin, though Mr. Latham mentions only fifteen.

Species.

**Viridis**; Green Toucan. Green, with a yellow belly, and red rump. This species is found in Cayenne, and is about fourteen inches long. The upper mandible is yellow, with red sides, and a black line in the middle; the lower one is black, the base and round the nostrils are red; the teeth in both are white; the irides and naked orbits are yellow; the legs are of a lead colour; the claws are black; the tail is wedged, beneath inclining to ash; head, chin, and throat, in the male black, in the female bay, terminated by a black narrow transverse band.

**Edentulus**; Toothless Toucan. In this the bill is not serrated at the edges. It inhabits Cayenne, and is twelve inches long. The upper part of the body is green, but beneath it is more of a yellowish colour; the head and neck are chestnut; the rump is red; the upper mandible is brown, the lower black; the thighs green, and it is thought to be a variety of the viridis.

**Pavonicus**; Pavonian Toucan. The general colour of this is green, but the feathers are sprinkled with red spots. It is also known by a mixture of red and changeable or peacock-coloured feathers interpersed. The bill is variegated yellow and black; the legs and claws are black.

**Piperivorus**; Piperine Toucan. Green; the fore parts are black; the vent and thighs red. This species has been described by Edwards under the name of the green toucan. Its length is about seventeen inches, and its general colour is of a dull green; the head, neck, and breast, are of a deep black; behind each ear is a somewhat lengthened orange-coloured spot, and immediately behind the lower part of the neck is an orange-coloured bar or collar; the belly is pale and yellowish-green; the thighs are purple; the vent is red, and the tail, which is coarsely crested, slightly tipped with dull red; the bill is about three inches long, and of a black colour, but towards the base it is variegated by red, white, and orange-yellow. In the female the head, neck, and breast, are brown instead of black, and the lower part of the belly is grey. It is a native of Cayenne, and fed to feed on the pepper of the country. The female of this species has been known to vary in having the bill of a horn colour, with a black bar near the end, and two others near the edge; the ridge also being black, and the yellow crescent at the neck is wanting.

**Aracari**. This species is green, but the abdominal band, vent, and rump, are red; the belly and breast are yellow. It is a native of Brazil, Surinam, and Cayenne, and is full sixteen inches long. The upper mandible is black on the back and tip, but the sides are whitish. The base is three-lobed at the nostrils, with a white arch at the root, lower black; the head, wings, and tail, are black; the breast and body are yellow and scarlet, with a black roundish spot in the middle of the breast, and a similar transverse one on the beginning of the belly; the thighs are tawny.

**Torquatus**; Collared Toucan. This bird is black above, and beneath it is whitish; the belly is green, the hind part is red, and the collar red. It inhabits the coasts of New Spain, is about eighteen inches long, and feeds on fish. The upper mandible is blackish, and the lower black; the irides are of a reddish-yellow; the head and neck are black; the lower tail-coverts are red; the thighs purplish; the legs are of a greenish-ash colour; the claws are black.

**Piscivorus**; Brazil Toucan. This is blackish, but the abdominal band and vent are red; the rump is white. It inhabits South America, and is twenty-one inches long. The bill is yellow, with a scarlet spot on the tip; the lower mandible is blue; the eye, back, wings, tail, belly, and thighs, are black; the temples, chin, breast, and rump, are white.

**Erythropterygion**; Red-breasted Toucan. Blackish; the cheeks, chin, and throat, white; upper tail-coverts sulphur, but the lower and crescent on the breast are red. This is found
found in various parts of South America. The beak and back of the bill are yellow; tip of the upper mandible, and hollow of the lower, red; the nostrils are edged with black; the orbits are blueish; the legs are plumbeous, and the claws are black.

**Tucan;** Yellow-breasted Toucan. This is also blackish; the abdominal band, vent, and rump, yellow. It measures about nineteen inches in length, and has been described by Mr. Edwards from a living specimen brought into England. According to this gentleman, the bill of this species is large in proportion to the size of the bird; it is compressed sideway, having a sharp ridge along its upper part, and toothed on its edges; the upper mandible is green, with a long triangular spot of orange colour on each side, and the ridge on the upper part yellow; the lower mandible is blue, with a shade of green in the middle; the point is red; it has about five transverse faint dully bars, which cross the joinings of the two mandibles; the nostrils are invisible in the black line that surrounds the bill; the iris of the eye is of a fair green colour; round the eye is a broad space of naked skin, of a violet colour; the skin beneath the feathers is of a violet colour, below which is a bar of scarlet feathers, which parts the yellow on the breast from the black on the belly; the covert-feathers of the tail are white above, and those beneath are of a fine red; the crown of the head, upper part of the neck, the back, wings, belly, and tail, wholly black, though on the upper side of the wings and tail it has a changeable gloss of bluish-purple; the legs and feet are all of a blue or violet colour. The specimen from which this description was made, was brought from Jamaica, but the bird is a native of the hotter parts of South America.

**Picatus;** Preacher Toucan. Blackish; breast yellow, vent and tips of the tail-feathers red, rump black. It inhabits Guiana and Brazil, and is more than twenty inches long. The bill is yellowish-green, tippet with reddish; the belly is red; the tail is dotted with red at the tip. This bird is said to have a frequent habit of moving its head from side to side, while uttering its notes; hence it has obtained the name of preacher.

**Dicolores;** Yellow-throated Toucan. Blackish; breast, belly, vent, and rump, red; the chin is yellow. It inhabits Cayenne, and is seventeen inches long. The bill is olive, with a black base; the mandibles are edged with red; the cheeks are of a sulphur colour; the throat is orange, but edged with sulphur.

**Toco;** White-throated Toucan. Blackish; chin, throat, and rump, white; orbits, circle on the breast, and vent, red. It inhabits Cayenne, and is about nine or ten inches long. The bill is of a reddish-yellow, the face is black; the upper mandible is black at the tip.

**Indicus;** Indian Toucan. The throat, quill-feathers, and tail, black; the cheeks and breast are white; belly and thighs are yellow; the crown is of a reddish-orange; rump crimson. It is found in divers parts of India. The bill is hardly serrate, and not so large as in the others.

**Luteus;** Yellow Toucan. This is of a yellowish-white; the neck is marked with two black lateral stripes; the tail and wings are variegated with black and white; the upper wing-coverts are yellow. It inhabits New Spain, and is about the size of a pigeon. The beak is black; the irides are yellow; the legs are brown; the claws are yellowish.

**Ceruleus;** Blue Toucan. Blue mixed with cinereous. It inhabits the coasts of New Spain. The bill is longer than the body; the eyes are black and the irides are tawny.

**Durius;** This is the blue-throated toucan of Mr. Latham, described from a catalogue of the museum of baron Fangere of Montpellier, where it is announced as an undescribed species.

**Albus;** White Toucan. This is entirely white.

**Rampicherla;** in Geography, a town of Hindoostan, in the circuit of Guntoo; 12 miles N.E. of Innakonda.

**Rampin, in the Mangs. See Toe.**

**Rampour, in Geography, a town of Bengal; 13 miles N. of Currackpore.—Allo, a town of Hindooftan, in Bahar; 31 miles N.W. of Bettiah.—Allo, a town of Almora; 30 miles N.N.W. of Bareilly. N. lat. 28° 45' E. long. 79° 22'.—Allo, a town of Hindooftan, in Oude, on the Ganges; 34 miles N.W. of Manickpore.—Allo, a town of Hindooftan, in Oude, on an island formed by the divided stream of the Dower; 35 miles N.E. of Lucknow.—Allo, a town of Hindooftan, in Oude; 25 miles E.S.E. of Goorackpore.—Allo, a town of Hindooftan, in Oude; 30 miles N.E. of Goorackpore.—Allo, a town of Hindooftan, in the Carnatic; 30 miles S.W. of Nellore.—Allo, a town of Hindooftan, in the circuit of Bagguland; 20 miles W. of Rewah.—Allo, a town of Hindooftan, in Behar; 22 miles N.W. of Bidizigur.—Allo, a town of Hindooftan, in the circuit of Schurunpore; 23 miles S.S.W. of Schurunpore.—Allo, a town of Hindooftan, in the circuit of Oudipour; 40 miles E.N.E. of Oudipour.

**Ramps, in Fortification, are gentle slopes made for the cannon to be drawn up and down by, and also for the easy communication of the troops posted in a battery that is raised above the level of the ground on which it is built. The rife of these slopes is about two inches, on twelve of a base, or the length of the ramp's base is six times the height, and this is general for the draught of carriages; but footways need not be of so gentle a slope, as a rife in one foot in three may answer the purpose; or, instead of ramps, stairs may be, and commonly are, used for the passage of the foot. The breadth of a carriage ramp is usually about nine or ten feet, that breadth being sufficient both for the carriage and footway; but those for foot-passage only need not be above three or four feet wide. Ramps may either rise on the side of an elevated work, or against a faulant angle of that work, or on each side of an entering angle.**

**Ramquilla, in Geography, a town of Sweden, in the province of Smaland; 5 miles N.W. of Calmar.**

**Ramsay, Allan, in Biography, a poet of considerable celebrity, who wrote in the Scottish dialect, was born in the year 1686, in the parish of Crawford, Lanarkshire. He received no other education than that of the parish school, and was apprenticed to a barber in Edinburgh. It has not been ascertained when he first began to make verses; but about the year 1735, several of his poems had been published. Soon after this he laid aside the trade to which he had been brought up, and adopted the more congenial one of a bookseller. In 1721 his detached poems were published, by subscription, in a quarto volume. In 1724 he began to publish his collection of songs, entitled “The Tea-table Mischellany,” which at length extended to four volumes. This work was followed by one, entitled “The Evergreen,” being a collection of songs written by the ingenious before the year 1600. These publications were well received; but his fame was greatly extended by his**

"Gentle
"Gentle Shepherd," which was afterwards enlarged from two pastoral poems, in the form of a regular drama. He now held a correspondence with several poets and other ingenious persons of the time, and his shop in Edinburgh was the resort of the men of letters who then flourished in the capital of Scotland. He is supposed to have opened the first circulating library in that city, and in 1736 he built a play-house, which was the first ever known in Edinburgh; but the act prohibiting the exhibition of plays in unlicensed buildings, caused it to be shut up. Ramfay, towards the middle of his life, withdrew from the field of authorship, and attended to the much more profitable buffets of selling, rather than writing of books. He died in 1758, at the age of 71. The poems of Allan Ramfay, says an eminent critic, "display none of the fire of the genius so conspicuous in those of Burns, but have occasionally an agreeable pastoral simplicity, and are often marked with a vein of humour, natural, though coarse. The Gentle Shepherd is, perhaps, one of the best pastorals with respect to the pictures of real life, which are drawn with great propriety, and generally present pleasing images."

Ramsay, Allan, son of the preceding, was born at Edinburgh about 1700, and having devoted himself to painting, went at an early period of his life to study in Italy, and there received instructions from Solomon and Imperiale. After his return, he practised in Edinburgh for some time, but afterwards removed to London, and by the influence of his countryman, the earl of Bute, was introduced into the vortex of the court, painted the prince of Wales, and on the death of Shaksleton in 1767, was appointed principal painter to the crown; although Reynolds was then in possession of the highest reputation.

Ramfay never ventured to attempt the higher walks of the art, but confined himself solely to portraits, which he painted agreeably. Notpossessed of brilliancy of genius sufficient to attempt strong character, with striking effects in his pictures, he contented himself with that portion of art which meets the expectations of common observers; never offending with affectation or neglect, he finished his pictures with care and neatness, and retained his friends and reputation till he ceased to practice. He was so far attached to his art, that he visited Italy four times: to what purpose does not appear, unless it were to derive benefit from the portraits of Pompeo Battoni; for no traces of higher character are observable in his productions. Yet he was a man of found sense and strong understanding; possessed of literary acquirements, and devoted to study. Though he understood the Latin, French, and Italian languages, he was not satisfied till he added a knowledge of the Greek, acquired when he was advanced in life. Thus endowed, he was emulous of literary fame, and published, under the title of "The Inveiglator," Essays on RIDDLE, as the text of truth, on the Naturalization of Foreigners, on Taste, &c.; and, as occasion prompted, the town was favoured by him with some fugitive pieces on the politics of the day. He was always held to be highly estimable as a man, and enjoyed his fame and good fortune to about the advanced age of 75.

Ramsay, Andrew Michael, called the chevalier Ramfay, was born at Ayr, in Scotland. He received a good education at Edinburgh, where he distinguished himself so much, that he was chosen to attend the son of the earl of Wemyys at St. Andrew's. After this he went to Leyden, with the view to farther improvement, where he became acquainted with Poiret, one of the leaders of the Quietists, some of whose doctrines he imbibed. He next went on a visit to the celebrated Fenelon, archbishop of Cambray, who converted him to the Roman Catholic religion, and Ramfey ever after this considered himself as the disciple of that excellent prelate. Upon his works he formed his literary taste, and he even adopted France for his country, and made use of its language in his writings. Here he obtained some polls of honour and emolument, and he was made knight of the order of St. Lazarus, whence he had the title of chevalier. His reputation caused him to be invited to Rome by the Pretender, in order that he might undertake the care and education of his children. This he accepted; but having found that little court so divided by factions, he quickly resigned his office, and returned to Paris. In the next year, 1725, he revisited his native country, and resided some years with the duke of Argyle, employing himself in the composition of several works. After his return to France, he entered into the service of the prince of Turenne, duke of Bonfilon. He died in 1745, at St. German-en-Laye, the retreat of the exiled Stuart family, at the age of 57. His principal writings were, "L'Histoire de la Vie et des Ouvrages de M. de Fenelon," "Essai sur le Gouvernement Civil," "Dixours sur le Poème Epicque?" "Le Physiocrate," being remarks on lord Shaftsbury's Characteristic; "L'Histoire du Marechal de Turenne," and "Les Voyages de Cyrus." The last is that which is by much the best known, and it has been frequently printed in the French and English languages. Voltaire has styled it a feeble imitation of Telemae; it is, however, written with elegance, but is tedious. Another of the chevalier's works was "A Dissertation on Free-Masonry," of which he was grand chancellor in France. In this he traces the origin of the institution to Palestine, in the time of the Crusades; and having found a great declension of the mystical ceremonies formerly practised, he strongly urged their renewal, and proposed a general assembly of the brotherhood of all nations to be held at Paris. Biog. Brit.

Ramsay, in Geography. See Ramsay.

Ramsay Point, a cape on the S.E. coast of the island of Lewis. N. lat. 57° 44'. W. long. 6° 36'.

Ramsbury, a village and parish in the hundred of Ramsbury, and county of Wilts, England, is situated about six miles to the eastward of the town of Marlborough, and 70 miles west by south from London. In the time of the Saxons it was a place of much importance, as to be constituted the seat of the king, when Wiltshire was made a distinct bishopric by Plegmund, archbishop of Canterbury, in the year 1009. Ramsbury church was then the cathedral church of the dioceze, and continued to be so till bishop Herman prevailed upon king William the Conqueror to unite the bishoprics of Wiltshire and Sherborne, and fixed his episcopal seat at Old Sarum. The church, an ancient building, is divided into a nave, two aisles, and a chancel, with a massive square tower at its western extremity. In the chancel is a long stone, which tradition affirms to be the grave-stone of a giant; also an old altar tomb of Purbeck marble, without any inscription, and several monuments commemorative of the Jonefs of Ramsbury manor, or park. This seat is now the property of Sir Francis Burdett, bart., in right of his mother, second daughter of the late William Jones, esq. The house was designed in the Greek style, by John Webb, nephew to Inigo Jones. The inclines are extensive and well wooded, and are intersected by a branch of the river Kennet, which spreads itself out in the form of a lake, from the sides of which the grounds rise in easy, sloping lawns.

Littletocot park, the seat of major-general Edward Leybourne
Ramsden, Jesse, in Biography, an eminent English mathematical and astronomical instrument-maker, the son of an inn-keeper at Salterhebble, near Halifax, in Yorkshire, where he was born in the year 1735. At nine years of age he was admitted into the Halifax free-school, where he acquired, during three years, the elements of classical learning; after which he was removed to the care of an uncle at Craven, by whom he was sent to a clergyman of the name of Hall, who had acquired much reputation by teaching at his school the mathematical sciences. Under this gentleman's instructions, young Ramsden became a proficient in geometry and algebra, and was advancing rapidly in these and other collateral branches of study when his father sent him to London, to apprentice him out with a clothier at Halifax. At the age of twenty he went to London, where he became clerk in a wholesale cloth warehouse. This situation he retained about two years and a half, when his inclination for the sciences revived so strongly, that he resolved to qualify himself for some business which should prove suitable to the bent of his mind. With this view he bound himself apprentice for four years to Mr. Burton in the Strand, who was esteemed one of the best workmen of his time in making thermometers and barometers, and in engraving and dividing mathematical instruments. After the expiration of his apprenticeship, he worked as journeyman with a fellow of the name of Cole, with whom he afterwards associated himself as partner. This connexion did not last long, when Mr. Ramsden opened a workshop on his own account, in which he soon recommended himself to the employment of the principal mathematical instrument-makers in London. In the course of his business his repeated examination of the instruments which were sent him to be engraved or divided, led him to discover their defects, and his genius suggested to him the means of removing them, or of correcting better instruments. In order to put his plan into execution, he made himself master of the practical operations of the trade, and formed the design of examining every astronomical instrument in use, with the view of correcting those which, being founded on good principles, were faulty only in the construction, and of prescribing those which were defective in both their respects. About this time, by his marriage with Miss Dollond, he became possessed of a part of Mr. Dollond's patent for achromatic telescopes. In the year 1766, Mr. Ramsden opened a shop in the Haymarket, where he continued till 1774, when he removed to Piccadilly, where he remained till the time of his death. Before his settlement in the Haymarket, he had improved the sextant, and he had invented his celebrated dividing machine. (See the art. ENGINE.) Having spent ten years in bringing this machine to perfection, he obtained from the Board of Longitude a premium of 1000l. Mr. Ramsden constructed an instrument for dividing straight lines, which has been described in a former volume of the New Cyclopaedia, and while he was employed on his dividing-machine he made great improvements in several other instruments. The THEODOLITE (see the article), before his time, confined merely to a telescope, turning on a circle, divided at every three minutes, by means of a VERNIER, which he; but in the hands of Mr. Ramsden it became a new and perfect instrument, serving for measuring heights and distances, as well as taking angles. The largest and most perfect theodolite ever constructed was made by him for general Roy, for the purpose of measuring the series of triangles in England. Though this instrument is only of eighteen inches radius, its accuracy is so great as not to admit of an error of a single second. With this instrument general Roy measured the angle between the polar star and the sides of his triangles, in order to have the exact difference between the observations of Paris and Greenwich, which he found to be 30°. Mr. Ramsden was a great improver of the barometer for measuring the height of mountains, which he could obtain to a degree of accuracy that was very surprising, and he caused to be engraved a table to accompany his barometers, which, without the trouble of calculation, gives the heights of places, according to the heights of the mercury, and even at different temperatures. He also pointed
pointed out a new method and apparatus adapted to the 
conveyance and support of the portable barometer. Mr. 
Ramsden made improvements on the electrical machine; 
and on manometers for measuring the density of the air; he 
vented an instrument for measuring inaccessible distances; 
laying balances which turn with less than a ten-thousandth 
part of the weight used; levels and a variety of other in-
struments. The pyrometer also exercised his talents, and 
on this occasion, as on all others, Mr. Ramsden showed a 
fort of natural and almost intuitive faculty in discovering 
the essential faults of an instrument, and in inventing the 
most simple and exact methods of correcting them. With 
respect to optics, he discovered a method of correcting, in 
a new and perfect manner, the aberration of sphericity and 
refrangibility in compound eye-glasses applied to all astro-
nomical instruments. Opticians had imagined that the purpose 
might be accomplished by making the images of the object-
glases fall between the two eye-glasses, which was attended 
with this great inconvenience, that the eye-glasses could not 
be touched without deranging the line of collimation, and 
the value of the parts of the micrometer. To remedy this 
inconvenience, he let out from a simple experiment, viz. that 
the edges of an image observed through a prism are less 
 coloured, according as the image is nearer the prism. This 
led him to attempt placing the two eye-glasses between the 
image of the object-glasses and the eye, without falling to 
correct the two aberrations; which he did by changing the 
radii of the curves, and placing the glasses in a manner very 
different from that commonly employed. In the Philoso-
phical Transactions for the year 1779, Mr. Ramsden has 
described a new reflecting object-glasses micrometer; to the 
paper on this subject we refer our readers, and also to the 
article Micrometer in this Dictionary. With this micro-
 meter the diameters of the planets may be measured; it 
may be adapted to all kinds of achromatic telescopes; it 
may be brought near to, or removed from, the object-glasses 
at pleasure, to render vision distinct; and it may be removed 
from the telescopes, if the observer wish to use the latter 
without a micrometer. The high degree of merit to which 
Mr. Ramsden's many and important inventions were intituled, 
led his friends to propose him as a member of the Royal 
Society, and he was elected in the year 1786.

The Equatorial or Transit instrument (see the articles) re-
ceived great improvements in the hands of Mr. Ramsden, 
who rejected the endless screw, which by preying on the 
centre destroyed its precision; he placed the centre of grav-
ity on the centre of the base, and caused all the movements 
to take place in every direction; he pointed out the means 
of rectifying the instrument in all its parts, and he applied 
it a very ingenious small machine, for measuring or cor-
recting the effect of refraction. The greatest equatorial in-
strument ever attempted, is that which he constructed for Sir 
George Shuckburg, on which he employed several years, 
and of which we have given a description and figure. Mr. 
Ramsden's meridian telescopes which he made for Blenheim, 
Manheim, Dublin, Paris, and Gotha, are also remarkable 
for the excellence of their object-glasses. With that of 
Dublin, Mr. Usher observed stars of the fourth magnitude 
in the open day, and those of the third very near their con-
junction with the sun. These telescopes are eight feet in 
length. There is a five-feet one at the observatory at Pal-
ermo. Mr. Ramsden made great improvements in the mural 
quadrant, of which a full account will be found in the article 
Circle, to which we refer our readers for much valuable 
information on the subject of astronomical instruments. 
Having in various parts of our work entered into the nature 
of Mr. Ramsden's improvements and inventions, it is unnec-
cessary to repeat here what has already been fully explained.

The field in which the inventive genius and superior talents 
of Mr. Ramsden were exercised, was, as we have seen, very 
extensive. In order that every part of his instruments might 
be fabricated under his own inspection, he collected in his 
workshops men of every branch of trade necessary for their 
construction. So important did he consider the principle 
of division of labour, that he always confined the same workmen 
to the same branch, and by that means arrived at the greatest 
correctness and nicety in executing it. Notwithstanding 
the great perfection of his instruments, which ought to have 
secured to Mr. Ramsden a large fortune, he sold them cheaper 
than any other artist in London, sometimes even one-third 
below the usual price. Such was the demand for them, 
from almost all parts of the world, that though he employed 
sixty men, he was unable to execute all the orders which he 
received. His great attention to business injured his health, 
and hallowed his death. He died at Brighton, where he 
had been for the benefit of the sea-air, November 5, 1800, 
in the sixty-sixth year of his age. He had been elected a 
member of the Imperial Academy of Sciences at Petersburg 
in 1794, and in the following year he was presented with the 
gold medal, adjudged by the Royal Society to persons dis-
tinguished for their scientific talents.

Mr. Ramsden was by nature endowed with uncommonly 
strong reasoning powers, and a most accurate and retentive 
memory, but, at the same time, with such a quickness of 
penetration, that he could, as it were, with a single glance, 
view in every light the subject on which he thought, and 
adopt the most advantageous mode of considering it. He 
polished, in an exquisite degree, that quality of mind 
which is emphatically styled elegance, which in the abstract 
sciences leads to clearness, simplicity, and precision, as in 
the fine arts and literature, it gives the last polish to genius, 
and is more generally known by the appellation of talent. In 
his habits he was temperate to abstinence, satisfied with 
small quantities of food, and a small portion of sleep. Un-
acquainted with dissipations or amusements, and giving but 
little time even to the society of his friends, the whole of 
those hours which he could spare from the duties of his pro-
fession, he devoted either to further improvements in his in-
struments, or to perusing books of science, particularly 
those mathematical works of the sublime writers which had 
any connection with the subject of his own pursuits. Mr. 
Ramsden's only relaxation from almost constant and severe 
studies, was the occasional perusal of the best authors, 
both in prose and verse; and when it is recollected that at 
an advanced age he made himself fully master of the 
French language, as to read with peculiar pleasure the 
works of Boileau and Molière, no one can believe that he 
is spent even his hours of amusement. Short and temperate 
as were his habits, a book or a pen was the constant 
companion of his meals; and when ill his broke his sleep, 
a lamp and a book were ever in readiness to beguile the 
verse of pain, and make bodily sickness minister to the 
progess of his mind. He was well skilled in the abstruser parts 
of mathematics, and conversant with the best writers on the 
sciences; and such was his manual dexterity, that there was 
not one tool in any of the numerous branches of his pro-
fession which he could not use with a degree of perfection 
equal to that of the very best workmen in that particular 
branch, and he could have begun and finished every single 
part of his most complicated instruments. For this article 
we are chiefly indebted to a very elaborate and excellent ori-
numbers of sauraffes, the largest species of the crane kind, are here seen at certain seasons of the year, so that any quantity of eggs may be collected. The lake gradually narrows, and from its northern edge lends off two small brooks; and at the other extremity it discharges itself into a much larger lake. This lake, it is said, is held in high respect by the inhabitants of Boodan, whose superstition leads them to consider the increase or decrease of its waters as portentous of good or evil to their nation. They fancy it to be a favourite haunt of their chief deities. Turner's Thibet, p. 212, &c.

RAMTEAK, or RAMTECH, a town of Hindoostan, in the circle of Goondwana, held sacred by the Hindoos, who pretend that Ram collected his army here, prior to his expedition against Ravan at Lanka, or Ceylon. The Hindoos believe all the Europeans to have descended from Ravan, and Ceylon to be an immense mountain of gold invisible to them. Near the town is a temple, in which they offer up their facrifices and devotions; 15 miles N.E. of Nagpore. N. lat. 21° 29'. E. long. 79° 57'.

RAMTRUT, in Mythology, the name of a deity worshiped by the Kariazes, a people of Hindoostan, whom he has a celebrated temple, at Onor. The characters under which he is represented more resemble those of a monkey than of a man.

RAMULOSE LEAF, in Botany. See LEAF.

RAMUNDA, or ROMLA BODA, in Geography, a town of Sweden, in Nericia.

RAMURAH. See RAMUR.

RAMUS, Peter, in Biography. See RAMISTS.

Ramus, in Anatomy. This word, signifying branch, and the term ramification, are used in describing the arteries, veins, and nerves, the divisions and subdivisions of which bear some analogy to the branching of a tree. In the same way we speak of trunks of arteries, &c. and describe them as branching out.

Ramus, in the Anatomy of Plants, a name given to the first or lateral branches, which go off from the petiole, or middle rib of a leaf. The subdivisions of these are called furculi; and the final divisions of these into the most minute of all, are by some called capillamenta; but in general, both these kinds are comprehended under the name of furcula.

RAMUSIO, or RAMUSIUS, GIAMBATTISTA, in Biography, an early collector of voyages and travels, the son of Paolo, an eminent lawyer, defended from a learned and distinguished family of Venetian citizens, was born at Venice in 1485. He was in early life deputed by the flate upon public business to Switzerland, Rome, and France; and in the latter country he so much ingratiated himself with Lewis XII., that he was by him caused to travel through almost the whole of his kingdom. As a reward for his services, he was made secretary of the council of ten at Venice, which post he at length resigned; and returning to Padua, employed himself in compiling his great work, “Raccolta delle Navigazioni e de Viaggi,” which was published at different periods between the years 1554 and 1559, in three volumes folio. He had prepared a fourth volume, which was burnt at the printer's. Ramusio died at Padua in 1557; of course, a part of his work was given to the world after his decease. Ramusio was author of a treatise "De Nili Incremento." He was a man of great learning, and was extremely conversant in history, geography, and the ancient languages: he had some knowledge in alchemy, and held a correspondence with many learned men and well informed persons, both in Italy and Spain. It was by their assistance, and at the desire of Tracaltorso, that he composed
the work already mentioned. This work was a collection of all the voyages and travels that had hitherto been published; in which he gave translations of those in foreign languages; and he prefixed dissertations, in which he diligently examined the pretensions of different authors, comparing them with one another.

RAN, in our Old Writers, is used for open and public robbery, so manifest that it cannot be denied. "Ran dicitur aperta rapina que negari non potest." Lamb. 125. Leg. Canut. cap. 58. Hence it is to this day vulgarly said of one who takes the goods of another injuriously and violently, that he has taken or finchted all he could rap and ran.

RAN, twenty cords of twine, wound on a reel; and every cord so parted by a knot, as to be easily separated.

RANA, in Geography, a town of Austria; 12 miles S. of Aigen.—Alfo, a town of Austria; 13 miles S.S.W. of Zwettl.

RANA, or Oranoo, one of the Sandwich islands, in the North Pacific ocean, situated about three leagues from Mowee and Morotoi, and lying to the S.W. of the passage between these islands. The country to the south is high and craggy; but the other parts of the island had a better aspect, and appeared to be well inhabited. It produces very few plantains, and bread-fruit trees; but abounds in roots, such as yams, sweet potatoes, and tarro. The number of inhabitants is estimated at 20,400. Its S. point is in lat. 20° 45'. E. long. 203° 8'. Cook's Third Voyage, vol. iii.

RANA, in Surgery. See Ranula.

RANA, in Zoology. The frog, a genus of the class Amphi-bia, of the division Reptiles, of which the generic character is: Body four-footed, naked; it generally has no tail, the hind legs are longer than the fore. This genus differs from the Lacerta (see the art. Lizard), in having a shorter body, broader, thicker head, and in general no tail. The animals of it feed on insects; they are full grown about the fourth year, and seldom live beyond the twelfth. Their fore-feet are more frequently, having four toes: their hind-feet are palmate and five-toed; they are extremely paddling to the female for days and weeks: the tadpole is excluded from the egg without feet, but with a tail resembling a fish's, which drops off as the legs are protruded; in this state they have likewise a sort of gills and lungs, and many have a small tube on the lower lip, by which they can affix themselves to other bodies; near the light eye is a vesicle, from which they discharge water: in breeding time, the fore-thumb of the male is warty: toads, as we all know, are filthy in their aspect, and live in damp, obfene, dark places, and crawl out only by night: their eggs are in a long chain: frogs are more active, and more about by day: these lay their eggs in a confuted maze.

Dr. Shaw, in his entertaining and instructive Zoology, says this genus may be divided into three sections; viz. 1. Frogs, commonly called Rana, with light active bodies, and which leap when disturbed. 2. Slender-limbed frogs, Hyla, Calamites, or Rana arborea, viz. such as have light bodies, very slender limbs, and toes terminating in flat, circularly expanded tips, enabling the animal to adhere at pleasure to the surface even of the smoothest bodies. Several of this division actually reside on trees, adhering by their toes to the lower surfaces of the leaves and branches. 3. Toads, Bufonae, or such as have heavy bodies, short thick limbs, and which rather crawl than leap when disturbed.

Gmelin has given a different arrangement, which, according to our usual custom, we shall follow in this article. He divides the genus into three sections, viz. A, those with warty and pulped up bodies; and short legs; these are toads. B, those with bodies rather oblong, smooth and with longer legs: these are frogs, properly so called. And C, whose hind feet are very long; and whose claws are lenticulate. Dr. Shaw enumerates more than fifty species, but Gmelin describes only thirty-six.

Section A.—Body warty, pulped up: shorter Legs.

Species.

PIPA; Surinam Toad. The toes of the fore-feet of this species are unarmed, four-clawed; those of the hind-feet are clawed and palmate.

This hideous and deformed animal inhabits the waters of Guiana, and is actually eaten by the natives. The male, after the exclusion of the eggs, collects the mafs together, and finears it over the back of the females with its paws, where they are received into small cells, impregnated by the males and closed up; after some time the perfect young are excluded from these hollow tubercles on the back of the female.

The size of the Pipa considerably exceeds that of the common toad; the head is flat, broad, and very short; the back is flatula-shaped; the eyes very small and remote; neck very short, wrinkled; the body is orbicular, flat, with a hard cartilaginous skin; the fore toes are round, and the hind ones very long, connected by an undivided membrane. This species was first made known to the Europeans about the latter end of the 17th century.

MUSICA; Musical Toad. The specific character of this is, that it has gibbous shoulders that are dotted; the body is varied with lurid and brown; the fore-feet are cleft, and the hind-feet are subpalmate and five-toed, with fearcely any claws. It inhabits the fresh waters of Surinam: it is larger than the common toad: in the evening, and during the whole night, it keeps up a continual musical kind of croaking; hence it takes its name.

*Boro; Common Toad. Body lurid and brown: of this animal there are three varieties, as follows: the first has its back of an olive colour; and an unequal yellowish-red band down the side: the body of the second is marked with confluent green spots and warts on the spots of the same colour, those of the intervals red, the spaces between bicoloured. The third is particularly distinguished for its size, being much less than the others. This of all the European toads seems to be the most universally known. It is found in flady places, in gardens, woods, and fields, and frequently makes its way into cellars, or any obscure recesses in which it may occasionally conceal itself, and where it may find a supply of food, or a security from too great a degree of cold. In the early part of spring, like other of this genus, it retires to the waters, where it continues during the breeding season, and deposits its ova or spawn in the form of double necklace-like chains or flings of beautifully transparent gluten, and of the length of three or four feet, in each of which are disposed the ova in a continued double series throughout the whole length, having the appearance of so many small jet-black globules or beads; being in reality no other than the tadpoles or larvae convoluted into a globular form, and waiting for the period of their evolution, or hatching, which takes place in the space of about fourteen or fifteen days, when they break from the surrounding gluten, and like the tadpoles of frogs, swim about in the water, and are nourished by various animalcula, gluten, leaves of water-plants, &c. &c. till, having arrived at their full growth, the legs are formed, the tail gradually
gradually becomes obliterated, and the animals leave the
water, and betake themselves to the surface of the ground.
This generally happens early in the autumn, at which period
it is not uncommon to find such numbers of the young ani-
mals in some particular places, that their appearance has fre-
cently given rise to the vulgar idea of their having been
flowered from the clouds.

The toad is an animal too well known to require any very
particular description of its form. It may be necessary to
observe, that it is always covered by tubercles, or eleva-
tions on the skin, of larger or smaller size in different in-
dividuals, and that the general colour of the animal is an
obscure brown above, much paler and irregularly spotted
beneath. The toad, however, is occasionally found of an
olive cast, with darker variegations; and in some speci-
mens, more especially in the earliest part of summer, the
shoulders and limbs are marked with reddish spots, while a
tinge of yellow often pervades the under parts both of the
limbs and body.

The toad arrives at a considerable age; its general term
of life being supposed to extend to fifteen, or even twenty
years; and Mr. Pennant, in his British Zoology, gives us
a curious account, communicated by Mr. Arscott, of Teholt,
in Devonshire, of a toad’s having lived, in a kind of do-
matic flat, for the space of more than forty years, and
of having been, in a great degree, tamed, or reclaimed from
its natural fihness or desire of concealment; since it would
always regularly come out of its hole at the approach of its
mater, &c. in order to be fed. It grew to a very large
size, and was considered as fo singular a curiosity, that even
ladies, laying aside their usual aversion and prejudices, re-
quelled to fee the favourite toad. It was, therefore, often
brought to table, and fed with various infects, which it
feizd with great avidity, and without seeming to be em-
barrased by the presence of company. This extraordinary
animal generally refided in a hole beneath the steps of the
house door, fronting the garden; and mighthave probably
survived many years longer, had it not been severely
wounded by a raven, which feizd it before it could take
refuge in its hole, and notwithstanding it was liberated
from its captor, it never again enjoyed its usual health,
though it continued to live above a year after the accident
happened.

The toad is looked upon with great aversion by the major
part of mankind; and it must be confessed, that its appearance
is disgusting, yet the eyes are remarkably beautiful, being
surrounded by a reddish gold-coloured iris, the pupil, when
in a state of contraction, appearing translucent.

We shall conclude the history of this animal, with mention-
ing the extraordinary circumstance of its having been
occasionally discovered inclosed, or imbedded, without
any visible outlet, or even any passage for air, in the sub-
flance of wood, and even in that of flone or blocks of marble.

“Foy my own part,” says Dr. Shaw, “I have no hesitation
in avowing a very high degree of scepticism as to these sup-
pofed facts, and in expressing my suspicions that proper
attention, in such cases, was not paid to the real situation
of the animal. That a toad may have occasionally latubilized
in some part of a tree, and have been in some degree over-
taken or inclosed by the growth of the wood, so as to be
obliged to continue in that situation, without being able to
efiect its escape, may perhaps be granted: but it would
probably continue to live so long only as there remained
a passage for air, and for the infest of insects, &c. on
which it might occasionally feed; but that it should be
completely blocked up in any kind of flone or marble, with-
out either food or air, appears entirely incredible, and the
general run of such accounts must be received with a great
many grains of allowance for the natural love of the marvell-
ous, the surprize excited by the sudden appearance of the
animal in an unfeeked place, and the consequent neglect
of minute attention at the moment, to the surrounding parts
of the spot where it was disovered.”

* Rubeta ; The Natter Jack. Of this the vent is ob-
tufe; and it has a yellow line on the back; the body beneath
is spotted with black, but above it is of a dirty yellow,
clouded with brown, and covered with porous pimpls of
unequal sizes. This species frequents dry and sandy places,
and is found on Putney Common, and near Reevetby-Abbey
in Lincolnshire, where it derives its trivial name. It never
leaps, neither does it curl, with the flow pace of a toad,
but its motion is more like running. Several are frequently
found together, and like others of the genus they appear in
the evening.

Gibbosa; Gibbous Toad. Body oval, convex, with a
longitudinal cicereous dentate band. A variety has its back
marbled with red and yellowish-afh; the belly is yellow,
spotted with black. The skin is found in divers parts of
India, the second at Surinam.

Bombina; Laughing Toad. Belly orange, spotted with
sky-blue; the pupil is triangular. Gmelin gives three var-
ties of this species; viz. 1. That which is dijinguished
with a black belly, marked with clear white spots and points.
2. One which is brown with white spots; the fides and
round the joints are red. 3. One which is dijinguished for
its loud fonorous voice. It is found in the fenny parts of
Germany and Helvetia; leaps like a frog; emits a clear
sound like a man laughing: it a good deal resembles the
common toad, but is small, black, and every where rough, with
dots on the upper part, and variegated beneath, with tran-
verse wrinkles under the neck.

Salsa; Salt Toad. Above of a dirty olive colour, but
beneath it is white, spotted with black. This species is found
in the flagrant waters of Berchtesgad, and is less than the
R. arboris, hereafter to be noticed; it avoids the night, is
inodorous, and emits no liquid from its minute perforated
warts: the legs are marked with brown bands, beneath it is
yellow.

Ventricosa; Tumbid Toad. The mouth of this is semi-
oxvate, and the throat ovate. A variety is marked with pale
white papules. It is found in South America, and in some
parts of India. The body is brown and orbicular; the tu-
bercles on the top of the neck longitudinally dijofed; the
back has three longitudinal wrinkles; the flanks are tumid
and dilated.

Marina; Marine Toad. Shoulders tumid; eye-lids
warty, concheate; the hind feet are subpalmate; there is a
variety, which is spotted with brown; beneath it is fhaded
with livid, the neck and shoulders are spotted with grey.
This is found in various parts of America, and is more than
six inches long. Its body is yellowish-grey, with a few
rather tawny spots: the warts are distinguised with an ele-
vated bay flop in the middle: the protuberances of the
shoulders are oval, smooth, and porous; the vent is sur-
rounded with wrinkled radii; the hind toes are connected
only as far as the first joint, the tail joint is fringed with a
bay membrane.

Brasilienisis; Brafil Toad. Yellowish-afh, with red
waved fpop, beneath fmoother.

Aruncus; Chili Toad. All the feet of this species are
palmate. It inhabits, as its name imports, the waters of
Chili: in its fize it resembles the R. temporaria defcribed
below: on the hind toes there is a flight appearance of
claws.

Lutea ;
Lutea; Yellow Toad. The body of this is yellow; all the feet are subpalmate. This is also found in Chili; and much resembles, in its habits, the R. ecuentalus, but is much less; the half joints of the toes are not connected.

Margaritipera; Pearled Toad. Body brown-red, sprinkled with pale red spots.

Cornuta; the Horned Toad. This takes its specific name from the circumcidence of having its eye-lids horned. It inhabits Virginia and Surinam, and of the whole tribe it is the most deformed. It is said, indeed, to surpasa all animals in ugliness. It is thus described: the head is large, and rounded before; the mouth is excessively large; the eye-lids are soft, mucronate, trid at the point; the eyes are seated in the middle; the body is of a greenish-brown, with broad longitudinal whitish stripes on the back; the legs are tranversely faciate with brown; when full grown, the back, the thighs, and vent, are spiny.

Sitirunda; Defart Toad. This species character is, that above it is ash-y-glutinous, varied with blackish-green spots, beneath of a dirty white; the hind feet are semi-palmate, with the appearance of seven toes. It inhabits the dry deserts near the Ural, sometimes hides itself in holes, and crawls out in the evening; it resembles the common toad, but is somewhat larger.

Vespertina; Siberian Toad. This has a transverse spot between the eyes, forked behind, and other spots running obliquely from the eyes to the nose; the body above is cinnamon, with longitudinal subfusonulent brown spots, varied with different shades of green; beneath it is dashed with a whitish-aff. As its trivial name imports, it inhabits Siberia, and is about the size of a common toad; it leaps slowly; the head is short; the body above is sprinkled with subwarty papille.

Ribiduna; Jocular Toad. Body brown, spotted above with cinereous; the dorsal line is yellow, or greenish; beneath it is smooth, whitish; haunches brown, spotted with milk-white. The head of this species is broad; the upper eye-lid is convex, sprinkled with pores; the apertures of the ears are flat; the back is porous; the sides are marked with obfolete warts; the fore thumb is disarticuated, thick at the base; the next toe shorter than the rest; the hind limb subfaciate; the hind feet have a callus within, resembling a fith toe; the toes have a wart beneath, near the joints.

This species is found in great numbers near the rivers which empty themselves into the Caspian sea; it never ventures on the dry land; it is very large, and frequently weighs more than half a pound; it resembles the R. temporaria, but is broader and shorter; its voice in the evening is like that of a man laughing.

Variabilis; Changeable Toad. Colour variable; back and sides gibbous; warts yellowish in the centre; it is very small on the middle of the back, and larger on the most prominent part of the flanks. It inhabits the sandy places in Germany, and is only about two inches long: in its habits, it holds an intermediate place between the toad and frog; when full awake its body is white, with green spots; in the heat of the sun it is entirely cinnereous; when asleep, the spots are fairly cinnereous, and when torpid the body has a flesh-coloured cut.

The head is rounded, and the mouth without teeth; the margin of the upper jaw is doubled; the tongue is fleshy, thick, placed far back, the base obscurely bident, very entire at the tip; it has hardly any upper eye-lid, the lower one is folding; cavities of the ears white; the warts resemble teats, very numerous on the groin; the chin is marked with prominent dots; the colour, when prepared in spirits, is yellowish, and above it is of a pale olive; the fore feet are three-toed, beneath they are emarginate, the thumb is larger; the second toe of the hind feet is very long.

Section B.—Body more oblong, smooth; legs longer. Frogs.

Species.

Typhonia; Hurricane Frog. Of this species, the distinguishing characteristic is, that the lobes of the ears are oval. It inhabits America, and is said to make a noisy croaking before hurricanes and whirlwinds. The back is marked with four longitudinal wrinkles, elevated points, and black spots; the hind toes are narrow, without claws, the second is very long.

Pentadactyla; Mackarel Frog. All the legs are faciate, five-toed; body veined, the dorsal streaks transverse, the lateral ones are ocellate. There is a variety which is brown; the fore feet have four toes, with the rudiment of a fifth; the hind feet have five toes, with the rudiment of a sixth.

Ocellata; Ocellate Frog. The ears are marked with an ocellate spot; feet with claws, the hind ones sub-palmate. It inhabits America.

Pipiens; Clamorous Frog. This is green, with numerous ocellate spots, surrounded with a yellowish ring. This species is smaller than the green frog, but, in its general habits, it bears a considerable resemblance to that animal. It is a native of North America, and frequents rivulets and ditches of water, and is so strong and vigorous, that it is said it can leap to the distance of five or six yards. In the spring and beginning of summer, it is said to indicate the approach of rain by the peculiar sound which it emits. In the living animal the ears are of a shining gold colour; the region of the anus is very much wrinkled; the third toe from the thumb longer than the rest; the body resembles that of the eculent, or green frog, but the hind thighs are longer; the fanks are longer still, and hind feet are longer than these, margined on each side; the toes are connected nearly to the tip, the fourth is longer than the rest.

Bicolor; Blue and Yellow Frog. Colour blue, ochreous beneath, feet unwebbed; toes flattened and orbicular. This elegant species is of a moderate size; it measures more than four inches in length. The whole of the upper surface is of a beautiful blue, while the under parts are of a pale orange, or ochre colour. The head is large, the mouth wide, and the tip of the nose truncated. All the toes are furnished with a large orbicular tip, and beneath each of the joints there is a process or tubercle. The upper parts of the female have a deeper shade of violet than those of the male. It is supposed to be a native of Surinam.

Maxima; the Great Frog. All the feet are palmate, as well as the toes, facinate; body veined and variegated; the top of the back obliquely spotted. Bands of the legs in pairs, approximate, above confluent.

Alpina; Alpine Frog. This is entirely black, and inhabits the declivities of the mountains in Austria.

Venulosa; Veined Frog. Feet cleft; the body veined with confluent spots. It inhabits Arabia and South America.

Virginia; Virginian Frog. Cinereous, spotted with red, beneath it is yellowish; the back is five-angled, with as many stripes. It is found in Virginia.

* Temporalia; or Common Frog. The back of this is flatish and sub-angular. There is a variety, which is of a dirty olive colour, with large warty spots, the head above plain, beneath whitish; twice the size of the common frog. Both are found in this country, and the latter also in Perù; it lives, during the spring, in water, among toads, and in the summer
fummer on land, at which time it is silent; it feeds on various insects, and is the prey of ducks and cranes, croaks very much when in muddy ditches; the variety makes, by night, a noise like that of an angry man.

Of all the European species this is the most common. The general color is of an olive-brown, variegated on the upper parts of the body with irregular blackish spots. The patch beneath each eye, which reaches to the tending on of the fore-legs, seems to constitute one of the principal specific distinctions. The under part of the body is of a pale greenish colour, and obscurely spotted. But it ought to be observed, that the color of the frog varies at different seasons of the year, and perhaps in different places. Towards the end of summer, for instance, the colours are much brighter; and as this species frequently calls its skin, the cuticle falling off irregularly from different parts of the body, produces considerable variations in the intensity of the colours.

The frog has a light elegant form and a lively appearance; the limbs are well calculated for its peculiar motions, and the hind feet being strongly webbed, enable it to swim well. The frog, it is said, does not reach its full size till it is five years old, and it lives from twelve to fifteen years. It retires during the heat of summer to the water, and in winter it becomes torpid, and is generally found in the soft mud at the bottom of stagnant waters; or in the cavities beneath their banks, where it remains till the return of spring.

The frog, as well as many other of the reptile tribe, is extremely tenacious of life. It survives, for a considerable time, the loss even of some of its essential organs, and it has been found to exist for several days when entirely confined under water.

The frog deposits its spawn in the month of March. This is composed of a gelatinous transparent mass, including the ova or eggs, in each of which is imbedded the embryo or tadpole, which has then the appearance of a round black globule. The period of hatching varies according to the temperature of the season, but it is commonly in about a month or five weeks. In its progress the egg becomes gradually larger, and before the tadpole is excluded, it is seen in motion within the surrounding gelatine. When they are first hatched, their only food is the remains of the gelatine in which they were included. A few days afterwards, if they are minutely examined, a pair of ramified branchie, or temporary organs, may be observed on each side of the head, which after a short time disappear. The tadpole, which is so extremely unlike the animal in its perfect state, seems to confine only of a head and tail. The head is large, black, and roundish; the tail is slender, and margined with a broad transparent fin. The motions of the tadpole are very lively. Its food consists of duck-weed and other small water plants, with different kinds of animalcula. The mouth is furnished with very minute teeth, and when the tadpole has reached a certain size, it may sometimes be heard gnawing the edges of the leaves on which it feeds. By means of a sucker placed between the lower jaw, with which the animal in this state is furnished, it can attach itself at pleasure to the under surface of aquatic plants. When it is very young, it sometimes hangs from this part by means of a glutinous thread, similar to some small flies.

The internal structure of the organs of the tadpole is very different from that of the future animal. In no respect is this difference greater than in the disposition of the intestines, which are coiled in the form of a flat spiral, like a cable. The first change which appears on the tadpole is at the end of five or six weeks after it is hatched. It is about this time that the hind legs first appear; and gradually increasing in length and size, they are succeeded about two weeks afterwards by the fore legs. These latter, indeed, are formed at an earlier period beneath the skin, and are sometimes protruded, and again drawn back by the animal, through a small hole on each side of the breast, before their complete evolution. The tail now gradually decreases, and afterwards more rapidly, so that in the space of a day or two, it is quite obliterated. After this change, the animal leaves the water, and covers the banks in myriads. The sudden appearance of such multitudes of young frogs, has probably induced the groundlegs but popular belief, of their having fallen from the clouds in flowers. The frog having now arrived at its perfect form, it changes entirely the nature of its food. It lived formerly on vegetables, now it depends solely for its existence on animal food. It lives chiefly on small flies, worms, and insects. To seize its prey, the structure and position of the tongue are remarkably well fitted. It is of considerable length, and is attached to the fore part of the mouth; and when at rest it lies backwards. The extremity is bifid, and secretes a glutinous matter, so that in this way it can secure its prey by darting out its tongue with great celerity, and to some distance from the mouth. This it does with so instantaneous a motion, that it is scarcely perceptible to the eye.

* MARGINATA; Bordered Frog. The sides of this are marginate, and the feet cleft. It inhabits India and South America.

+ ESCULENTA; Edible, or Edible, or Green Frog. Of this species the distinguishing characteristics are, that it is of an olive colour, spotted with black, with three yellowish lines on the back; the abdomen is whitish.

Of all the European frogs this is the largest species. The general appearance is very like that of the R. temporaria, but it is larger in size, and of an olive-green colour, strongly marked on the upper part of the body with roundish black spots. The limbs are elegantly marked with transverse bands of the same colour. Three distinct pale yellow stripes run from the tip of the nose down the whole length of the back; the middle one being slightly depressed, but the two lateral ones are considerably elevated. The head is proportionally larger than that of the common frog.

The green frog is rare in England, but is very common in France, Italy, and Germany, where it is employed as an article of food.

This species, it is observed by naturalists, does not leave its winter retirement till a much later period than the common frog; and in those countries where it is used as food, it is worth while to attend to this fact: for if they are pretended to be brought to market at an earlier period, the common frog, and sometimes even toads, must be sublimated. During the breeding season, the croaking of the male is so loud, that it may be heard at a great distance; and in those places where they are numerous, it becomes so intolerable to those who are unaccustomed to hear them, that they are often deprived of sleep. At this time, too, a large infected globular vesicle is protruded from each side of the head of the male. The globules of spawn in the green frog are proportionally smaller than in the former species; they have somewhat of a yellowish cast. The prolong of the tadpole, towards the evolution of the perfect animal, is considerably flower in this species. The fore legs do not appear before October, and the animal does not assume its perfect shape till the beginning of November. The tail at this time begins to decrease, and in the space of four days entirely disappears.

This species is extremely voracious, seizing, it is said, on young
young birds of different kinds, mice, and even ducklings, and, as it does with the rest of its prey, swallowing them whole. At the end of four years it has reached its full growth. It begins to breed the year following, and the period of its life is sometimes extended to sixteen years.

**Australis**; Australian Frog. The body of this is brown above, beneath blueish; the fides are speckled with ochre colour; the toes of the fore feet are fpiny. It inhabits New Holland. The second toe of the hind foot is very long; the claws are red.

**Paradoxa; Paradoxical Frog.** This is of a yellowish and olive colour, variegated with rufous bands; the hind legs or thighs are obliquely streaked.

In its general form this species resembles the R. temporaria. The oblique longitudinal stripes on the hind legs constitute the principal mark of disftinction. There are four toes on the fore feet, and they are unwieved; the hind feet have five toes, and are deeply palamated to the very ends of the toes. Near the shortell toe there is an oblong callus, forming a spurious one. The upper jaw is becet with a row of small denticulations. This species is a native of South America, and is more common in Surinam than in other places.

Naturalists, says Dr. Shaw, have been extremely puzzled with regard to the real nature of what has been taken for the tadpole of this frog. At one time it was confidered by Linnaeus as a species of lizard, and therefore arranged by him under the genus lacerta. At another time he has placed it under the present genus, with the specific name piceus. It was described by Edwards under the denomination of the frogfish of Surinam. The structure of the animal, which has been the subjeét of so much discussion, shews clearly that it is the larva or tadpole of a frog; and it is supposed, with no small degree of probability, that the differences in the accounts given of this animal by naturalists have arisen from the different phases of its progress, in which it has been found. But as this tadpole is so much larger in size, in proportion to the perfect animal, than any other species yet known, it may be the larva or tadpole of some of the larger species, and not that of the R. paradoxa, which is but a small frog.

**C. Hind Feet very long; the Claw linear.**

**Arborea; Tree-Frog.** The body of this species is green, beneath granulate; feet cleft. Gmelin enumerates five varieties of this species. 1. Those which have four toes to their fore feet, and five to those that are behind; the knees are warty beneath. 2. Those that are of a green colour, with a yellow line on each side. 3. The body of this variety is reddish. 4. Of this it is brownish-green. 5. The slenderfes of the body marks this variety.

"In the beauty of its colours," says Dr. Shaw, "as well as in the elegance of its form, and agility of its movements, the tree-frog exceeds every other European species. It is a native of France, Germany, Italy, and many other European regions, but is not found in the British islands. Its principal residence, during the summer months, is on the upper parts of trees, where it wanders among the foliage in quest of insects, which it catches with extreme celerity; stealing softly towards its prey, in the manner of a cat towards a mouse, and, when at the proper distance, seizing it with a sudden spring, frequently more than a foot in height. It often suspends itself by its feet, or abdomen, to the upper parts of the leaves; thus continuing concealed beneath their shade. Its size is smaller than any European frog, except the R. bombina. Its colour, on the upper parts, is more or less bright in different individuals; the abdomen is whitish, and marked by numerous granules; the under surface of the limbs is reddish; and the body is marked on each side by a longitudinal blackish or violet coloured streak, separating the green of the upper parts from the white of the lower. The inferior edge of this dark lateral stripe is tinged with yellow. The body is smooth above, and moderately short or plump; the hind legs are very long and slender; the fore feet have four, and the hind feet five toes, all of which terminate in rounded, flat, and dilated tips, the under surface of which, being soft and glutinous, enables the animal to hang with perfect security from the leaves of trees. The skin of the abdomen is also admirably calculated by nature for this peculiar power of adhesion, being covered with small glandular granules, in such a manner as to fallen closely even to the most polished surface; and the animal can adhere at pleasure to that of glass, in whatever position or inclination it be placed, by merely prefling itself against it.

Though the tree-frog inhabits the woods during the summer months, yet, on the approach of winter, it retires to the waters, and there submerging itself in the rot supplemental, or concealing itself beneath the banks, remains in a state of torpidity; and again emerges in the spring, at which period it deposits its spawn in the waters, like the rest of this genus. The male at this period inflates its throat in a surprising manner, and ejects a very loud and sharp croak, which may be heard to a vast distance. The spawn is deposited about the end of April, in small clustered masses; the included globules or embryos being of a pale yellowish-brown colour. The tadpoles become perfect frogs, by the total decay of the tail, about the beginning of August; and soon begin to ascend the neighbouring trees, where they continue to reside during the remainder of the warm season; as do likewise the parent animals, after the breeding season is past. During their residence among the trees, they are observed to be particularly noisy on the approach of rain; so that they may be considered, in some measure, as a kind of living barometers; more especially the males, which, if kept in glasses, and supplied with proper food, will afford an infallible presage of the changes of weather.

**Leucophyla; White-spotted Frog.** Body smooth, hoary, with oblong milk-white spots; the fore feet are lobate, the hind feet palmate. It inhabits America, and weighs only about forty-six grains. Eyes of a fine golden colour, and between these, on the sides and middle of the back, there are oblong white spots; the humours are slender.

**Squintigera; Scaly Frog.** In this a scaly band reaches half-way round the back; the sides and throat have folds; the fore feet are semi-palmate, the hind feet are palmate. This is about two inches long, and is supposed to be an inhabitant of America. The body is varied with grey and brown in thick aggregate specks, and a few spots down the hind part of the back, in a perpendicular direction; the body consists of minute, sub-pellucid, rhomboid, imbricate scales; the hind limbs are twice as long as the fore.

**Boans; Cronking Frog.** Body smooth, with continuous dots beneath; feet palmate. There are two varieties. 1. The body above is of a blueish lead-colour. 2. The body of this is inclining to orange. It is found in America, and differs only from the tree-frog in having the feet webbed, and the body marked with white spots.

**Rana Arborea, the Tree-Frog.** See Ranunculus Vi-
ridis, and the preceding article.

**Rana Piscatoris.** See Lophius Piscatoris, and Sea-
Devil.
RANARIDIL, in Geography, a town of Austria; 11 miles S. of Aigen.

RANASAGUR, a town of Hindostan, in Bahar; 18 miles W. of Arrah. N. lat. 25° 37'. E. long. 84° 31'.

RANCAGUA, a jurisdiction of South America, in Chili. It derives its name from the inhabitants living in single houses, without the appearance of a village; every family lodging in their lonely cottage, four, six, or more leagues from each other. It is not, however, without a capital, consisting of about 50 houses, and between 50 and 60 families, most of them being Melitizos, though their cast is not perceivable by their complexion. The whole jurisdiction may contain about 1000 families, Spaniards, Melitizos, and Indians. Ulloa's Voyage, vol. ii.

RANCE, ARMAND-JOHN LE BOUTHILLIER DE, in Biography, the initiator of the order of La Trappe, was of noble descent, and born at Paris in the year 1626. At a very early period he exhibited an extraordinary genius for classical and polite learning; and at the age of 16, he had read many classical works, in the Greek as well as the Latin languages, and is said to have studied by heart during his early period to have understood Homer. When he was only 13 years of age, he prepared for the prel view a new edition of Anacreon, with notes, that displayed considerable talent and research. This was published in 1639. Four years previously to this, he had received the clerical tonsure, and had been nominated a canon of Notre Dame at Paris. He was permitted to receive the king to the sinecure priory of Boulogne, near Chambord; and he was subsequently promoted to three different abbies, among which was that of La Trappe, and to other places of honour and trust in the church. He studied divinity at the Sorbonne, and in 1651, he was ordained priest; and in less than three years, the degree of doctor of divinity was conferred upon him by the faculty of the Sorbonne. Having thus completed his studies, he entered into the world, and, like one broken from his shackles, he devoted himself eagerly to its honours, pleasures, and gaieties. He soon became a favourite at court, and was appointed almoner to the duke of Orleans, and one of the deputies of the second order in the assembly of the clergy in 1655. On a sudden, and for a cause that never was well understood, he became disgusted with the world, and resolved to renounce for ever its pleasures, enjoyments, and vanities. No sooner had the abbé de Rance formed the resolution than he withdrew to his estate in the country, to deliberate concerning the mode of life which he should pursue. Having made up his mind to embrace the monastic life, he sold his estate, and bestowed the money which it produced on the Hôtel-de-Dieu at Paris. He also resigned all his benefices and dignities, excepting his priorship of Boulogne, and the abbey of La Trappe; the latter of which he retained by a special permission of the king, in order to introduce into it a reformation of the statutes and discipline. He took the habit, and made his profession in the year 1664, and left about establishing the gloomy and austerer discipline of monkery in its full perfection. The part it seems peculiarly suited to the corruptions to which he belonged, being the most gloomy, harren, and desolate spot in the whole kingdom of France. Here the days of the monks were constantly spent in prayers, tears, contemplation, silence, the perusal of holy books, the hardships of bodily labour, and the practice of the most rigid austerities. All other designs and occupations, however laudable and excellent in themselves, they were to regard as vain and useless to persons of their order. The least relaxation, or amusement of the most innocent nature, they were not allowed; and they were prohibited from engaging at all in literary studies. Strange! that a mind flored with liberal knowledge, and distinguished by good taste, should have been so far perverted by superstitious and fanaticism, as to devise or sanction such regulations.

That the world might be acquainted with the discipline of his community, he published "A Treatise on the Sanctity and Duties of the Monastic State." As de Rance advanced in years, the severe discipline to which he strictly conformed, rendered him so infirm, that, finding himself unequal to the duties of his post, he resigned it into the king's hands, but was permitted to appoint his successor. At length, worn out with infirmities and mortifications, and lying on a bed of ashes and straw, he died in 1700, in the 74th year of his age. He was author of a great number of theological and other pieces, among which may be mentioned "Moral Reflections on the Four Evangelists," "The Constitution and Rules of the Abbey of La Trappe," in 2 vols.; and "A Discourse on Purity of Intention." Moreri.

RANCE, in Geography, a river of France, which runs into the sea near St. Malo.

RANCHANO, a small island near the coast of Darien, in the Pacific ocean.

RANCHERIA, a town of South America, in the province of San Cristobal, and province of St. Martha; 20 miles N.E. of Hacha. N. lat. 14°. W. long. 72° 36'.—Alfo, a small island in the Pacific ocean, near the coast of Veragua. N. lat. 7° 5°. W. long. 82° 16'.

RANCHERIAS, a name given, in the province of Panama, to assemblages of Indian huts under the jurisdiction of a village. These rancherías are situated to the southward, in the small chasms or breaches of the mountains.

RANCID, in Rural Economy, from the Latin rancidus, of rancio, to be rank, a term applied to substances, which have contracted a strong offensive smell and taste by keeping, as bacon, butter, and all fat substances are apt to do. It would be a very useful discovery, to find out any easy simple method of preventing this effect from taking place.

RANÇON, in Geography, a river of France, in the department of the Lower Seine, which runs into the Seine, at Caudebec.—Alfo, a town of France, in the department of the Upper Vienne; 8 miles E. of Bellac.

RANCONET, ARMAND DE, in Biography, a learned and worthy magistrate, who flourished in the 16th century, was born at Bordeaux, in which city his father was an advocate of parliament. Having received the advantages of a good education, he became deeply skilled in the Roman law, to the study of which he joined that of philosophy, mathematics, and antiquities. Having been some time a counsellor in the parliament of Bourdeaux, he was raised to the post of president of the fourth chamber of inquests in that of Paris. The religious contents of the time were fatal to him. When the cardinal of Louvain assembled the parliament of Paris, to procure its opinion concerning the punishment of heretics, Rancet brought the works of Sulpicius Severus, and read aloud the passage in which that writer condemns the execution of Priscillian; upon this the prelate caused him to be imprisoned in the Bafhele, where he died of grief in 1559, at the age of 60. His latter days had been singularly unfortunate. He was reduced by want to be a corrector of the press to the Stephens. He saw his daughter die on a dunghill, and his son executed, and his wife was killed by lightning. This learned man published fearlessly any thing in his own name, but contributed much to the labours of others. He is said to have had the chief part in the valuable treatise, "De Verborum Significatione," and in the "Formula" of Briffon; and Pithou affirms,
affairs, that he compiled the Dictionary that bears the name of Charles Stephens. He wrote "Le Trefor de la Langue Françoise, taut ancienne que moderne," Moreri.

RANCONNIERES, in Geography, a town of France, in the department of the Upper Marne; 9 miles W. of Bourronne.

RANDEL, Dr. John, in Biography, organist, doctor in music, and music professor in the university of Cambridge. He was brought up in the king's chapel, was one of the children of that choir who first performed in Handel's oratorio of Esther, at the house of Bernard Gates, master of the boys in James-Ireet, Westminster, on Wednesday, February 23, 1731, when it was performed in action, previous to its having been heard in public, or any where but at Cannons, the magnificent seat of the duke of Chandos, for whose chapel it was composed in 1720.

Raland was not rated very high in his profession: he was regarded as a flight organ-player, and had never distinguished himself as a composer. He obtained his degree at the installation of the duke of Grafton in the university of Cambridge, for which he composed the ode written by Mr. Gray, to the establishment of all the musical profession, by undertaking to have it performed by the musicians resident in the university, without putting his grace to the expense of additional hands and voices from London, as Drs. Greens and Boyce had thought necessary on former occasions at Cambridge, and Dr. William Hayes at Oxford.

As Dr. Randal's professional life was unmarked by talents, his death, which happened in 1799, was hardly noticed, except by the candidates for the professorship, and his organist's places.

RANALSTOWN, in Geography, a post-town of Ireland, in the county of Antrim, in the neighbourhood of which is Shanes castle, the seat of lord O'Neill. It is situated on the river Maine, to the northward of lough Neagh. Randalstown is 4 miles N.W. from Antrim, and 88 N. by W. from Dublin. Before the union, it was represented in parliament. Carlile, &c.

RANDANS, a town of France, in the department of the Puy-de-Dôme, and chief place of a canton, in the district of Riom; 12 miles N.E. of Riom. The place contains 10447, and the canton 7996 inhabitants, on a territory of 130 kilometers, in 11 communes.

RANDASALMI, a town of Sweden, in the government of Kuopio; 52 miles S. of Kuopio.

RANDAZZO, a town of Sicily, in the valley of Demona; 25 miles W. of Taormina. N. lat. 37° 57'. E. long. 15° 4'.

RANDER, a town of Hindoostan, in Guzerat, on the Taptee, opposite to Surat.

RANDEG, a town of Austria; 8 miles N.E. of Bavarian Weidhoven.

RANDERADT, a town of France, in the department of the Roer; 10 miles N.W. of Juliers. N. lat. 50° 59'. E. long. 6° 8'.

RANDERS, a town of Denmark, in North Jutland, on the Gulden. This town is reduced, and has now only one parish church, a grammar-school, an hospital, and a chapel near the town. The chief articles of trade consist of leather gloves, salmon, earthen-ware, and strong beer. It was formerly well fortified; 20 miles E. of Viborg. N. lat. 56° 28'. E. long. 10° 3'.

RANDESSACKER, a town of the duchy of Wurzburg, on the Main; 2 miles S. of Wurzburg.

RANDIA, in Botany, is so named by Houttoun and Linnaeus, in honour of Mr. Isaac Rand, F.R.S., an apothecary in London, who filled the place of lecturer and de-

Vol. XXIX.

monstrator of botany in the Chelsea garden, from the year 1722 to 1730. He published in 1750 an octavo index of the official plants of that collection, 518 in number, specifying the part of each used in physic. He also printed, in 1739, a general catalogue of the Garden. His name often occurs among the botanists of that period. The Randia, however, of which two supposed species are defined in Linn. Sp. Pl. 213, 214, by the names of militiae and aculeatae, both West Indian shrubs, is now sunk in Gardenia; see that article, where we have suggested a doubt, possibly not well founded, of the propriety of this measure. Both species of Randia are united by Willdenow, Sp. Pl. v. 1. 1230, on the authority of Swartz, as well as in Ait. Hort. Kew. v. 1. 370, under the name of Gardenia Randia. This plant, sent by Houttoun to Miller, before the year 1735, does not appear to exist in our floses at present. Its form may be seen in Browne's Jamaica, 143, t. s. i. 1. That author says the pulp of the berries flains paper or linen of a fine permanent blue, which refills the action of soap and of acids. The shrub is frequent in the low lands of Jamaica, on the most barren clay soil.

RANDBITZ, in Geography, a town of Bohemia, in the circle of Schlau; 12 miles N.N.E. of Schlau. N. lat. 50° 35'. E. long. 14° 24'.

RANDELPH, Thomas, in Biography, an English poet of great celebrity, was born at Newnham, in Northamptonshire, in 1605. He was educated at Westminster school, and having completed his course, he was elected to Trinity college, Cambridge. He shewed an early turn for poetry, and at ten years old wrote "The History of the Incarnation of our Saviour," in verse. He acquired an unfortunate, and, to him, a fatal habit of conviviality, which diverted him from the pursuit of any profession, and which led him to waste his scanty patrimony, and his health, in the company of wits and men of pleasure in the metropolis.

He died in his 35th year, to the great regret of those who admired his poetry and loved his company. He possessed an excellent genius, and had his life been extended, it has been thought he might have attained to a very high rank among the poets of his age. His miscellaneous poems were collected after his death by his brother, who published them at Oxford, in 1640. They have been, but not of late years, several times reprinted. He likewise composed fix dramatic pieces of the comic class, one of which, "Hey for Honely, down with Knavery," was taken from the Plutus of Aristophanes. His pieces are said to be some of the best in the manner then prevalent, which consisted in playing with words and thoughts, and connecting remote ideas by fanciful refinements. His expressions are often elegant, and his verses harmonious. His friend, Sir Christopher Hatton, cured, at his own expense, a monument of white marble to be erected over his grave, the inscription on which, in Latin and English verse, was made by Peter Haul'd. Biog. Brit.

RANDELPH, John, a learned prelate of the church of England, defenced from a respectable family in Kent, was born July 6th, 1749. He was the younger son of Dr. Randolph, formerly president of Corpus Christi college, Oxford, who died in March 1783, after having presided over the college for the long space of 35 years. The president's father was recorder of Canterbury, and had several sons, among whom was Dr. Francis Randolph, principal of Alban Hall, Oxford. The whole family have been remarkable for their orthodoxy zeal and attachment to the established religion of the country. The subject of this article became a student of Corpus Christi college, Oxford, where he took his several degrees, that of D.D. he had by diploma in 1783. Previously
RAN

viously to this he had been appointed preceptor of poetry, proctor, and in 1782 Regius professor of Greek. In this same year he was made prebendary of Salisbury, canon of Christ-church, and Regius professor of divinity; and in 1783 rector of Ewelme. In 1799 he was elevated to the bishopric of Oxford, from which he was translated to that of Bangor in 1807, and then to the metropolitan see of London in the year 1809. Notwithstanding these high preferment he puffed a great part of his life in the university of Oxford, and it was generally believed that when he was elevated to the see of Oxford, the university was complimented with the nomination by the crown. His lordship was author of many fanglo sermons, and charges delivered on different occasions; also of "De Graeco Linguæ Studio Praebentio habita in Schola Linguorum," 1783, and "Concio ad Clerum in Steando Provincialis Cantuariensis Provinciae ad D. Pauli," 1790. His lordship was a zealous promoter of the National schools in opposition to those founded by Lancaster, and he was understood to be a violent opponent to the bible society, and to the spread of what has been termed sectarism. One of his last works was a Report of the Progres made by the National Society, to which the general committee referred in terms of gratitude, at their first meeting after his lordship's decease, in the following terms: "Whose latest employment had been to flate, for the information of the public, the progress of a work to which he had contributed his time, his labour, and his counsels, the committee could not fail to entertain a common sentiment of profound regret for the loss which they have sustained, and to cherish in their minds the liveliest recollection of the service which has so successfully fulfilled by him in this second report. They wish, therefore, to add to this document, designed for general circulation, their sense of what is due from the public, and themselves, to the memory of one who was a constant and affilidous promoter of this salutary institution, from its first establishment to the last hour of his life. The committee trust, that this testimony, though limited to a single object in the large field of pastoral duty in which he was incessantly engaged, may serve to denote the benefits which have resulted from his prompt, unwearying, and effectual exertions."
The following is the character drawn of him by Mr. archdeacon Jefferyson, and which alludes to his zeal for the church of which he was an active member. "Fearless now of being cenured for mercenary adulation, or reproved by unconfident merit, a just tribute may be paid to the character of that departed and exalted prelate, who is, and will be, most lamented where he was born and most entirely known. This opportunity, therefore, is willingly embraced of offering a heart-felt condolence to the ministry of the diocese on the affecting and important loss, which, in these perilous times of contending sects and unsettled opinion, has arisen to them, and to the church:—To them, in the premature privation of a dioecesan, firm in his support of ecclesiastical authority, but considerate in its application; eminently verded in the letter of ecclesiastical law, but liberal in its practical construction, reluctant in interference, but determined in duty, flow in the profussion of service, but prompt in its execution; disinterested in patronage, unwavering in measures, correct in judgment, attentive in counsel, and kind and compassionate to diftrees:—To the church, in the premature privation of a father, diligent in her rites and services, but unobtensive in piety and devotion; found and unrelaxing in her doctrines and faith, but discreet in zeal, and comprehensive in charity; ever vigilant in defending her interests, ever forward in asserting her privileges, and ever able in the assertion and the defence." The bishop died suddenly on the 28th of July 1813. He was one of the governors of the Charter-house; trustee of the British Museum; dean of the Chapel royal; visitor of Sion college; and provincial dean of Canterbury. Gent. Mag.

RANOLD, in Geography, a post-town of America, in Massachusetts, formed of the S. precinct of Brantree, in Norfolk county, in the year 1783: 15 miles S.E. of Bolton. The inhabitants are mostly farmers, but manufacture large quantities of shoes for market.

RANOLD, a county of Hillborough district, in North Carolina, bounded N.E. by Orange, and N.W. by Guildford. The number of inhabitants is 10,112, and they are mostly Quakers; the other denominations are Presbyterians, Baptists, Methodists, and Universalists. Their good land produces 40 or 50 bushels of Indian corn, or 20 of wheat, per acre. The chief town is Ashborough.

RANOLD, a county of Virginia, bounded N. by Monongalia, and S. by Pendleton. The number of inhabitants is 2854.

RANOLD, a post-town in Orange county, Vermont, being the 4th town W. of Thetford, on Connecticut river. The number of inhabitants is 2555. White river, by its two branches, waters the E. and W. side of the town. It has a large bed of iron ore, two forges, and a flitting mill. The congregational meeting-house has a steeple, and is large; 47 miles from Rutland.

RANOLD, a county of the Indiana territory.

RANOLD, a town of Morris county, in New Jersey, containing 1271 inhabitants.

RANDOM, a township of Sussex county, in Vermont, W. of Brunsviow.

RANDOM, a small island in Trinity bay, near the N. east of Newfoundland. N. lat. 48° 15'. W. long. 53° 45'.

RANDOM, Shetland island, a flat made when the muzzle of a gun is raised above the horizontal line, and is not designed to shoot directly, or point-blank.

The utmost random of any piece is about ten times as far as the bullet will go point-blank; and the bullet will go farthest when the piece is mounted about forty-five degrees above the level range.

The space or distance of the random is reckoned from the platform to the place where the ball first grazes.

RANDOM, in Geography, a river of Brandenburg, which runs into the Ucker; three miles S. of Uckermunde.

RAND, a lake of Norway, in the province of Aggerhus, 35 miles long, and two broad; 20 miles N. of Christiannia.

RANDSBERG, a town of Sweden, in Winf Gothland; 76 miles E. of Uddevalla.

RANDYCHOAR, a town of Bootan; 18 miles N. of Beyhar.

RANA, a town of Welf Bothnia; 60 miles W. of Torseca.

RANELACH, Rutland and Gardens, built and opened for musical performances and public amusements in 1742. The building was erected in the Ipacious garden belonging to the residence, at Chelsea, of Lord Ranelagh, one of the ministers of Charles II., when paymaster of the army. It was planned by the late Mr. Lacey, afterwards joint-patentee of Drury-lane theatre with the great actor Garrick.

At the first opening of this stupendous building, several experiments were made in placing the orchestra, in filling it, and in the time of performance, before it was settled as an evening promenade. The orchestra was at first placed in the middle of the rotunda. The performance was in a morning; and oratorio choruses chiefly furnished the bill of fare. Sir John Barnard complaining to the magistrates, that
that the young merchants and city apprentices were frequently seduced from their counting-houses and shops by these morning amusements, they were prohibited, and the doors opened at fix o'clock in the evening. The performance, however, did not begin till eight o'clock, but was ended at ten.

It was intended to rival Vauxhall, and was little injured by bad weather; as the company, at such times, had a safe and pleafant retreat into the rotunda, and as few went thither but in carriages.

Its success as an evening's amufement remained undiminished more than forty years. It was ruined by the late hours to which it was gradually brought by fine folks, who, at length, never came thither till past ten o'clock, when the musical performances were over, and sober people used to return home before eleven o'clock to their flippers, which enabled them and their fellows to go to bed, and ride, at their accustomed time.

But, at length, perfons of rank and fashion made a de- bauch of this innocent amufeement, and went to it and departed from it as late as at a masquerade. This precluded all that had anything to do themselves, or any employment for their fellows in the morning, and so much refined the company, that at midnight there had been seldom sufficient money received at the entrance, to cover the expence of the lamps, the terms of admiflion being only 3s., for which, besides a good concert by the bell performers in London, the company was furnished with excellent rolls, butter, and tea. In the year 1803 it was shut up, and only used occasionally for a masquerade, a festival, or an exhibition of fire-works. But since the period just-mentioned, the building has been pulled down, and the materials sold piecemeal, as was the cafe at Cannons, the splendid mansion of the duke of Chandos, (or Palazzo, as it would have been called in Italy,) and the ground is now (1809) of no other utility than occasionally to drill and exercife the Chelsea volunteers.

RANES, in Geography, a town of France, in the department of the Orne; 10 miles S.W. of Argentan.

RANESTAD, a town of Sweden, in Angermanland; 50 miles N.N.E. of Hernfand.

RANFORCE RING. See Reinforced Ring.

RANG, in Geography, a town of Sweden, in the province of Skonen; 11 miles S.S.W. of Lund.

RANGA, in Hindoo Mythology, one of the many names of Siva, the perfonification, according to the Hindoo mythologists, of the deftructive or changing form of the deity. (See Siva.) The epithet Sri, meaning holy, or divine, or bleffed, prefixed, has given this name to the capital of My- nore; Sri Ranga-pattan being the city of the bleffed Ranga, altered by Europeans to Seringapatam. See Sri.

RANGALORE, in Geography, a town and fortresses of Hindooftan, in the circur of Cicaole; 38 miles W. of Cicaole.

RANGAMATTY, a circur of Bengal, bounded on the N. by Bootan and Affam, on the E. and S. by Affam, and on the W. by Baharpund, Bettebund, and Goollah; about 40 miles long, and from 10 to 40 broad. Rangamatty, the capital, is 128 miles N.N.E. of Moorehabad, and has a celebrated pagoda. Lat. 26° 8'. Long. 96° 6'.

RANGAÑJA, a town of Bengal; 15 miles N.E. of Chittigong.

RANGAPALEAM, a town of Hindooftan, in Coim- betore; eight miles N.N.E. of Daraporem.

RANGAPIILLA, a town of Hindooftan, in the Carnatic; six miles N.E. of Pondicherry.

RANGASUNDRAM, a town of Hindooftan; 15 miles W. of Tinveelly.

RANGE, in Gunnery, the path of the ball, or the line it describes from the mouth of the piece to the point where it lodges. The flight of a shot is diftinguifhed, by artillermen, into three different ranges, of which the firft is called the point-blank, the fcond the random-shot, and the third the ricochet, or rolling and bounding shot. The firft, or point-blank, is to fuppofe a piece ftruck upon a level plain, and laid level, then the distance between the piece and the point where the shot touches the ground firft, is called the point- blank range of that piece; but as the fame piece ranges more or les, according to a greater or les charge, the point-blank range is to be underftood to be that, when the piece is loaded with that charge which is commonly ufed in action. This range is much lefs than the greatest range, or ran- dom-shot; but the piece cannot be leveled, on, as it is generally expreffed, 'printed at an object intended to be batted, if that object is not within the distance of the pointblank range; for beyond that the fhot is very uncertain, therefore rarely ufed in the fervice, and on land only when the fhot cannot fail of doing great execution in the place on which it falls. In ricochet firing, the piece is only elevated from three to fix degrees, and loaded with a small charge, in order that the ball may be bounded, and roll along the infide of the para- rapet. The fhot, thus difcharged, goes rolling and bounding, killing and maiming, or detroying all it meets in its courfe, and creates much more disorder by going thus slowly, than if thrown from the piece with greater violence. See CANNON, GUN, and PROJECTILE.

Range of a Projectile, Amplitude of the. See Amplitude.

RANGE, Point-blank. See Point-blank.

RANGE, in a Ship, denotes a fufficient length of the cable, drawn up on the deck, before the anchor is cast loose from the bow, to let it limp to the bottom, without being interrupted, that the flukes may be forced the deeper into the ground, by the additional weight which the anchor acquires in finking. For this reafon, the range, which is drawn up out of the tire, ought to be equal in length to the depth of the water, where the ship anchors.

RANGER, a sworn officer of the forest, whose bufines is it to walk daily through his charge, to drive back the deer out of the purlieus or defarted places into the forest lands; and to prefent all trefpaffers done in his bailiwick at the next court held for the forest.

The ranger is made by the king's letters, and has a fee paid yearly out of the exchequer, and certain fee-deer. In the Charta de Forefta mention is made of twelve kinds of rangers. It is now principally a honorary and finceure employment; but the holders sometimes likewise receive pay.

RANGES, in Ship Building, horned pieces of oak, like belaying cleats, but much larger, bolted to the midle of a ship, in the wail, for belaying the tacks and feetes. Also those pieces of plank fixed between the ports, with femi-circular holes in them for keeping flint in.

RANGIFER, in Zoology, a variety of the Cervus Tar- randus; which fee.

RANGING, in War, the difpofing of troops in a condition proper for engagement, or for marching. In Building, the side of a work that runs straight, without breaking into angles, is faid to range, or run range.

RANGOON, in Architecture, a town of the 3rd P 2 Birm.
Birman empire, situated on a branch of the Irrawaddy, called the Rangoon river, which forms the only communication that the Pegue river has with the sea. The town, in its present state, has been extended by increasing trade and consequent population far beyond the limits which formerly comprehended Rangoon, as it was originally founded, in 1755, by Alompra, the sovereign of the Birmen empire, Rangoon, or DagOEung, which signifies victory achieved, was denominated Dagon, before Alompra took it, and laid the foundation of the present town. Here, flood, in former days, a large and populous city, called in the Pali, or sacred language, Singouterra; the site of which Alompra diligently explored, and raised on its ruins the present flourishing sea-port of the Pegue dominions. Dagon, often called Shoe-Dagon, or the golden Dagon, is a name peculiar to the temple; a noble edifice, three miles distant from the banks of the river. (See Dagine.) Rangoon stretches along the bank of the river about a mile, and is not more than a third of a mile in breadth. The city, or quay, (mious being a term applied either to a city or a district,) is a square surrounded by a high stockade, in the manner of the country, and on the N. side it is further strengthened by an indifferent fosse, across which a wooden bridge is thrown; in this face there are two gates, in each of the others only one. Wooden flages are erected in several places within the stockade, for musqueteers to stand upon in case of an attack. On the S. side, towards the river, which is about 20 or 30 yards from the palisade, there are battery huts, and three wharfs, with cranes for landing goods. A battery, of twelve cannon, six and nine-pounders, raised on the bank, commands the river; but the guns and carriages are in such a wretched condition, that they could do little execution. Close to the principal wharf are two commodious wooden houses, used by the merchants as an exchange, where they usually meet in the cool of the morning and evening, to converse, and transact business. The streets of the town are narrow, and much inferior to those of Pegue, but clean and well paved; there are numerous channels to carry off the rain, over which strong planks are laid, to prevent an interruption of intercourse. The improvement of the town has been very much owing to the activity of the descendant of a Portuguese family, named Jannee, of low origin, but advanced at length to the important office of Shawbunder, or intendant of the port, and receiver of the port-customs. Under his direction and influence, the streets were paved, several well built wooden bridges were constructed, and also a wharf, which, extending into the river, and raised on posts, enables the ships to deliver and receive cargoes without the assistance of rivercraft; under his direction also a spacious custom-house has been erected. This is the only lay building in Rangoon that is not constructed of wood, it is composed of brick and mortar, and the roof covered with tiles; within, there is a number of wooden flages for the reception of bale goods. The houses, in general, are raised on posts from the ground; the smaller supported by bamboos, the larger by strong timbers. All the officers of government, the most opulent merchants, and persons of consideration, live within the fort; shipwrights, and people of inferior rank, inhabit the suburbs; and one entire street, called Tackally, is exclusively assigned to common prostitutes, who are not permitted to dwell within the precincts of the fortification. Swine are suffered to roam about the town at large; they do not belong to any particular owners, but are regarded as servants of the public, or common scavengers; as they go under the houses and destroy the filth. The Birmans are also fond of dogs, numbers of which infest the streets; the breed is small, and very noisy. The borders of the terrace on which the temple of Dagoeung is raised, are planted with shady trees in regular rows; and from this eminence there is a beautiful and extensive prospect; the Pegue and Rangoon rivers are seen winding through a level woody country, and the temple of Syriam, little inferior to others at Pegue and Rangoon, stands near the junction of the Irrawaddy. The road leading from the city to the temple is formed with care, a wide causeway in the centre throwing off the rain to the sides; and numberless little spaces are ranged along the edge of the road, in which are niches to receive small images of their divinity Gaudma. Several kiosons or monasteries lie in this direction, generally removed at a short distance from the public way, under the shade of pipal or tamarind trees. The Birmans being, like other inhabitants of the east, fond of processions, scarcely a week passes in which there is not a religious display at Rangoon; either a funeral of fame person who leaves sufficient to defray the expense of a pompous public burning, or the ceremony of admitting youths into the convents of the Rahaans, on which occasion parents and friends spare no expense in entertainments and presents to the Rahaans. See Rahaans. The population of Rangoon is considerable; there are 5000 registered taxable houses in the city and suburbs; so that if each house be supposed to contain six people, the total will amount to 30,000. Having long been the asylum of insolvent debtors from the different settlements of India, it is crowded with foreigners of desperate fortunes, who find from the Birmans a friendly reception, and generally support themselves by carrying on a small trade. The exchange, if it may be so called, exhibits a motley assemblage of merchants, such as few towns of much greater magnitude can produce; Malabars, Mozguns, Perfians, Parnees, Armenians, Portugueze, French, and English. The members of this discordant multitude, engaged in various branches of commerce, are not only permitted to reside under the protection of government, but likewise enjoy the most liberal toleration in matters of religion. They celebrate their several rites and festivals, totally disregarded by the Birmans, who have no inclination to make proselytes. In the same street may be heard the solemn voice of the Muezin, calling pious futilities to early prayers, and the bell of the Portuguese chapel tinkling a fummons to Romish Christians. Processions meet and pass each other without giving or receiving cause of offence. The Birmans never trouble themselves about the religious opinions of any sect, nor disturb their ritual ceremonies, provided they do not break the peace, or meddle with their own divinity Gaudma; but if any person commit an outrage, which the Mussulmen, in their zeal for the true faith will sometimes do, the offender is sure to be put into the flocks; and if that does not calm his turbulent enthusiasm, he is banished to tranquillity. The Parnees, the Armenians, and a small proportion of Mussulmen, engrofs the largest share of the trade of Rangoon; and individuals from their number were frequently selected by government to occupy employments of trust, that related to trade and transactions with foreigners, the duties of which the Birmans conceive that such persons could perform better than themselves. These people, particularly the Armenians, naturally beheld with a jealous eye any ordinance of a commercial nature, that may tend to diminish their influence, and deprive them of that dictatorial power, which they assume and exercise over all merchants and mariners that resort to Rangoon; but of none are they so apprehensive as of the English: a connection with whom might teach the Birmans to transact foreign business without their assistance, and give them a more adequate lance of their own interest. The
The French have long maintained an agent at Rangoon, and are thoroughly acquainted with the advantages which the country of Pegue affords. The imports into Rangoon from the British settlements in the years 1794—5, amounted, according to Mr. Symes, to more than twelve lacks of rupees, about 135,000l sterling: these consisted chiefly of coarse piece goods, flaps, hardware, and broad cloth, the demand for the last article being considerable; and returns were almost wholly made in timber. Teak, the most durable wood that is known, and best adapted for the construction of ships, is produced in the Birman and Pegue empire inexhaustible abundance. The river of Rangoon is equally commodious for the construction of ships; the spring tides rise 20 feet in perpendicular height; the banks are soft, and so flat, that little labour is necessary for the formation of docks: vessels of any burden may be built. Nature, says Symes, has liberally done her part to render Rangoon the most flourishing sea-port of the eastern world. The entrance of the river, about twelve miles below Rangoon, and the banks on each side, bear a near resemblance to those of the Ganges; but the navigation is much more commodious. The channel is bold and deep, from six and a half to eight fathoms, uninterrupted by shoals or inequality of soundings. At this place the breadth of the river is estimated to be from three quarters to one mile. On the bank of the river, opposite to Rangoon, is a considerable town, called Maindu, the residence of the governor of the province of Dalla. This government is entirely distinct from Rangoon, on the cast side. The city of Dalla, from which the town takes its name, is said to be on the west side of the China Buckier river, and was formerly a place of considerable importance. The town of Maindu is composed of one long street; at the end of which is a creek, which goes all the way to Baffin, and has twelve feet depth of water, at high tide; on the west side is a smaller creek, on the bank of which stands a village called Mima-Shunra, or the village of profiteers, being wholly inhabited by women of that description. Rangoon lies in N. lat. 16° 47'. E. long. 96° 9'. Symes's Embly to Ava, in 3 vols. 2vo. See BIRMAN Empire.

RANGSIO, a town in Sweden, in Helsingland; 15 miles W.N.W. of Soderhamn.

RANGUANA, a small island in the bay of Honduras, near the coast of Mexico. N. lat. 16° 25'. W. long. 88° 52'.

RANHADOs, a town of Portugal, in the province of Beira; 18 miles N.W. of Castel Rodrigo.

RANINA, Arts et Veu, in Anatomy, the artery and vein situated on the inferior surface of the tongue. See ARTERY and VEIN.

RANINAL VESSELS, Bleeding from. See FRENUM LINGUE, Division of.

RANISH, in Geography, a small island near the W. coast of Scotland. N. lat. 57° 55'. W. long. 5° 5'.

RANK, a due order, or a place allotted a thing suitably to its nature, quality, or merit.

Kings are persons of the first rank on earth. In castles, procellions, &c. every person is to observe his rank.

RANK, in Military Discipline, denotes a series, or row of soldiers, placed side by side; a number of which ranks form the depth of the squadron or battalion, as a number of files does the width.

When infantry is drawn up three deep, the first rank is called the front rank; the second, the centre rank; and the third, the rear rank.

To close the ranks, is to bring the men nearer; to open it, is to set them farther apart. To double the ranks, is to throw two into the space of one, by which the files are thinned. See Doubling.

RANK, in the Army and Navy, is used for the order of precedence; which see.

In the army the officers in the life-guards are entitled to the rank of lieutenant-colonel, when they obtain or purchase a majority, provided they are of seven years standing. Their commissions in this case run major and lieutenant-colonel. But if an officer should not have completed either of those periods, he obtains the rank of major only until its completion. A lieutenant-colonel attains to the rank of full colonel if he has been seven years major, or twenty-one years in the British service. Cornets in the life-guards rank as sub-lieutenants in their own corps, and as first lieutenants in the army. The English fuzileers enjoy the same privilege. Sub-lieutenants in the Welsh fusileers, rank only as second lieutenants in the army. Marines do the fame.

Officers of the regular forces command the officers of equal degree belonging to the other services. Officers of the militia, fencibles, yeomanry cavalry, and volunteer corps, rank together, according to the dates of their respective commissions. These regulations are subject to some exceptions, specified in the articles of war. Officers of the militia rank generally with the regular forces as junior of their respective commissions. An enjoin in the guards ranks no higher than an enjoin in the regulars. The chief of the engineers ranks as colonel; director, as lieutenant-colonel; sub-director, as major; engineer in ordinary, as captain; engineer extraordinary, as captain-lieutenant; sub-engineer, as lieutenant; practitioner-engineer, as enjoin.

In the navy the admiral or commander-in-chief of his majesty's fleet has the rank of a field-marshial; admirals, with the flags on the top-mast-head, rank with generals of horse and foot; vice-admirals, with lieutenant-generals; rear-admirals, as major-generals; commodores with broad pendants, as brigadier-generals; captains of post-ships, after three years from the date of their first commission, as colonels; other captains, commanding post-ships, as lieutenant-colonels; captains, not taking post, as majors; and lieutenants, as captains.

Rank, Brevet, rank without pay, nominal distinction, which sometimes entitles the holder of it to command in mixed service. The brevet rank in the militia is confined to the colonels and adjutants of the several corps in that establishment. The former receive the brevet rank of colonels in the army whilst actually embodied for service, and command all lieutenant-colonels in the line when they do duty together. Adjutants in the militia may have the brevet rank of captain, provided they have served five years as lieutenants in the militia, or in other forces on the British establishment. In the line, an adjutant who has the rank of captain, may command as such when there is no superior officer on the parade, or for duty. This is not the case in the militia. No adjutant, let his brevet rank of captain be ever so ancient, can command the youngest captain of a company. The same difference prevails with respect to the captain-lieutenancy; which is literally brevet rank. In the regulars, a captain-lieutenant, the infant he is promoted to a company, takes rank according to the date of his first commission, and, as we have observed, may be major by brevet; but no captain-lieutenant can ever avail himself of that seniority to the prejudice of a captain of a company in the militia; nor can an officer in the latter establishment take advantage of his standing, when he quits one regiment to serve in another, even in time of war, although he may have the requisite qualifications in both counties.

Brigade majors rank with captains, provided they have
in the circar of Sanore; 20 miles W. of Bijnagar. N. lat. 15° 18'. E. long. 75° 37'.
RANNYDEE, a town of Bengal; 11 miles S. of Curruckdegh.
RANNYGONG, a town of Hindooftan, in Dowlatabad; 15 miles S.S.W. of Amedinagar.
RANNYGUNGE, a town of Bengal; 35 miles N. of Dinagepur.
RANNYPOOKRA, a town of Bengal; 30 miles W.N.W. of Rogonatpur.
RANO, a small island in the N. part of the gulf of Bothnia. N. lat. 65° 43'. E. long. 22° 52'.
RANRAN, a town of Cochinchina, and the capital of a province. N. lat. 12° 50'. E. long. 108° 56'.
RANSACKEN, a town of the duchy of Wurzburg; 3 miles S. of Wurzburg.
RANSOM, a sum of money paid for the redemption of a person out of slavery, or for the liberty of a prisoner of war.

With regard to prisoners of war, it is allowed that there is no obligation of releasing those who are detained as such, till after satisfaction has been obtained. Whoever makes a just war has a right, if he thinks proper, to detain his prisoners till the end of the war; and then, in releasing them, he may justly require a ransom, either as a compensation at a peace, or, if the war continue, for diminishing his enemy's prisoners, at the fame time that he strengthens him with the return of folder, Prisoners of war, among European nations, are exchanged or ransomed during the war; and this is generally stipulated in a previous cartel. If sovereignties at war have agreed on a cartel for the exchange or ransoming of prisoners, they are faithfully to observe it no less than every other convention; but if, as was formerly the general practice, the state leaves to every prisoner, at least during the war, the care of redeeming himself, such particular conventions offer many questions, of which some of the principal are the following. He who has acquired a lawful right of demanding a ransom from his prisoner, may transfer his right to a third person. This was practised in the last ages. But as the perdon taking a prisoner is obliged, for the sake of his reputation, to treat him with justice and humanity, he is not to transfer his right, in an unlimited manner, to one who might probably abuse it. When he has agreed with his prisoner, concerning the price of the ransom, he may transfer the right to whom he pleases. On the conclusion of an agreement made with a prisoner for the price of his ransom, it becomes a perfect contract, and cannot be rescinded from, under a pretence that the prisoner is discovered to be richer than was imagined; for there is no manner of necessity that he should be rated according to the wealth of a prisoner, because that is not the scale for measuring the right of detaining a prisoner of war. But it is natural to proportion the price of the ransom to the prisoner's rank and character; the liberty of an officer of distinction being of greater consequence than that of a private man, or inferior officer. If the prisoner has not only concealed, but disgraced his rank, it is a forbid fraud, and gives a right for annulling the agreement. If a prisoner, having agreed on the price of his ransom, dies before payment, it has been queried whether this price be due, and whether the heirs are obliged to discharge it? Unquestionably, says Vattel, they are obliged to it, if the prisoner died in the possession of his liberty; for, from the moment of his release, in consideration of which he had promised a sum, this sum becomes due, and does not at all belong to his heirs; but if he had not
not obtained his liberty at the time of his death, it can be no debt to him, or to his heirs, unless the agreement was otherwise; and he is not reputed to have received his liberty, till he is absolutely permitted to depart free; when neither the prisoner he was, nor the sovereign, opposed his release and departure. If indeed he has only been permitted to take a journey for applying to his friends, or his sovereign, in order to obtain the means of ransoming himself, and he dies before he is released of his full liberty, before his final discharge from his parole, nothing is due for his ransom. If, after agreeing on the price, he is detained in prison till the time of payment, and he dies before the debt is paid by his death, and does not affect his heirs; such an agreement on the part of him, who detains his prisoner, being no more than a promise of giving him his liberty for a certain sum paid down. A promise of buying and selling does not suppose the purchaser to pay the price of a thing, if it happen to perish before the bargain is concluded. But if the contract of sale be perfect, the purchaser shall pay the price of the thing sold, though it should happen to perish before the delivery of it, provided there was no fault or delay in the seller. For this reason, if the seller has absolutely concluded the agreement of the ransom, and from that time owns himself a debtor for the stipulated sum, remaining no longer as a prisoner, but for the security of the payment, his intervening death does not extinguish the debt: the ransom agreed on remains still due. If the agreement says, that the ransom shall be paid on a certain day, and the prisoner happens to die before that day, then the heirs are bound to discharge it; for the ransom was due, and the day was assigned, only, as the term for payment. Upon the same principles, strictly speaking, it follows, that a prisoner, releaved on condition of procuring the release or discharge of another, should return to prison, in case the latter happens to die before he could procure him his liberty. Such an unfortunate cafe, however, is entitled to regard, and equity seems to require that this prisoner should continue in the enjoyment of liberty, provided he pays a just equivalent; it being now out of his power to purchase it precisely at the price agreed on. If a prisoner fully set at liberty, after having promised, but not paid, his ransom, happen to be taken a second time, it is evident that, without being excused from paying his first ransom, if he is willing to be set at liberty, he must pay a second ransom. On the contrary, though the prisoner has agreed for the price of his ransom, if before the execution of the compact, before he is set at liberty in virtue of it, he be detained by his party, he owes nothing. It is here evidently suppos'd, that the finishing hand was not put to the compact, and that the prisoner had not acknowledged himself debtor for the rate of his ransom. He whose prisoner he was, had, as it were, only made him a promise of selling, and he had promised to purchase, but the purchase and sale had not actually passed into effect; the property was not actually transferred. The property belonging to a person does not pass to him who takes him prisoner, unless at the same time he seizes on such things. Of this there is no doubt, especially in our times of moderation, when prisoners of war do not fall into slavery. And even by the law of nature, the property of a slave's goods does not, without some other reason, pass to the master of a slave. There is nothing in slavery of which this can itself be the natural effect. If a man obtain a power over the liberty of another, does it follow that he has likewise a right over his property? Therefore, if a shipowner, or a master of a ship, has not ransomed his prisoner, or the latter has found means to conceal something from his search, what he has preferred should belong to him, or he may employ it towards the payment of his ransom. At present even prisoners are not always stripped. The death of a prisoner puts a period to the right of him who had taken him; therefore a hostage, given for the procuring of a person's liberty, is to be released the moment the prisoner expires; and if the hostage dies, the prisoner is not released by such death. The reverse of this is true, if one, instead of being a hostage for the other, had been subsumed in his stead. Vattel's Law of Nations, b. iii. ch. 17.

Formerly it was a common practice to ransom British ships, when captured by an enemy, by delivering to the enemy what was called a ransom-bill, which secured to the captor the price agreed upon, and operated as a bill of sale of the ship and cargo to the original owners, and as a protection to the ship against other cruisers of the enemy during the remainder of the voyage. A hostage was delivered to the captor, for securing to him the punctual payment of the stipulated sum. This ransom-bill, independent of the hostage, was considered as a contract of the law of nations, and obligatory upon the owners, as well as upon the captain and hostage who signed it; and actions have been often brought upon them in our courts of common law. And where the ship, or goods were injured, the amount of the ransom was usually taken to be the measure of the demand of the injured upon the underwriters, in respect of the capture. But this practice of ransoming ships captured by the enemy being found to operate more to the disadvantage than for the benefit of this country, it was thought proper at length to prohibit it altogether. And therefore by Stat. 22 Geo. III. c. 25. § 1. it is enacted, that it shall not be lawful for any of his majesty's subjects to ransom, or to enter into any contract or agreement for ransoming, any ship or vessel belonging to any of his majesty's subjects, or any merchandizes or goods on board the same, which shall be captured by the subjects of any state at war with his majesty, or by any person committing hostilities against his majesty's subjects. By § 2. all contracts and agreements which shall be entered into, and all bills, notes, and other securities, which shall be given by any person or perfons for ransom of any such ship or vessel, or of any merchandizes or goods on board the same, shall be absolutely void in law, and of no effect whatever. And by § 3. a penalty of $500. is given to the informer, for every offence against the act. This statute has put an end to all questions on the law of ransoms. Marshall's Treatise on the Law of Insurances, vol. ii.

In our Law Books, ransom is also used for a sum paid for the pardoning of some notorious crime. Horn makes this difference between ransom and amercia-ment, that ransom is the redemption of a corporeal punishment due to any crime. It is never usual to affix a larger fine than a man is able to pay, without touching the implements of his livelihood, but to inflict corporal punishment, or a limited imprisonment, instead of such fine as might amount to imprisonment for life. And this is the reason why fines in the king's court are frequently denominated ransoms, because the penalty must otherwise fall upon a man's person, unless it be redeemed or ransomed by a pecuniary fine (Murr. c. 5. § 3. Lamb. Edinlurch. 57.) according to an ancient maxim, "non habet in crimina baud in corpore." Yet, when an act statute speaks both of fine and ransom, it is held, that the ransom shall be treble to the fine at least. Dyer. 232. RANSTADT, in Geography, a town of Germany, in the principality of Stolberg; 17 miles N.E. of Frankfort on the Main. RANSTADT, or Mark Ranstadi, a town of Saxony, in the
the territory of Merseburg; 10 miles S.S.E. of Merseburg. N. lat. 51° 18'. E. long. 12° 14'.

RANT, in the Drama, an extravagant flight of passion, overhooting nature and probability.

Lee's tragedies abound with rants; yet the wildest of them, it is observed, have frequently met with applause on the stage.

We find instances of rants, even in our severest poets. Such, e. gr. is that in the beginning of Ben Johnstone's Cato, where the patriote, in speaking to Rome, says, "I'd plow up rocks, steep as the Alps in dust; and have the Tyrrhenian waters into clouds, but I would reach thy head!"

RANTAMPUR, in Geography, a circar of Hindoostan, in the country of Agimere, bounded on the N. by Jenagur, on the E. by Agra, on the S. by Kottah, and on the W. by Oudipour and Siroyo. — Alto, a town and forteres, being the capital of the above named circar; 86 miles E. of Agimere. N. lat. 28° 35'. E. long. 76° 58'.

RANTZAU, John, in Biography, a general in the Danish service, was born in 1492, and at the age of 13 he entered into the army. In 1515 he began to travel into foreign countries, visiting in succession England, Spain, Germany, Italy, Greece, Syria, Palestine, and other parts of the East. In 1517 he was knighted at Jerusalem; and upon his return to Denmark, was appointed to accompany duke Christian, afterwards Christian III., on his tour to Brandenburg, and other towns of Germany. When Frederic I. accepted the crown of Denmark, he was promoted to be a general in 1533, and entruted with the command of the troops in Holstein. He became greatly distinguished in his military character, and on various diplomatic contests, and died in 1569. As an author he is known by the following works: "A true and brief Account of the Wars carried on in 1559, by Frederic king of Denmark, and Adolphus duke of Holstein," &c.; "A Description of Cimbriz," printed in Welphalen's Monumenta inedita, tomi. i. Gen. Biog.

RANTZEN, a town of the duchy of Stiria; 6 miles N.W. of Muckran.

RANTZENBACH, a town of Austria; 6 miles S.S.W. of St. Polten.

RANVILLE, a town of France, in the department of the Calvados; 5 miles N.E. of Caen.

RANULA, dim. of rana, a frog. This term is, in Surgery, applied to a swelling of the salivary ducts under the tongue. Whether the tumour is so named from a whimsical fussipation that it bears a resemblance to a frog, or from its being fancied to oblige the patient to make a croaking noise, in attempting to articulate, is a point which surgical writers leave undetermined. The swelling is round, of a greyish colour like a hydatid, soft, compressible, indolent, and, in the early stage, almost transparent. At first, it is of about the same fize as a nut, or cherry; but, by degrees, its volume becomes much more considerable. It is very frequently met with in young children: its occurrence in adults is more uncommon. It consists of a subacute dilatation of the excretory tube of the submaxillary, or else of the sublingual gland, the orifice of which duct is by some cause or another flopped up, or obliterated; so that the confined salivary accumulates, becomes liquid and collects to flow in the usual manner. In proportion as the ranula increases, the incipient fize of it having been neglected, its enlarged fize raises up the tongue, and forces it backward; the consequence of which is, that mastication, deglutition, and respiration, are obstructed. The voice becomes indistinct, and hoarse; the motion of the tongue is restrained: this organ cannot be put out of the mouth. By degrees, the incisor and canine teeth of the lower jaw are loosened; the layer of mucusses, composing the lower parietes of the mouth, is depreffed; and the swelling, having attained a considerable fize, makes a very manifest prominence beneath the chin. In this advanced stage, that is to say, when the ranula has existed ten or twelve years, as practioners occasionally fee instances of, the appearance of the swelling is quite altered from what it originally was. The tumour is now hard, elaflic, painful, ulcerated, and, as it were, farcomatos: it is as large as a turkey's egg, and not situated at the side of the frcum, but anteriorly under the tongue, to which it is closely adherent. The mouth emits a very fetid smell; and the breathing is so-much obstructed, that the patient, through fear of suffocating, is obliged to lie with his mouth wide open, when he goes to sleep.

While a ranula is recent, the fluid which it contains is a vifcid saliva, resembling the white of egg, and sometimes of rather a yellow colour. In time it is gradually changed, becoming turbid and puriform; and, in certain instances, soft, friable, greyish concretions, from the fize of a pea to that of an almond, commonly called salivary calculi, are found in the kind of cyst, which is produced by the dilatation of the salivary duct. These calculi effentially conflict of a large proportion of the phophate of lime, united with a mucilaginous substance; and concrections of the fame kind frequently occur in the tonsils, and in the salivary glands themselves, as well as their excretory ducts. Forefetus, l. xiv. obf. 26. p. 112. Blegney, Nouvelles Découvertes, &c. tom. i. ann. 1679, p. 230. Mém. de l'Acad. chirurgic. tom. v. p. 464. Petit, Œuvres Polhibes, &c. tom. i. p. 188. Blissius, Òbl. 14. p. 81.

A ranula, whether recent or inveterate, cannot be cured except by a surgical operation. The curative indication, in the first of these fates, is to make an outlet for the fluid accumulated in the tumour, and to make an opening sufficiently capacious to let the saliva readily pass into the mouth. Merely making an incision into the swelling, or opening it with a trocar, or a fetic drawn through it, are flated to be ineffectual methods. The tumour does indeed subside as soon as the aperture is made; but the edges of the wound grow together again, and the disease recurs. There is an absolute necessity for first making an incision the whole length of the swelling, and then removing, with the aid of fitters and a pair of dilating forceps, a portion of the edges of the recent wound. This flight lots of subflance prevents the return of the complaint, and always infures a free paffage for the saliva; an advantage of which there is no certainty in any other mode of proceeding. By this flight operation, ranula in children may be cured in the course of a few days, without the least occasion for the application of any dressings whatsoever. It has been proposed to dilate the constricted orifice of the salivary duct with a probe. (Mém. de l'Acad. de chirurgie, tom. iii. p. 460.) But this orifice is difficult of detection, and the swelling cannot be in this manner eflily emptied. M. Laflis seems to entertain doubts whether Warton's canal can ever be made to resume its original fize, after once being clofed. Patho logic Chimurg. tom. i. p. 405.

When a ranula has existed a long while, is attended with considerable hardships, and is of large fize, it is a tumour which requires to be completely extirpated. A transverse incision, parallel to the opening of the mouth, is to be made in it through its whole extent. The surgeon is then to cut out...
out the upper portion of the swelling, situated in front of the frænum of the tongue, to which it is also adherent, and next the inferior portion, which sometimes extends into the interstice between the genio-hyoidei and genio-glosso muscles, with which it becomes confounded. A pair of forceps, a hook, scissors, and a straight bistoury, are the instruments necessary for this operation. A degree of hemorrhage always ensues. The use of a detergent gargle, made of barley-water and honey of roses, will serve to finish the curse in a very moderate space of time.

In confirmation of the latter observation, Laffius addsuces the following case: A young man, aged 22, had a ranula, which had continued ever since he was born, and was equal in size to a turkey’s egg. The incisor teeth of the lower jaw were loosened, and forced forward by the succive increase of the swelling. A fenton had been palps quite through it, without any useful effect. The breath of the patient and his saliva were intolerably fetid. The tumour was closely adherent to the lower and anterior part of the tongue; and extending laterally, confounded itself with this organ, of which it impeded the motion. A straight, narrow bistoury was introduced into one of the openings at the side of the tumour, and carried completely across to the opposite aperture. Thus a transverse incision was made into the cavity of the diseased. By means of the same instrument and a hook, the lateral portions of the swelling were removed. A profuse hemorrhage ensued, caused by the total division of the frænum, the palatine veins, and one of the palatine arteries. It was flopped by putting under the tongue a large quantity of dry lint, and by compressing the dorium of the tongue several hours with the fingers, while the thumb was employed in compressing the parts behind the chin from below upwards. This double fort of preflure answered the purpose. No caution was found necessary, and, by the use of deterrent gargles, the patient was cured in about a fortnight.

When a ranula of long duration, situated at the side of the tongue, and of considerable size, forms a tumour, that makes its appearance outwardly towards the base of the jaw, Laffius seems to disapprove of making a free incision through the skin, for the purpose of extirpating that part of the swelling which cannot be removed through the mouth; a plan which, in one instance, practised by Marchetti. Obf. Med. Chirurg. obf. 31. p. 48. See Laffius’ Pathologie Chirurgicale, tom. i. chap. 61.

RANULARES, in Anatomy. See RANINA. RANUNCULACEE, in Botany, the 6th natural order in Juflieu’s system, or the first of his 13th clas, for whose character see GERANIA. The Ranunculaceae are defined as follows. Calyx of many leaves, sometimes wanting. Petals definite, mostly five. Stamens indefinite, except in Myosurus; their anthers incorporated with the filaments. Germens few, indefinite, or definite, rarely solitary, placed on a common receptacle; each of them furnished with a style, which is rarely wanting, and a simple stigma. Capsule, or rarely berries, as many as the germens; in some infestures fingle-seeded, and not bursting; in others many-seeded, splitting half way down, at their inner margin, into two valves, bearing the seeds at the edges. Corolla minute, lodged in a cavity at the upper part of the large horny alurnum. Stem generally herbaceous. Leaves alternate; rarely (in Clematis and Atro-ene) opposite; some of them half flowering the stem; some compound, pinnate or fringed; some, as is more frequently the case, simple, and these are mostly palmate or lobed, their flowers often pale at the base. See RANUNCULUS. Vol. XXIX.

Juflieu divides the order in question into four sections.

Scéti. 1. Capsules single-seeded, not bursting; berries in Hydrargit.

This section consists of Clematis, Atroge, Thalidrum, Hydrargit, Anemon, Hamondys, Commeron, Adonis, Ranunculus, Ficaria, and Myosurus.

Scéti. 2. Capsules many-seeded, splitting at the inner edge. Petals irregular.

The calyx in this section is often coloured, being what Linnaeus terms corolla; that author considering the petals of Juflieu as nectaries. The genera are Trollius, Helleborus, Styporum, Nigella, Gareillida, Aquilegia, Delphinium, and Acanth. Some species of Delphinium have but a single capsule.

Scéti. 3. Capsules many-seeded, splitting at the inner edge. Petals regular.

Caltha, Persicaria, Zanthorrhiza, Cimicifuga.

Scéti. 4. Germens solitary. Berry of one cell, with many seeds, affixed to a single lateral receptacle.

The only genera are Atene and Podophyllum, and these we feel disposed to remove to Juflieu’s next order, Papaveraceae. See that article.

We cannot but remark that the petals, as Juflieu terms them, in Trollius and Helleborus are by no means definite, and that they greatly exceed the number five. Neither are they irregular in Trollius. As to the other genera of his 2d section, the parts in question are such obvious nectaries, that they can have no other function to perform, except possibly in Aquilegia, where their limb partsakes of the nature of petals.

RANUNCULOIDES, a genus of Vaillant’s, founded on the Ranunculus bedendorae and aquatilis of Linnaeus, and named from its resemblance or affinity to RANUNCULUS; see that article. No one has followed Vaillant in this influence, nor is there any real mark of distinction for his supposed genus. Ranunculoides is, besides, the specific name of a rare British Anemone, but ranunculina would have been better Latin; as in Helleborus ranunculina, Sm. Pl. Ir. f. t. 37. Willd. Sp. Pl. v. 2. 1336. See Helleborus.

RANUNCULUS, an ancient name, whose origin is as obvious as its fene is obscure. The word is, no doubt, derived from rana, and means a little frog. The Greeks call the same plant Νεανος, which is nearly synonymous. Most etymologists suppose this name to allude to the native flation of the plant, in bogs and watery places, such as frogs frequent. But the original Νεανος of Dioscorides is the beautiful Ranunculus aquatilis of Linnaeus, or Garden Ranunculus, which inhabits corn-fields, and does not grow in wet places; though indeed the other three species, described by that ancient writer, do; these are our lanuginosa, muricatus, and aquatilis. It seems possible that the divisions of the leaves in all these plants may have suggested the idea of a frog’s foot, which supposition is confirmed by the English name, Crowfoot. Ambroinus hints at a resemblance between the root and the foot of a frog, which is not, to us, by any means apparent.—Linn. Gen. 281. Schreb. 377. Willd. Sp. Pl. v. 2. 1527. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 587. Prodr. Fl. Græc. Sibth. v. 1. 380. Ait. Hort. Kew. v. 3. 351. Pursh v. 2. 391. Julf. 233. Poirer in Lamarck Dict. v. 6. 97. Lamarck Illführ. t. 498. Gapan. t. 74. (Ficaria; Dill. Gen. 108. t. 5. Huds. Angl. 244. Julf. 233. Ranunculodea; Vaill. Mem. de l’Acad. des Sciences for 1719, German edition, 321.)—Clas and order, Polyandria Polygynia. Nat. Ord. Multifilis, Linn. Ranunculea, Julf.

Gen. Ch. Cal. Perianth of five ovate, concave, fome-

G
what coloured, deciduous leaves. Cor. Petals five, obtuse, polished; with small claws. Nectary a cavity in each petal, just above the claw. Stam. Filaments very numerous, half the length of the corolla; anthers firmly united therewith, erect, oblong, obtuse, of two separate lobes. Pj. Germanos numerous, collected into a head; styles none; stigmas reflexed, very small. Peric. none. Receptacle beft with extremely minute falkes, to which the seeds are attached. Seeds numerous, naked, irregular, uncertain in figure, with a reflexed point.

Obf. The elliptical mark of this genus conflits, as Lin-~
neus remarks, in the nectary, the refi of the parts being uncertain; hence he takes occasion to point out the ufe of advertising to that organ, which before his time had been neglected, and which his opponents accuse him of sometimes making of too much importance. The great Juffieu will not, in this obvious cafe, ufe the language, though he adopts, unacknowledged, the idea of Linneus; nor will he allow the manifold neftes of fome of his RANUNCEAE (fee that article) to be other than petals. "Such," to use his own words, in his preface, p. 26, "is the love of undivided paffion!"

The nectary in RANUNCULUS, fays Linneus, is, in fome species, a naked pore; in fome it is bordered with a cylin-~
drical margin; in others clofed with a notched fcale. Ficaria of authors has only a three-leaved calyx, with a superabundance of petals. The ends in fome fpecies are roundifli; in others defpeffed, prikey, and fewer in number. R. hederaeeus has but five flamen; falcatus has a fivord-~
shaped point to each feed, and appendages to the base of the calyx; fereilater, and a few besides, have an awl-shaped receptacle, and confluently a fpiked fruit.

Eff. Ch. Calyx of five leaves. Petals from five to eight, with a honey-bearing pore in the calyx of each. Seeds naked.

This extenfive genus is divided into two fections, by the form of the leaves. The fpecies are all herbaceous, generally of an acrid quality. The prevailing colour of the flowers is yellow; we know of none that are blue, except by accidental variation in R. afaticus. They are plants of temperate or cold climates; none of them alpine. Linneus, in Sp. pl. ed. 2, enumerates twenty-eight fpecies; the 14th edition of Syll. Vegg. has forty-four, and Willdenow reckons up fifty-one. Fifteen are natives of Britain, as mentioned in Pl Brit.; but the 11th fpecies in that work, partulus of Linneus, mud be expunged, as a mere variety of biilfetus, n. 8. The original number is, however, made up, by a newly-discovered Scotifh fpecies, the alpgeflis, figured in Engl. Bot. v. 34. t. 2390.

So many additions have been made to this genus by the labours of Poiret in Lamark's Diét. v. 6, and the discoveries of Michaux and Pursh, that, with fome neceffary corrections, and a few communications of our own, the whole subject requires to be detailed.

Sect. 1. Leaves fimple and undivided.

more in diameter. The whole plant is of an excufively acrid burning quality, faid to produce inflammation in the vifera of sheep, whence the name flammula, a little flame. Dr. Withering recommends the distilled water, as preferable to all other medicines, for procuring inlantaneous vomiting in cafes of poison.

2. R. reptans. Creeping Spear-wort. Linn. Sp. pl. 773. Fl. Lapp. t. 198. v. 3. f. 5. Lightf. 289; fig. in frontifpiece to v. 1. Fl. Dan. t. 186.—Leaves linear-lan-~
ceolate. Stem creeping.—About the margins of alpine lakes, on a fandy soil; common in Scotland, flowering in June and July. We have always thought this a variety of the former, as mentioned in Fl. Brit.; but Willdenow contends for the contrary. He truly afferts that it differs in having a thread-shaped creeping stem; linear entire leaves, tapering down into their falkes; flower-falks folidary, erect, fingle-flowered; and much smaller flowers. Neverthelefs, we have feen to many intermediate varieties, and fuch a dipofition in weak plants of the Flammula to take root at their joints, that we molt incline to our original opinion, fuggestcd fift by Linneus himfelf in his Sp. Pl.

casionally ferrated, as in the rude cut of Ambrofius, but not commonly so. Calyx hairy. The whole herb is more or less covered with clofe-preffed hairs, visible also in Flammer. Flowers large and brilliant, very confpicuous.

pointed.

5. R. filiforms. Slender Creeping Crowfoot. Michaux Boreal-Amer. v. 1. 920. Pursh n. 4. Lamark Dict. n. 4.—"Stem thread-shaped, creeping, jointed, almoft naked. Leaves linear-awelked, obtufe. Flowers axillary, folidary, flalked."—In inundated places, on the banks of the river St. Lawrence; at Hudson's bay and Labrador; flowering in June and July. This is decribed as a very small, slender, smooth fpecies, very much refembning R. reptans, n. 2. We have feen no fpecimen.

It  is  a  hardly  perennial  in  our  gardens,  not  difticult  of  culture,  yet  not  common,  flowering  in  May.  The  ber- 165.  bage  is  glaucous.  Stem  erect,  leafy,  twelve  or  fifteen  inches  high,  branched  above.  Leaves  generally  more  or  lefs  fringed  with  foft  hairs.  Calyx  green,  fMOOTH,  concave,  partly  mem- 183.  branous  and  white  at  the  edge.  Petals  of  a  pure  and  brilli- 202.  ant  white.  Authors  yellow,  as  in  other  fpecies.  We  have  never  seen  the  ripe  feeds.  12.  R.  heterophyllus.  Various-leaved  Slender  Crowfoot.  (R.  bonarienfis;  Lanarcf  Dict.  n.  9.)—Leaves  talked,  toothed,  heart-shaped  or  ovato-lanceolate,  with  three  central  ribs.  Stem  erect.  Flowers  talked,  foltary,  oppofite  to  the  leaves.  Seeds  obtufe,  granulated.—Gathered  by  Com- 211.  meron at  Buenos  Ayres,  in  marthly  places.  Root  fibrous.  Stem  erect.  Flowers  talked,  foltary,  oppofite  to  the  leaves.  Leaves  alternate,  on  long  ifalks;  the  lower  ones  ovate,  or  heart-shaped;  the  upper  lanceolate,  or  ovate;  all  obtufe,  more  or  lefs  crefmate  or  toothed,  about  an  inch  long,  fMOOTH,  furcifiehed  with  three  central  ribs,  and  several  lateral  branching  veins.  Foutflarks  bordered  at  their  bafe;  the  lowermost  much  the  longest.  Flowers  very  fmall,  wiflim,  on  foltary,  ifraft,  fimple,  lateral  ifalks,  an  inch  or  an  inch  and  half  long,  oppofite  to  the  leaves.  Fruit  ovate  or  obovate.  Seeds  obtufe,  or  obovate,  rough  with  minute  points.  The  calyx  is  smooth  and  reflexed,  often  remaining  till  the  feeds  are  ripe.  13.  R.  rigelliformis.  Long-talked  Crowfoot.  Leaves  on  long  ifalks,  heart  or  kidney-shaped,  wavy  or  crefmate.  Stem  creeping,  thread-shaped.  Flowers  talked,  foltary,  oppofite  to  the  leaves.  Petals  ovate.  Seeds  obtufe,  dotted.  —Native  of  Chili  and  New  Granada.  We  have  fpecies  from  Matius  and  Cavanilles,  but  this  fpecies  does  not  fex  to  be  any  where  decribed.  The  flemens  are  long,  thread- 165.  shaped,  much  branched,  proftrate,  creeping  or  perhaps  floating,  fending  out  from  each  joint  long  fibrous  radicles,  and  one  or  more  smooth,  roundifh,  heart-shaped  or  kidney- 173.  shaped  leaves,  hardly  an  inch  wide;  their  ftockflarks  meafuring  from  two  to  three  inches.  Flowers  very  fmall,  white,  foltary,  oppofite  to  the  leaves,  on  slender  ifalks,  rather  longer  than  thofe  of  the  foliage.  Stamens  few.  Fruit  rather  oblong.  Seeds  obovate,  obtufe,  comprefified,  minutely  dotted.  This  _Ranunculus_  is  perhaps  molt  nearly  akin  to  our  British  _bederaceus_,  hereafter  defcribed,  though  very  certainly  diftinct,  and  as  the  fpecies  are  at  precent  arranged,  they  muft  remain 3  G  2  at
at a distance. In habit and general resemblance they closely accord.  
14. R. Cymbarius. Small Trailing Crowfoot. Pursh n. 5. "Leaves heart or kidney-shaped, with five blunt teeth. Stem creeping, thread-shaped. Flower-flakes solitary, 
mottied two-flowered. Petals linear. Fruit oblong."—In 
famine marshes, near the salt-works of Onondago, New York, 
flowering in June and July. Perennial, somewhat reminding 
the following. Flowers small, pale yellow, sometimes 
white. Pursh. 
15. R. fulviglaucescens. Salt-marsh Crowfoot. "Pallas's Tra- 
vels, small edition, v. 3. 173." Wild. n. 12. (R. rutheni- 
cus; Jacq. Hort. Vind. v. 3. 19. t. 21. R. repens, flore 
caule singulare, foliis variis feccis; Amm. Ruth. 81. t. 13. 
f. 2.)—Leaves ovate, somewhat heart-shaped; toothed at 
the extremity. Stem creeping, thread-shaped. Flower-
flakes solitary, mostly single-flowered. Petals obovate. 
Fruit nearly globose.—Found by Gmelin, on the banks of 
the Neva; by Pallas in the salt plains of Siberia, 
beyond the lake Baikal. The flowers are yellow, as big as 
our common Crowfoots, being more than ten times the 
fize of the last. Their petals are about ten, obovate. The root 
fends out long runners, like a garden strawberry. Gmelin's 
specimen is much smaller than Jacquin's figure. 
Wildl. n. 10. Ait. n. 8. (R. inulaceanus; Ded. Pempt. 429. 
R. autumnalis Chitt.; Ger. Em. 1544. R. inulaceanus Chitt.; 
ib. 955.)—Leaves ovate, serrated. Flower-flakes radical, 
single-flowered, hairy. Native of Portugal and the north 
of Africa, cultivated in England before 1640, but now 
fearfully seen. It flowers in May and June, and has a 
perennial fibrous root, more like Gerarde's fig. 10 than 11. 
Leaves all radical, flaked, ovate, ribbed and veiny, some-
what hairy, strongly and unequally serrated, an inch or an 
inch and half long; sometimes, according to Chittus, blif-
tered. Flowers yellow, on simple, hairy, upright, radical 
flats, three or four inches long. Petals more than five, 
narrow-obovate. The old authors delineate two kinds, 
generally supposed to be varieties, but which may possibly 
be species. We have not seen either, except in a dried 
state. 
17. R. Ficaria. Pilewort, or Leffer Celandine. Linn. 
Ruff. t. 21. Bulliard t. 43. (Chelidonium minus; Matth. 
Valgr. v. 1. 578. Fuchsl. Hilt. 867. Ger. Em. 816.)— 
Leaves heart-shaped, angular, smooth, stalked. Petals 
numerous.—Native of wafle ground throughout Europe, 
in moil, shady, or bulfy places, flowering in the early 
spring. Dr. Sibthorp found it common in Greece; and 
there can be no doubt of its being, as all botanists have 
judged, 

n. 13.—Radical leaves wedge-shaped, ovate, five-toothed at 

at the extremity; those of the stem seli-sel, palmate. Native 
of the alps of Siberia. Wildenow says he received this by 
the name of grachtis, meaning glatis, with which it agrees 
in the fize, and perhaps colour, of the flower, but is 
abundantly distinct in the leaves." Several Siberian 
unnamed specimens, in the Linnean herbarium, answer ex-
actly to Wildenow's description. The radical leaves are 
feral, flaked, between half an inch and an inch in length, 
smooth; rounded and entire at the base; abruptly and 
violently cut into broad blunt teeth, we might almost say 
lodes, at the summit. Stem erect, usually single-flowered, 
with two or three, alternate, self-sel, more deeply lobed, or 
palmate, leaves. Calyx brown, hairy. Petals five, inver-
versely heart-shaped, apparently white. The flower is so like gla-
cialis, that we cannot but suspect the difference of the leaves, 
however great, to be but casual. At any rate, they are 
sometimes so deeply cut, that this species might perhaps, 
without violence, have been placed in the following fection, 
next to glacialis. 
(Thora major et minor; Caner. Epit. 825. 826. Th. val-
denis, et montis Baldi; Ger. Em. 963. Pfeudo acuminum 
pardaliannes; Matth. Valgr. v. 2. 430.)—Leaves kidney-
shaped, abrupt, crenate, reticulated; the radical ones on 
long flats. Stems with one or two flowers. Braeas lan-
colate.—Native of the alps of Switzerland, Auffina, and 
Greece, as well as of mount Baldis, near Verona, flow-
ering rather early in summer. It is said to have been formerly 
in the English gardens, but has never fallen under our ob-
ervation. Root perennial, of thick, tapering, fleshy fibres 
or rather knobs. Stem solitary, smooth, simple, near a span 
high; terminating in one, rarely more, long-flaked golden 
flowers, about half an inch wide; its calyx-leaves lanceolate, 
coloured, smooth, like every other part of the plant. Leaves 
at about two inches wide, and one long, rather coriaceous, strong-
ly reticulated with veins, nearly crenate, terminating either 
abruptly, with a notch, or elongated into three acute, entire, 
triangular, central lobes; the uppermoft, or floral, ones, 
lanceolate and entire; the radical ones only on long slender 
flats. Flowers globular, of a few, large, tumbid, ovate 
sects, with hooked points. The root of this plant is reported 
to be extremely acrid and poisonous, its juice having been 
used formerly, by the Swifs hunters of wild beasts, to en-
venom their darts, whose wound by that means becomes 
speedily fatal and incurable. Hence the name, from ᶜ浬>, 
corruption, or venem. We can see no possible reason for dis-
tinguishing the greater and smaller kinds, even as permanent, 
or well-marked, varieties. 

Section 2. Leaves dissected and divided. 
Wildl. n. 15. Ait. n. 11. (R. creticus latifolius; Chitt. 
Hilt. v. 1. 239. Ger. Em. 853.)—R. macrophyllus; 
Desfont. Atlant. v. 1. 437. Lamarck Dict. n. 19.—Radic- 
als leaves kidney-shaped, crenate, somewhat lobed; tem-
leaves in three deep, lanceolate, entire segments. Stem many-
flowered.—Native of Crete; cultivated in the Oxford 
garden in 1658, but perhaps now lost. The root is perennial, 
of many thick, tapering, fleshy fibres. Stem thick, mod-
erateley branched, eighteen inches, or more, in height, hairy 
as well as the rest of the herbage. Radical leaves from two to 
four inches long, and more in breadth, kidney-shaped, reticu-
lated with strong veins, light green, downy, unequally di-
vided into about seven, three-clift, or coarsely notched, shal-
low lobes; flem-leaves alternate, in three deep, oblong, ob-
tate, entire lobes; the base tapering or wedge-shaped. 
Flowers feral, yellow, nearly as large as R. Linnis, n. 3. 
Calyx reflexed, ovate, loosely hairy. & appears, by the ac-
count of M. Desfontaines, to differ merely in having the 
lower
lower leaves more deeply lobed than usual, and somewhat less hairy.

21. *R. caffiuscens*. Callabian Crowfoot. Linn. Sp. Pl. 775. Wild. n. 16. Ait. n. 127. (R. aconitifolius, folio rotundato, ad radicem praeflante; Loef. Pruf. 225. t. 72.)—Radical leaves roundish-heart-shaped, crenate, undivided; stem-leaves in several deep, lanceolate, toothed and jagged segments. Stem many-flowered. —Native of Prussia and Siberia, flowering in May. Loddiges are said to have introduced it into England, in 1754. Though the character of this approach the bull, the two plants are very different. The radical leaves of the present, though heart-shaped, are almost orbicular, their two lobes meeting each other; their margin simply crenate, but not at all divided; their surface minutely downy. Stem much branched; smooth below; downy above; bearing several fingered, veiny, smooth, fleshy leaves; the lower ones largest, many-lobed, and jagged; the upper with only three lanceolate, entire lobes. Flowers rather small, deep yellow. *Calyx* hairy towards the base. 

22. *R. auriculus*. Wood Crowfoot, or Goldlocks. Linn. Sp. Pl. 775. Wild. n. 17. Ait. n. 13. Pursh n. 9. Fl. Brit. n. 5. Engl. Bot. t. 624. Curt. Lond. f. ac. 2. t. 41. Fl. Dan. t. 665. Ger. Em. 954. (R. primus folyvstresc; Fuch. Hift. 156. Dalech. Hift. v. 1. 1299.)—Radical leaves kidney-shaped, deeply three-cleft, crenate; stem-leaves divided to the base into linear segments. Stem many-flowered. Calyx coloured. —Native of woods and shady places, throughout Europe; also in Pennsylvania; flowering in April and May. *Root fibrous, perennial.* Herb of a pale pleasant green, and deitiute of the acrimony usual in this genus. Stems a foot high, erect, branched, scarcely downy, except near the top. Leaves generally a little downy; the radical ones on long stalks, deeply divided into three or five, wedge-shaped, crenate, or cut lobes; the rest in many linear, entire, or partially cut, spreading divisions. Flowers terminal, erect, solitary at the top of each branch, of a bright golden hue. Calyx pale yellow, hairy, scarcely at all reflexed. *Nectary* a naked pore in each petal, not cloved by any scale. In cold backward seasons the petals are sometimes wanting, or rather identified with the calyx, which is then dilated, and more coloured than usual.

23. *R. abortivus*. Small-flowered Virginian Crowfoot. Linn. Sp. Pl. 776. Wild. n. 18. Ait. n. 14. Pursh n. 6. —Radical leaves heart-shaped, undivided, crenate; lower stem-leaves pedate; upper in three deep linear segments. Calyx reflexed, coloured. Petals oblong. —In wet places, by the sides of ponds and ditches, from New York to Carolina, flowering in July and August. Pursh. In ponds at Buenos Ayres. Commerson. This species appears to have been cultivated in Chelsea garden 100 years ago, but it has, long since, disappeared, nor has any author given a figure of the plant. Its habit is most like *federatus*, n. 26. *Root perennial,* of many long fibres. Herb smooth. Stem from six to eighteen inches high, branched, leafy. Radical leaves like those of a violet, not an inch long, crenate, smooth; their stalks two inches, or more, in length; lower stem-leaves ternate, their lateral leaflets deeply divided, all cut or crenate: uppermost leaves nearly sibbly, in three deep, lanceolate, entire divisions. Flowers small; yellow according to Pursh, but Commerson, in his MSS. calls them flesh-coloured; each stands on a simple solitary stalk, half an inch or an inch long, either from the forks of the branch, or at their junctures. The calyx is reflected, large, membranous and coloured. We find scarcely any certain traces of petals, but the plant may be variable in those parts, like *aconitas*. *Stamen* few. *Germen* large, globule. —Linnaeus took his specific character, caule rudiforme, from specimens not fully grown; yet he had an authentic one by him, with above thirty flowers. In Commerson's the upper leaves are more flaked than usual.

25. *R. trilobus*. Three-lobed Barbary Crowfoot. Def. font. Atlant. v. 1. 437. t. 113. Wild. n. 19. Stem erect, much branched. Leaves smooth, deeply three-lobed, cut; uppermost linear, obtuse, undivided. Seeds compressed, tuberculated.—Gathered by Desfontaines, in moist fields, near Mayane, in Barbary. He describes it as akin to *R. parviflorus*, except in its upright growth, and smooth, deeply three-lobed leaves. The lowest leaf of all is undivided and crenate. Flowers very small, yellow, situated as in the two last. Seeds in a round head, small, compressed, orbicular with a point, covered with tubercles on both sides. To us this species seems, by its seeds, allied to *parvulus* of Linnaeus, which is a variety of *binflus*, hereafter described.

27. *R. aconitifolius*. Aconite-leaved White Crowfoot. Linn. Sp. Pl. 776. Wild. n. 21. Ait. n. 16. Curt. Mag. t. 204. (R. inomatus quartus; alfo R. plo no flore: albo; Cluf. Hift. v. 1. 236. R. acaniti folio; Ger. Em. 954. R. albus multiflorus; ib. 957. R. albus, filo denfo; Baum. Hift. v. 3. 844, not 860.)—Leaves veiny, smooth, in five deep, pointed, toothed lobes; the middle one three-cleft: floral leaves fleshy, fingered, lanceolate, cut. Stem branched, many-flowered. —Native of the Alps of Switzer-land, France, Austria, &c.; a hardy and long-established perennial in our gardens, flowering in May and June; generally in a double state, as figured by Curtis. He remarks that it requires moisture, shade, and a pure air. The stem is one and a half or two feet high, partly purplish, smooth, with spreading branches. Leaves dark green, with a glau- cous hue beneath; the radical ones on long stalks; the rest nearly sibbly; all composed of more or less distinctly separate, often flaked, leaflets, strongly veined and coarsely toothed; the uppermost smaller, more simple, quite fleshy. Flowers;
Flowers white, three-quarters of an inch in diameter, not very ornamental in their single wild state, but much admired when double, and formerly called Fair Maids of France. Their pearly whitefens is enhanced by the violet calyx.

28. *R. plataniolus*. Plane-tree-leaved White Crowfoot. Linn. Mant. 79. Wild. n. 22. Ait. n. 17. Fl. Dan. t. 111. (R. albus, flore ampliss.; Lob. Ic. 668. R. alpinus albus; Ger. Em. 951.)—Leaves veiny, smooth, deeply palmate, five-lobed, cut and toothed; the middle ones three-cleft: floral leaves sessile, fingered, linear-awl-shaped, entire. Stem branched, many-flowered.—Native of the Alps of Germany, Norway, Switzerland, Italy, and of the Pyrenees, in shady places. Said to have been introduced into the English gardens in 1759, by Meffrs. Kennedy and Lee. This is very different from the last, with which Linnaeus originally confounded it. The leaves are larger, not divided quite to the base, though their lobes are more cut and jagged; the floral ones are remarkably long, slender, and entire. *Flowers two as large, and rather more abundant. Leaves of both have occasionally seven or nine lobes, instead of five.

29. *R. specicus*. Spike-fruited Crowfoot. Desfont. Atlant. v. t. 438. t. 115. Wildl. n. 23.—Leaves radical, five-lobed, toothed. Stem nearly simple, hairy. Fruit cylindrical, thrice as long as the calyx.—Gathered by Desfontaines in marshes at Algiers. *R. bulbiferum*, of numerous, oblong, fleshy, tapering knobs. Stem solitary, erect, a span high, hairy, simple, except at the top, where it divides into two or three simple fingle-flowered flanks; sometimes accompanied by a few *bracteas*, in three or four deep linear segments; sometimes naked. Leaves all radical, on hairy flanks, heart-shaped, rounded, five-lobed, strongly toothed, villous, about an inch and a half broad. *Calyx* of five ovate-oblong, coloured, hairy, spreading leaves. Petals five, obovate, yellow, the size of *R. acris*. *Fruit* cylindrical, slender, an inch and a half or two inches long. *Seeds* very numerous, ovate, comprefsed, bordered each with a hooked, prominent beak.

30. *R. paludosus*. Marsh Crowfoot. Poirié. Voy. en Barb. v. 2. 184. Linnac. n. 22. Desfont. Atlant. v. 1. 439.—"Downy. Lower leaves in three deep, many-cleft, fan-shaped segments; upper simple, linear, entire. Stem branched, many-flowered. Calyx erect."—Gathered by Poirié, in the borders of extensive marshes, near la Calle, and in some other parts of Barbary. *Root* fibrous, densely falcuated. Herb downy, with short, close-fledged hairs. Stem several, eight or ten inches high, with spreading leafy branches, bearing abundance of widely-spreading, deep-yellow flowers, the size of the foregoing, on slender flanks of various lengths. Radical leaves stalked; the earliest ones ovate, undivided, deeply toothed; the rest almost pinnate, with three long, narrow, deeply cut, fan-shaped segments; those on the lower part of the stem less compound; the uppermost linear, undivided, acute, entire. *Fruit* ovate, or almost elliptical, obtuse. *Seeds* oblong, smooth, compressed, scarcely pointed.

31. *R. illyricus*. Ilyrian Silky Crowfoot. Linn. Sp. Pl. 776. Wildl. n. 24. Ait. n. 18. Jaqc. Aurdr. t. 222. Ger. Dod. Pemplt. 428. Em. 953. (R. grumófod radice quarts; Cuf. Hift. v. 1. 240.)—Leaves flabby with silky hairs, linear-lanceolate, ternate, entire. Calyx silky, reflexed. Stem branched. Flower-flanks woolly.—Native of Hungary, France, Italy, Austria, Thrace, and of the Swedish isle of Oeland; cultivated here in Gerard’s time. Clusius received his specimens, from a physician of Ferrara, with the name of *R. illyricus*, which has been retained, abundantly enough, for a plant found in so many different countries, and for which so many expressive appellations might easily have been contrived. The root is perennial, composed of numerous, small, round granulations. Whole herb more or less clothed with flow-white, silky, or partly cottony, down. Stem a foot high, or more, somewhat branched, bearing several bright lemon-coloured flowers, nearly the size of *R. Lingua*, their calyx-leaves ovate, reflexed, externally silky. *Leaves* all linear-lanceolate, entire, seldom divided; the radical ones on long flanks, ternate or pinnate, those about the middle of the stem ternate, almost fiddle; upper ones simple, the usual length of each leaf or leaflet is two or three inches.—Dodonæus takes this for the second *Bázipheros*, or *Ranunculus*, of Dioscorides, with whose description it in some measure agrees. That species is said to be extremely acid. Hence Dodonæus, who is copied by Gerarde, supposes our plant may be the *Gelopóphylus of Pliny*, which cauòed those who took it to dye laughing. But this opinion depends on too many conjectures to deserve attention; even if any benefit could accrue from accepting the point. We must observe however that Dr. Sibthorp thought the above *Ranunculus* of Dioscorides to be our *languinofus*, which is a common Greek plant, and answers better to his description.

32. *R. falbelloïs*. Fan-leaved Crowfoot. Desfont. Atlant. v. t. 438. t. 114. Wildl. n. 25.—Sm. Fl. Græc. Sibth. t. 959. unpublished. (R. albiflorus, afflabilis radice; Column. Eschr. 312. t. 513.)—Radical leaves undivided or twice ternate, toothed or deeply cut, flaked; upper ones ternate or simple. Stem hairy, simple below, few-flowered. Fruit elliptical.—Found by Desfontaines, near Algiers, on moist uncultivated hills, flowering in winter: by Sibthorp on the northern mountains of Greece. *Root* perennial, of many oblong, tapering, chaffered frîbes, rather than knobs. Stem a span high, hairy, somewhat divided above, and bearing two or three yellow flowers, the size of our common *R. bulbiferus*, accompanied by deeply two or three-cleft *bracteas*. Leaves chiefly radical, on longish flanks; several of the earliest undivided, fan-shaped, strongly toothed; the rest deeply three-cleft, and subdivided.

33. *R. aflaticus*. Perian Crowfoot, or common Garden Ranunculus. Linn. Sp. Pl. 777. Wildl. n. 26. Ait. n. 19. Mill. Ic. t. 216. Sm. Fl. Græc. Sibth. t. 518. unpublished. (R. aflaticus, grumofad radice; Cluf. Hift. v. 1. 240—243. Ranunculi vari; Ger. Em. 958—960. i2/3,920.; Dioec. book 2. chap. 206.)—Leaves once or twice ternate; leaflets three-cleft, cut. Stem hairy, branched. Petals thrice as long as the calyx. *Fruit* cylindrical.—Found by Dr. Sibthorp wild in various parts of Asia Minor, but most plentifully in the isle of Cyprus, where it still retains one of its ancient names, mentioned by Dioscorides, ap2pil/2pilw, or Wild Parsley. In the gardens of Europe it has been cultivated, ever since the latter part of the sixteenth century, under the form of innumerable varieties, chiefly double, of every variegated hue. In a wild and single flate the large and splendid petals are of a most vivid crimfon, occasionally varying to yellow. The *root* is perennial, of numerous, brown, fleshy, tapering knobs. Stem twelve or fifteen inches high, erect, round, downy, hoary, leafy, branched from the middle to lower part, and bearing from three to five large long-flaked flowers, whose *calyx* is brown, hairy, and reflected, but one-third the length of the broad, obovate, concave petals. *Leaves* rather hairy, mottly flaked, variously three-cleft and notched, more or less compound; the floral ones, as usual, narrower and more fimple. *Fruit* cylindrical. *Seeds* oblong, with recurved points.

34. *R. japonicus*. Japan Crowfoot or Ranunculus. Thunb. Tr. of Linn. Soc. v. 2. 337. Wildl. n. 27. (R. aflaticus;

36. R. glacialis. Alpine Hairy-cupped Crowfoot. Linn. Sp. Pl. 777. Fl. Lapp. ed. 195. t. 3 f. 1. Willd. n. 29. Alt. n. 21. Fl. Dan. t. 19. (R. montanus purpureus, calycy villosa, Felicis Paternz ; Bauh. Hill. v. 3. b. 846. Scheuchz. Alp. v. t. 399, and 139 t. 20 f. 1.)—Leaves ternate, three-cleft, cut, their segments elliptical. Stem nearly simple. Calyx very hairy.—Native of the highest alps of Lapland, Switzerland, Dauphiny, Germany, &c. in the neighbourhood or ice and snow, flowering in June and July. Root perennial, with very long strong fibres. Stem from three to six inches high, simple and naked in its lower part; leafy near the top, bearing one or two, very rarely three, flowers, on long, smooth falks. Leaves green, scarcely hairy, rather fFelcy; the radical ones more or less compound, on long falks; their segments broader, more elliptical, and blunter than in the former. Flowers large and handfome, of five broad, roundish, white petals, rose-coloured or purple underneath; the calyx purplish-brown, angulariy rough, with shining tawny hairs. When we contemplate the great diversity of subdivision in the foliage of this species, we are disposed to believe our Frigidus, n. 18, may possibly be a mere variety. Their flowers precisely agree, as well as their general habit.

37. R. Seguieri. Sharp-leaved Alpine Crowfoot. Villars Dauph. v. 3. 737. t. 49. Willd. n. 30. (R. Columna ; Allion. Pedem. v. 2. 50. t. 67. f. 3. 4. Wulf. in Jacq. Coll. v. 4. 345. R. alpinus epil folio, flos albo magnco ; Pont. Comp. 177. Seguier Veron. v. t. 490. t. 12. f. 2. 3.)—Leaves ternate; segments wedge-shaped, subdivided, dentifere, acute. Stem branched, about three-flowered. Calyx smooth.—Native of mountain Baldus, where it was first found by Pontedera; as well as of the mountains of Dauphiny, Piedmont, and Carniola; in snowy situations. This resembles some of the most luxuriant varieties of glacialis, but differs in the acute and decurrent segments of its leaves, as well as its smooth pale calyx; for Villars is incorrect in describing that plant as "externally downy." It is quite smooth, in his own and Allioni's specimens; the hairiness being confined to the top of the flower-falks, where it is very dense and conspicuous; while the same part in glacialis is smooth, up to the base of the hairy calyx. The petals, and even the calyx, are white. Villars is surely right in removing the fynonym of Columna, cited by Allioni, which we refer, with hardly any scruple, to fivelobatus, n. 3, a very different plant.

38. R. nivalis. Palmate Alpine Crowfoot. Linn. Sp. Pl. 778. Fl. Lapp. cd. 2. 195. t. 3 f. 2. Willd. n. 31. (Excluding the variety.)—Leaves palmate, five-lobed, spreading, entire; thssue of the item fellile. Stem single-flowered, smooth. Calyx hairy, half the length of the petals.—Found by Linnaeus in Lapland, by the alpine ri-vulets on the snowy mountains of that country. Martens had previously gathered it at Spitzbergen. The root is fibrous, and fender. Stem simple, erect or ascending, smooth, fFaly, about six inches high. Radical leaves two or three, on long falks, heart-shaped at the base, rather deeply palmate, in five broad, divaricatcd, ovate, entire lobes, venous and quite smooth; fitem-leaves one or two, fellile, with five deeper, longer, more lanceolate lobes; the uppermost only three-lobed, or occasionally quite undivided. Flower solitary, on a long, terminal, hairy falk. Calyx of five ovate yellowish leaves, rough with black fih hairs. Petals yellow, ovate, twice the length of the calyx.

39. R. pygmaeus. Dwarf Small-flowered Alpine Crowfoot. Pursh n. 10. (R. nivalis pygmaeus; Linn. Fl. Lapp. ed. 2. 196. t. 3 f. 3. R. lapponicus ; Fl. Dan. t. 144.)—Leaves palmate, somewhat pedate, five-lobed, spreading entire; the upper ones almost fellile. Stem single-flowered. Calyx nearly smooth, rather longer than the petals.—Native of Lapland and Labrador. Perennial, flowering in May and June. Much smaller than the foregoing. Middle lobe of the radical leaves very deeply se-parated. Stem-leaves less perfectly fellile, and with narrower segments, than in nivalis. Flower not a quarter the size of this species; its petals yellow, roundish, scarcely fo long as the calyx, which is likewise small, and very fightly hairy.

40. R. montanus. Yellow Mountain Crowfoot. Willd. n. 32. Alt. n. 22. (R. nivalis ; Jacq. Aufr. t. 325, 326. Sibth. in Prodr. Fl. Græc. n. 1273 ? Villars Dauph. v. 3. 742. Cranzt Alluir. fasc. 2. 92 t. 4 f. 3. 4. R. n. 1168 ; Hall. Hill. v. 2. 71, excluding the references to Linnaeus. R. minimus alpinus luteus ; Bauh. Hill. v. 3. 842, two upper figures.)—Leaves five-lobed, rounded, cut; thfssue of the item fellile, with deep, lanceolate, entire segments. Stem single-flowered, rough with erect hairs. Calyx hairy.—Very abundant on the alps of Switzerland, Dauphiny, and Germany; not of Lapland. It was one of those many alpine plants, introduced into the English gardens in 1775, by a perfon bent on purpose to collect them, at the expense of Dr. Fothergill and Dr. Pitcairn. This species has been confounded with the Linnæan nivalis, by all writers previous to Villdenow; yet they are truly distinct. The montanus has remarkably long, subdivided, tubercous roots, with very long strong fibres. Stem hairy throughout, the hairs erect; sometimes quite leaffles. Lobes of the radical leaves un-
equally cut and toothed, not entire. *Calyx-leafs narrower, and leafs hairy. Petals larger, and of a deeper yellow. This is the *nivalis of most botanists, few having seen the true Linnean Lapland plant. The variety of montanus with a leaflets *flens, figured in Jacquin's t. 326, at the right hand, was taken for a new species, and called *acuta, by Favrod and Reyner, as appears by their dried specimens.

44. R. montanus. Gouan's Pyrenean Crownfoot. Wild. n. 33. (R. pyreneus; Gouan Illutr. t. 17. f. 1, 2.)—Leaves five lobed, rounded, cut; those of the *flens, deeply palmate; the uppermost with acute, entire lobes. Stem single-flowered, rough with deflexed hairs. Calyx hairy.—Gathered by Gouan on the Pyrenees, where it flowers soon after the melting of the snow. We have a specimen from the late M. Bruznonnet. This is a larger plant than the preceding, especially in its *flora, and differs, as Willdenow remarks, in having the *flens-leaf toothed or cut; but that character applies only to the lower one. The upper *flens-leafs, if there be more than one, confit of entire, acute lobes. The most decided mark of distinction appears to us in the hairs of the *flora, below the leaves, which in Gouan's plant are either widely extended or bent downwards; in the montanus the hairs of every part of the *flora are erec or clof-preffed. To this no perfon has hitherto adverted.

42. R. alpestris. Alpine White Crownfoot. Linn. Sp. Pl. 778. Wildl. n. 34. Ait. n. 23. Sm. Tr. of Linn. Soc. v. 10. 343. Engl. Bot. t. 2390. Jacq. Altr. t. 110. (R. n. 1167; Hall. Hift. v. 2. 71. R. montanis species prima et secunda; Cluf. Hift. t. 1. 234. R. montanus, flore minore, & majore; Ger. Em. 964. R. minimus alpinus albuns; Baulh. Hift. v. 3. 845; two lower figures.)—Leaves very smooth; radical ones somewhat heart-shaped, obtuse, in three deep, lobed segments; *flora-leaf lanceolate, entire. Stem mofily single-flowered.—Native of the highest alps of Austria and Switzerland, and of the mountain of Clova, in Anguifhire, Scotland, in which last place it was discovered by the late Mr. George Don, by the sides of little rills, flowering, though sparingly, in the spring of 1809. The *roots are perenial, with long fibres. Whole herb very smooth, and rather glaucous. Stem erec, from one to four inches high, almost always simple and single-flowered, naked, except one or two simple, linear-lanceolate, obtuse, entire leaves, apparently of the nature of *brachys. Radical leaves several, *flained, in three deep, subdivided, acute lobes. Calyx-leafs oval, smooth, edged with white. Petals of a pure and brilliant white. Haller fays this is one of the most acute of its tribe, bliftering the "flora; and yet the alpine hunters chew it, by way of refainment.

43. R. lapponicus. Long-flaked Lapland Crownfoot. Linn. Sp. Pl. 778. Fl. Lap. ed. 2. 194. t. 3. f. 4. Lapland Tour, v. 1. 156, 252.—Leaves smooth, in three very deep, oblong, pendent, notched lobes. Flower-flasks elongated, naked, single-flowered. Petals the length of the smooth calyx.—This rare species, not known out of the limits of Lapland, was discovered by Linnæus in two or three different places, near the river Juchtan, flowering in June. Professor Swartz also gathered it, many years after, near Lulua. It grows in watery situations, and is very different from all others of this genus. The aspect of the plant, at first fight, recalls the idea of Adoxa Mosa ohottellina. The *root is long, thread-shaped, and creeping, throwing up here and there, from its joints, a little, short, simple, solitary, smooth *flora, sometimes an inch or two high, sometimes scarcely distinguishable. Leaves one from the base, and another from the top, of the *flora, on slender, weak foot-flaks, two or three inches in length; each leaf an inch or an inch and half wide, smooth, veiny, rather fleihty, some what kidney-shaped, in three very deep, almost distinct, broad wedge-shaped lobes, having a few broad and rounded, blunt notches, each tipped with a minute glandular point. Flower-flaks from three to five or fix inches high, terminating the *flora, solitary, simple, naked, smooth, each bearing a small yellow flower, scarcely half an inch in diameter. *Calyx of three elliptical, concave, smooth, pale, reflexed leaves. Petals five or fix, obovate, ribbed, about the length of the *calyx; their nectarary closed by a scale. *Stamen from nine to twelve. Petals from fix to twelve. Seeds in a round ovate, smooth, with strongly recurved points.

44. R. hyperboreus. Arctic Crownfoot. Retz. Scand. ed. 1. Wildl. n. 26. "Rottb. in Copenh. Tranf. v. 10. 458. t. 4. 16." (R. Fl. Dan. t. 331, excluding the fynonym of Ammann, which belongs to *salpiglosus, n. 15. R. n. 50; Gmel. Sib. v. 4. 204. t. 83; b, excluding the Linnean fynonym.)—Leaves smooth, in three deep, divaricated lobes; the lateral ones cleft. Stem creeping. Flower-flaks the length of the leaves. Petals scarcely longer than the smooth calyx.—Native of Iceland, Greenland, Norway, and Siberia, in watery places. Gmelin and Linnaeus confounded this with *hederaceus hereafter mentioned; Gunner mislabeled it for *salpiglosus, which he called R. Ammanni, Fl. Norv. n. 826. From both, as well as from *salpigonius, it is very distinct. The *floras are long and creeping, or floating, throwing out from each joint, several simple, very long, fibrous radicles, with a flaked leaf, not a quarter the size of *salpiglosus, whose lobes are by no means toothed or cleft, the lateral ones only being simply cleft. The flowers are small, pale yellow, solitary, each on a lateral, not axillary, *flora, whose length is about equal to the adjoining leaf with its foot-flak. *Calyx-leafs only three or four, smooth, coloured. Petals about the same number, and scarcely longer, obovate. Seeds ovate, gibbous, with a hooked, but very short, beak.

45. R. montepellionis. Montpellier Crownfoot. Linn. Sp. Pl. 778. Wildl. n. 37. (R. saxatilis, magnlo flore; Bauh. Prodr. 96. Sauv. Monp. 181.)—"Leaves in three deep, cleft segments. Stem simple, villous, nearly naked, single-flowered."—Native of rocky places about Montpellier, according to Bauhin, who thus describes his plant. "Root compofed of long capillary fibres. Leaves from the root several; on long, somewhat woolly, *flanks, each leaf hardly so broad as the nail, in three small segments, which are again divided into two or three acute ones. The *flora is about three inches high, slender, woolly, bearing one large flower, of a brilliant golden yellow, compofed of five petals, with many reddish *flamines." We know no authentic specimen nor figure of this plant. Linnaeus has marked it as never seen by him; but a specimen sent him by Gouan, from the Pyrenees, marked R. alpinus humilis, magnlo flore, which we have been dipofed therefore to confider as R. Gouani, n. 41, affwrs very well to Bauhin's defcription, and it is not improbable that these suppoled two species are one and the same. Yet Poiret, who profefles to have gathered R. montepellionis at Montpellier, and in Barbary, speaks of them as distinct, though, it must be confef ted, his defcription is hardly sufficient to establish the point in dispute.

cylindrical. Seeds compressed, with straight beaks.—Native of low meadows, from Canada to Pennsylvanla, but rare, flowering in July and August. This species was sent by professor Thunberg, in 1781, to Kew garden, from whence we procured a specimen the same year. Mr. Aiton makes it biennial; Jacquin and Pursh perennial. The stem, like the footstalks, is very hairy. Whole herb of a light green, two feet or more in height, branched, many-flowered. Leaflets one and half or two inches long, strongly veined, with spreading segments. Flower-footstalk terminal, long-fibrous, furrowed, rough with close-prehensile hairs. Flowers small, their little, round, yellow petals not so long as the calyx, which is smooth and bent downward. Seeds in a cylindrical head, numerous, ovate, gibbous, compressed, smooth, very minutely dotted, each tipped with a short, sharp, erect, or slightly flexed, beak. Reception hairy. Mr. Pursh's description does not, in every circumstance, answer to the Linnean plant; for the flowers are not near so big as R. acris, nor are their footstalks round.

47. R. ternatus. Ternate-leaved Japanese Crowfoot. Thunb. Jap. 241. Willd. n. 39.—"Calyx reflexed. Leaves all ternate; leaflets three-cleft. Stem many-flowered."—Native of the Japanese island of Nipon, flowering in May. Nothing more is known of this species, concerning whose peculiar characters, or affinities, we can form no precise opinion.

48. R. bicornatus. Twice-ternate Magellanic Crowfoot.—Leaves smooth, twice ternate, cut; segments ovate, acute. Stem creeping. Stalks single-flowered, the length of the leaves. Petals obovate, the length of the smooth calyx.—Gathered by Commodon, in the strata of Magellan. No author appears to have taken up this species, of which a specimen, from Commodon's herbarium, was given by Thouin to the younger Linneus. The whole plant is smooth. The leaves bear a considerable resemblance to those of R. Seguieri, but are rather smaller, and distinctly twice ternate. The habit of the plant more accords with lapponicus and hyperboreus, however unlike at first sight. The stem is thread-shaped and creeping, seldom four from each joint, a few fibrous radicles, a pair of upright, flaked leaves, two or three inches in height, and one flower, whose footstalk naked footstalk is about as tall as the leaves. This flower appears to be extremely like that of lapponicus, though scarcely more than half so large. The dried petals have the same opaque whitenss as is observable in that species, and others, on their upper surface, and are probably yellow when fresh.

49. R. pedunculata. Long-footstalked Magellanic Crowfoot.—Leaves ternate, deeply cut, somewhat hairy. Stems hairy, taller than the leaves, two-flowered. Calyx reflexed, nearly smooth. Seeds globose, smooth, with recurved, hooked beaks.—Gathered by Commodon in the strata of Magellan, with the preceding. This has a general likeness to several common European kinds, which we shall next describe, but is essentially distinct. The radical leaves are several, on hairy footstalks, four inches long, their circumvallation roundish, measuring an inch, or inch and half, across; the leaflets almost always quite distinct, with short partial footstalks, their form wedge-like, or fan-shaped, more or less deeply cut, seldom regularly three-cleft. Stems several, erect, flaked, rough, with spreading hairs; simple and naked to the height of four or five inches, then dividing into two upright, hairy, simple flower-footstalks, greatly elongated, (from one to seven or eight inches), after flowering, and accompanied at their base by a solitary, flaked, deeply divided, palmate or fingered, leaf, an inch long. The flowers are much like those of bulbosus, or acris. Calyx leaves ovate, concave, reflexed, bearing a few external hairs. Petals yellow, wedge-shaped, fluted, nearly twice as long as the calyx. Fruit globose. Seeds globose, tumid, keeled, even and smooth; their beaks rather spreading, hooked at the tip.

50. R. bulbosus. Bulbous Crowfoot, or Butter-cups. Linn. Sp. Pl. 778. Willd. n. 40. Ait. n. 25. Fl. Brit. n. 7. Eng. Bot. t. 515. Pursh n. 12. Curt. Lond. fac. 1. t. 38. Mart. Ruff. t. 28. Ger. Em. 953. Lob. Ic. 666.—Leaves hairy, ternate, three-cleft, cut. Stem many-flowered. Calyx reflexed. Seeds compressed, smooth. Root bulbous.—Very common in Europe, as well as North America, in meadows and pastures, flowering throughout the summer. The root is a round, solid, perennial bulb, about an inch in diameter, increasing by offsets from the top, and sending out from its base many long stout fibres. Stems several, erect, a foot high, branched, leafy, round, hairy, many-flowered, destitute of trailing shoots or runners. Leaves flaked, variously cut, more or less hairy. Flowers terminal, solitary, on angular furrowed footstalks, rough with erect, bristly hairs. Calyx hairy, bent back to the footstalk. Petals nearly equal in size to R. longiflorus, a deep shining yellow. Nectary covered by a notched scale. Fruit globose. Seeds orbicular, greatly compressed, bordered, smooth, and even, tipped with a short blunt beak.—This is one of the most acid, and even caustic, species. Villars says the root may be used as a blister, instead of cantharides, but not so fatally. It is most active in the spring, and must not then be left on the skin more than four or six hours, for fear of leaving a dangerous spreading sore.

51. R. hirsutus. Pale Hair-y Crowfoot. Curt. Lond. fac. 2. t. 40. Fl. Brit. n. 8. Eng. Bot. t. 1504. Ait. n. 26. (R. Philomotis; Elh. Beitr. fac. 2. 145. Herb. 116. Willd. n. 41. Lamark Dict. n. 48. Pursh n. 13. R. fardous; Crantz Auffr. fac. 2. 84. Lamark Dict. n. 47. R. palillior; Villars Dauph. v. 2. 751. R. bulbosus; Hudson. Angl. 241. R. rectus folius pallidioribus, hirsutus; Banh. Hiff. 3. p. 2. 417. R. leucanthemus; Matl. Valgr. v. 1. 559. R. palustris; apii folio lanuginoso; Banh. Pin. 180. Morif. lect. 4. t. 20. f. 27 and 28.)—R. parvulus; Linn. Mant. 70. Fl. Brit. n. 11. Willd. n. 60. Ait. n. 31. Lamark Dict. n. 73. R. agrarius; ib. n. 46? R. mininus faxatilis hirsutus; Banh. Prodr. 96. R. mininus apulus; Column. Ecphr. 314. t. 316. f. 1.—Leaves ternate, notched. Stem erect, branched. Calyx reflexed. Seeds orbicular, compressed with a short ascending beak, bordered; tuberculated at the sides.—Native of moist ground, in various parts of Europe, from Britain to Greece, flowering from June to October. The root is fibrous and annual. Stem erect, generally much branched, leafy, spreading, many-flowered, fluted, clothed with soft, widely spreading hairs; in variety smaller, smoother and weaker, sometimes, in a very starved state, bearing but one or two flowers. Leaves on longish, more or less hairy, footstalks, pale green, hairy, ternate, varying much in size; their leaflets wedge-shaped, sometimes deeply three-lobed, sometimes only bluntly notched; upper ones narrower and more simple, nearly sessile. Stipulas membranous, hairy, somewhat dilated, attached to the base of the footstalks. Flowers on long, terminal, furrowed, hairy footstalks, solitary, smaller than in bulbosus. Calyx hairy, reflexed. Petals roundish; of a bright shining yellow above; paler and opaque beneath. Nectary closed by an abrupt scale. Fruit globose. Seeds lenticular, compressed, brown, with a triple-ribbed greenish border; their beaks short, ascending, very obscurely hooked; their fides fiddled with minute sharp tubercles, especially towards the margin, where they are often circularly arranged, as Poirier (or

Vol. XXIX.
Lamarck) describes them in his *R. agrarius*, cited above.—This species has been very little understood. It is remarkable that any botanist should confound it with *bulbosus*, or with *federatus*, and that Mr. Curtis, in labouring to distinguish it, did not advert to the distinctive character of the tuberculated seeds, by which it approaches a very different tribe, hereafter described, consisting of *parviflorus*, *muricatus*, &c. Even Ehrhart has not noticed this circumstance. We are obliged to Mr. Edward Forrer, F.L.S. for tracing out the identity of *R. parviflorus* and *hirufus*, and we cannot but prefer Curtis's original name for the species, rather than Ehrhart's pedantic one of later date. On the account of priority *federatus* perhaps ought to have been retained; but this name is founded on a very dubious opinion, that the plant of which we are speaking caused the Sardonic laugh. Valerius Cordus, indeed, says it grows copiously in Sardinia, and it has certainly the appearance of Smallage, *Apium*; so far answering to the ancient history. But the account of Cordus seems taken from Dioscorides, whose "second *Ranunculus*" is more probably the Linnaean *lancinosus*, a still more general plant of the south of Europe than that of which we are speaking. After all, the famous Sardian herb, compared to Smallage, may be actually wild Smallage or Celerby, *Apium gravescens*, which is sufficiently acrid and poisonous to warrant our supposition, though it becomes sweet and wholesome by culture. In this uncertainty it is quite safe to call our plant *R. hirufus*.

52. *R. palustris*. Oriental Marsh Crowfoot. Linn. MS. (R. orientalis palustris, apii folio, caule subhirsuto; Tourn. Cor. 20.)—Leaves hairy, in three or five deep segments, bluntly notched, with rounded dilated sinuuses. Stem erect, branched, almost leafy. Calyx spreading. Seeds ovate, compressed, very smooth, with a short recurved beak. —Native of the Levant. An oriental species, with Tournefort's synonym, is preferred in the Linnaean herbarium, and named *palustris*, but we can find no mention of it elsewhere. This is certainly a most distinct species, though not taken up by any recent author. The root consists of many flabby knobs, tapering into fibres, and resembling thos of *R. aflatens*, though not so thick. Stem two feet or more in height; hairy below; much branched, and almost leafy above; the branches terminate. Leaves chiefly radical, on long hairy stalks; their outline somewhat pentagonal; heart-shaped at the base; hairy on both sides, about two inches wide; their three principal lobes spreading, deeply separated by wide rounded sinuuses, and notched unequally at the extremity with broad, rounded, abrupt teeth; the upper or floral leaves are small, short, linear, undivided. Flowers, as far as we can judge, yellow, not large. Calyx hairy, spreading widely, but rarely reflexed. Seeds in a round head, brown, shining, quite smooth, compressed, most like those of *bulbosus*, but more ovate, and with a longer, more recurved, and somewhat hooked, beak. Their edge is green, simple, not tripe-ribbed as in the last.

53. *R. polybractes*. Many-rooted Siberian Crowfoot. Wildl. n. 42. —Lamarck Dict. n. 38.—Radical leaves palish, with wedge-shaped, three-toothed segments; stem-leaves fleshy, fingered. Stems many-flowered. Calyx spreading. Seeds ovate, compressed, smooth, with a blunt beak.—Native of Siberia. Root fusciculated. Radical leaves like *R. federatus*, three-toothed; their lateral lobes two-toothed, wedge-shaped like the leaf itself, their segments bluntly three-toothed. Stem a finger's length, fimple, erect or ascending, two or three from one root. Stem-leaves fleshy, fingered, wedge-shaped at the base; their segments linear, bluish, entire. Flower-stalks two, three, or four, long, single-flowered, round, not furrowed, very finely downy like the stem. Calyx-leaves coloured, smooth, obtuse, spreading. Petals yellow, the size of *R. Flammula*. Fruit roundish. Seeds ovate, compressed, smooth, crowned with the permanent blunt stigma. Wild by. Now from the above description this species appears related, in many points, to the last, though they can hardly be the same.

55. *R. profusus*. Prostrate Crowfoot. Lamarck Dict. n. 35. Fl. Franconii, n. 5. 197.—Leaves ternate, three-cleft, very hairy. Stems entirely prostrate, creeping, zigzag. Calyx smooth.—Native of dry hilly places about Paris. Lamarck and Poiret cite this a distinct species from the last, not only because its herbage is much smaller and more hairy, but because the *flens* are, even when in flower, entirely prostrate. We have never met with any thing answering to this description in England. The flowers are said to be refractile *repens*, having likewise a smooth calyx. Our *repens* has hairs on that part.

56. *Q. intermedius*. Intermediate Crowfoot. Lamarck Dict. n. 44.—Lower leaves three-loved, cut; upper somewhat fingered. Flower-stalks mostly solitary. Calyx reflexed. Seeds compressed, smooth. Root fibrous.—Found at the borders of ponds in France, about Paris and at Fontainebleau. This plant, according to Poiret, is, as it were, intermediate between *bulbosus* and *repens*; having besides, many characters in common with *profusus*. The root is fibrous, fasciculated. Stems several, low, scarcely branched, almost leafless except at the bottom, weak, fricated, slightly downy, often forked above. Radical leaves on long stalks, almost smooth, in three rounded, often cut, lobes; the *fleaves* have three linear or lanceolate irregular lobes; the uppermost are very narrow, almost fingered. Flowers axillary, or terminal, two or three on each branch, on very long and slender, nearly smooth, stalks. Calyx-leaves reflexed at the time of flowering, as in *bulbosus*, coloured, concave, bearing some very fine long hairs. Petals of a fine yellow, fricated, middle-fingered. Fruit oval or globose. Seeds smooth, compressed, roundish, with a green border. We know nothing of this species but from the above description.

57. *R. lucidus*. Shining-leaved Crowfoot. Lamarck Dict. n. 36.—Leaves with three or five lobes, somewhat pinnatifid, shining, smooth. Stem erect, many-flowered. Calyx reflexed.—Support’d to be a native of the Levant; cultivated in
in the botanic garden at Paris. Root perennial. Stems one or two feet high, branched, leafy, very smooth, tender, striated. Leaves alternate, filched, widely spreading, smooth, shining as if varnished on their upper surface, divided into three or five dilated lobes, the lowermost constricted at their base, unequally cut, obtuse. *Petioles long*, somewhat downy; dilated at their base into a broad membranous expansion. Flowers numerous, situated at the ends, as well as in the forks of the branches, on long, simple, cylindrical, rather downy *flats*. Calyx leaves coloured, smooth, concave, reflexed after the flower expands. Petals rather large, roundish, of a fine shining yellow. This plant has some agreement with *R. repens*, from which it differs in having entirely upright *flames* and a reflexed *calyx*, as well as shorter more dilated lobes to the leaves. Such is Poiret's account. This surely cannot be our *polystylo*, n. 52, which has hairy leaves, and no resemblance or affinity to *repens*; neither could the intelligent author have overlooked Tournefort's eynomy for that plant.

58. *R. polyanthemos*. Many-flowered Crow-foot. Linn. Sp. Pl. 779. Fl. Suec. ed. 2. 196. Willd. n. 44. Art. n. 28. Lamarck n. 41. Lob. Ic. 666. (R. fylvefris fuscundus; Dod. Pempt. 427. R. fylvefris cauliscul; Ger. Er. 951, as to the figure. R. fylvefris; Tabern. Kreuter. 107. Ic. 42. R. nupellifolius; Crantz facc. 3. 90. t. 4. f. 1, 12) — Leaves in five deep, repeatedly subdivided lobes; segments all linear. Stem erect, many-flowered. Flower-flats furrowed. Calyx spreading. Seeds ovate, bordered, compressed, smooth. — Native of moor, elevated, rich meadows, in Upland, and elsewhere in Sweden, but rarely. *Lineatus*. In Germany, and perhaps in Switzerland, on the authority of various writers. Root perennial. Stem erect, two or three feet high, branched, many-flowered, leafy, clothed with upright, or somewhat spreading, hairs. *Radical* and lower *flaves* three inches wide, on long very hairy *flats*, divided to the very base into three lobes, the lateral lobes again divided almost to the base, so that the leaf may truly be called, in the strict sense, five-lobed; each lobe is deeply, more or less repeatedly, cut, into three- or four- or five-lobed segments, finely hairy on both sides, paler beneath: the uppermost leaves are nearly sessile, in about three deep, linear, entire divisions. *Flaves* long, terminal, angular or rounded, rough with upright hairs. *Flowers* large, yellow, drooping, not closing, in wet weather, according to *Lineatus*. Calyx spreading, pale, externally hairy. *Fruit globose*. Seeds ovate, short, compressed, smooth at the sides, bordered and roughish at the edges, tipped with a broad, short, recurved beak. We have described this from the authentic Linnaean specimen, which seems distinct from the following; and antlers extremely well to the figure of *Tabernamontanus* more especially, nor does it ill accord with that of Dodonaeus, reprinted in Gerard's herbal. The last-named author however certainly applies that figure to the common English *R. acris*, which he says he found double. Hence some doubt may arise whether the true *polyanthemos* was ever cultivated in England, as it seems to depend on Gerard's authority only for a place in Hort. Kew. We have never seen it alive. Possibly it may be found in a double flate in some old garden. The above description of the leaves, and the greater size of the whole plant, will distinguish it from *acris*. The *calyx* is hairy in both, notwithstanding Willdene's remark to the contrary.

60. *R. Breyninius*. Woolly-fruiting Alpine Crow-foot. Crantz Aultr. falc. 2. 91. t. 4. f. 2. (R. Breyninius; Brit. falc. 2. 91. t. 4. f. 2. — Native of meadows and pastures in all the more northern countries of Europe, very common in England, flowering in June and July. The double-flowered variety is frequent in gardens. The *root* is perennial, tuberous, with long simple fibres. Stem erect, two feet high, round, striated, rough with spreading hairs below, and with close-preted ones above, branched, slightly leafy. Leaves hairy, the leaflets very less divided than in the leaf, and with broader, wedge-shaped, by no means linear, segments: the upper ones linear, either deeply three- or five-lobed, or simple. *Flaves* round, not furrowed. *Calyx* green, spreading, hairy. Petals bright shining yellow. *Fruit globose*. Seeds much like the leaf. A dwarf alpine variety was brought by Mr. Dawton Turner from wet rocks, near the summit of Snowdon, whose *stem* is but three or four inches high, and bears but one or two *flowers*. This when cultivated in a garden gradually attains the size and habit of the common kind.

61. *R. lappaceous*. Bur Crow-foot. — Leaves ternate; leaflets flat, three-footed, sharply cut, hairy. Stem erect, many-flowered. Calyx spreading. Seeds ovate, keeled, erected, with elongated, revolute-pointed beaks. — Native of Port Jackson, New South Wales; communicated by Dr. White. This has much of the habit of *R. acris*, but is very distinct. The *flaves* are a foot, or more, in height, branched, roundish, rough with close-preted hairs. *Radical* leaves numerous, on long hairy *flaves*, very hairy, about the size of *acris* or *repens*, but remarkable for the partial *flaves*, sometimes an inch or two long, that support the leaflets, especially the terminal one; the leaflets are broad, wedge-shaped, more or less deeply three-lobed, coarsely and sharply cut. The lower leaves are narrower and less cut; the upper entire and lancelolate; the uppermost of all simple and linear. *Flowers* larger than in *acris*, white in the dried specimen, but perhaps yellow when fresh, finely veined, on long hairy, angular, terminal *flaves*. Calyx spreading, clothed with long hairs. *Nectary* covered with a wedge-shaped scale. *Fruit globose*. Seeds ovate, turgid, keeled, retraced with veins, smooth, each tipped with a prominent angular beak, nearly its own length, whose point is strongly recurved, and even revolute.

RANUNCULUS.

Italk round. Stem simple or divided. Leaves heart-shaped, three-lobed, toothed. —Native of Cappadocia. Root perennial, hard, the thickness of a goose-quill, and resembling the root of Doroicum. Radical leaves roundish-heart-shaped, with three very short lobes, all pointed, furrowed with a few coarse teeth, and clothed on both sides with scattered close-prepried hairs. Stem a flat high, clothed with close-prepried hairs, either simple, or divided above the leaf, each leaf flatly flowered. Corolla yellow, the fize of R. polyanthemos. Fruit roundish. Seeds compressed, hooked. Willdenow, from a drie specimen.

63. R. lanuginosus. Broad-downy-leaved Crowfoot. Linn. Sp. Pl. 779. Wild. n. 47. Ait. n. 30. Pursh n. 16. Fl. Dan. t. 397; Sm. Fl. Græc. Sibth. t. 519; unpubl. (R. montanus subfruticos latifolius; Bauh. Prod. 66. R. nemorosus hirtutus, foliis caryophyllaceæ; Loepr. Prutt. 220. t. 71. R. magnus valde hirtutus, flore luteo; Bauh. Hist. v. 2. 417. R. n. 1172; Hall. Hist. v. 2. 72. Boélly J. N. 90; Dioef. book 2. chap. 206.) —Leaves heart-shaped, five-lobed, lobed, toothed, filky. Stem erect, many-flowered, hairy. Flower-flawks round. Calyx spreadded. Seeds ovate, compressed, with elongated, revolute-pointed beaks.—Native of Germany, France, Switzerland, Carniola, Greece, and North America. Mr. Pursh observed it in old fields and meadows, from Pennsylvania to Carolina, flowering from June to October. Dr. Sibthorpe found it in shady watery situations in the Połonopneus, but most plentifully in the north of Greece, and with great reason concluded it to be the second Ranunculus of Dioscorides, with whose description it sufficiently well agrees, except being mild, rather than very acrid, in febile qualities, if we may trust modern authors. Linnæus distinguishes two varieties, between which we can discover no difference, and Haller unites them. The opinion of this great Swiss botanist however lobs some of its weight, by the doubt he expresses whether this plant be distinct from R. repens, n. 54; to which it has indeed a slight general resemblance, though differing very much in its upright stem, deflute of runners; its very soft filky leaves, by which this plant is known at once from every other European Ranunculus; and the revolute tare points of its seeds, which nearly agree with lappaceus in that respect; but the seeds themselves are compressed, and, as far as we can see, deflute of reticulated veins. The root is perennial, with many long, stout, cylindrical, fliy fibres, or perhaps slender knobs, intermingled with capillary branched radicles. Stem 12 or 18 inches high, branched, leafy, round, clothed with long, spreading or deflexed, hairs; its base purplish, as are also the long hairy footflawks of the radical leaves. These and the lower footflawks are three inches wide, divided about half way down into five or seven broad, sharply notched lobes, whose edges finish have a pale spot, with a purple vein, adjoining to their termination. The upper leaves are deeply three-cleft, with ovate and toothed, or lanceolate and entire, lobes. Flowers yellow, much like those of acris. Calyx hairy, spreadded. Fruit globose. Seeds with awl-shaped, strongly revolute beaks, by which this species is clearly distinguishable from repens, polyanthemos, acris, if such a mark were necessary, and by which it forms a chain of affinity between these species and our lappaceus. It is somewhat remarkable that R. lanuginosus has not been found in Britain, and still more so, that any obscurity should envelope the botanical history of so distinct a species.

64. R. sericeus. Silky Crowfoot. Lamark Dicét. n. 26. —Leaves ternate, very filky; leaflets wedge-shaped, deeply three-cleft, jagged and toothed. Stem erect, many-flowered, filky. Calyx spreadded. Seeds ovate, compressed, with short erect beaks.—Gathered in the ile of Bourbon by Commeron, from whom we have specimens. Roots, as well as the general habit and size of the plant, like the laft, but the whole herb is much more deeply clothed with hising filky hairs. The leaves are ternate, some of them almoft twice ternate; their lobes deeply and repeatedly cut, in a radiant manner, with sharp teeth. Flowers like the laft. Fruit ovate. Seeds with broad straight beaks, longer, and not so much curved or hooked, as even those of acris.

65. R. tomentosus. Shaggy Crowfoot. Lamark Dicét. n. 70. Pursh n. 17.—Leaves downy, three-lobed or notched, the uppermoft oval, entire. Stem reining, somewhat spreadding, shaggy, one or two-flowered. Calyx hispid, slightly reflexed.—Gathered in North Carolina, by M. Boce. A small, almost reining, very hairy plant, with fibrous roots. The flèmes are very low, and nearly prostrate, offending at their extremities, two or three inches long, tender, covered with whitith tufted hairs, difposed in two rows. Leaves flalked, thick, downy, generally with three lobes, which are either distinct or confluent; some leaves are merely crenate and rounded. Footflawks long and hairy. The uppermoft flèmes is fife, oval, acute, entire. Flowers one or two, on terminal, unequal, fimple flawks, clothed with two rows of hairs. Calyx hispid, a little reflexed. Petsal white or yellow, rounded at the end. Poiret. We have seen no fpecimen, nor did Mr. Pursh meet with the plant himfelf.

66. R. marylandicus. Maryland Crowfoot. Lamark Dicét. n. 69. Pursh n. 18. Leaves ternate, three-lobed, acute, cut, pale and nearly smooth beneath. Stem simple, almoft naked, downy. Calyx smooth, reflexed. Found in fhady woods, from Pennsylvania to Virginia, flowering from May to July. Purph. R. fibrus, perennial. Stems fimple, erect, downy, flender, about ten inches high; Poiret by miflake, as we preume, fays ten feet. Leaves radical, on long downy flawks, ternate; the two lateral ones opposite, flalked; all with three confluent, lanceolate, acute, cut lobes; their upperfe surface green; the under paler and whitith, almoft smooth. There are no other flèmes than what fland almost fiffle, at the base of the flower-flawks, and either have three or five fllow irregular lobes, or are fimpfly cut. Flowers two or three, terminal, on ftort, fcarcey downy, flawks. Calyx two or three, terminal, on short, white, downy, flawks. Petsals rather large, oval, rounded at the end, pale yellow. Poiret.

67. R. recurvus. Recurved Crowfoot. Lamark Dicét. n. 65. Pursh n. 19.—Leaves in three deep, acute, cut, wedge-shaped lobes. Stem many-flowered. Calyx and corolla reflexed. Petsals nearly linear. Seeds compressed, dotted, with revolute, awl-shaped beaks.—Native of fhady woods, from New York to Carolina; flowering from June to Anguit. Purph. We received fpecimen from the Rev. Dr. Muhlenberg, of Lancaster, Pennsylvania. The root is perennial. Stems a span high, very hairy; branched and leafy at the upper part. Leaves two or three inches wide, rather hairy, on very hairy flawks; their side-lobes for the most part deeply cloven. Flowers flalked, small. Calyx pale-purplish, ribbed, clothed with fine long hairs. Petsals small, narrow, almoft white. Fruit globose. Seeds ovate, lenticular, minutely dotted, smooth, with flender, revolute-pointed beaks.

68. R. septentrionalis. Smooth North-American Crowfoot. Lamark Dicét. n. 64. Purph n. 20.—Leaves ternate, membranous, smooth, deeply lobed, acute, cut. Stem two-flowered, hairy, like the bafe of the footflawks. Calyx reflexed.
Ranunculus.

reflexed. — Native of North America. Described by Poiret from Lamarck's herbarium, and adopted by Pursh.

Root perennial, fibrous, falciculated. Stems nearly simple, hollow, eight or ten inches high, almost leafless; downy in their lower part. Leaves falked, thin, smooth, composed of three falked leaflets, the central one having three deep spreading lobes, the others often but two; all sharp, cut and toothed. There is usually but one stem-leaf, which is nearly sessile, ovate, with narrow segments. Fossil leaves long, slender, more hairy towards their base. Flower-falkets two, terminal, unequal, very slender, smooth, each bearing, about half way up, one small linear leaf. Calyx reflexed, coloured, smooth, except a few terminal hairs, deciduous. Petals pale yellow, rounded. Fruit small, globular. Seeds nearly orbicular, lenticular, with sharp straight beaks. Poiret.

69. R. bispidus. Hispid American Crowfoot. Michaux Boreal-Amer. v. 1. 321. Lamarck Dict. n. 27. Pursh n. 21.—Very hairy, erect. Leaves ternate, sharply lobed. Stems few-flowered; leaflets below. Calyx close-prell. Seeds obovate, with awl-shaped, indented beaks. —Found in wet fields, and on the banks of ditches, from Virginia to Carolina, flowering from June to August. Root perennial. Flowers small, pale yellow. Pursh. A specimen sent by Gronovius to Linnaeus, as akin to his Languinopus, but distinct, anwsers very well to the characters of Michaux, and we have taken from that specimen the above account of the seeds. The flower is nearly as big as acris. Whole herbage, especially the fossil leaves, very hairy.

71. R. multifidus. Many-cleft Arabian Crowfoot. — Forsk. Ægypt.-Arab. 102. Lamarck Dict. n. 67. — "Leaves many-cleft; the lower ones pinnate. Stem many-flowered. Calyx the length of the corolla. Seeds ovate, acute. — Gathered by Forskall, in ditches near the town of Taes. He describes the stem two feet high, erect; round in the lower part; falked above; hairy. Fruit oval. We have no other authority, than the authors quoted, for this species or the last.

72. R. pedatifidus. Radiating-leaved Crowfoot. — Leaves deeply pedatifid, with linear, obtuse, divided or three-cleft, radiating, entire segments. Stem one or two-flowered. Seeds ovate, hairy, with small recurved beaks. — Native of Siberia. Four specimens from that country are in the Linnaean herbarium, but the species, though very distinct, appears never to have been described. Root perennial, of many long, cylindrical, falky fibres, and crowned with numerous capillary remains of old fossil leaves. Stem a span high, erect, round, falkated, leafy, falciform or divided, clothed with long, soft, lax hairs. Radical leaves on long hairy stalks, deeply cut, in a pedate manner, into five, seven, or more, narrow, linear, obtuse, elegantly radiating segments, some of which are deeply three-cleft, and their lobes again cleft, others merely divided, and others undivided; all entire at the edges, and somewhat hairy on both sides, with long, lax, white hairs. The fossil leaves are mostly falciform, leaflets divided; the uppermost in three, rarely more, deep, linear, falciform segments. Flowers apparently yellow, the size of R. acris. Calyx woolly at the base; its segments partly dilated and coloured, all shorter than the petals, and closely pressed to their under side. Fruit ovate. Seeds not very numerous, ovate, ovate, with short, awl-shaped, reflexed beaks.

73. R. echophyllos. Chervil Crowfoot. Linn. Sp. Pl. 780. Willd. n. 48. Lamarck Dict. n. 32. (R. teniolus luteus, grumosus radice, foraeantis feu italicus; Bar. t. 581? bad.)—Leaves thrice compound, with linear segments. Stem falky, with few flowers. Calyx reflexed, hairy. Root with tapering falky fibres. — Native of the south of Europe. The only certain specimen of this plant, that has ever come under our observation, exiils in the Linnaean herbarium. The root consists of numerous, long, falky, gradually tapering, downy falkets. Stem erect, about a span high, falkly, slightly falked, branched, bearing three or four flowers. Radical leaves falked, repeatedly ternate, with numerous linear, or somewhat lanceolate, entire segments, hairy beneath. Fossil leaves an inch and half long, falky; dilated, membranous, and ribbed at the base. Stem-leaves few, much leaved compound, and often nearly falked. Flowers solitary, on long, terminal, falkly, hairy, quadrangular stalks. Calyx strongly reflexed, coloured; externally hairy. Petals yellow. Fruit not sufficiently advanced to be described. At the back of this specimen Linnaeus has written Ranunculus hyberus, pulsatilla foliosa, T. Cor.; but there is no such page in Tournefort's Corolla, nor any thing to which it can refer; except R. lilius, pulsatilla folio, flore parvo, a species unknown to us. A very different plant from the true R. echophyllos, was given by the abbe Fourret to the younger Linnaeus, under that name. It seems rather to be filiformis, n. 52, a species allied, in many points, to what we are describing.

74. R. melefoliator. Milfoil Crowfoot. Vbl. Symb. v. 2. 63. t. 37. Desfont. Atlant. v. 1. 441. t. 116. Willd. n. 49. Lamarck Dict. n. 53. Sm. Fl. Grec. Sibth. t. 521, unpublished. (R. montanus leptomphyllum, asphodeli radice; Column. Ecphr. 312. t. 311.)—Leaves thrice compound, with elliptic-linear segments. Stem falkly, with few flowers. Calyx erect, somewhat hairy. Root with ovate knobs. — Native of Italy, Greece, Syria, and Barbary. The root, in Dr. Sibthorp's specimens, consists of many oval falky knobs, scarcely half an inch long, intermixed with fibres. Columna describes and delineates the fibres as terminating the knobs; a very material difference. The falkets, in the Greek and Italian specimens, are falkly and falked-flowered; in the more luxuriant ones from Aleppo and Tunis, somewhat branched, bearing two or three flowers. The falked leaves are more numerous, as well as more compound, than in the last. Flowers large. Calyx closely pressed to the corolla; sometimes nearly falked. Fruit oblong. Seeds with small recurved beaks. We can scarcely doubt, notwithstanding the above-mentioned diversity respecting the root, that the synonym of Columna belongs to the present, rather than the foregoing, species.

75. R. oxyfermus. Sharp-leaved Crowfoot. Willd. n. 51. Lamarck Dict. n. 37. — "Radical leaves oblong, obtuse, deeply and unequally toothed; stem-leaves falked, fingered, cut. Seeds awned."—Native of Siberia, near the river Terek. Root apparently annual. Radical leaves falked, ovate, obtuse, with unequal deep teeth; hairy, like their fossil leaves, on both sides. Stem erect, branched, hairy, a foot or more in height. Stem-leaves digitate; the segments of the lower ones unequally pinnatifid; of the upper linear and entire. Calyx reflexed. Corolla yellow, the size of R. bulbofas. Fruit elliptical. Seeds rather compressed, acule,
acree, with upright, awl-shaped, brily points. Will
deneu.

ments. Seeds prickly at each side. Stem erect. Frequent in corn-fields throughout Europe, flowering in the middle of summer. Roots fibrous, annual. Stem one or two feet high, much branched, many-flowered, leafy, nearly smooth. Leaves of a light green, slightly hairy, flaked, once or twice ternate, as well as deeply three-cleft; the ul
timate segments almost linear, entire, or rarely notched. Flowers small, lemon-coloured, flaked, lateral and terminal. Calyx spreading, hairy. Petals obvate, veined. Fruit devoided. Seeds very large, compressed, with erect, awl
shaped, hooked beaks; these seeds armed with numerous, prominent, awl-shaped prickles, largest towards the margin. From the observations of Mr. Brugn., this appears to be one of the most virulent of its genus, especially when young, causing speedy inflammation and gangrene in the stomachs of sheep and oxen; who nevertheless eat it with avidity. Vinegar much diluted with water, poured down their throats, proved a quick and certain remedy. The expression juice of the plant, given to dogs, is no lefs fatal.

luclus echinatus; Bauh. Hilt. v. 3. 846. Fumill. Peruv. 58. t. 18. f. 1.)—Leaves simple, three-lobed, notched, bluntish, smooth. Stipules dilately fringed. Seeds prickly at each side. Stem diffuse.—Native of watery places in various parts of the south of Europe; frequent in Greece. It occurs also in North America, in old fields, from Virginia to Carolina, flowering in June and July, ac
Journal Mr. Pursh. The root is annual, consisting of numerous long fibres. Herb smooth and succulent, with bright green. Stems several, various in length, spreading, and somewhat procumbent, leafy, rough, shining; purplish in the lower part. Leaves an inch and a half to three inches wide, three or three rather deep lobes, broadly and irregularly notched. Footstalks from one to four inches, or more, in length, with a concave sheathing base, bordered with a membranous stipula, whose edges are regularly fringed with dinted hairs. Flowers the size of the last, yellow, tolatary, on axillary flaks, rather shorter than the leaves. Calks reflexed, nearly, or quite, smooth. Petals obvate, almost twice as long as the calyx, at least in the European spec
mens, though they appear to be but of the same length in American ones. Fruit capitate. Seeds large, ovate, compressed, with broad, awl-shaped, angular, somewhat rec
urved beaks; these seeds covered with smaller, more uni
form prickles, than in R. arvensis. Commerson gathered, by the sea-shore at Monte Video, a variety of this with more luxuriant herbage, and smaller flowers, of which Ven
tenat makes a species of the name of ventriciosus, founding its character on the inflated bases of the footstalks, of which, however, we can see nothing in our original specimes from Thouin’s herbarium. Its stipulas are fringed precisely as in our European muricatus, to which we agree with Poiret in referring it, though we can fearlessly do the same by the following.

tus 7; Lamarck Dict. n. 75.)—Leaves simple, three
obed, notched, smooth. Stipulas bearded at the summit. Seeds prickly at each side. Stem erect, branched. Founded by M. Boé, near Charleston, South Carolina. This seems to differ from the last, in its simple, short, upright stem; but more especially, if Ventenat’s plate and description be correct, which we cannot doubt, in having each stipula crowned with a tuft of hairs, instead of being dis	antly fringed throughout. The petals are said to be larger than those of the American variety, at least of muricatus; but that circumstance is of small moment here, as to a spe
cific distinction.

79. R. parviflorus. Small-flowered Crowfoot. Linn. Sp. Pl. 780. Wildl. n. 54. Ait. n. 34. Fl. Brit. n. 13. Eng. Bot. t. 120. (R. hirundinus annuus, flore minimo; Rau Syn. 248. t. 12. f. 1. Pl. Phyt. t. 55. f. 1.)—Leaves simple, three-lobed, notched, hairy. Seeds covered, at each side, with hooked prickles; these beaks recurved. Stem diffuse. Native of the more temperate parts of Europe. Found on banks, and in wate as well as cul	ivated ground, in England, where the foil is gravelly; as also in Greece, flowering in the early part of summer. The root is annual. Stems prostrate. Whole herb hairy, smaller in every part than R. muricatus. Flowers-flalks opposite to the leaves. Petals pale yellow, feacely longer than the spreading calyx, fugacious, and often imperfect. Fruit capitate. Seeds ovate, with a broad, short, hooked beak, their flat brown sides densely covered with short, hooked prickles. R. trilobus, Desfont. Atlant. v. 1. 437. t. 113. Lamarck Dict. n. 77, seems a variety, not of this, but of our birfutus, n. 51.

drical. Seeds dotted; these beaks recurved and spinous.—Native of the Levant. Root annual. Stem various in luxuriance, silky, leafy; in the Linnaean species much branched and disarticulated, with many flower-surfaces, which are flaked, composed in general of three deeply laciniate, often punctuated, acute, hairy leaflets. Flowers large, pale yellow, on long, stout, simple, lateral or terminal, solitary, spreading flals. Calyx rather spreading than decidedly reflexed, nearly smooth. Fruit three quarters of an inch long, slightly elliptical, obtuse. Seeds in many rows, compressed, minutely dotted at each side, gibbous at the base, each terminating in a very broad, rather short, compressed, recurved, spinous-pointed beak. We know of no figure of this or the following.

81. R. grandiflorus. Large-flowered Oriental Crowfoot. Linn. Sp. Pl. 781. Wildl. n. 56. Lamarck Dict. n. 63. (R. orientalis, aconiti folio, flore luteo maximo; Tourne. Cor. 20.)—“Stem erect, two-leaved. Leaves many-cleft; those of the stem alternate, sessile.”—Gath
ered by Tournefort in the Levant. We have seen no speci
men. Willdenow marks this as a perennial species, and indicates his having seen it in a dried state. We regret that he did not subjoin a description of the plant, the Lin
næan specific character being very insufficient. What Peiret has given is evidently compiled from the short ma
terials furnished by Linnaeus and Tournefort. The Abbé Scèlin is said to have gathered R. grandiflorus near Confan	ineple; on whose authority it finds a place in Prodr. Fl. Grac. v. 1. 585.

WiUd.  
Leaves Jacq. capillary Ait. fides the our other England, zdly, Stem branched capillary all the (R. R. the Ait. tlieir Alt. the the inch immerfed, ereft. the Fl. Willd. 48. the Ger. 39. deeply the the Waldil. 83. 84. Native of the waters of Hungary. Annual. Stem nine inches high, erect ; branched in the upper part. Leaves that are under water very numerous, entirely covering that part of the stem, oblong, the length of the nail, each supported by a capillary footstalk an inch long ; the floating leaves small, wedge-shaped, three-lobed, entire, as long as the former, their footstalls thicker and shorter. Branches an inch long, erect, rising above the water, and bearing elliptical obtuse leaves, tapering each way, from four to six lines long, on short footstalks. Flowers extremely small, yellow. Willdow.

83. R. polyphyllus. Many-leaved Water Crowfoot. "Walfr. et Kitaibel Hung." Willd. n. 58. "Leaves under water oblong, flaked, capillary; floating ones wedge-shaped, three-lobed; those above the water elliptical. Stem erect." — Native of the waters of Hungary. Annual. Stem nine inches high, erect; branched in the upper part. Leaves that are under water very numerous, entirely covering that part of the stem, oblong, the length of the nail, each supported by a capillary footstalk an inch long; the floating leaves small, wedge-shaped, three-lobed, entire, as long as the former, their footstalls thicker and shorter. Branches an inch long, erect, rising above the water, and bearing elliptical obtuse leaves, tapering each way, from four to six lines long, on short footstalls. Flowers extremely small, yellow. Willdow.

85. R. aquatilis. White Floating Crowfoot. Linn. Sp. Pl. 781. Willd. n. 60. Ait. n. 37. Fl. Brit. n. 15. Engl. Bot. t. 101. Ger. Em. 829.—Leaves capillary under water; above somewhat peltate. Stamens numerous. Seeds corrugated.—Native of pools, ditches, and rivers, throughout Europe, mantling the surface with its copious white blossoms, in the early part of summer. The roots are long, fibrous, and perennial. Stems floating under water, long, round, branched, leafy. Leaves flaked, smooth; the uppermost floating, usually peltate, with various blunt notches; the next deeply three-lobed, or even ternate; the lowermost immerced, repeatedly three-eleft, with innumerable capillary segments. Flowers floating on long simple flanks, opposite to the leaves. Petals obovate, much longer than the calyx, white, with yellow claws. Nectary tubular. Stamens thirty or more. Fruit like the last, but the seeds more numerous, and generally bristly, somewhat obovate.

Varieties, as we deem them, of this species are, if, that whose leaves are all immersed, and entirely capillary, figured in Ger. Em. 827. f. 3.; 2dly, the circinatus of Sibth. Oxon. 175, figured in Phil. Phyt. t. 55. f. 2, whose leaves are all likewise in capillary divisions, but finer and smaller than the former: 3dly, the fluvialis of Willdow, n. 61, pecudanoides of Desfont. Allant. v. 1. 444, figured in Fl. Dan. t. 376, whose leaves are not only in capillary segments, but considerably elongated, by the influence, as we conceive, of the running water, in which this fort is always found. The seeds indeed are not bristly, in our specimens of this last variety, but naked, as in hederaceus, which species agrees with every variety of aquatilis, in the corrugations of the seeds, as above described.

We have thus added twenty-four species to Willdow's number, following his arrangement, for the present at least; not only for the convenience of our readers, but because it would be very difficult to make a perfect one on any known principles; the several species being allied by so many characters, and so dissimilar in others, that nothing could be more precarious than to seek the clue of nature through such a labyrinth. The seeds perhaps ought to form the basis of a specific arrangement, if they might not even lead to generic distinctions.

No small curiosity in the history of this genus is the R. alatus, of Poiret in Lamarec's Dict. n. 72, which, by his description, proves to be no other than Gymnophyles aquatilis of Jullieu. (See Gymnostyles.) The pinnula of Poiret, n. 82, appears to us a variety of aquatilis, growing in shallow, and perhaps fluctuating, waters; whence, though its leaves are all deeply cut, their segments are not quite capillary, but linear and oblate. We have Swifs specimens answering to this author's description.

RANUNCULUS, in Gardening, contains plants of the hardy, herbaceous, perennial kind, of which the species cultivated are, the Perian crowfoot, or garden ranunculus, (R. afatius); the aconite-leaved crowfoot (R. aconitifolius); the upright meadow crowfoot (R. acris); the creeping crowfoot (R. repens); and the embracing-leaved crowfoot (R. amplexicaulis). But there are other species that may be cultivated for variety.

Of the first species the varieties are exceedingly numerous, being sometimes divided into two classes, as the old Turkey-kinds, and the Perian kinds, the varieties of the latter amounting to many hundreds, and being considerably more various, rich, and beautiful in colour than those of the others.

But in the former of these kinds they arise with a strong generally unbranching stalk a foot high, terminated by one large double flower, sometimes emitting one or two smaller ones from its sides, and of which there are red-flowered, scarlet-flowered, yellow-flowered, and scarlet turban-flowered, &c.; but being seldom tinged with different colours, as in the Perian kinds.

And in the latter kind the plants rise eight or nine inches high, generally branching from the bottom, producing from five or ten to twenty or more flowers on each root, and of which there are single-flowered, semi-double-flowered, full-double-flowered, large and full like a double rose, being generally filled with petals to the very centre, forming a regular globular body, of admirable elegance, of all sorts of the most beautiful colours in different varieties, and of numerous degrees of deeper and lighter shades, tinges, and tints in the several colours. Indeed Martyn observes, that the varieties produced of late years from the seeds of semi-double flowers are unbounded; and that Mr. Mad-dock remarks that they are more numerous than of any
other flower. Accordingly his catalogue, he says, boasts nearly eight hundred, all with their proper names: ranged under the heads of — dark and dark purple; light purple and grey, &c.; crimson, &c.; red, &c.; roly, &c.; orange, &c.; yellow and yellow spotted, &c.; white and white spotted, &c.; olive, &c.; purple and coffee-striped, &c.; red and yellow-striped; red and white striped.

And according to the above flower gardener a fine ranunculus should have a strong straight stem from eight to twelve inches high. The flower should be of an hemispherical form, at least two inches in diameter, consisting of numerous petals gradually diminishing in size to the centre, lying over each other, so as neither to be too close nor too much separated, but having more of a perpendicular than horizontal direction, in order to display the colours with better effect. The petals should be broad, with entire well-rounded edges; their colours dark, clear, rich or brilliant, either of one colour or variously diversified, on an ash, white, sulphur or fire-coloured ground, or else regularly striped, spotted or mottled, in an elegant manner.

In the second species there is a variety with double flowers, which has been obtained by seeds, and is preferred in many curious gardens for the beauty of its flowers. It is by some gardeners called the Fair Maid of France. The root is perennial, and composed of many strong fibres; the leaves are divided into fine lanceolate lobes; the four fide-lobes are upon footstalks coming from the side of the principal stalk, and the middle one terminates it; they are deeply serrate, and have several longitudinal veins. The stalks rise a foot and half high, and branch out at the top into three or four divisions, at each of which there is one leaf, of the same shape with the lower, but smaller. The flowers are pure white, and very double, each standing upon a short foot-stalk. The flowers come forth in May.

In the third sort there is also a variety with double flowers, which is the most generally cultivated in the garden. It is frequently among other herbaceous perennials, under the name of Yellow Bachelor’s Buttons.

And in the fourth species there is a variety with double flowers, which is the most cultivated in the gardens for its ornamental effect.

Method of Culture. — The first sort and different varieties may be readily increased by the off-sheaves taken from the root, and new varieties may be raised from seed. In the first of these methods the off-sheaves should be separated from the roots in dry weather, in the latter end of summer, when the flowering is over, and the stems and leaves are declining, being placed in bags or boxes, in a dry place, till the autumn, when they should be planted out in rows six or eight inches apart, and fix of them to each, in separate beds, prepared with light sandy earthy compost, to the depth of two or three feet; taking care to protect them carefully from the frost during the winter. When the buds begin to break through the ground they should be kept perfectly clear from weeds, protecting them from frosts; and when they have flowered and the stems are decayed, the root should be taken up; cleared from dirt, and placed in bags or boxes till the autumn, when they must be planted again.

But in the second mode, the seed should be collected from the bolt plants of the semi-double kinds, and be sown in flat pans or boxes, filled with light rich earth, in August, covering it in about a quarter of an inch thick with the same sort of earth, placing them in a shady situation, so as to have a little of the morning sun. The pots should remain here till the beginning of October, when the plants sometimes appear, though it is often later before this happens, when they should have a more open exposure with the full sun; but when frost is apprehended, they should be removed under a common hot-bed frame, being only covered in the nights and bad weather with the glaases, guarding them well against rains and frost. In the spring following they should be exposed to the open air, being very lightly reseeded with water, having a situation to enjoy the morning sun; and when their leaves and stems begin to decay, the roots may be taken up, dried in a proper place, and then put up in bags to be planted out in the same manner as the old roots in October.

In the following summer they will produce flowers; when such as are good should be marked, and the others removed from them. The plants intended to flower should not be suffered to run to seed, as roots which have produced seeds seldom furnish fine flowers afterwards. The disappointments experienced in purchasing these roots, chiefly depend upon this circumstance.

It may be noticed that the roots intended for the borders should be planted towards the spring in little clumps or patches, three, four, or five roots in each, putting them in either with a dibble or trowel, about two inches deep, and three or four inches farther from each patch, and the patches from about three to five or ten feet distant, placing them in a varied manner in the borders.

And in regard to their general culture after planting, such of the forward autumn-planted roots of the choice sorts in beds as have shot above ground, should in winter, where convenient, have occasional shelter from hard frosts, by mats supported on low hoop arches; or in severe weather be covered close with dry long litter, removing all covering in open weather; and in the spring, when the flower-buds begin first to advance, shelter them in frothy nights with supported mats, suffering them, however, to be open to the full air every day; but the latter plantings, which do not come up in winter, or very early in spring, whilst frothy nights prevail, will not require any protection, and all those distributed in patches about the borders must also take their chance in all weathers; those of the different coloured plants will succeed one another in flowering from the beginning of April until the middle of June, though the May blow generally thaws to the greatest perfection. After the blow is past, and the leaves and stalks withered, the roots should be taken up and dried in the shade, then cleared from all off-sheaves and adhering mould, putting them up in bags or boxes till next planting season, when they must be planted again, as directed above.

But in each season of planting, it is highly necessary, in the principal fine varieties, to put them either in entire new beds, or the old ones refreshed with some fresh rich earth or compost, working the old and new well together, in order to invigorate the growth of the plants.

All the other species are capable of being easily raised by the roots, which should be divided or parted in autumn when past flowering, or in the spring before they begin to flower, and the slips be either planted at once, where they are to remain, or in nursery-rows for a season, then planted out finally. They succeed in any common soil and situation, and may be differed about the different flower-borders and clumps, where they constantly remain, only trimming them occasionally; and once in a year or two, or when they have increased into large bunches, taking them up in autumn or spring, to divide them for further increase, replanting them again directly.

In saving seed for raising new varieties, it must be suffered to continue on the plant till it becomes brown and dry,
dry, then be cut off, with the heads, and spread upon paper, in a dry room, exposed to the sun, and when quite dry, be put into a bag, and hung in a dry place till it is wanted.

All these plants are highly ornamental; the first fort in beds and pots, and the other in the borders, clumps, and other parts of pleasure-grounds.

**Ranunculus, Globes, in Botany.** See *Helleboræ.*

**Ranunculus Viridus, in Zoology,** the name of an animal common in many parts of the world, and usually known by the name of the tree-frog, or rana arborea.

The creature is easily distinguished from the common frog, by its being much smaller, and of a green colour. It usually sits upon the leaves of trees and shrubs, and makes a great noise in an evening; but that is rather like the fingering of a small bird than the croaking of a frog.

These creatures have been kept alive many years together in glafs vefvils, giving them flies and other small insects: and in winter, when these are scarce, they usually become very lean and feeble; but in summer, when they are plentiful, they will grow fat again, as if at their liberty. This is esteemed a poisonous creature. Ray. See Rana.

**Ranz des Vaches,** a celebrated air among the Swiss, played upon the bagpipe by the young cow-keepers on the mountains. The air will be found on our music-plates. In the article Music, the powerful effects of this tune are mentioned, from Rouleau’s Dict. de Musique.

**Racolonda, in Geography,** the title of a diamond-mine in Hindoostan, placed in Mr. Montefior’s map about 15 geographical miles to the west of Ralicotte, and 12 from the north bank of the Kifnath, but Mr. Rennell does not know what authority he has for this position. Tavernier, who visited Racolonda, gives its distance from Golconda at 17 gos, of 4 French leagues each. He crofled a river that formed the common boundary of Golconda and Vidafour; about 4 gos, or more, before he came to Racolonda; and this river can be no other than the Beemah, which to this day forms the eastern boundary of Vidafour, and passes about 80 or 82 miles to the west of Golconda, crofled from the road to it from Racolotta. If we reckon the 82 miles at 13 gos, that is, forming a scale from the distance between Golconda and the river Beemah, each goz will be 6.5 geographical miles in horizontal distance (or nearer three than four French leagues); and Racolonda will be placed about 25 geographical miles on the W. of the Beemah, or E. of Ralicotte.

**Racoon L’étaff,** a town of France, in the department of the Vogeis, and chief place of a canton, in the district of St. Die, on the Meurte; 7 miles N. of St. Die. The place contains 2528, and the canton 5500 inhabitants, on a territory of 70 kilometres, in 5 communes.

**Rouda, or Rounda, denoting gardens,** an island of Egypt, in the Nile, in front of Old Cairo, about 500 yards in breadth, where is built the *Meklaa,* signifying measure, or Nilo-meter, a pillar, by the gradations on which the rise of the Nile is measured.

This island is called Roudd, or gardens, because it is laid out in gardens, and inhabited only by gardeners.

**Raputty,** a town of Hindoostan, in Malwa; 20 miles N.N.E. of Tanda.

**Rapa,** in Botany, (an ancient name, of whose etymology no plausible account has come to our knowledge,) the Turnip. See *Brassica, species* 7.

**Rapaapo,** in Geography, a town of America, in New Jersey; 30 miles S. of Woodbury.

**Rapacious Animals,** in the general, are such as live upon prey.

*Vol. XXIX.*
will. If the woman conceived, the law formerly esteemed it no rape; from an opinion, that she cannot conceive, unless she confented: but this opinion has been since questioned. Coke on Litt. li. cap. 11.

This crime, by the Jewish law, Deut. xxii. 25. was punished with death, in case the damsel was betrothed to another man; and in case she was not betrothed, then a heavy fine of fifty shekels was to be paid to the damsel's father, and she was to be the wife of the ravisher all the days of his life; without that power of divorce, which was in general permitted by the Mosaic law.

The civil law (cod. 9. tit. 13.) punishes the crime of ravishment with death and confiscation of goods; including under this crime both the offence of forcible abduction, and also that of forcibly disfavouring; either of which, without the other, is in that law sufficient to constitute a capital crime. And the fleeing away a woman from her parents or guardians, and debauching her, is equally penal by the emperor's edict, whether she consent, or is forced.

Rape was punished by the Saxon laws, particularly those of King Athelred, with death; which was also agreeable to the old German or Scandinavian constitution. Instead of this, another punishment was instituted by William the Conqueror, viz. castration and loss of eyes, which continued till after Bracton wrote in the reign of Henry III. But it was then the law, and still continues in appeals of rape, that the woman should immediately after go to the next town, and there make discovery to some credible persons of the injury she has suffered; and afterwards should acquaint the high constable of the hundred, the coroners and the sheriff, with the outrage; the time of limitation for this purpose was by flat. Wilm. 1. cap. 13. extended to forty days. But there is now no time fixed; for as it is now usually punished by indictment at the feet of the king, the maxim of law takes place, nullum tempus occurrit regi: however, the jury will rarely give credit to a flat complaint. During the former period it was also held for law, that the woman (by consent of the judge and her parents) might redeem the offender from the execution of his sentence, by accepting him for her husband, if he also was willing to agree to the exchange, but not otherwise.

In the 3 Edw. I. by the flat. Wilm. 1. cap. 13, the punishment of rape was much mitigated: the offence being reduced to a trepaps; if not prosecuted by the woman within forty days; and subjecting the offender only to two years imprisonment, and a fine at the king's will. But in the 13 Edw. I. it was found necessary to make the offence of rape felony, by flat. Wilm. 2. cap. 34. And by 18 Eliz. cap. 7, it was made felony without benefit of clergy; as also the abominable wickedness of carnally knowing or abusing any woman-child, under the age of ten years; in which case the consent or non-consent is immaterial, as, by reason of her tender years, she is incapable of judgment and discretion. Sir Matthew Hale is indeed of opinion, that such proficile actions committed on an infant under the age of twelve years, the age of female discretion by the common law, either with or without consent, amount to rape and felony, as well as incest, as before the statute of Queen Elizabeth; but the law has in general been held only to extend to infants under ten. A male infant, under the age of fourteen years, is presumed by law incapable of committing a rape; and, therefore, cannot be found guilty of it.

The civil law seems to suppose a prostitute incapable of any injuries of this kind; not allowing any punishment for violating the chastity of her who hath indeed no chastity at all, or at least hath no regard to it. But the law of England holds it to be felony to force even a concubine or harlot; because the woman may have forborne that unlawful course of life.

As to the material facts requisite to be given in evidence and proved upon an indictment of rape, we shall here only observe, that the party ravished may give evidence upon oath, and is in law a competent witness; but the credibility of her testimony must be left to the jury, upon the circumstances of fact that concur in that testimony: e. gr. if the witnesses be of good fame; if she professedly discovered the offence and made search for the offender; if the party accused fled for it: these and the like are concurring circumstances, which give greater probability to her evidence. But, on the other side, if the be of evil fame, and stands unreported by others; if she concealed the injury for any considerable time after she had opportunity to complain; if the place, where the fact was alleged to be committed, was where it was possible he might have been heard, and the made no outcry; these and the like circumstances carry a strong, but not conclusive, presumption, that her testimony is false or feigned. Moreover, if the rape be charged to be committed on an infant under twelve years of age, she may still be a competent witness, if the hath sense and understanding to know the nature and obligation of an oath; and, even if she hath not, it is thought by Sir Matthew Hale that the ought to be heard, without oath, to give the court information; though that alone will not be sufficient to convict the offender. And, indeed, it is now settled, that infants of any age are to be heard; and if they have any idea of an oath, to be also sworn: it being found by experience, that infants of very tender years often give the clearest and truest testimony. Blackst. Com. book iv.

The civilians make another kind of rape, called subornatio, rape of subornation, or seduction; which is, when a person seduces or entices a maid to uncleanness, or even marriage, and that by gentle means; provided there be a considerable disparity in age or condition between the parties. In this case, the father and mother intend their action reciprocally for the crimen raptus, or subornatio.

The French laws make no difference between the rape of violence and that of solicitation, or subornation; they make both capital. This kind of rape our laws call Rapeishment; which fee.

Rape of the Forest, is a trepaps committed in the forest by violence.

This is mentioned in the laws of Henry I. as one of the crimes cognizable alone by the king.

Rape is also a name given to the wood or stalks of the chaffers of grapes, when dried, and freed from the fruit.

The rape is used in making vinegar, serving to heat and four the wine: but it is first put into a place to four itself, before it be call into the vinegar vessel; to which end, presently after the vintage, it is carefully put up in barrels, like wine or beer, or else it will heat itself and be spoiled. There is no other way of keeping rape hitherto discovered, but to fill the vessel, in which it is contained, with wine or vinegar.

Rape, Rape, is also used for a part or division of a county: signifying as much as a hundred.

Though sometimes rape is taken for a division containing several hundreds. Thus Suffolk is divided into fix rapes, viz. those of Chichester, Arundel, Bramber, Lewes, Pevensey, and Hastings: every one of which, besides its hundreds, has a castle, a river, and forest belonging to it.

The like parts in other counties are called tithings, lathes, or wauperakes.

Rape, in Botany. See Nupes.

Rape, Broom. (See Orobanche.) It frequently grows to
R A P

to the roots of genista or broom, whence it is called *rapum gentile*, or broom rape; it is also found among corn. The herb preferred, or its syrup, is said to be of excellent use in splenetic or hypochondriac disorders, and an ointment prepared of it with tallow's fat, is good for hard and febrile tumours.

Rape, *Wild*. See MUSTARD.

Rape, in Gardening, the common name of a plant of the cabbage kind. The variety called the French turnip, or *Brassica napus*, has been long cultivated upon the continent, and preferred to the common turnip as a culinary vegetable. And it has been lately noticed in the "Transactions of the Horticultural Society," that it has been brought to the principal London markets for more than twelve years past by one person only, and sold chiefly to foreigners, though, when once fully known, it will be found a very useful and acceptable root in most families, as being more delicate in its flavour than the common turnip. It is used in much the same manner. It enriches soups, and there is not any necessity for cutting away the outer skin or rind, but only to scrape it, as it is a great deal thinner than that of the turnip. When stewed with gravy it forms an excellent dish, and being white and shaped like the carrot, when laid alternately with those on a dish, they become very ornamental. The French dress them somewhat in this manner.

The roots are to be washed quite clean by means of a brush; then scraped, cutting a thin slice away from the top and bottom parts, so as to make them all of equal lengths: after which boil them in water, with a little salt, until they are tender; then put them into a few pipes, with a gill of veal gravy, two or three spoonsful of lemon pickle, one of mushroom ketchup, a little mace, and salt, letting them simmer, but by no means boil, for a quarter of an hour; afterwards thicken the gravy with flour and butter, serving the whole up quite hot. Some add a few spoonfuls of cream mixed with yolk of egg to this, just before dishing up; and others dress them in a similar manner to the above, laced rather thinly, with Madeira, or other wines, after they have been fried to a brownish colour. See *Brassica*.

Rape, in Agriculture, the name of a plant much cultivated for its seed, and also as a green food for cattle and sheep. The methods of culture and management that are necessary in raising crops of this sort, have been already described and explained. (See Cole.) It may, however, be here necessary to detail a few of the experiments that were made under the direction of the Dublin Society, by Mr. W. Whyn Baker, about the years 1769 and 1770, as they tend to throw additional light on the nature of the plant, as well as its cultivation, though the soil was not the most suitable for it. It was a shallow soil, of a strong adhesive nature when wet, and when perfectly dry, in lumps, almost impregnable; but between wet and dry, reducible. It lies upon a bed of lime-floury loamy, and has a natural declivity to the north-west; naturally very poor, and, he believes, never received any manure until he cleared it. Three acres of this land were, in 1768, under potatoes, in the ordinary method of the country, in seven-feet beds, and four-feet trenches. In 1769 they were under drilled turnips.

The frost, snow, hail, and rain which they had this year in the months of March and April, rendered it impossible to get the ground in any tolerable condition for the rape-feed before the 18th day of April. On that day twenty broad feet were sown, with twelve ounces of rape-feed to each foot or ridge. He intended to have sown it earlier, but the event will shew, that, as it was, he sowed it too early, at least upon this ground.

It was low in coming up, and made but a poor figure until July. After which it shot forward; but instead of affording a plentiful mowing crop for the purpose of foddering cattle, it soon began to run up very fast, broke out into branches, with few and small leaves, like rape in blossom from the autumn sowing, but with strong branches and few leaves; and, in a short time after, began to grow hard, pipcy, and the feed to form.

It September he began to sow it for cattle, and they ate it with great eagerness; but every day it became worse, by growing harder; infomuch, that before it was exhausted there was great wafle, as to the object of fodder, but it wonderfully raised the dung-hill, which, in his mind, is of the first moment to the farmer: for if he has manure in plenty, and disposes of it judiciously, there is hardly any thing he need to fear, except climate.

It was very far in October before all its rape was cut, (and the feed coming forward very fast,) although it was brought home in great perfection. It was so strong, that the mowing of it could not be accomplished with a common scythe; it would have broken an hundred; but he had by him a short strong scythe, with a thick back, intended to mow bushes and other rubbish; with this instrument he got it moved, but not so close to the ground as he wished, it being next to impossible to mow such strong plants as these were close to the ground; and he became the less solicitous about it, as from the strength of the rape shoots and roots, and the weeds which were upon the ground, owing to the rape shooting up in tall stems, he gave up his intention of fowing the ground with wheat, as was originally intended. Hence he concludes, that the rape was sown much too early.

On the 16th of July he transplanted some of this rape in rows upon ridge four feet wide; these plants flourished much better than the former, and were at least four times the size of any of those left in the ground where they were sown. Nevertheless, these also ran to seed; but the cold nights coming on prevented their forming their seed like the former. They were vastly more tasty, and much better food for cattle.

On the 24th of July, he drilled rape-feed upon the same ground.

\[1 \text{. Six ridges four feet wide, and thirty-two perches long in single rows.}\]

\[2 \text{. Six ridges the same length and breadth, in double rows, ten inches asunder.}\]

It is observed, that the double and single rows were drilled alternately on the same ground, on the 18th day of July.

\[3 \text{. Six ridges four feet wide, and thirty-two perches long, drilled in single rows.}\]

\[4 \text{. Six ridges the same length and breadth, in double rows, ten inches asunder.}\]

He remarks, that these were sown in alternate rows, on the same ground, on the 24th of July. And that the several rows were thinned the latter end of August, and twice horse-hoed during the summer. On the third of April 1771, he had a row of each of these cut and weighed, and the produce was as follows:

RAP

On the whole, it is flatted, that the first fowing in July afforded considerably greater produce than the first, for the plainest reason, that the earlier we sow this feed, the sooner it runs; and consequently affords the least produce for the purpose of foddering cattle in the yards for making dung, and seems to account very strongly for the state of the first experiment.

And the double rows produced uniformly more than the single rows; and indicate that the double are to be preferred in drilling rape for foddering cattle.

The following trials are on fowing rape-feed broad-call. On the 24th of July two acres were fown broad-call, with ten pounds of seed to each acre, in the same field where the other experiments were carried on; but the soil not so fluff by a good deal, has abundantly fewer loofe stones in it, is very shallow, and poor, to an incapability of producing any thing to profit, without great allowance of manure.

In July he manured it with the dung of his yard, confiding of that of horned cattle, horels, and fwine. The dreefling was indeed very high; about two smart one-horse cart-loads to a perch. He having ever found that one acre, highly improved, is much more valuable than five imperfectly handled, was the reason why he gave this poor piece to liberal a dreefling.

The rape came up but slowly for a time, as he finds to be the nature of the plant, but at length it shot forward, and flourished away: but in winter it met with a fate which he was not aware of, nor did he expect. The wood-pigeons lay upon it prodigiously, and did it great damage. Some plants he observed in the froft to appear as if they had been fitched: whether that was owing to the wounds given by the birds, and thereby giving the froft the greater force, or whether it was owing entirely to the severity of the froft, is not in his power to determine. However, very early in the spring this rape fhot forward, and as the days lengthened the visits of the pigeons were less frequent, until they totally left it.

From this rape breaking out into blofflom sooner than he expected, he is inclined to believe that the 24th of July is too early to fow it for the purpose of foddering cattle in the yard.

However, early in April he began to sow this rape for the horned cattle, fuch as cows, plough bullocks, young cattle, calves, and fwine. They all ate it with the greatest eagerness, and were foddered with it every evening, until the 19th of May inclusive, and wheat fraw in a morning, fave four calves of the preceding year; and they were foddered twice a day with rape, and had fraw before them alfo, and throve upon it vaftly better than the other cattle; for no other reason, he believes, than because they were allowed more than the others: in short, they were in fuch order, that he dares believe the butchers would have been glad to have had them for killing.

Exp. I. April fowing. Ran, not answering the purpose.
II. Ditto transplanted. Ran, but not fo foon as the other.

Rape is a great deal cultivated in fome diftricts in the county of Essex for the feed. The fystem is very profitable, but this fort of crop is found to draw or exhaust the land a good deal. It is thought by fome to prepare well for wheat, especially when fed off upon the land. In fome places they, however, consider it more beneficial to till, after this crop has been feeded for fpring corn, than to put in wheat, which, however, is ftil the molt common practice. Clover would certainly be better than either method.

He observes, that he need not tell the farmer how necessary it is to be frugal of provender in an hardy dry fpring, as the weather was, when he was like to be hard run with forty head of cattle, many of which he fhoold actually have been obliged to fell at fo improper a feonon, had he not been possedled of these two acres of rape. He adds, that there is yet another circumstance which renders this a truly valuable fodder. The milk of the cows increafed prodigiously; and the milk and butter were as good, fweet, and well-flavoured, he thinks, in every particular, as ever he tafted in June. Even the cream for the tea appeared to be perfectly free from any foreign flavour. The cows got hay every day, in the fame manner as he has in former years mentioned them to have, when feeding upon cabbages.

The simplicity of the culture for rape, for the purpose of feeding cattle, he cannot but think a particular recommendation to the farmer, and the cheapnefs of the feed in purchafe, or the cafe with which he may raife it, are objects which cannot fail, he thinks, of being perufual to him. And all perfonft, who have annexed to their farms any boft, or other waft ground, the improvement of which can be executed by burning, might freely raife fuch quantities of rape for the purpose of moving pafture, as would enable them to keep almoft any number of cattle; by which they would not only be bringing in the waft land, but making that the foundation of improvement to their found land, by the immeasurable quantities of dung they might raife by this means from the waft land. Here the advantage to the cultivator would be double.

On the firt day of May he had four perches of this rape measured out for weighing. It was mowed, immediately drawn home, and weighed. The four perches afforded seven hundred and two quarters: multiplying this by forty, fows the acreable produce to be fifteen tons. The quantity indeed but small. However, the feonon in which it is to be had renders it more than ordinarily valuable, and, he thinks, bids fair to make it an object of husbandry, as a paflure for cattle.

This year, 1770, Mr. Baker ploughed up fix acres of wheat fubble, as soon as the wheat came off, harrowed it down the 12th, 13th, 14th, and 15th of September, then fowed rape-feed over the whole field, and gave it a light buft harrowing. The rape came up very thin, and made fo poor an appearance in the fpring, that he ploughed up the field, and fowed fpring corn. This is a strong indication that but little is to be expeted from fowing rape upon wheat fubble; because after the wheat comes off it seems to be too late in the year to fow rape. But fomething may be chargd, as he observes, to the natural moistuie of the foil. See Cole.

The following is the recapitulation of his experiments on rape, as paflure for cattle.
consequence, clover, and is consequently prejudicial to the next succeeding winter crop. Other districts think very differently on this point. In feeding the crop, the produce is here considered to be general from twenty-nine to thirty-four bushels of grain. In the greatest crops and best seasons, in particular parts it is supposed to rise even to one as five and six quarters the acre.

In Berkshire, the fruit of the crop is not so much cultivated as it should be, as it will succeed well on soil where turnips will not, and with equally beneficial effects to the future crops, when sown on the ground. When employed it is usually sown and managed so as to come into a high state of perfection in the early spring months, when meal is most readily supplied from the deficiency, and found remarkably useful, one acre of it affording more feed than two of turnips.

This fruit of the crop is still less grown in Oxfordshire, though occasionally had recourse to, especially on the rich land about Banbury. Some few it in mixture with the tankard turnip feed, for the purpose of weaning lambs upon: they begin with the rape, and it teaches them to eat the turnips; it is found to be a very good food for this fruit of fowl.

In the county of Suffolk, the South Down sheep farmers hold it in great estimation, sowing it either alone or in mixture with tares as a food for their livestock; very rarely for the purpose of feeding. The ewes and lambs are wattled upon it the year round, and it is very generally allowed to be most efficacious, and highly nutritious to the young lambs. Some, at the lambing season, hardly allow their ewes any other food but this, as the rape is found to produce a larger supply of milk than turnips; which, it is supposed, has the effect of extending the udder, without affording any considerable flow of milk. This crop is conjectured, however, in some cases, to have the effect of causing the slipping of the lambs, where the ewes are fed upon it. But such an effect is very improbable to arise in this way; other ailments may have been overlooked.

In some cases on Down land, ray-grasses is sown with the rape for sheep feed, one gallon of rape-feed and two of ray-grasses to the acre. The rape is first fed off; and after, the ray-grasses takes and affords a basic food for the spring season. The rape crop is usually put in about June, or the following month, one gallon to the acre. When folded off, a rood and a half is a sufficient daily consumption for a flock of six hundred sheep, or rather more.

As it has been found in the improving of peat boggy marshy lands, that what is principally wanted is a crop which can be sown and reaped in the summer months; and which may require neither labour nor attendance during the moist seasons of autumn, winter, and spring; the writer of the "Treatise on Landed Property" has suggested that fortunately, such a crop is natural to, and has long been in use to the climate of this island, as well as one of the most profitable in the agriculture of it; and that this is rape; which is not only sown, but reaped, in the very height of summer; and which is known to delight in a soil of this nature. It has, however, not only lately been found capable of being raised with advantage on more productive soil, as a first crop after draining, from some recent trials made in the north, after the above operations, levelling, paring, and burning, and turning the ashes in. The result of which was, though the crop was too late in being put in, and the land laid in an improper manner, such as to prove clearly that rape-feed may be raised with profit as a first crop on drained moor soils. And it is thought highly probable that many extensive tracts of land, which now lie entirely waste, and as nuisances in their neighbourhoods, may through this means be improved with immense profit to their proprietors. The experiment may be tried at a small expense. The cost of the labour and seed required for a sufficient trial are inconsiderable. The proof, it is supposed, is not whether rape will thrive as hedges, but whether it will mature its seed, on the given soil, in the given situation.

After being recompensed for the previous expenses, in one or more rape crops, as there is here no danger of the exhaustion of the soil,—of impoverishing, perhaps, ten feet depth of vegetable mould, it remains to lay the foundation of more permanent profits, which is to be done by sowing of grass; feeds either with or over the rape crop, or by light, cautious sowing after removing the flax, as may be necessary, until there is a firmness of surface and a fitness for mixed cultivation, which may be much hastened by the use of heavy calcareous and earthy substances at any time during the process of improvement.

Rape Cake, the refuse or cake remaining after the oil has been expressed from rape-feed. It is said to be useful as a manure. See MANURE.

This substance is found by chemical trials to contain a large quantity of mucilage, some albuminous matter, and a small quantity of oil. It should be kept as dry as possible before it is applied to the soil, and be employed in that way while it in a fresh state. It is successfully applied in several ways and intentions, and affords an excellent dressing for turnips. See the next article.

Rape Dust, the small reduced parts of the dried refuse of rapefeed, or the rape cake, after the oil has been obtained from it. This substance has been found useful as a topdressing for crops of different kinds.

The rape cake, when reduced into powder or dust by means of a machine, has been extensively used in Norfolk; and when for turnip crops, it has been the custom to sow it some weeks before the seed of that root is put into the ground. In the practice of Mr. Coke of that district, it has, however, been found, that by having it brought into a fine powder it may be drilled from the fame machine, at the same time with the turnip seed; and that, by thus delivering the manure and the seed from the same pipes and shares of the drill machine, a ton of dust does six acres in the place of three. See TURNIP.

In Lancashire some farmers use it with great advantage as a manure for potatoes, putting it in with the fets in the proportion of about thirty-two bushels to the statute acre; but if the ground were well prepared, and the dust carefully deposited for the reception of the fets, it is supposed, a much smaller quantity would be sufficient. It produces much luxuriance in the crops, and a very fine produce.

Rape Oil, the oil obtained by means of expression from the seeds of this plant, in mills constructed for the purpose. The refuse oily substance of this kind may be employed as manure in mixture with rich earthy matters, with great advantage, wherever it can be procured in any quantity at a reasonable price.

Rape, in Geography, a river of Chili, which runs into the Pacific ocean, S. lat. 34° 8'.—Allo, a town of Chili, on the aforementioned river; 70 miles S. of Valparayo.

Raperlah, a town of Hindoostan, in the Carnatic; 13 miles N.E. of Ongole.

Rapha, in Anatomy. See Raphe.

Raphael, one of the seven archangels, who are said to be continually before the throne of God, and ready to perform his commands. We have no such name in the Old

or
RAPHAEL.

or New Testament; but his history occurs in the book of Tobit, c. xii. If the story of Tobit be true, it is not improbable that the angels, both good and bad, whose names do not appear to have been known before the Babylonish captivity, are figurative personages; and Raphael might only denote the salutary protecting agency of divine providence, so dispersing events as to produce a happy issue.

Raphael Sanzio, da Urbino, in Biography, during whole life, and by the exertion of his talents, in conjunction with those of Leonardo da Vinci, Titian, Michael Angelo, and some few others, the art of painting reached its acme in modern times, was born in the city of Urbino, on the morning of Good Friday, in the year 1483. He was descended from a respectable family, and many of his ancestors had been painters; as was his father Giovanni Sanzio, whose talents, however, did not elevate him to the first rank. He cultivated with care the inclination which his son Raphael exhibited, at an early age, for painting; and was soon repaid by the assistance he acquired from him, in several of the pictures he was employed to paint in his native city of Urbino. But finding that the taste of Raphael merited more skillful guidance than he was able to give it, he placed him under the tuition of Corradini, better known by the name of Carnevale, for a short time, till he could be received as a pupil by Pietro Perugino, at Perugia.

This matter was then in very high esteem, though his style was dry and meagre, in comparison with that of Masaccio, and others of the Florentine school. It is not surprising that Raphael, endowed as he was by nature, and trained as he had been in art, should soon become the rival, rather than the pupil, of such an artist. Accordingly we find, that his aptitude for the practice of art enabled him quickly to acquire his master's manner, and that in so perfect a degree, that connoisseurs were puzzled in their judgments upon the works which proceeded from Perugino's studio; and ordinary observers completely deceived. Vafari speaks of an Assumption of the Virgin, crowned by her Son, and the twelve apostles below, round her tomb, contemplating the celestial glories; with three small pictures in the same frame below it, of the Annunciation, the Adoration of the Magi, and Simon embracing the Saviour, painted at this period by Raphael, as being wrought with extreme beauty, and precisely like the work of Perugino.

We have to lament that we are left ignorant of the time when Raphael went as a pupil to Pietro, how long he remained with him, or when he left him, or rather was left by him; as that matter returned to Florence, to finish some pictures he had begun there some time before. He must certainly have been very young, from the number of pictures which he subsequently executed, previous to his going to Rome in his 25th year, and probably not more than 16 or 17, when he acquired his liberty by the departure of Perugino.

From Perugia he went to Citta di Castello, where he painted a St. Nicola crowned by the Virgin and St. Augustin, for the church of St. Augustine; and for that of St. Dominico, a picture of the Crucifixion of Christ, accompanied by angels, the Virgin, St. John, &c.; which would certainly have been considered as Perugino's, if Raphael had not left his name to them. But he was considered to have much surpassed him in another work, representing the marriage of the Virgin and St. Francisco, for the church of St. Francisco, in the same city. He acquired by these productions a great and deserved extent of fame, and thus early entered with success that course, which conducted him to the highest pinnacle of renown as an artist.

Attached to his person by friendship, and attracted by his skill as a designer, Pinturicchio, then employed by pope Pius II. to adorn the library of the Duomo at Sienna, sought the assistance of Raphael, and engaged him to compose designs for his work. This he undertook, but proceeded only to the preparation of some of the cartoons, when his ambition and his curiosity were stimulated, and his work interrupted, by the renown spread through the country of the cartoons painted by those great rivals, Leonardo da Vinci and M. Angelo, for the council-hall at Florence. He immediately determined, in conjunction with almost all his brother artists of the day, upon going to see and form his judgment upon them for himself; and consequently left his engagement with Pinturicchio, and proceeded to Florence.

In this city he found many attractive beauties, both of nature and art, that he resolved to fix his residence there for some time. His agreeable person and manners, combined with the extraordinary talents he had manifested, infured him friends; and he became intimate with several artists of celebrity, among whom were Ghirlandaio, St. Gallo, and Taddeo Taddi; the latter of them, a learned man, and friend of cardinal Bembo, took the youthful painter to his house and table, and thus afforded him the best introduction to the world, while he pursued his more immediate studies. This kindled the gentle heart of Raphael accepted with grateful emotion; and as he painted several pictures during his residence in that city, he presented two of them to Taddi. One of these pictures, a Madonna with the Child, and St. John bringing a little bird to him, the heirs of Tadi fold to the archduke Ferdinand Charles of Austria at a great price: the other is lost sight of. He also presented a picture to his friend Lorenzo Nati, which afterwards found a place in the Medicean gallery, and a duplicate in that of the monastery of Valombrosa.

From Florence Raphael was recalled to Urbino, by the death of both his father and mother; and there, when he had arranged his private affairs, he was engaged by Gindobaldo de Montefeltro, and several others, to paint religious subjects for the altars of their chapels; and among these he painted at this time, there were the two little St. Georges, now in the gallery of the Louvre. These commisions he executed with great taste and delicacy; and Vafari, who enumerates them, more particularly speaks of one of Christ praying in the garden, painted for Francesco Maria, duke of Urbino, as being finished with all the neatness of a miniature. What is become of most of these pictures, it is not easy to ascertain; but it is a curious fact, that not one of them remains at this time to adorn the native city of this great artist.

Thence he returned to Perugia, and painted several pictures. For the church of the Frati del Servi, one of the Virgin, with St. John Baptist, and St. Nicholas. For that of St. Stevens, in the chapel of our Lady, he painted in fresco a picture of Christ in glory, with God the Father, surrounded by angels and six saints, three on each side. Upon this picture he wrote his name in large letters of gold, and very condescendingly, as if he himself was pleased with the performance of it. He also painted here a picture for the nuns of St. Antonio da Padua, of our Lady with the Infant upon her lap clothed, and near her St. Peter, St. Paul, St. Cecilia, and St. Catherine. The airs and attitude of the two female heads were regarded as the most tasteful work of the time, wrought with the greatest degree of beauty and grace. Above the picture, in a semicircle, was represented
represented the Almighty Father; and at the foot of it, in three compartments, were the scenes of our Lord's sufferings, viz. his agony in the garden, carrying his cross, and dead upon the lap of the Virgin. It is not known what become of the centre picture, or the uppermost compart- ment; the lower ones formed a part of the Orleans collection. The execution of these works was performed in a style much improved upon that of Perugino; with more breadth, more lightness, and more freedom and variety of action; proving that he had not ill spent the time he had devoted at Florence to the study of the works of other painters. Hence we may date the commencement of what is termed his second manner, from his first visit to that city.

Soon after he had produced these works at Perugia, that zeal for cultivation, which always accompanies true genius, led him to determine upon again visiting Florence, at that time the emporium of science and of art. Though the native strength and purity of his mind were such as to conduct him, under favourable circumstances, to his future prominent station; yet he does not appear to have been so extraordinary and original an inventor in the art itself as M. Angelo, or his great predecessor and rival, Lionardo da Vinci. He knew how to take a hint of what was offered to his view, and to cultivate and improve it to his purpose; but it yet remains a problem, whether Raphael, alone, and without the leading aid of those great and original artists, would have ever seen the sublime of painting. His power may rather be said to have confined in ability to employ the materials furnished by their invention, viz. the style of Michael Angelo, in form; and of Lionardo da Vinci, in chiaro-scuro and colour; in beautiful conceptions, illustrative of the character and passions of man; and in an admirable feclution of subject, and mode of conveying it.

He himself appears to have been conscious of this; for we find him in the midst of honourable employment, leaving the prosecution of it, to study and improve himself by a constant observation of the works of other renowned artists, and again repairing to Florence, where alone he could find the true source of sound cultivation, and in which he made so good use of his time, as to fit him in great measure for the glorious field of exertion which awaited him.

On his return to the renowned abode of these great artists, from whose works he sought improvement, he had a letter of recommendation and introduction from the dukes of Urbino to Pietro Soderini Gonfaloniere of the city; and was thus introduced to the best circle of improvement and information.

It would have been highly gratifying to have been enabled to trace the steps of a man so distinguished in the art, from the earliest commencement of his studies; but the neglect of dates, by his historians, counteracts every wish to follow them more closely; and the record of facts leaves us only the means of conjecture. That he began to paint original pictures very soon after he was placed with Perugino is evident, and he must then have been very young, for it is on record, that the pictures by Pinturicchio, for which he made the cartoons at Sienna, were completed in 1503, at which time he was 20. If we allow, as we reasonably may, two years for their execution, it will place his first visit to Florence in 1501, at the age of 18; and it certainly cannot have been far from that period. In every part of his life, modesty, ingenuity, and the ardour of a mind entirely devoted to his art, characterized his conduct. His industry and ingenuity seem to have kept equal pace; and the rapidity and certainty with which he must have painted, to produce so many pictures in so short a space of time as he lived, are not the least extraordinary part of his history.

On this, his second abode at Florence, he studied deeply the works of Mafaccio, and the cartoons of Angelo and Da Vinci; and attached himself in friendship to Baccio della Porta, better known by the name of Fra. Bartolomeo; than whom no one was better qualified to direct him rightly in whatever was grand and dignified, and from whole judicious information in the art of calling draperies and of colouring, Raphael evidently improved exceedingly; while he had the pleasure, in return, of communicating to his friend the principles of perspective. Yet notwithstanding these helps, he did not entirely free himself from the formal and dry manner of his master, though he painted affably both in portrait and history. In the former he produced the portraits of Angelo Doni and his lady Maddalena Strozzi; and in the latter he painted for Dominico Caneggiani, a Madonna, with the Infant playing with St. John brought by Elizabeth, who regards St. Joseph as he stands near, leaning both his hands upon a stick, and inclining his head towards her. This picture appears to have been re-touched, or possibly completed only in 1516, as the name of Raphael, with that date, in letters of gold, is written upon the drapery of the Virgin. He also made a cartoon during his residence in Florence for a picture which he had previously engaged to paint for the Baglioni family at Perugia, and left the city to go and paint it in the church of St. Francesco in that place. The subject of it was our Saviour carried to the sepulchre, accompanied by the Virgin, St. John, &c.; and it was exceedingly admired for the beauty and expression of the figures, and the skill and perfection of the draperies. This picture was removed from Perugia by pope Paul V., and a copy, by Cefare d’Arpino, placed in its stead: it afterwards found a station in the Borghese palace at Rome.

When Raphael had completed this work, he returned to renew his studies at Florence, and was employed by the family of Dei, to paint a picture for their altar in Santo Spirito, which he began, and conducted through the preparatory parts; and in the mean time painted another for the city of Sienna, of the Madonna in an open country, with the Child flanding by her, and St. John kneeling before him, but was interrupted, in its execution, by a summons from pope Julius II. to Rome, and left it in the hands of his friend Gherlandone, to finish a piece of blue drapery which it wanted. This picture was afterwards sold to Francis the First, King of France, and is at present in the French collection, known by the name of the Belle Jardinière. The unfinished sketch of the picture begun for the Dei family, was bought, after the death of Raphael, from his heirs, by Baldassare Turini, and placed by him, in its original state, at the altar of his country church; it afterwards came into possession of the house of Buonvicini di Pefcia, and was sold, by that family, to the grand duke Ferdinand, who, on removing it, placed a copy by Carlo Sacconi in its stead. This was done at night, and with the utmost secrecy, for fear of a disturbance among the populace, by whom it was highly prized.

Raphael was indebted for the high patronage of the pope, which placed him in the proper sphere for the exercise of talents such as he possessed, to the friendship of his relation Bramante d’Urbino the architect; and never was recommendation better supported by ability. Upon his arrival in Rome, in 1508, he was received with great courtesy by Julius, and the Camera della Segnatura, in the Vatican, alligned to him. He immediately began the preparation for his first picture, which was the School of Theology, better known by the name of the Dispute of the Sacrament, and in observing which, it is worthy
worth of remark how his mind enlarged, in regard to style in the art, as he became accustomed to consider largely of his work; and according to the field of employment which he found before him. The difference in style between one part of the picture, and that of the other, evidently points out where he began it; viz. on the right of the upper part, where the remains of the school of Perugino appears, and is spread through the centre, where the glory which surrounds our Saviour is represented in the Gothic manner, by rays of gold. As he proceeded, his style enlarged, and the lower part of the picture exhibits an immense improvement, and is almost equal to any of his subsequent productions.

In the same room are the paintings of the School of Athens, the Parthenion, painted in 1512, (where, surrounding Apollo and the Muses, he has introduced portraits of the great poets, both of antiquity and of his own time,) and the Jupiferus, comprising two subjects, one of the emperors Jovianus delivering the digest of his code of laws to Tribonius, and another of pope Gregory IV., giving the decretal to a member of the conclave. Over each of these subjects, respectively, are painted circular ones of single figures, representing Theology, Philosophy, Poetry, and Justice.

When pope Julius saw the superior taste and talent with which Raphael produced the former of these works, he immediately ordered the whole of the Stanze, or chambers, which it was intended to decorate, to be entwined to him; and all that had previously been done by Perugino, Pietro del Borgo, Il Sodoma, and Bramante di Milano, to be removed. But of this order Raphael made only a partial use; preferring entire the work of his first manner, and, partially, the ornamental labours of Il Sodoma.

While he was engaged upon these great works, he was not altogether indifferent to the more agreeable exercise of the pencil, and he painted for the church of the Augustines, the pictures of the prophet Isaiah, and the Sibyls who are supposed to have predicted the coming of Christ. He also painted the portrait of his great patron, Julius, now in the Louvre, and several smaller cabinet pictures of Madonnas, and other religious subjects. By these labours he acquired the renown they so well merited, and his manners appear to have been in perfect accordance with the beauties of his mind. His person also was handsome, and he was beloved, esteemed, and admired. Yet he continued to study, and to improve his talents, employing persons to collect specimens and make drawings from Grecian remains. Full of taste and feeling, he spared no pains to perfect his powers by a thorough knowledge of all that had been done in art, both ancient and modern. In consequence, however, the fact, related by Vafari, may be doubted, of his being admitted, while Michael Angelo was absent, to see the work of that great artist in the church of Sixtus IV.; the taste in which he wrought became aggrandized, and similar to that introduced by M. Angelo. About this time he painted the Galatea for Agostino Ghigi, and the Madonna di Foligno, at the desire of Sigismondo Conti, secretary of pope Julius II., for the great altar of the church at Araceli, and which is now at the Louvre.

In another chamber of the Vatican he painted four other large pictures, the subjects of which are, the miracle of Bolsena, when the officiating priest, who doubted of the real presence in the Eucharist, is offering up the host, and perceiving, with astonishment, that it drips drops of blood; the release of St. Peter from prison; the Hebdorod; and Attila arrested, in his journey to Rome, by a vignon of St. Peter and St. Paul; these were completed in 1512, 13, and 14.

In these pictures his great improvement in colouring and style is most evident, and he continued to carry it still further into practice in another room, for which also he had composed four other subjects, known as the Incendio del Borgo; the coronation of Charlemagne by Leo III.; the fame pope defending his conduct to the, same emperor; and the descent of the Saracens at the port of Olbia.

Whilst Raphael was engaged on the Heliodorus, his first great patron, Julius II., died; but fortunately for the arts, if not for the tiara, he was succeeded by another, Leo X., who was even more attached to them, and more fond of the renown arising from the cultivation of whatever adorns society. By him, therefore, Raphael was ardently encouraged to proceed with his labours, and he continued to make designs for other apartments, particularly for the great hall of Constantinople, as it is now called; but he did not live to execute them. The Incendio del Borgo was the last upon which he himself wrought; the rest were completed by Giulio Romano. He was also employed by Leo to make the cartoons now at Hampton Court, as exemplars for works in tapestry, to be executed in Flanders, and which were completed at the expense of 70,000 crowns. Fortunately for us the originals were never returned to Rome, and were purchased afterwards by Charles I.

Upon the death of Bramante, in 1514, the superintendence of the architectural concerns of the Vatican was entrusted to Raphael, who had already exhibited his knowledge and taste in that art, by the introduction he had made of it in his pictures. He invented and began a palace for himself, and made several designs for others.

Notwithstanding the immense application necessary for the invention and completion of these important labours, together with the designs he composed for the ornamental parts, and the scriptural subjects on the ceilings and the coining of the loggia and Stanze of the Vatican, he found time to execute in freSCO the designs which adorn the palace of Agostino Ghigi; the capital portrait of his great friend Leo X., with the cardinals de Medici and Roffi, now in the Louvre; the St. Michael, and the vignon of Ezekiel, both in the same grand depot; a Madonna, Child, and St. Anne, for Florence; and a large picture of Christ bearing his Cross, for the monastery of St. Maria della Spalata, at Palermo. Of this picture it is reported, that being sent on shipboard to go to Sicily, the vellum was beaten from its course by a tempest, and the mantuns left; when it drifted to Genoa, and of course its preservation was attributed to the divine influence of this great work. The Genoeese chafe also to suppose that the band of God had thus pointed out their city as the proper place for its residence; and would not relinquish it for a length of time, till the papal influence interfered, when it was configured to its original destination. He also painted the picture of St. John, which adorned the Orleans collection; and last of all, the Transfiguration; which indeed he had not quite finished when the unrelenting hand of death fet a period to his labours, and deprivd the world of further benefit from his talents, when he had only attained an age at which most other men are but beginning to be useful.

The immediate cause of his death is allowed to have been brought on by too great an indulgence in gallantry, and, Vafari adds, by mismanagement of his physicians, who bled him when they ought to have administered reforatives. On his death bed he made his will, leaving his favourite pupils, Giulio Romano and II. Fattoro, his heirs, and ordering his burial
burial to take place in the Pantheon (the church of Santa Maria Rotunda), where a monument still remains to his honour. He died on the same day of the year on which he was born, Good Friday, in 1520, at the age of 37, deeply lamented by all who knew his value. His body lay for a while in state, in one of the rooms wherein he had displayed the powers of his mind, and he was honoured by a public funeral; his last produce, the Transfiguration, being carried before him in the procession; and, that Raphael might not be deprived of so noble a memorial of this extraordinary man, it was placed by the cardinal de Medici in the church of St. Pietro a Montorio, instead of being sent to France, as was originally intended.

Mr. Fufeli, in his edition of Pilkington, has given so discriminating and just an idea of the peculiar excellencies of Raphael, that we shall conclude our history of him by quoting it. "The general opinion has placed Raphael at the head of his art, not because he possessed a decided superiority over every other painter in every branch, but because no other artist ever arrived at uniting with his own peculiar excellence all the other parts of the art in an equal degree with him.

"The drama, or in other words the representation of character in conflict with passion, was his sphere; to represent this, his invention in the choice of the moment, his composition in the arrangement of his actors, and his expression in the delineation of their emotions, were, and are, and perhaps will be unrivalled. And to this he added a style of design dictated by the subject itself, a colour suited to the subject, all the grace which propriety permitted, or sentiment suggested, and as much chiaroscuro as was compatible with his supreme defect of perplicity and evidence. It is therefore only when he forsook the drama, to make excursions into the pure epic or fabliche, that his forms become inadequate, and were inferior to those of M. Angelo; it is only in subjects where colour from a vehicle becomes the ruling principle, that he is excelled by Titian; he yields to Correggio only in that grace and that chiaroscuro which is less the minifter of propriety and sentiment, than its charming abuse, or voluptuous excess; and which fascinates to the eye what was claimed in vain by the mind.

"Michael Angelo appears to have had no infancy: if he had, we are not acquainted with it: his earliest works equal in principle and elements of style the vigorous offsprings of his virility: Raphael we fee in his cradle, we hear him hammer: but propriety rocked the cradle, and character formed his lips. Even the trammels of Pietro Perugino, dry and servile in his style of design, formal and gothic in his composition, he traced what was essential, and separated it from what was accidental, in figure and subject. The works of Lionardo, and the cartoon of Pifia, invigorated his eye, but it was the antique that completed the fyllem which he had begun to establish on nature. From the antique he learned disjermination and propriety of form. He found that in the construction of the body, the articulation of the bones was the true cause of ease and grace in the action of the limbs, and that the knowledge of the was the true cause of the superiority of the antients. He discovered that certain features were fitted for certain expressions, and peculiar to certain characters; that such a head, such hands, and such feet, are the flamen or the growth of such a body, and on phyfognomy established uniformity of parts. When he designed, his attention was immediately directed to the primary intention and motive of his figure, next to its general measure, then to the bones and their articulation, from them to the principal muscles or thofe eminently wanted, to their attendant nerves, and at last to the more or less essential

minutiae; but the character part of the subject is infallibly the characteristic part of his design, whether it be a rapid sketch, or a more finished drawing. The strokes of his pen or pencil themselves are characteristic: they follow the direction and texture of the part; flesh in their rounding, tendons in straight, bones in angular lines.

"Such was the felicity and propriety of Raphael, when employed in the dramatic evolutions of character! both suffered when he attempted to abstract the forms of sublimity and beauty; the painter of humanity, not often wielded with success super-human weapons. His gods never rose above prophetic or patriarchal forms; if the singer of Michael Angelo impressed the divine countenance oftener with threnodie than awe, the gods of Raphael are sometimes too affable or mild, like him who speaks to Jacob, in a ceiling of the Vatican; or too violent, like him who separates light from darkness, in the loggia of the same place. But though, to speak with things, he was chiefly made to walk with dignity on earth, he soared above it in the conception of Christ on Tabor, and still more in the frown of the angelic countenance that withers the strength of Heliodorus.

"Of ideal female beauty, though he himself, in his letter to count Calighion, tells us, that from its scarcity in life, he made attempts to reach it by an idea formed in his own mind, he certainly wanted that standard which guided him in character: his godesses and mythologic females are no more than aggravations of the generic forms of Michael Angelo. When the drama inspired Raphael, his women became definitions of grace and pathos at once. Such is the exquisite line and turn of the half-averted kneeling female with two children, among the speculators of the punishment inflicted on Heliodorus; her attitude, the turn of her neck, supplies all face, and intimates more than he ever expressed by features."

RAPHAEL, in Geography, a fertile and healthy district, being the well-nigh moist in the Spanish part of St. Domingo. Its northern boundary is found in part of the French parish Gonfalves. The air round St. Raphael is very fabulous, but the town, which is in a hollow, is very hot; to leagues S. of Cape François.

RAPHAEL, St., Cape, lies at the S. end of St. Domingo, and is the S.E. limit of Samana bay.

RAPHANEA, in Ancient Geography, a city of Syria, between which and Acre, or Aract, a city of Judea belonging to the kingdom of Agrippa, the Sabbatical river flowed. Joseph. de Bell. i. vii. e. 24. Raphanea is, perhaps, the Arpal of scripture. 2 Kings, xviii. 34. xix. 15. 11. x. 9. xxxvi. 19. xxxvii. 13. Jerem. xlix. 23.

RAPHANIA, in Medicina, an appellation given by Linnaeus, and afterwards by Dr. Cullen and others, to a severe and fatal disease, which has been described as epidemic in Sweden at particular season, and imputed to the use of the raphanus raphanifrum of Linnaeus as food.

It is not necessary to describe the symptoms of this disease in this place: since it is, in fact, the fame malady which has been epidemic in various other countries of Europe, during seasons of scarcity; and has been attributed to various other species of unwholesome grain, but more especially to diseased rice, affected with the ergot, to the lolium temulentum, to charlock, &c. We have already entered at great length into the history of the symptoms and imputed causes of this formidable malady, which has been more commonly denominated ergot, from one of its supposed sources. (See Ergot.) We have endeavoured also to shew, that it constituted one of the varieties of epidemic disease, described by the ancients, under the appellation of Ignis Sacer (which see); and that, instead of being properly imputed to the

3 K admixture
admixture of any of these substances with the corn used for food, the disease is to be ascribed with more probability to the insufficient nourishment afforded by damaged corn, or the actual death of it, which usually occur together; especially as these diseases have commonly been epidemic in years of scarcity, which is the only circumstance that can be observed in common to all the epidemics described by authors. In addition to the works on ergot and ignis facer, formerly referred to, consult, for an account of raphania, Pulletney's View of the Writings of Linnaeus; Rotham's Paper, in the Amœnités Academ. of Sweden; Tiffot, Epitôle Med. Pract.

RAPHANIS, in Botany, the name by which the Attics, among the Greeks, called the radish; for the word raphanas, or raphanus, with them, does not express the radish, but the cabbage. The Greek of all other places occurred in calling the radish raphanas, and the cabbage raphanae, and it is owing to this that we have many authors who confound together these two plants, though so very unlike one another in appearance and use. It is generally to be understood, that wherever Theophrastus mentions the word raphanas, he means by it the cabbage; and the same being observed, in regard to all the other Attic writers, the whole danger of confusion and error will cease.

RAPHANISTRUM, a name given by botanists to the wild radish, and designed to express its affinity to the cultivated one. See Raphanus.

Gen. Ch. Cal. Perianth inferior, erect, of four oblong, parallel, converging, deciduous leaves, gibbous at the base. Cor. crucifera, of four inerferly heart-shaped, spreading petals, whose claws are rather longer than the calyx. Nectariferous glands four; one at each side, between the outer lamen and the pili; and one at each of the opposite sides between the longer lamen and the calyx. Stem. Filaments six, awl-shaped, erect; two opposite ones the length of the calyx; the rest as long as the claws of the corolla; anthers simple. Pfl. Germen oblong, tumid, tapering, the length of the stamens; style scarcely any; stigma capitate, undivided. Peric. Pod oblong, pointed, swelling here and there, imperfectly jointed, without valves. Seeds roundish, smooth.

Oft. Raphanus of Tournefort and Gartn. has a fpoagy fruit, of two cells, not burbling. Raphanistrum of the same authors has a jointed fruit, separating at the joints.

1. R. sativus. Common Garden Radish. Linn. Sp. Pl. 935. Willd. n. 1. Ait. n. 1. Ger. Em. 257. (R. primus; Matth. Valgr. v. 1. 399.)—Leaves lyrate. Pod roundish, tumid, of two cells.—The native country of this well-known plant, so commonly cultivated in gardens, is not ascertained. Linnaeus mentions China; but his authority does not appear. Its chief value with us consists in it, the root, esteemed for its grateful pungency, mixed with a watery coolness. The shape of this part varies, from its natural pindle-like figure, to a globular one, and the colour of the skin from purple to white. We doubt much whether the R. sativus of Baulin, commonly called the Black Spanish Radish, which Linnaeus marks as, can belong to this species. Its fprines, and black rugger coat, seem to indicate more than a mere variety. We have not examined the herbage. The leaves of R. sativus are lyrate, notched, and rough, especially the lower ones; the upper part of the herb is smoother, and somewhat glaucous. Stem branched. Flowers purple, corymous; soon racemose. Pods erect, tumid, juicy, pale, glaucous, smooth, slightly flattened, various in length and thickness, tipped with an awl-shaped beck. Linnaeus cultivated at Upland a Chinese variety, or possibly species, whose leaves are broader and smoother, and whose habit more lax. The oil of the seeds is said to be used in China.

2. R. caudatus. Long-tailed Radish. Linn. Mant. 95. Linn. fl. Plant. Rac. f. 1. t. 10. Willd. n. 2.—Leaves lyrate. Pod compressed, of one cell, wavy, longer than the whole plant.—Native of Java, where, according to the younger Linnaeus, it is cultivated, and the pickled pods known by the name of Mougri. In Sweden, as well as in England, it may be treated as a hardy annual, like the foregoing; but the present species does not occur in Hort. Kew., though Mr. Lambert met with it last year in a country garden in Wiltshire. The appearance of the plant, weighed down to the ground by its immoderately long serpentine pods, is altogether extraordinary. The lobes and indentations of the leaves are sharper than in the Common Radish, but the flowers and other parts, except the pods, scarcely betray any difference.

3. R. Raphanistrum. Wild Radish, or Jointed Charlock. Linn. Sp. Pl. 935. Willd. n. 3. Ait. n. 2. Fl. Brit. n. 1. 6. Eng. Bot. t. 856. Curt. Lond. f. c. 4. t. 46. Mart. Hort. t. 71. Fl. Dan. t. 678. (R. sylvestris; Ger. Em. 240.)—Leaves simply lyrate. Pod round, jointed, even, of one cell.—A troublesome weed in the cornfields of Europe, flowering in June and July. The root is annual, small, and tapering. Stem branched, round, glaucous, rough, with prominent bristles, leafy. Leaves rough, lyrate; the upper ones oblong, simply toothed. Flowers numerous, lemon-coloured, changing to white in decay; with pale veins; sometimes the petals are white from the first. Pods cylindrical, or rather tapering, beaked, knobbled or imperfectly jointed, smooth, becoming fleshy as they ripen. In a young state they are divided into two cells, but the partition is obliterated, and coalesced in one fpyngous mass, as they ripen. Linnaeus was of opinion that the seeds of this plant caued a convulsive disease, thence termed by him Raphania, of which he has given a history in Amer. Acad. v. 6. 370, with a figure, and elaborate synonymy of the plant. We have never met with any circumstance to corroborate this hypothesis.

4. R. maritimus. Sea Radish. Linn. Eng. Bot. t. 1643. Ait. n. 3. (R. Raphanistrum; Fl. Brit. t. 723. R. maritimus, flore luteo, silique articulatæ, secundum longitudinem eminenter striatis; Rau. Syn. 296. Raphanistrum silique articulata striata maximæ; Morif. v. 2. 266. Rau. Hlth. v. 1. 366.)—Radical leaves interruptedly lyrate. Pod round, jointed, smooth, deeply furrowed, of one cell. Found on the sea-shore in various parts of Britain, flowering in May. The late Rev. Dr. Walker, and Mr. J. Mackay, observed it on the western coasts of Scotland; and the former cultivated this plant, till his death, as an eufulent root, preferable to horse radish; he also found that cattle were very fond of the leaves. Mr. Turner and Mr. W. Borrer gathered the fame on rocks, near Beachy Head, Sussex. The root is large and succulent, lasting two or three

11
RAPHANUS.

three years. *Stem* three or four feet high, round, roughest at the base. *Leaves* all rough, and rarer sharply toothed; the radical ones interruptedly lyrate, which we have never observed in the last-described species. *Flowers* of a deeper yellow, and less veiny. *Pods* strongly jointed, and very deeply furrowed longitudinally, delitute of hairs or other roughnesses. There can be no doubt of this being a distinct species from the former, though generally confounded therewith.

5. R. *tuberous*. Siberian Radish. Linn. Sp. Pl. 935. Murray Comment. Gott. for 1775. 48. t. 11. (R. n. 28; Gmel. Sib. v. 3. 266.)—Leaves pinnatifid, somewhat toothed. Pod round, beaded, downy, of one cell.—Native of Siberia. The seeds were sent by Professor Pallas to the Goettingen garden, where the plant flowered in June. *Root* annual, long, and slender. *Stems* from three to five inches high; or more, as the seeds ripen, ascending, leafy, hairy, simple or branched. *Leaves* sometimes elegantly and neatly pinnatifid, almost pedate, either in a simple or interrupted manner, roughish at the edge only, sometimes more dilated, with distant and broader lobes. *Flowers* large, yellow, sweet-scented in an evening, their petals strongly margined. *Pods* inflamed, copiously and neatly beaded in appearance, rather than diffusely jointed, downy, each with a sharp taper beak.

6. R. *tenuifolius*. Slender Purple Radish. Pallas Trav. v. 3. append. 741. t. L. f. 3. Willd. n. 5. Ehrb. Sel. n. 38. (Chorispermum tenuilifolia; Brown in Ait. H. Kew. v. 4. 129.)—Leaves smooth, oblong, toothed; the lowermost pinnatifid. Pod awl-shaped, jointed, smooth, of two cells.—Native of deferts near the Caspian sea. A hardy annual in our gardens, flowered in June and July. *Root* long, simple, tapering, and slender. *Herb* smooth, scarcely branched, leafy. *Leaves* elliptic-oblanceolate, toothed or pinnatifid, tapering down into longish footstalks. *Flowers* small, purple. *Beak* of the pod very long and slender. The ingenious Mr. Brown separates this from *Raphanus* chiefly, as it seems, because the cotyledons are flat, not folded.

8. R. *lanceolatus*. Lanceolate Radish. Willd. n. 7.—"Leaves oblong-lanceolate, somewhat toothed at the apex. Pod tumid, smooth, two-celled, with a squarish beak."—Native of the Wett Indies. *Stem* a foot and half high, erect, zigzag, with short branches, smooth like every other part of the plant. *Leaves* falched, oblong-lanceolate; the uppermost lanceolate, narrow, entire; the lower ones bluntly toothed at the extremity. *Flowers* of a middling size, yellow, in a terminal cluster, six inches long. *Pods* half an inch long, with a long, obtuse, obscurely quadrangular beak. *Willdenow.*

9. R. *pilosus*. Hairy-falched Radish. Willd. n. 8.—"Leaves lanceolate-linear, pinnatifid at the base. Stem rough with brilly hairs. Pod round, smooth, jointed, of one cell."—Native of Guinea. *Stem* two feet, or perhaps more, in height, branched, divaricated. *Leaves* three inches long, narrow, smooth, pointed; pinnatifid at the base; toothed in the middle; entire at the extremity. *Clusia* auxiliar from every leaf, of few flowers. *Pods* an inch and half long, round, jointed, of one cell, with a short beak, all of them turned one way. *Willdenow.*

R. *erucoides*, Linn. Suppl. 299, is rightly referred by Mr. Brown, in Ait. H. Kew. v. 4. 126, to *Sinapis Alliata*, Jacq. Hort. Vind. v. 2. t. 168. *Willd. Sp. Pl. v. 3. 557. (See *Sinapis*) Willdenow cites it, doubtfully, under *Brassica Chrysanthus* of Villars, a very different plant; for which he also by mistake quotes Barcel. 1c. t. 1016, a synonym properly belonging to *Sisymbrium Barrelieri.*

Linnaeus once referred *Bunus Calile* to this genus of *Raphanus*.

*Raphanus*, in Gardening, contains plants of the herbaceous, annual, esculent kind, of which the species cultivated is, the common garden radish (R. sativus).

There are several varieties; some of which have the appearance of distinct species, from their shape, size, and colour of the roots; as the long-rooted, which is that commonly cultivated in kitchen-gardens for its roots. Of this there are several subordinate variations: as the small-rooted, and the long-rooted striped radish. The small-rooted is most commonly preferred by the gardeners near London, as they require much less room than those with large tops; for as forward radishes are what produce the greatest profit to the gardener, and these are commonly sown upon borders near hedges, walls, or pales, the large-topped sorts would be apt to grow mosty at top, and not swell to much in the root as the other, especially if the plants should be left pretty close.

The small round-rooted, which is not very common here, but in many parts of Italy it is the only one cultivated; the roots of this are very white, round, small, and very sweet. It is now frequently bought to the London market in the spring, generally in bundles, and is sometimes mistaken there for young turnips; when eaten young, it is crisp, mild, and pleasant.

The large turnip-rooted, or white Spanihs, which has a moderately large, spheroidal white root, and is esteemed chiefly for eating in autumn and the early part of winter. Both these sorts are commonly called indiscriminately turnip radishes.

The black turnip-rooted Spanihs, which has a root like the preceding, white within, but with a black skin; and is greatly esteemed by many for autumn and winter eating. There are likewise some other sub-varieties of the radish noticed by gardeners, as the common salmon radish, and the short-topped early salmon radish. Also the small red turnip-rooted radish. Gardeners, too, often call the long-topped sort the fallad radish.

Method of Culture.—These are raised from seed by different sowings from the end of October till April, or the following month. They should have a light fine mould, and the more early sowings be made on borders, under warm walls, or other similar places, and in frames covered by glaesses. The common spindle-rooted, short-topped sorts are mostly made use of in these early sowings, the seed being sown broadcast over the beds after they have been prepared by digging over and raking the surface even, being covered in with a flight raking. Some few carrots with the early crops of radishes.

It is usual to protect the early sown crops in the borders, during frosty nights and bad weather, by mats or dry wheat straw, which should be carefully removed every mild day. By this means they are brought more forward, as well as form better roots. When mats are used, and supported by pegs or hoops, they are readily applied and removed.
A second more general sowing should be made in January or February. When the crops have got their rough leaf, they should be thinned out, where they are too thick, to the distance of two inches, as there will be constantly more thinning by the daily drawing of the young radishes.

When the weather is dry in March, or the following month, the crops should be occasionally well watered, which not only forwards the growth of the crops, but increases the size of the roots, and renders them more mild and crisp in eating.

And the sowings should be continued at the distance of a fortnight, till the latter end of March, when they should be performed every ten days, until the end of April or beginning of the following month. In fowining these later crops, it is the practice of some gardeners to sow cobs-lettuces and spinach with them, in order to have the two crops coming forward at the same time, but the practice is not to be much recommended, where there is sufficient room.

But in fowining the main general crops in the open quarters, the market-gardeners generally put them in on the same ground where they plant out their main crops of cauliflowers and cabbages, mixing spinach with the radish-seed as above, fowing the seeds first, and raking them in, then planting the cauliflowers or cabbages; the radishes and spinach come in for use before the other plants begin to spread much, and as soon as those small crops are all cleared off for use, the ground all over to kill weeds and loosen the soil, drawing earth about the items of the cauliflowers and cabbages.

The turnip radish should not be sown till the beginning of March, the plants being allowed a greater distance than for the common spindle-rooted sort. The seeds of this sort are apt to degenerate, unless they are set at a distance from that kind.

The white and black Spanish radishes are usually sown about the middle of July, or a little earlier, and are fit for the table by the end of August, or the beginning of September, continuing good till frost spoils them. These should be thinned to a greater distance than the common sort, as their roots grow to a large as turnips, and should not be left nearer than six inches.

To have these roots in winter, they should be drawn before hard frost comes on, and laid in dry land, as practised for carrots, carefully guarding them from wet and frost; as in this way they may be kept till the spring.

In regard to the culture of the general crops, they require very little, except occasional thinning where they are too thick, when the plants are come into the rough leaf, either by hoeing or drawing them out by hand: though for large quantities, small hoeing is the most expedient mode of thinning, as well as most beneficial to the crop by loosen ing the ground; in either method thinning the plants to about two or three inches distance, clearing out the weakest, and leaving the strongest to form the crop.

In order to save the seed, about the beginning of May some ground should be prepared by digging and levelling; then drawing some of the strawcovered and bell-coloured radishes, plant them in rows three feet distant, and two feet alhund in the rows; obviating, if the season be dry, to water them until they have taken root: after which they will only require to have the weeds hoed down between them, until they are advanced so high as to overspread the ground.

When the seed begins to ripen, it should be carefully guarded against the birds. When it is ripe, the pods will turn brown: then must be cut, and spread in the sun to dry; after which it must be thrashed, and laid up for use where no mice can come at it.

Method of Culture on Hot-beds.—This method is sometimes practiced in order to have the roots early, as in January or the following month. They should have eighteen inches depth of dung to bring them up, and fix or seven inches depth of light rich mould. The seed should be sown more moderately thick, covering it in half an inch thick, and putting on the lights: the plants usually come up in a week or less; and when they appear, the lights should be lifted or taken off occasionally, according to the weather; and in a fortnight this the plants to the distance of an inch and half or two inches, when in six weeks they will be fit to draw. Where there are no frames to spare, the beds may be covered with mats over hoops, and the sides secured by boards and straw-bands. And when in want of dung, if the beds be covered with frames, and the lights put on at right and in bad weather, the plants may be raised for use a fortnight sooner than in the open borders.

RAPHE, in Anatomy, a Greek term, signifying future, applied to some parts of the body; thus we have the raphe corporis calloti in the brain (see BRAIN); raphe perinei, feroti, and penis. See Generation.

RAPHENGIUS, sometimes called Raphenhius, Francis, in Biography, a learned orientalist, was born in 1539 at Lanoy, near Lille, in Flanders. He had the early part of his education at Ghent, but on the death of his father, it was intended to bring him up to trade, and for that purpose he was sent to Nuremberg. Here he had access to books, resumed his studies, and took an opportunity of going to Paris, where he made great progrès in the Greek and Hebrew languages. The civil wars obliged him to quit France, and he came to England, where, for some time, he taught Greek in the university of Cambridge. After this he returned to the Low Countries, and became a corrector of the presses to the celebrated printer Plantin, whose daughter he married in the year 1565. He made himself very serviceable in the printing office, especially with respect to the famous Antwerp Polyglot Bible, printed in 1571 by order of Philip II. of Spain. When Plantin removed to Leyden, he left his business at Antwerp under the care of Raphelengius, and upon his return the latter went to Leyden. The curators of the university of that place conferred upon him the professorship of Hebrew, to which was added that of Arabic. He died in 1597. His literary works were "Variae Lectiones et Emendationes in Chaldæis Bibliorum Paraphraesin," "Grammaticæ Hebrew," "Dictionarium Chaldæicum," and "Lexicon Arabicum." He had a son of the same name, a man of talents and learning, who published "Notes upon Senea's Tragedies," and "Eulogies, in Verse, of fifty Perfons, with their Portraits."

RAPHIA, in Botany, from jas, a point or needle, so that it ought to have been Raphis, a genus of Palms, with a very pointed fruit, established by Palliot Beauvois, in his Flore d'Ouvrre et de Brin, t. 8.

RAPHIA, in Ancient Geography, a famous city in the Mediterranean, between Gaza and Rhinocorura. This was perhaps Gath of the Rephaim. Raphia is famous for the victory of Philiopator, king of Egypt, over Antiochus the Great, king of Syria. (3 Maccab. 1. 11.) Josephus says (Antiq. i. xiii. c. 21.) that Raphia was taken by Alexander Jannæus, and after being ruined in the wars, was repaired by Gabinus. There are extant some ancient medals struck at Raphia, and some historians of this city are found in the lists of the calven counsels.

RAPHIDIA, in Entomology, a genus of insects of the order Neuroptera, of which there are two species. The generic character is as follows; Mouth with a curved toothed
toothed horny mandible; the thorax is long and cylindrical; it has three femmata; the wings are deflected; the antennæ filiform, as long as the thorax, the anterior part is elongated and cylindrical; it has four feelers, which are short and filiform; the tail of the female is terminated by a large recurved bristle.

* Ophiopus. The wings of this species are immaculate. It inhabits divers parts of Europe in woods, and preys on other insects.

* Notox. Wings with a brown marginal spot. It inhabits England, and has been thought to be only a variety of the former. The body is black; the head is also black with a tectaceous spot; the legs are tectaceous; the appendage of the female is as long as the body.

Raphoe, in Geography, a bishopric of Ireland, in the ecclesiastical province of Armagh, which comprises the greater part of the county of Donegal, being 44 miles in length from north to south, and 32 in breadth, comprehending 515,250 Irish acres. It contains 31 parishes, in which are 32 churches. The dean, archdeacon, and four prebendaries, compose the chapter. The patronage of 6 parishes, which form the corps of the deanery, is in the crown; of 15 others, in the bishop; of 7, in the university of Dublin; and of 3, in lay hands. It is not precisely known at what time this fee was founded, but it must have been as early as the ninth century, since bishops of Raphoe are mentioned at that time. Beaufort.

Raphoe, a small post-town of Ireland, the parish church of which serves as a cathedral, where is the bishop's palace. It is 107 miles N. by W. from Dublin.

Raphone, a township in Lancaster county, Pennsylvania, containing 284 inhabitants.

Raphoun, in Ancient Geography, a city beyond Jordan, on a brook, not far from Caraim.

Rapicio, Grovita, in Biography, an Italian man of letters, was born about the year 1480, at Chieri, in the territory of Brevia. Devoting himself to the instruction of youth in literature, he first opened a school at Bergamo, where he wrote a Latin treatise on the education of youth, which was afterwards printed at Venice. He next taught at Vicenza, and various other cities in Italy, and was for many years employed at Venice in instructing, in polite literature, the youths defined for public life, and among others, the care and instruction of the sons of cardinal Bembo were devolved upon him. Cardinal Pole, in one of his letters, speaks of Rapicio in high terms of commendation. He died at Venice in 1553. He was author of various harangues, poems, and epistles, but his chief work was entitled "De numero Oratorio," in five books, printed at Venice in 1544. "In this," says his biographer, "he minutely investigates the principles of writing the Latin language with sweetness and harmony, and he replies to Melanchthon's affections, that rules of this kind are rendered useless by our ignorance of the ancient pronunciation. Moreci."

Rapidean, in Geography, a small river of Virginia, which runs into the Rappahanock, about 10 miles above Fredericksburg.

Rapide, Ilse au, a small island of Upper Canada, in the river St. Lawrence, in front of the township of Matilda, containing about 200 acres.

Rapide, a river which runs into Hudson's Bay.

Rapides, a county of the territory of Orleans, containing three parishes, viz. Rapides, including 2200 inhabitants, Catahoula 1164, and Avoyelles 1209.

Rapier, properly denotes a long, ordinary, old-fashioned cutting sword, such as those worn by the common folders.

The word is formed from the French rapiere, of the Greek ῥαπίς, κερατός, to finite, or 

In this sense do the French still use the term; so that among them, to take the rapier, is to enter in the army.

Rapier, in a modern sense among us, usually denotes a small sword, as contradistinguished from a back-sword, or cutting-sword.

Rapillo, in Mineralogy, the name given by the Italians to the sand or powders (improperly called ashes) thrown out of the crater of volcanoes in immense quantities, towards the conclusion of an eruption. See Volcano, and Volcanic Products.

Rapin, René, in Biography, a Jesuit, was born at Tours in 1621. He entered the society in 1639, and was a teacher of the belles lettres in it during nine years. He became eminent by several publications in the Latin and French, and obtained a high rank among the literary characters of his time. It is, however, as a Latin poet that he is chiefly known: his didactic poem on Gardens, entitled "Hororum, lib. iv," first printed in 1665, has passed through many editions, and has been regarded as one of the most elegant and classical pieces of modern Latin verse. By others it has been thought a work of art and study, rather than an effort of poetical feeling and fancy, and treats on gardening more as a branch of rural economy than as one of the fine arts. His other Latin poems are sacred elegies, heroic, elegiac, and lyric poems. Father Rapin died at Paris in 1687. He was no les esteemed for his virtues and amiable qualities, than admired for his talents; and he polished all that polish and grace for the society of the great world, which have distinguished this order from other religious communities. His works were collected and published, in 3 vols. 12mo. 1681. There is a fine edition of his "Hororum," published by Brotiol at Paris, in 1786. Rapin was great as a critic, in which line he is known by his "Reflexions sur l'Eloquence, fur la Poésie, fur l'Histoire, et fur la Philosophie," and also by his "Comparaisons de Virgile et d'Homer," printed in 2 vols. 4to. Bayle. Moreci.

Rapin de Thoyras, Paul, well known as the historian of England, was born at Caufres, in Languedoc, in 1661. He was descended from a noble family of Savoy, which came into France in the reign of Francis I., for the sake of professing the reformed religion. The subject of this article, after having received his education, went to his father, who was an advocate in the chamber of the edict of Nantes, for the purpose of studying the law. He was in due time admitted an advocate, but the chamber being suppressed in the same year, he went with his father to Toulouf. On the revocation of the edict of Nantes, in 1685, he withdrew to England, after which he went to Holland, and entered into a company of French cadets at Utrecht. In 1689 he followed the prince of Orange into England, and obtained an encomium in lord kingston's regiment, which went to Ireland. He was engaged in several battles, particularly at the siege of Carrickfergus and Limerick, and at the battle of the Boyne, and so much distinguished himself, that he obtained a captain's commission. In 1693 he was nominated governor to the son of the earl of Portland, reigned his commission to a younger brother, and received from the crown, for his part services, 100l. a year. He travelled to different countries in company with his pupil, and resided with him some time at the Hague. By the death of king William he was deprived of his pension, and his engagement as private tutor being over, he retired, in 1707, to Weif, in the duchy of
of Cleves, where he devoted himself to the composition of the history of England. Here he died in 1725. He had, previously to his decease, published in the year 1717, "Dissertation sur les Whigs et Tories," which was translated into English. His great work, "L'Histoire de l'Angleterre," was printed at the Hague in 9 vols. 4to. in the years 1725-6. It commences with the remotest periods, and is brought down to the proclamation of William and Mary. It has been twice translated into our own language, and was, till the appearance of Hume, the most popular history of England, and Tindal's, or rather Birch's, and other continuations, have been adapted to it. It is written in a proflix and unamiated stile, but deserves the praise of much solid information.

"His work," says an excellent writer, "is of great authority, on account of his perpetual references to original documents, and the ample quotations which he frequently makes from important state papers, confer upon it additional value. He has so copiously detailed the matters which were agitated in the turbulent, but prudent parliament of Charles I., as to give a clear view of the rife of those parties which to this day divide the people of England. On the dark and horrible transactions of the reign of Charles II. he perhaps throws as much light as it is now possible to obtain. In reference to that important period, he has flated historical difficulties with candour, and in discussing the merits and demerits of parties, he has weighed evidence with laudable scrupulousness." (See Shepherd's "Systematic Education.") Rapin, during the collection of his materials, undertook the useful labour of making an "Abrégé de Rymer's Fossae," which was published in Le Clerc's "Bibliothèque Choixée;" and translated into the English by Mr. Stephen Whatley, and published in 1735, under the title of "Acta Regia," and in folio.

RAPINE, RAPINA, in Law. To take a thing in private; against the owner's will, is properly theft; but to take it openly or by violence, is rapino, or robbery.

RAPINIA, in Botany, was so called by Loureiro, Fl. Cochinch. 127, after father René Rapin, a French Jesuit, author of an elegant Latin poem on gardens, who died in 1687, aged 66. If this writer contributed nothing to improve the science of botany, he has, doubtless, helped to promote a love of plants, and may therefore claim a botanical wreath. A Jesuit of his day is doubly entitled to respect, for having, like the good Loureiro, turned his mind to an elegant and improving pursuit, from those two corruptors of the human heart and understanding, political intrigue, and scholastic divinity; in which most of his brethren fought their temporal, and often nobly their eternal, good. The Rapinia of Loureiro however, proved, on the examination of his specimens by the late Mr. Dryander, to be the Sphnuclea of other authors; and this last-mentioned name is now generally adopted. See that article.

RAPINO, in Geography, a town of Naples, in Abruzzo Citra; nine miles S. of Civita di Chieti.

Gen. Ch. Cal. Perianth inferior, of four oblong, spreading, deciduous leaves, gibbous at the base. Cor. cruciform, of four obovate, entire, spreading petals, whose claws are shorter than the calyx. Stam. Filaments fix, about the length of the calyx, the four opposite ones rather the longer; anthers simple. Pet. Germin oblong; style awl-shaped, the length of the calyx; stigma obtuse. Pers. Pouch lenticular, pointed, corrugated, of two cells, and two cohering, not spontaneously separating, coriaceous valves; partition membraneous. Seeds roundish, solitary in each cell; cotyledons flat.

Eff. Ch. Calyx spreading. Pouch of two cells, and two convex valves, not burking.

1. R. paniculatum. Panicked Rapistrum. Ait. n. 2. (R. arvense, folio auriculato acute; Tourn. Infl. 211. Myagrum paniculatum ; Linn. Sp. Pl. 894. Wildl. Sp. Pl. v. 3. 409. Fl. Dan. t. 204. Myagrum simul, frugua rotundata; Bauh. Prodr. 52.)—Native of cultivated fields in various parts of Europe, from Sweden to Greece, but not, as yet, observed in Britain. Root annual, tapering. Stem about two feet high, erect, round, roughish, leavy, branched. Leaves oblong, acute, undivided, rough, somewhat toothed, clasping the item with their arrow-shaped base. Flowers small, yellow, in numerous clusters, which become greatly elongated when in fruit. Pouch scarcely bigger than mustard, a little abrupt, finely reticulated. One of the seeds is often, but not always, abortive. Mr. Brown refers to this genus the Búnia eúspitak of Linnaeus, which agrees with our R. paniculatum in having flat, not spirá, cotyledons, but has otherwise the characters of Búnia.

Rapistrum is also a species of the fow-cabbage, or crumbs.

RAPOLLA, in Geography, a town of Naples, in Basilicata, the see of a bishop, united to Melì; six miles W. of Venosa. N. lat. 45° 58'. E. long. 15° 44'.

RAPORE, a town of Naples, in Principato Ultra; 9 miles E. of Conza.

RaposO, a town of South America, in the country of Popayan.—Allo, a river of Popayan, which runs into the Pacific ocean, N. lat. 3° 48'.—Allo, a small island in the Pacific ocean, near the coast of Popayan. N. lat. 4°.

RAPPAHANOCK, a large navigable river of Virgin- ia, which rises in the Blue Ridge, and runs about 130 miles from N.W. to S.E., and enters into Chesapeak bay, between Windmill and Stingray points. It waters, in its course, the towns of Falmouth, Frederickburg, Port-Royal, Leeds, Tappahannock, and Urbonne.

RAPPE, in Commerce, a money of account in Switzerland, 10 of which are equal to a good hat; and 6 are equal to a plattet, shilling, or escalin. This is the cafe at Basel, but at Lucern the plattet is only 3 rappen, and the Zurich escalin = 32 rappen.

Rappe, in Ichtyology, a name given by some to the capito fluviatili rapas of Gfner, more frequently known by the name of the coropus piceus.

RAPPERSCHWEIT, in Geography, a town of Switzerland, and capital of a distict to which it gives name; situated on the S. side of the lake of Zurich, over which there is a bridge, 1852 paces in length, built in 1358 by the counts of Habsburg. The town was founded in 1091, and formerly had its own counts. In 1358 it was sold to the Sons of Albert, archduke of Austria. In 1464 it put itself under the cantons of Uri, Schwitz, Unterwalden, and Glarus, with a revere of its liberties; but the cantons gradually made themselves masters of it. At the peace of Aarau in 1712, its liberties were restored, though the country remains subject to the sovereignty of Zurich and Berne; 15 miles S.E. of Zurich.

RAPPIN, a town of Anterior Pomerania; 7 miles N. of Bergen.
RAPPO Rappo, a bay on the coast of Mowee, one of the Sandwich islands.

RAPPOLTSKIRCHEN, a town of Austria; five miles S. of Tun.

RAPPORT, Fr. in Myric, is sometimes used for proportion, and sometimes for relation, words which will be explained in their places.

RAPPS, in Geography, a town of Austria, on the river Tay; four miles S.W. of Drofenord.

RAPSO, a town of Ilthia; 52 miles S.E. of Capo d’Ilthia.

RAPTEC, a river of Hindoostan, which runs into the Dewah, five miles S.W. of Sellempour.

RAPTU HEREDIS, in Lavo, an ancient writ which lies for taking away an heir, holding in foage; of which there are two forts; one when the heir is married, the other when not. See Ravishment.

RAPTURE, RAPTURA, an extasy, or transport of mind. See Extasy, Exultation, Rhapsody, &c.

RAPUNCULUS, in Botany, the Rampion, owes its name to a resemblance in the root to a Rape, or oblong Turnip. This root, Campanula Rapunculus of Linneus, is biennial, scarcely larger than a radish, which it resembles also in shape, but the colour is white. Its flavour is sweet and mild, notwithstanding some degree of milkiness in the juice, in which it accords with other, usually bitter and acrid, species of its genus. The Rampion is now much less cultivated than formerly, and almost a stranger at our tables.

RAPUNTUM, a name used by Tournefort and Morison for some plants referred to Lobelia by Linneus. (See Lobelia.) Gortner, having adopted Plumier’s Lobelia, the Linnean Scutella, restores Rapuntum; but such a misnomer could now lose to inconvenience only.

RAPUTIA, so called by Aublet, because the plant grows in the forests of Orope in Guiana. Jullieu and Lamarck have retained this curious name. Schreber has changed it for Scutella; see that article hereafter.

RARAKIT, in Geography, a town of the island of Ceram, at the foot of a mountain covered with trees, which serves as a harbour for pirates.

RARE, in Physics, denotes a body that is very porous, whose parts are at a great distance from one another, and which contains but little matter under a great deal of bulk.

In this sense rare flands opposed to dense.

The corporeal philosophers, e.g. the Epicureans, Gafendorffs, Newtonians, &c. assert that bodies are rarer some than others, in virtue of a greater quantity of vacuum included between their pores. The Cartesians hold, that a greater rarity only consists in a greater quantity of matter subtilis included in the pores. Lastly, the Peripatetics contend, that rarity is a new quality superinduced upon a body without any dependence, either on vacuum, or subtile matter.

RARECOURT, in Geography, a town of France, in the department of the Meuse; 10 miles S.W. of Verdun.

RAREE, a town of Hindoostan, in Concan; 20 miles N.N.W. of Goa.—Also, a town of Hindoostan, in Bahar; 11 miles N.N.W. of Durlungah.

RAREFACTION, Rarefactio, in Physics, the act by which a body is rendered rare; that is, is brought to pollens more room, or appear under a larger bulk, without accession of any new matter.

Rarefaction is opposed to condensation.

Our more accurate writers restrain rarefaction to that expansion of a mass into a larger bulk, which is effected by means of heat. All expansion from other causes they call dilatation.

The Cartesians deny any such thing as absolute rarefaction: extension, with them, constituting the essence of matter, they are obliged to hold all extension equally full.

Hence, they make rarefaction to be no other than an accession of freth, subtile, and infensible matter, which, entering the parts of the body, sufficiently diffuses them. See this disproved under Vacuum.

It is by rarefaction that gunpowder has its effect; and to the same principle also we owe our zolipakes, thermometers, &c.

The degree to which the air is rarefiable exceeds all imagination: Merlennus, long ago, by means of an intense heat, found that air might be rarefied so as to pollens more than seventy times its former space.

Mr. Boyle afterwards found, that air, by its own elasticity, and without the help of any heat, would dilate itself so as to take up nine times its former space; then 31 times; then 60; then 150; at length, by many degrees, he found it would reach to 8000 times; then 10,000, and finally to 13,579.

Such is the rarefaction of common air, from its own principle of elasticity, and without any previous condensation; if but it be compressed, the same author found its greatest space when most rarefied, is to its least when most condensed, as 55,000 to 1.

Such an immense rarefaction, Sir Isaac Newton shews, is inconceivable on any other principle than that of a repelling force inherent in the air, by which its particles mutually fly from one another.

This repelling force, he observes, is much more considerable in air than in other bodies, as being generated from the most fixt bodies, and that with much difficulty, and scarcely without fermentation; those particles being always found to fly from each other with the most force, which, when in contact, cohere the most firmly. See Air.

The members of the French Royal Academy have bestowed much attention on the different rarefacions, or rather the different rarities of the air at different heights. M. Mariotte established this as a principle, from experiments, that the different rarefacions, or condensations, of the air, follow the proportion of the weights with which it is pressed.

Hence, supposing the mercury in the level of the sea suspended to twenty-eight inches, which is the weight of the whole atmosphere; and that fifty feet height of air are equivalent to a line, or one-twelfth of an inch of mercury; so that the barometer, at the height of fifty feet from the sea, would fall a line; it is easy finding what height of air would be equal to a second, or any other line of mercury: for as twenty-eight inches of mercury one-twelfth are to twenty-eight inches, so is the height of sixty feet of air to a fourth term, which is the height of air corresponding to a second line of mercury.

And after the same manner may the height of air corresponding to each line be found, which will make a geometrical progression, the sum of which will be the whole height of the Atmosphere (which see); and, of consequence, a certain part of that sum will be the height of a mountain, at whose top the barometer shall have sunk a certain quantity.

Mellers, Culliini and Maraldi, upon measuring the heights of several mountains, found, that this progression of M. Mariotte was defective; that it always gave the height of the mountains, and consequently the rarefacions, less than they really were; and from some further experiments, M. Amon-
RAS

Ras Mohammed, a cape on the coast of Arabia, in the Red sea. N. lat. 27° 54'.

Ras al Mar, a town of Perßia, in the province of Segelgian; 200 miles S.W. of Zareng.

Ras al Nafoj, a cape of Egypt, in the Red sea. N. lat. 23° 10'.

Ras Rouche, a cape on the E. coast of Arabia. N. lat. 21° 55'.

Ras Viré, a cape on the coast of Arabia, forming the S. point of the gulf of Curia Maria. N. lat. 17° 25'.

Ras Zafrazione, a cape on the coast of Egypt, in the Red sea; 32 miles S.S.E. of Suez. N. lat. 29° 14'.

RASA, a small island in the Indian sea, near the coast of Africa. S. lat. 17° 48'.

RASAIN, a town of Perßia, in the province of Farfallan; 110 miles N.W. of Schiraz or Shiraz.

RASAL, or Rasal-sem, Cape, a cape of Africa, on the coast of Tripoli. N. lat. 32° 36'. E. long. 21° 10'.

RASALEMA, a river of Africa, which waters the city of Fez.

RASALGATA, Cape, or Ras Roufe, a cape on the E. coast of Arabia. N. lat. 22° 24'. E. long. 58° 15'.

RASANT, or Rasant flank, in Fortification. See Flank.

The defence of the baflion is rafant.

RASANT Fire. See Fire.

RASC, in Geography, a river of Servia, which joins the Ibar; 16 miles N.E. of Jenobafar.

RASCETA, a word used by the Arabian physiscons to express the wrift or ankle.

RASCH, in Geography, a town of Bavaria, in the territoty of Nuremberg; two miles S.S.E. of Altorf.

RASCHNA, or RIZANA, a town of Servia; eight miles S. of Parakin.

RASCHWITZ, a town of Bohemia, in the circle of Leitmeritz; four miles E. of Außche.

RASCIA, a port of Servia, watered by the Rasca.

RASCINES, a town of Spain, in the province of Bilbao; 21 miles S.E. of Santander.

RASE, RASARIUM, in our Old Writers, feems to have been a meafure of corn now difufed; toll shall be taken by the rafe, and not by the heap or cantel.

RASE, in the Manoe. To rafe, or glance upon the ground, called in French raser le fapis, is to gallop near the ground, as our English horfes do.

RASEB, Al, in Geography, a fortified pafs in the mountains of Grand Bucharia; 60 miles N. of Vafihgerd.

RASEBORG, a fear-port town of Sweden, in the gulf of Finland; 30 miles S.E. of Abo.

RASEC, a town of Perßia, in the province of Segelgian; 60 miles S.W. of Zareng.

RASGRAD, or RAGHRAT. See HRASGRAD.

RASH, in Clock-Work. See RATCH.

RASH, in Medicine, an erupion or efflofence upon the skin, thrown out in fevres, or forthes.

RASHAUA, in Geography. See RASSAGUL.

RASHED, a town of Nubia, in Sennaar; 15 miles N. of Gefflin.

RASICULMO, Cape, a cape on the N. coast of Sicily. N. lat. 38° 18'. E. long. 12° 49'.

RISTER, or RAZIERE, in Commerce, a meafure of corn in Dunkirk and Flanders. At Dunkirk, they have the fæ raifer, and the land raifer; 8 of the former being = of the latter; 54 farifers or 60 land raifers answer to 31 English quarters. Each faifer contains 9884 inches, and each land raifer contains 8786 inches; 17 40 of the former, and 19 57 of the latter, are equal (each) to 10

English
RAS

English quarters. At Dixmude 29.51 raiieres are equal to 10 English quarters, and each raiiere contains 582 1 inches.

At Gravelines 21.29 raiieres are equal to 10 English quarters, and each contains 8080 inches. At Nieuport 16.93 raiieres are equal to 10 English quarters, and each raiiere contains 10177 cubic inches. At St. Omer 21.77 raiieres = 10 English quarters, and each contains 7900 cubic inches. At Liife or Lille, the raiiere is divided into 8 parts; of these there are two forts, one, used for wheat or rye, the other, called raiiere de Mars, for oats or beans; 38 of the former, and 40 of the latter, are reckoned for one lot. The raiiere of wheat weighs about 128 lbs. and of these are equal to 19 feet, Paris measure, or about 10 English quarters; 39.64 raiieres of Liife are equal to 10 English quarters, and each contains 4339 cubic inches.

RASILIS ÆRUGO, in the Material Medica of the Ancients, one of their kinds of verdigris. It was prepared in the following manner; they took some sharp vinegar over the fire in a strong earthen vessel, and covered it with a bras pot inverted, well cleaned, and without any vent-hole. And after some time the vessels were to be separated; and the verdigris, which was found concreted on the inside of the bras pot, was scraped off, and put up for use.

RASILITA, in Geography, a town of Italy, in Friuli; 26 miles S.S.E. of Friuli.

RASIN, a town of Hindooftan, in Dowlatabad; 18 miles W.S.W. of Carmullah.

RASINTA, a town of Italy, in Friuli; 14 miles N. of Udina.

RASKOW, a town of Poland, in the palatinate of Braclaw; 34 miles S. of Braclaw.

RASMAN, an island in the Red sea. N. lat. 13° 58'.

RASMEND, a mountain of Peru, in the province of Hrakt; 60 miles N.E. of Havelnad.

RASON, an island in the Adriatic. N. lat. 44° 6'.

E. long. 15° 25'.

RASO, or Ell of Turin, in Commerce, is equal to 22 Ge- noeis palms, or 23 English inches; the foot 143.2 French lines, or 37 English inches; hence 180 Piedmontese rai are equal to 119 English yards, and 33 Piedmontese feet = 35 English feet. At Cagliari, 166.7 rai = 100 English yards, and each of them equal to 21.6 English inches. At Chamberry 158.5 rai = 100 English yards, and each = 22.7 English inches. At Nice, 166.7 rai = 100 English yards, and each = 21.6 English inches; 154.5 rai of Turin = 100 English yards, and each = 23.3 English inches.

RASP, a coarse sort of file.

RASCH, in Geography, a town of Austria; eight miles E. of Zwiet.

RASATORIUM, (from rado, to scrape), a surgical instrument with which the peritoome was, by the old practitioners, scraped from the bones, and the bones themselves sometimes rasped.

RASPBERRY BUSH, in Botany. See Rubus.

For the dietetic and medicinal use of raspberries, see Summer Fruits.

RASPECON, in Ichthyology, a name given by some to the uranoscopfe, or stargazer.

RASPENBURG, in Geography, a town of Germany, in the principality of Weimar, near which are some medicinal springs; 12 miles N. of Weimar. N. lat. 51° 13'.

E. long. 11° 35'.

RASPHUYS, or Rasp-houfe, a celebrated work-houfe, or houfe of correction, at Amsterdam. See Work-houfe. Vol. XXIX.

RASPUGLY, in Geography, a town of Bengal; four miles S. of Calcutta.

RASSADES, a cluster of small islands, in the river St. Lawrence. N. lat. 48° 15'. W. long. 68° 48'.

RASSAGU, one of the Kurile or Kurillskoy islands, lying 40 versts from Mutova, and in extent about 30 versts measured either way. It has lofty mountains and steep rocky shores, with very few sandy bogs. On the mountains, here and there, is a good forell-foil, birch, alders, and the nut-bearing pine; the vales and flats abound in herbs. On the land is no other animal besides the fox, but the cliffs of the rock afford nesting-places for all kinds of sea-birds; and the beavers and seals lie scattered on several parts of the island. Here are no trees that yield fish. The Kuril on this island are not numerous, and some of them are baptized.

N. lat. 48° 20'. E. long. 154° 14'.

RASSE CORONE, in Natural History, a name given by the Ceylonoese to a particularly fine kind of cinnamon, which is the bark of a tree, growing nowhere but in that island. The name they give it signifies soap or burning cinnamon. This choice kind was formerly exported annually, in considerable quantity, by the Dutch East India company, who prohibited the mixing any other kind of cinnamon with it, under a very severe penalty. Phil. Trans. No. 409.

RASSOULPOUR, in Geography, a town of Hindooftan, in the Circar of Nagore; 22 miles N.W. of Dild-wana.—Alfo, a town of Hindooftan, in the Circar of Go- hud, on the Jumna; 40 miles E. of Gohud.

RASSOVAT, or Axiospolis, a town of European Turkey, in Bulgaria; 24 miles N. of Dirlata. N. lat. 44° 25'.

E. long. 27° 37'.

RASTADT, a town of the duchy of Baden, situated on a large plain on the river Merg; the town is new, and regularly built, and the principal street is broad and handsome; 16 miles S.W. of Durlach. N. lat. 48° 52'.

E. long. 8° 15'.—Alfo, a town of Bavaria, in the bishohip of Bamberg; five miles N.W. of Bamberg.—Alfo, a town of the duchy of Wurzburg; three miles S. of Melrichshadt.

RASTAGARA, a town of Egypt; 90 miles E. of Cairo.

RASTEDE, a town of Germany, in the county of Oldenburg; 11 miles N. of Oldenburg.

RASTENBURG, a town of Pruffia, in the province of N. Watangen, founded in 1329, and after having been destroyed by the Lithuanians in 1348, was rebuilt, together with its castle, and put into a better state of defence; it is enclosed by a wall, and, in 1666, surrounded by a rampart. The burghers, most of whom are Lutherans, are about 200. The inhabitants derive their subsistence from a little commerce, breeding, agriculture, and mechanic trades; 46 miles S.E. of Königsberg. N. lat. 53° 58'.

E. long. 21° 27'.

RASTICO HARBOUR, Grand, a bay in the gulf of St. Lawrence, on the N. coast of the island of St. John. N. lat. 46° 23'.

W. long. 62° 50'.

RASTORFF, a town of Austria; seven miles E. of Ehrenprunn.

RASTOWICA, a river of Poland, which runs into the Dnieper, on the borders of Russia.

RASURA, a word used by the pharmacutic writers to express the shavings of woods, or other hard substances, to make them readily yield their virtues by decoction. Physicians also use it to express the corrosion of acrid humours.

RASURE in a Deed, in Law. See DEED.

RASZNA, in Geography, a town of Servia; 24 miles N. of Niffa.

RAT, in Zoology. See Mus.
It has been observed that this country was formerly infested with two kinds of rats, the house-rat and the water-rat; but that it is believed that the latter, within this last half century, has destroyed the former. This is probably, however, only imaginary, since it is well known that the house-rats are frequently brought, in great abundance, into the different sea-ports of the kingdom, in corn, and other vessels. It seems not improbable, but that these different varieties of rats may intermigrate, and that the latter become house-rats, as there is considerable diversity in the colour of the house-rats, some approaching to nearly black, which is the natural colour of the water-rat, while the genuine house-rat is always of a darkish or dapple brown. In their habits they have some circumstances in which they agree, as in that of making burrows in the ground; but the water-rat is capable of living much in the water, and of feeding on fish and other aquatic animals, while the house-rat mostly lives upon grain, and other produce of that kind.

The water-rats are also said, by Dr. Darwin, to eat the foliage as well as the seeds and fruits of vegetables, as he has seen a young rat of this kind devour a large leaf of the water-plantain (alisma plantago). They likewise, as well as the house-rats, are destructive of young animals, such as ducklings, goslings, chickens, and rabbits. But the great mischief which the water-rats produce, is in feeding on, and destroying, the roots of a great variety of vegetables, in their innumerable burrows. The above writer has been known to have seen some new-planted apple-trees taken out of the ground with nearly the whole of their smaller roots eaten, and the larger ones peeled by them. With the house kind, they are, likewise, extremely destructive of the food of poultry, and swine, and of course are highly detrimental near waters. It is remarked by the above able writer, that as these animals, like the dog, are of a lascivious nature, and, as some materials have a strong scent, resembing, perhaps, that of their venereal organs, they are liable to be attracted by such smells, as dogs are, on the same account, he supposes, inclined to roll themselves in putrid carrion; and male cats to eat marum valerian, and cat-mint. It is of this principle that rat-catchers avail themselves, and by inducing the propensity, deceive them to their destruction, by blending with their favourite foods different strong-scented substances, such as the essential oil of rhodium, or musk, with the poisonous powders of ilychnos mus vonica, or of delphinum litavgiaria, or perhaps of arsenic.

The first step taken by rat-catchers, in order to clear a house, &c. of those vermin, is to allow them all together, to one proper place, before they attempt to destroy them; for there is such an instinctive caution in these animals, accompanied with a surprising facility in discovering any cause of danger, that if any of them be hurt, or purloined, in an unusual manner, the rest take the alarm, and become so shy and wary, that they elude all the devices and stratagems of their pursuers for some time after. The place where the rats are to be assembled, should be some closet, or small room, into which all the openings, but one or two, may be secured; and this place should be, as near as may be, in the middle of the house, or buildings. It is the practice, therefore, to attempt to bring them all together in some such place before any attempt be made to take them; and even then to avoid any violence, hurt, or fright to them, before the whole be in the power of the operator. In respect to the means used to allure them to one place, they are various; one of those most easily and efficaciously practised is the trailing some piece of their most favourite food, which should be of the kind that has the strongest scent, such as toadled cheese, or broiled red-herring, from the holes or entrances to their accidies in every part of the house, or contiguous buildings, whence it is intended to allure them. At the extremities, and in different parts of the course of this trailed tract, small quantities of meal, or any other kind of their food, should be laid, to bring the greater number into the tracks, and to encourage them to pursue it to the centre place, where they are intended to be taken; at that place, where time admits of it, a more plentiful repast is laid for them, and the trailing repeated for two or three nights. But besides this trailing, and way-baiting, some of the most expert of the rat-catchers have a shorter, and, perhaps, more effectual method of bringing them together, which is, the calling them, by making such a kind of whistling note as resembles their own call, and by this means, with the assistance of the way-batts, they call them out of their holes, and lead them to the repast prepared for them at the place designed for taking them. But this is much more difficult to be practised than the art of trailing; for the learning the exact notes, or cries, of any kind of heads or birds, so as to deceive them, is a peculiar talent, not easily attained to in other cafes.

And in practising either of these methods great caution must be used by the operator to suppress, and prevent, the scent of his feet and body from being perceived; which is done by overpowering that scent by others of a stronger nature. In order to this the feet are to be covered with cloths rubbed over with allfatetids, or other strong smelling substances; and even oil of rhodium is sometimes used for this purpose, but sparingly, on account of its dearness, though it has a very alluring, as well as disgusting effect. If this caution of avoiding the scent of the operator's feet, near the track, and in the place where the rats are proposed to be collected, be not properly observed, it will very much obstruct the success of the attempt to take them; for they are very shy of coming where the scent of human feet lies very fresh, and intimates, to their fagacious instinct, the presence of human creatures, whom they naturally dread. To the above-mentioned means of alluring by trailing, way-baiting, and calling, is added another of very material efficacy, which is the use of oil of rhodium, which, like the marum valerian, is a very extraordinary and fascinating power on these animals. The oil is extremely dear, and therefore very sparingly used. It is exhaled in a small quantity in the place, and at the entrance of it, where the rats are intended to be taken, particularly at the time when they are to be left brought together in order to their destruction; and it is used also, by inuring it on the surface of some of the implements used in taking them, by the method before described, and the effect it has in taking off their caution and dread, by the delight they appear to have in it, is very extraordinary.

It is usual, likewise, for the operator to disguise his figure as well as scent, which is done by putting on a gown or cloak, of one colour, that hides the natural form, and makes him appear like a poul, or such inanimat thing; which habit must likewise be scented as above, to overpower the smell of his person; and besides this he is to avoid all motion, till he has secured his point of having all the rats in his power. When the rats are thus enticed and collected, where time is afforded, and the whole in any house or out-buildings are intended to be cleared away, they are suffered to regale on what they most like, which is ready prepared for them; and then to go away quietly for two or three nights; by which means those which are not allured the first night are brought afterwards, either by their fellows, or
the effects of the trailing, &c. and will not fail to come duly again, if they are not disturbed or molested. But many of the rat-catchers make shorter work, and content themselves with what can be brought together in one night or two; but this is never effectual, unless where the building is small and entire, and the rats but few in number.

With respect to the means of taking them when they are brought together, they are various. Some entice them into a very large bag, the mouth of which is sufficiently capacious to cover nearly the whole floor of the place where they are collected; which is done by spreading some veal, placed in the middle of the bag, with oil of rhodium, and laying in the bag baits of proper food. This bag, which before laid flat, becomes gathered, with the mouth spread open, is to be suddenly closed when the rats are all in it. Others drive or frighten them, by flight noises or motions, into a bag of a long form, the mouth of which, after all the rats are come in, is drawn up to the opening of the place by which they entered, all other ways of retreat being secured. Others, again, intoxicate or poison them, by mixing with the repast prepared for them the cocculus indicus, or the nux vomica. A receipt for this purpose has appeared, which directs four ounces of cocculus indicus, with twelve ounces of oatmeal, and two ounces of treacle or honey, to be made up into a moist pate with strong beer: but if the nux vomica be used, a much less proportion will serve than is here given of the cocculus. Any similar composition of these drugs, with that kind of food the rats are most fond of, and which has a strong flavour, to hide that of the drugs, will equally well answer the end. If, indeed, the cocculus indicus be well powdered, and infused in strong beer for some time, at least, half the quantity here directed will serve as well as the quantity before mentioned. When the rats appear to be thoroughly intoxicated with the cocculus, or sick with the nux vomica, they may be taken with the hand, and put into a bag or cage, the door of the place being first drawn to, lest those which have strength and fكنfe remaining should escape. By these methods, when well conducted, a very considerable part of the rats in a farm, or other house, and the contiguous buildings, may be taken and destroyed. But various other methods have been practised.

In the Transactions of the Bath Agricultural Society, the following compositions are advised for destroying these mischiefive creatures, and which are stated to have been attended with great success. First, to a quart of oatmeal, add six drops of oil of rhodium, one grain of muffle, and two or three of the nuts of nux vomica finely powdered; make them into pellets, and put them into the rat-holes. This, it is said, was at first greedily eaten, and did great execution; but the wife animals, after a time, ceased to eat it. Secondly; this composed of three parts of oatmeal and one of flave's acre, mixed well into a pate with honey. Pieces of this pate were laid in their holes, and again did great execution. Thirdly; this is a method of destroying them by laying a large box down on its front side, with the lid supported open by a string over a pulley; and by trailing toadish cheese and a red-herring from their holes to this box, and placing oatmeal and other food in it, which they are for a few nights to be permitted to eat unmolested; and finally, to watch them by moon-light, the inside of the box being painted white; and, when many of them are seen, to let down the lid; by which contrivance sixty of them are stated to have been taken at one time. But though the usual ways of destroying rats are by traps and poison, Mr. Forlthy advises never to use arsenic, or corrosive sublimate, for that purpose, except under particular circumstances, as they are deadly poisons: nux vomica will, he thinks, generally answer the end as well, without the danger. He suggests it as a very good plan, to prevent accidents, to enchoice the traps in cafes, having holes in the ends of them large enough to admit rats, but small enough to exclude dogs, cats, &c. And that, as a bait for rat-traps, the following composition may be made use of with advantage. Take a pound of good flour, three ounces of treacle, and six drops of the oil of caraways: put them all in a dish; and rub them well together till they are properly mixed: then add a pound of crumb of bread. The traps baited with this mixture should be set as near their haunts as possible; but, for two or three days, so as not to fall or strike on the rats going in, but letting them have free liberty to go in and out at pleasure, as this makes them saucers. Some of the bait should also, he thinks, be laid at the rat-holes, and a little of it scattered quite up to the traps, and so on to the bridge of each trap, where a handful may be placed. It may also, he thinks, be proper to fasten the traps with the following mixture, for the purpose of enticing the rats into them. Take twenty drops of the oil of rhodium, five or seven grains of musk, and half an ounce of oil of aniseed; put them in a small phial, and shake it well before using; then dip a piece of twisted paper or rag in the mixture, and rub each end of the trap with it, if a box trap, and put two or three drops on the bridge, leaving the paper or rag in the trap. Of whatever kind the trap is, it should be scented; but once in a twelvemonth will be sufficient. Then throw some chaff mixed with a little wheat about the bottom of the trap, in order to deceive the rats; for they are very fagacious, and will not enter a suspicious place. This will be necessary to be done only at the first time of setting the traps; for, after some rats have been caught and have watered and dunged in them, rats will enter boldly when they find others have been there before them; do not, therefore, wash or clean out the trap, as some people do before they set it again, but let the dung and urine remain in it. Keep the places where the traps are set as private as possible; and when they are set for catching, mix no bread with the bait, as the rats will, in that case be apt, to carry it away.

And it is useful, this writer remarks, when the holes are found quiet, and that no rats use them, to fill them up with the following composition. Take a pint of common tar, half an ounce of pearl-ashes, an ounce of oil of vitriol, and a good handful of common salt, mix them all well together in an old pan or pot. Take some pieces of paper, and lay some of the above mixture very thick on them; then fill the holes well up with them, and build up the mouth of the holes with brick or stone, and mortar; if this be properly done, rats will, he affirms, no more approach these while either smell or taste remains in the composition.

But with a view to destroy rats in places where traps cannot be set, it is recommended to take a quart of the above bait, then to raft into it three nuts of nux vomica, and add a quarter of a pound of crumb of bread, if there was none before; mix them all well together, and lay it into the mouth of their holes, and in different places where they fre-quent; but first give them of the bait without nux vomica, for three or four succeeding nights; and when they find it agrees with them, they will eat that mixed with the nut with greedines.

However, as it is frequently found that rats are very troublesome in fews and drains, in such cafes arfenic may be used with success in the following manner. Take some dead rats, and having put some white arfenic, finely powdered, into an old pepper-box, shake a quantity of it

5 L. 2
on the fore-parts of the dead rats, and put them down the
holes, or avenues, by the sides of the fewers at which they
come in; this puts a stop to the live ones coming any further:
for when they perceive the arfenic, they will retire imme-
diately; whereas, if they were put down without the arfenic,
the live ones would eat them.

It is by means of arfenic, notwithstanding the above ob-
ervations, that the most certain method of deſtruying these
troubleſome vermin, (provided they can be made to eat it,) 
takes place; which we have found to anſwer best, when it is
prepared by being finely levigated, and mixed up with very
strong old cheefe and oatmeal.

In a note in the Agricultural Survey of Lancashire, it is
rated, that it is greatly to be lamented that Mr. Heath-
cote’s method of deſtruying rats and mice is not generally
known and practifed; if it were, there would be a total ex-
tirpation of those obnoxious and destructive animals; for in
one night he totally destroys them (where he is employed),
be they ever so numerous, as can be well attedled by hundreds
in the neighbourhood of Ormskirk, who have employed
him. And it is added, that the compofition he makes ufe
of he puts in their holes and burrows, and from the small
quantity he uſes, it is alſonſhing it ſhould have ſuch an eſfect:
it will keep good two years. It is alſo itated, that a farmer
recommends, for the deſtruction of rats, one ounce of pounded
quick-lime to four ounces of tallow cake, to be beaten toge-
ther and made into balls, and placed in their runs, which has
clearly many buildings. But it has been proved by expe-
tience, is it said, that an ounce of aerated barytes finely
powdered, mixed with the tallow, in place of lime, is more
effeſtual. And it has been remarked by the author of Phy-
tologia, with the view of deſtruying the water-rats, that
they poſsefs some kind of ingenuity ſimilar to the beaver in
the construction of their houses near the brinks of rivers and
pools; which have two apertures, one above ground
amongst the grafs, and the other beneath the ſurface of the
water; and unleſ they can hide their upper opening amid
weeds, or grafs, they forfaie the ſituation. Thus, if a
rim, three or four feet in breadth, round a fish-pond be kept
fo low as to rife onlty two, three, or four inches above the
level of the water; and if this be kept clean from high grafs
or weeds, the rats will defert the pond.

But after all, it is probable that this highly deſtructive
animal, and great peſt to the farmer, might be moſt readily
exterminated by parifhes uniting for the purpoſe, and rai-
ing certain fums of money to be applied in this way, under
the direcțion of a proper perfon who is fully acquainted with
the bufneſs.

In many grafs and other diſtricts in the kingdom these
animals prevail very much, efpecially the grey kind, parti-
cularly in all those where there are no regular railed fiadles
or iflands for the graſs to rye upon, which is the cafe in a
graſs in a great number. The miſchief, injury, and deſtruction
of graſs which is produced in this way, is ſcarcey to be cal-
culated; and they are besides very miſchievous, troubleſome,
and inconvenient in several others; so that they ſhould be ev-
ery where extirpated as much as poſsible. And in corn
traits, iflands or fiadles ſhould every where he provided in
order to prevent miſchief being done by them. See Ver-
min, and Stand, Corn.

A gunner's quarter-gunners, seventy-four through left hwd; them all of the gunner's or Watch, in then and They.

RATAN, in Geography, a small island on the W. side of the gulf of Bothnia. N. lat. 63° 58'. E. long. 20° 39'.

RATCH, or RASH, in Clock Work, a sort of wheel having twelve fangs, which serve to lift up the detents every hour, to make the clock strike.

RATCHETS, in a Watch, are the small teeth at the bottom of the fusee, or barrel, which flop it in winding up.

RATCHIN LOGA, in Geography, a large lake of Thibet. N. lat. 35° 43'. E. long. 82° 27'.

RATCLIFF, a town of America, in Maryland; 22 miles S. of Salisbury.

RATE, a standard or proportion, by which either the quantity or value of a thing is adjusted.

The rates of bread, &c. in London, are fixed by authority. See AYliffe of Bread.

The rates of interest, as now established by law in England, is five per cent. The rate of interest in Italy, is three per cent.; in Sweden, six; in France, five; in Spain, ten; in Barbadoes, ten; in Ireland, twelve; in Turkey, twenty. Low rates of interest advance the prices of land.

The rates or fares of hackney-coachmen, chairmen, and watermen, are fixed by act of parliament. See Hackney Coaches, &c.

The rates of exchange, factorship, &c. are different. See Exchange, Factorage, &c.

Rate of a Ship of War, is its order, degree, or distinction, as to magnitude, burden, force, &c.

The British fleet is accordingly distributed into fix rates, exclusive of the inferior vessels that usually attend on naval armament; as sloops of war, armed ships, bomb-ketches, fire-ships, and cutters or schooners, commanded by lieutenants.

Ships of the first rate mount a hundred cannon, and some more, having forty-two-pounders on the lower deck, twenty-four-pounders on the middle deck, twelve-pounders on the upper deck, and fix-pounders on the quarter-deck and forecastle. They are manned with eight hundred and fifty men, including their officers, seamen, marines, and servants.

In general, the ships of every rate, besides the captain, have the master, the boatwain, the gunnner, the chaplain, the purser, the surgeon, and the carpenter; all of whom, except the chaplain, have their mates or assistants, in which are comprehended the fail-maker, the master at arms, the armourer, the captain's clerk, the gunsmith, &c. The number of other officers is always in proportion to the rate of the ship. Thus, a first rate has six lieutenants, fix master's mates, twenty-four midshipmen, and five surgeon's mates, who are considered as gentlemen; besides the following petty officers: quarter-masters, and their mates, fourteen; boatwain's mates, and yeomen, eight; gunnner's mates and assistants, fix; quarter-gunnerns, twenty-five; carpenter's mates, two, besides fourteen assistants; with one steward, and steward's mate to the purser.

Ships of the second rate carry ninety-eight and ninety

guns upon three decks; of which those on the lower battery are thirty-two-pounders; those on the middle, eighteen-pounders; on the upper deck, twelve-pounders; and those on the quarter-deck, fix-pounders, which usually amount to four or fix. Their complement of men is seven hundred and fifty, in which there are six lieutenants, four master's mates, twenty-four midshipmen, and four surgeon's mates, fourteen quarter-masters and their mates, eight boatwain's mates and yeomen, fix gannon's mates and yeomen, with twenty-two quarter-gunnerns, two carpenim's mates, with ten assistants, and one steward and steward's mate.

Ships of the third rate carry from sixty-four to eighty cannon, which are thirty-two, eighteen, and nine-pounders. The eighty-gun ships, however, begin to lose their repute, and give way to those of seventy-four, seventy, &c. which have only two whole batteries; whereas the former have three, with twenty-eight guns planted on each; the cannon of their upper deck being the same as those on the quarter-deck and forecastle of the latter, which are nine-pounders.

The complement in a seventy-four is fix hundred and fifty; and in a sixty-four, five hundred; having in peace, four lieutenants, but in war, five, and when an admiral is abroad, fix. They have three master's mates, sixteen midshipmen, three surgeon's mates, ten quarter-masters and their mates, six boatwain's mates and yeomen, four gannon's mates and yeomen, with eighteen quarter-gunnerns, one carpenter's mate with eight assistants, and one steward and steward's mate under the purser.

Ships of the fourth rate mount from sixty to seventy guns, upon two decks and the quarter-deck. The lower tier is composed of twenty-four-pounders; the upper tier, of twelve-pounders; and the cannon on the quarter-deck and forecastle are fix-pounders. The complement of a fifty-gun ship is three hundred and fifty men, in which there are three lieutenants, two master's mates, ten midshipmen, two surgeon's mates, eight quarter-masters and their mates, four boatwain's mates and yeomen, one gannon's mate and one yeoman, with twelve quarter-gunnerns, one carpenter's mate and fix assistants, and one steward and steward's mate.

All vessels of war under the fourth rate, are usually comprehended under the general name of frigates, and never appear in the line of battle. They are divided into the fifth and sixth rates, the former mounting from forty to thirty-two guns, and the latter from twenty-eight to twenty. The largest of the fifth rate have two decks of cannon, the lower battery being of eighteen-pounders, and that of the upper deck of nine-pounders; but those of thirty-fix and thirty-two guns have only one complete deck of guns, mounting twelve-pounders, besides the quarter-deck and forecastle, which carry fix-pounders. The complement of a ship of forty-four guns is two hundred and eighty men; that of a frigate of thirty-fix guns, two hundred and forty men. The first has three, and the second two lieutenants; and both have two master's mates, fix midshipmen, two surgeon's mates, fix quarter-masters and their mates, two boatwain's mates and one yeoman, one gannon's mate and one yeoman, with ten or eleven quarter-gunnerns, and one purser's steward.

Frigates of the sixth rate carry nine-pounders; those of twenty-eight guns having three-pounders on their quarter-deck, with two hundred men for their complement; and those of twenty-four, one hundred and fifty men; the frigate has two lieutenants; the latter, one; and both have two master's mates, four midshipmen, one surgeon's mate, four quarter-masters and their mates, one boatwain's mate and one yeoman, one gannon's mate and one yeoman, with six or seven quarter-gunnerns, and one purser's steward.

The
The flops of war carry from eighteen to eight cannon; the largest of which have fix-pounders; and the smallest, 8 in. those of eight or ten guns, four-pounders. Their officers are generally the same as in the sixth rates, with little variation; and their complements of men are from one hundred and twenty to sixty, in proportion to their force or magnitude.

Bomb-veils are on the same establishment as floops; but fire-ships and hospital-ships are on that of fifth rates. If the dimensions of all ships of the same rate were equal, it would be easy to collect them into one point of view in a table; but as there is no invariable rule for the general dimensions, we shall select those of fame of a late construction in each rate.

Ships of one hundred guns, and above, and downwards to sixty-four, are termed ships of the line.

Ships of the line, fifties, frigates, and royal yachts, are commanded by post-capitains; floops of war, bombas, fireships, armed ships, fire-ships, and armed en fluit, under fifty guns, by commanders; schooners, cutters, &c. by lieutenants; flagship-ships occasionally by masters; and small craft by midshipmen, who have passed for lieutenants.

Ships of the second rate, and those of the third, which have three decks, carry their sails remarkably well, and labour very little at sea. They are excellent in a general action, or in cannonading a fortres. Those of the third rate, which have two tiers, are fit for the line of battle, to lead the convoys and squadrons of ships of war in action; and, in general, to suit the different exigencies of the naval service. The fourth rates may be employed on the same occasions as the third rates; and may be also defined for service among the foreign colonies, or on expeditions of great distance; since these veils are usually excellent for keeping and maintaining the sea. Veils of the fifth rate are too weak to suffer the shock of a line of battle; but they may be defined to lead the convoys of merchant ships, to protect the commerce in the colonies, to cruise in different stations, to accompany squadrons, or be sent express with necessary intelligence and orders. The fame may be observed of the sixth rates.

The frigates which mount from twenty-eight to thirty-eight guns upon one deck, with the quarter-deck, are extremely proper for cruising against privateers, or for short expeditions, being light, long, and usually excellent sailors.

**RAT

**RATENSTADT,** in Geography, a town of Hindoostan, in Mysoor; 25 miles E. of Ratnagiri.

**RATEEN,** or **RATTEN,** in Commerce, a thick woolen stuff, quilted, woven on a loom with four treads, like fergins, and other stuffs that have the whole or quilling.

There are some rates drefled and prepared like cloths; others left finfly in the hair; and others where the hair, or knap, is frized.

Rateens are chiefly manufactured in France, Holland, and Italy; and mostly used in linings.

The frize is a fort of coarse rateen; and the drugget is a rateen half linen, half woolen.

**RATEIL,** in Zoology, a name given by the Hottentots to an animal inhabiting the Cape of Good Hope, which lives on honey, and is a great enemy to bees: hence called the Viverra Melivora; which see. It has a blunt black nose; no external ears, but a small rim round the orifice; a rough tongue, short legs, very long claws, which are straight like those of a badger, and guttered beneath; the colour of the forehead, crown, and whole upper part of the body, is a cinereous grey; the cheeks, and space round the ears, throat, breast, belly, and limbs, black; from each ear to the tail extends along the sides a dusky line, leaving beneath another of grey. Its length from the nose to the tail is forty inches, and the tail twelve.

This animal preys in the evening, and ascends to the highest parts of the desert to look about; and will then put one foot before its eyes, to prevent the dazzling of the sun. The reason of its going to an eminence is for the sake of hearing or observing the honey-guide cuckoo, or cuculus indicator, which lives on bees, and, as it were, conducts it to their haunts. Pennant.

**RATENSTADT,** in Geography, a town of Hungary; 16 miles S.E. of Baes.

**RATESPONDE de Mulher,** a town of Portugal, in the province of Entre Duero e Minho; 15 miles N.E. of Villa de Conde.

**RATH,** a word used in the composition of names of places in Ireland, as Rathdrum, &c. It signifies an intrenchment, or fort.

**RATH,** ripe, in Agriculture, a term applied to some early ripe corn crops, and which have a degree of rind on the straw; such as some varieties of barley, &c.

**RATHANGAN,** in Geography, a poft-town of the county of Kildare, Ireland, situated on the Athy branch of the Grand Canal; 28½ miles W. from Dublin, and 5 miles N.N.W. from Kildare.

**RATHCONRATH,** a small town of the county of Weithmarch, Ireland, which gives name to a barony. It is 44 miles N. by W. from Dublin, on the road to Lanefborough, and 6 miles W. from Mullingar.

**RATHCOOLE,** a small poft-town of the county of Dublin, Ireland, where fairs are held for cattle and pedlars' wares. It is on the great southern road, 7½ miles S.W. from Dublin.

**RATHCORMUCK,** a poft-town of the county of Cork, Ireland, which returned two members to the Irish parliament, before the union. It has gone much to decay, in consequence of the prosperity of Fermoy, which is little more than three miles distant. It is near the river Bride, 111 miles S.W. from Dublin, and 135 N.E. from Cork.

**RATHDOWNY,** a poft-town of the Queen's county, Ireland; 89 miles S.W. from Dublin.

**RATHDRUM,** a poft-town of the county of Wicklow, Ireland, situated on the river Owen. It has a monthly fair.
fair for flannels, of which there is a considerable manufacture. The adjoining country is very interesting, and the Wicklow copper-mines are not far distant. Rathdrum is 29 miles S. from Dublin.

RATHENAUN, or Ratemao, a town of the middle mark of Brandenburg, on the Havel; 38 miles W. of Berlin. N. lat. 52° 38'. E. long. 12° 32'.

RATHER, or Neather, a river of England, which runs into the Lune, four miles N. of Kirkby Lonsdale, in the county of Westmoreland.

RATHERIUS, in Biographia, a very learned prelate in the tenth century, commenced his ecclesiastical career by embracing a monastic life at the abbey of Lobbes, or Laubes, in Flanders. Here he distinguished himself by his abilities and acquirements. In the year 928, after Hilduin had been driven out of the see of Liege, he accompanied him into Italy; and in 931 he was, by the express order of the pope, put in possession of the see of Verona. As, however, this was in direct hostility to the king of the country, he was exposed to much persecution, and at length banished from Italy. After spending five years in exile, he returned with the hope of regaining his bishopric; but he was unsuccessful, and was ordered to withdraw. He obeyed, and retired into Provence; from this place he went to the abbey of Lobbes, where the recollection of the honour, which he had formerly reflected on that establishment, secured him a welcome reception. Shortly after this, he was sent for by the emperor Otto, who placed him near the perfon of his brother Bruno. This prince, having been made archbishop of Cologne in the year 953, presented Rathesius to the bishopric of Liege; from which, however, he was driven in about two years. As the emperor Otto was at this time in Italy, our prelate made an effort to recover his former see of Verona. Accordingly he laid his case before a synod assembled at Pavia, which passed a decree that he should be re-established in that bishopric. His peace was soon interrupted by controversy with the clergy, who could not endure his reproofs of their irregularities and corruptions; till at length they became so irksome to him, that he determined to take his final leave of Italy. He accordingly went to France, where he purchased some estates, and obtained the abbies of St. Amand, Aumont, and of Anay. He died at Nanter, about the year 973. His works are numerous, some of which are inserted in father d'Achery's "Spicilegum." They are said to afford evident proofs of great sagacity and judgment, while they breathe throughout an ardent love of virtue. They also shew, that he was not devoid of zeal and intrepidity in exposing the irregularities and vices of the times, and particularly the corrupt morals of ecclesiastics. Moreni. Molheim.

RATHFRILAND, in Geography, a poll-town of the county of Down, Ireland. It is situated on a rising ground, and has four great straight roads leading up to it, and centering in the town. It is on the road to Downpatrick, and much frequented. The neighbourhood abounds with granite of a close texture, and fit for building. On the summit of the hill are the ruins of a castle, formerly one of the residences of the Magunnes, lords Iveagh. Rathfriland is 57½ miles N. from Dublin, and 7½ miles N.E. from Newry.

RATHKEALE, a poll-town of Ireland, in the county of Limerick. It is situated on the river Deel, and was formerly a corporation town, and of much more consequence than at present. It has several fairs, one of which for horses is much frequented, as also its races. In the reign of queen Elizabeth, it sustained an attack of the English army. The ruins of a priory, founded by a perfon of the name of Harvey, are still remaining. Rathkeale is 108 miles S.W. from Dublin, and 14 miles W.S.W. from Limerick.

RATHLACKEN, a post-town of the county of Mayo, Ireland, on the sea-coast, not far from Rathlacken or Re-lakin head, and west of the entrance to Killala bay. It is 132 miles W.N.W. from Dublin, and 5 miles N. from Killala.

RATHLIN, Raghill, or Raghely, an island situated between the north coast of Antrim, in Ireland, and Scotland, and confidered as belonging to the former. It is about five miles in length, and three quarters of a mile in breadth, being bent in an angle towards the middle. This angle lies opposite to Ballycastle, and forms a tolerable bay, called Church bay; but in a westerly wind, though the anchorage is good, few vessels can ride it out, from the swell along the coast. The number of plantation acres is about 2000, which support a population of about 130 or 140 families, amounting to about 1100 persons. The cultivated land is kindly enough, and produces excellent barley. But kelp is the great source of wealth to this island, 100 tons of which have been exported from it in one year. The horses, as well as the sheep, are small, but serviceable; and the black cattle are not large, though they do well when brought to the main land, and better foil. The inhabitants are a little hot, licentious, and honest race of people, much attached to their own island, and regarding Ireland as a foreign country. The monuments of antiquity are small tumuli, in one of which, when opened, a stone coffin was found, beside which an earthen vessel was placed. Within the tumuli lay a considerable number of human bones, which might have been the remains of more ignoble men than the person whose remains the coffin covered. Brazen swords and spear-heads have also been found. The remains of a fortres are visible, where Robert Bruce is said to have defended himself for some time, when obliged to fly from his country. N. lat. 55° 20'. W. long. 6° 6'.

RATHMANSFORD, a town of Silezia, in the principality of Neisse; 4 miles N.N.W. of Weidenaus.

RATHOWEN, a poll-town of the county of Wexford, Ireland, near the borders of Longford; 48 miles W.N.W. from Dublin.

RATHSCHACH, or Radesche, a town of the duchy of Carniola, on the Save; 9 miles W.N.W. of Gurkfeld.

RATHSPRESENTGERS, in Commerce, silver coins of Aix-la-Chapelle, being double, single, or half pieces of 22, 16, and 8 marks. By the aysay, the rathspresentger is worse than the English standard of 11 oz. 2 dwt., by 4 oz. 2 dwt. Its weight is 4 dwt. 1½ gr.; its content in pure silver 56.9 grs.; and its value in sterling 8d. The double of the same is worse by 2 oz. 15 dwt.; its weight 6 dwt. 23½ grs.; its content in pure silver 116.3 grs.; and its value in sterling 1s. 43d. This coin bears on one side an eagle within a circle, marked 16 on his breast, (52 on the double piece), and within another circle the legend, REGNUM CURIA PRINCIPALIS PRIMA; and next the edge, URBS AQUENSIS. URBS REGALIS. REGNISEDIS; on the other side, or reverse, an altar, with two swords and a crown over it, on the double piece; but on the single, a crown and the date within a circle; the legend on both is LOCUS CESAREA CORONATIONIS; Caesar being a general title for the emperor. Kelly's Un. Cambit.

RATI, in Geography, a small island in the Grecian Archipelago, near the S. coast of Nicaria.

RATIBOR, a town of Silezia, in a principality of its name, on the Oder, which here becomes navigable; 70 miles
The principality is bounded N. by the principality of Oppeln, on the E. by Poland, on the S. by Telfchen, and on the W. by the principality of Jagendorf. Its soil is better than that of Oppeln, as it produces a sufficient supply of wheat, rye, and barley, with fruits; and besides, it has also good pasturage grounds. Its only river is the Oder, which passes through its western part; but it is abundantly watered in all its parts with streams, ponds, and lakes. It contains only three cities, and the inhabitants are universally Polish. It became a principality in 1288, and about 200 years afterward it was united to Oppeln, from which it has never been separated.

**RATIFICATION, Ratification**, an act, approving of, and confirming, something done by another, in our name.

A treaty of peace is never secure till the princes have ratified it.

All procuration imports a promise of ratifying and approving what is done by the proxy, or procurator: after treating with a procurator, agent, factor, &c. a ratification is frequently necessary on the part of his principal.

**Ratification** is particularly used, in our Law, for the confirmation of a clerk in a benefice, prebend, &c. formerly given him by the bishop, &c. where the right of patronage is doubted to be in the king.

Ratification is also used for an act confirming something we ourselves have done in our own name.

An execution, by a major, of an act passed in his minority, is equivalent to a ratification.

**RATING.** See Rating.

**RATINGEN, or Ratingen,** in Geography, a town of the duchy of Berg; 4 miles N.E. of Duffeldorp. N. lat. 51° 3'; E. long. 6° 47'.

**RATINO,** a town of Naples, in the county of Molife; 6 miles S.E. of Molife.

**RATIO, in Arithmetic and Geometry,** that relation of homogeneous things, which determines the quantity of one from the quantity of another, without the intervention of any third.

The homogeneous things, thus compared, we call the terms of the ratio; particularly that referred to the other, we call the antecedent; and that to which the other is referred, the consequent.

Thus, when we consider one quantity by comparing it with another, to see what magnitude it has in comparison of that other; the magnitude this quantity is found to have in comparison with it, is called the ratio of this quantity to that; which some think would be better expressed by the word comparison.

Euclid defines ratio by a mutual relation of two magnitudes of the same kind in respect of quantity. But this definition is found defective; there being other relations of magnitudes which are constant, yet are not included in the number of ratios: such as that of the right line, to the line of the complement in trigonometry.

Hobbes endeavoured to improve Euclid’s definition of ratio, but without success; for in defining it, as he does, by the relation of magnitude to magnitude, his definition has not only the same defect with Euclid’s, in not determining the particular kind of relation; but it has this farther, that it does not express the kind of magnitudes which may have a ratio to one another.

Ratio is frequently confounded, though very improperly, with proportion. Proportion, in effect, is an identity or similarity of two ratios.

Thus, if the quantity A be triple the quantity B; the relation of A to B, i.e. of 3 to 1, is called the ratio of A to B. If two other quantities, C, D, have the same ratio to one another that A and B have, i.e. be triple one another, this equality of ratio constitutes proportion; and the four quantities A : B :: C : D, are in proportion, or proportional to one another.

So that ratio exists between two terms; proportion requires more.

There is a twofold comparison of numbers: by the first, we find how much they differ, i.e. by how many units the antecedent exceeds, or comes short of, the consequent.

This difference is called the arithmetical ratio, or exponent of the arithmetical relation or habit of the two numbers. Thus, if 5 and 7 be compared, their arithmetical ratio is 2.

By the second comparison, we find how oft the antecedent contains, or is contained in, the consequent; i.e. as before, what part of the greater is equal to the less.

This ratio, being common to all quantity, may be called ratio in the general, or by way of eminence: but is usually called geometrical ratio; because expressed, in geometry, by a line, though it cannot be expressed by any number.

Modern authors distinguish ratio, with regard to quantity in the general, into rational and irrational.

**Ratio, Rational,** is that which is as one rational number to another; e.g. as 3 to 4.

**Ratio, Irrational,** is that which cannot be expressed by rational numbers.

Suppose, for an illustration, two quantities, A and B; and let A be less than B. If A be substracted as often as it can be from B, e. gr. five times, there will either be left nothing, or something. In the former case, A will be to B, as 1 to 5; that is, A is contained in B five times; or A = B. The ratio here, therefore, is rational.

In the latter case, either there is left a part, which being substracted certain times from A, e. gr. 3 times, and likewise from B, e. gr. 7 times, leaves nothing; or there is no such part: if the former, A will be to B as 3 to 7, or A = B; and therefore the ratio, rational. If the latter, the ratio of A to B, i.e. what part A is of B, cannot be expressed by rational numbers; nor any other way than by either lines, or by infinite approaching series.

The exponent of a geometrical ratio is the quotient arising from the division of the antecedent by the consequent. Thus, the exponent of the ratio of 3 to 2, is $\frac{3}{2}$; that of the ratio of 2 to 3, is $\frac{2}{3}$; for when the lesser term is the antecedent, the ratio, or rather the exponent, is a proper fraction. Hence the fraction $\frac{3}{2} = \frac{2}{3}$, and consequently the ratio is unity, the antecedent itself is the exponent of the ratio; thus, the exponent of 4 to 1, is 4. See EXponent.

If two quantities are compared, without the intervention of a third; either the one is equal to the other, or unequal: hence, the ratio is either of equality or inequality. If the terms of the ratio be unequal, either the less is referred to the greater, or the greater to the less: that is, either the less to the greater, as a part to the whole, or the greater to the less, as the whole to a part. The ratio, therefore, determines how often the less is contained in the greater, or how often the greater contains the less; i.e. to what part of the greater the less is equal.

The following differences of ratios are sometimes found in early authors.

The ratio which the greater term has to the less, e. gr. 6 to 3, is called the ratio of the greater inequality: the ratio which the less term has to the greater, e. gr. 3 to 6, is called the ratio of the lesser inequality.

This ratio corresponds to quantity in the general, or is admitted
admitted of by all kinds of quantities, discrete or continued, commensurable or incommensurable; but discrete quantity, or number, does likewise admit of another ratio.

If the lefs term of a ratio be an aliquot part of the greater, the ratio of the greater inequality is said to be multiplex, multiple, and the ratio of the lefs inequality, submultiplex.

Particularly, in the first cafe, if the exponent be 2, the ratio is called duplicate; if 3, triple, &c. In the second cafe, if the exponent be 4, the ratio is called subduplicate; if 5, subtriple, &c.

E. gr. if the exponent be 2, 3 is in a triple ratio; because 3 contains two thrice. On the contrary, 2 to 6 is a subtriple ratio; because 2 is the third part of 6.

If the greater term contains the lefs once, and over and above an aliquot part of the same; the ratio of the greater inequality is called superparticularis, and the ratio of the lefs subsuperparticularis.

Particularly, in the first cafe, if the exponent be 1, it is called fentence; if 2, subfentence, &c. In the other, if the exponent be 3, the ratio is called subfentence; if 4, subfubfentence, &c.

E. gr. 3 to 2 is in a fentence ratio; 2 to 3 in a subfentence.

If the greater term contains the lefs once, and over and above several aliquot parts; the ratio of the greater inequality is called superparticularis; that of the lefs inequality is subsuperparticularis.

Particularly, in the former cafe, if the exponent be 1, the ratio is called superparticularis tertius; if 2, superparticularis quartus; if 3, superquadruparticularis quintus, &c.

In the latter cafe, if the exponent be 3, the ratio is called subsuperparticularis tertius; if 4, subsuperparticularis quartus; if 5, subsuperquadruparticularis quintius, &c.

E. gr. the ratio of 3 to 2 is superparticularis tertius; that of 3 to 5, subsuperparticularis tertius.

If the greater term contains the lefs several times, and, besides, some quota part of the same; the ratio of the greater inequality is called multiplex, superparticularis; and the ratio of the lefs inequality, submultiplex, subsuperparticularis.

Particularly, in the former cafe, if the exponent be 2, the ratio is called dupla fentence; if 3, triplic i fentence, &c. In the latter cafe, if the exponent be 3, the ratio is called subdupla fentence; if 4, subtriplica fentence, &c.

E. gr. the ratio of 16 to 9 is triplica fentence; that of 4 to 9, subdupla fentence.

Lastly, if the greater term contains the lefs several times, and several aliquot parts of it besides; the ratio of the greater inequality is called multiplex, superparticularis; that of the lefs inequality, submultiplex, subsuperparticularis.

Particularly, in the former cafe, if the exponent be 2, the ratio is called dupla superparticularis tertius; if 3, triplic i superparticularis quartus, &c. In the latter cafe, if the exponent be 3, the ratio is called subdupla superparticularis tertius; if 4, subtriplica superparticularis quartus, &c.

E. gr. the ratio of 25 to 7 is triplica superparticularis quintus, that of 3 to 8, subdupla superparticularis tertius.

There are the various kinds of rational ratios; the names of which, though they occur but rarely among the modern writers (for in lieu of them they use the smallest terms of the ratios, e. gr. for duplicate 2:1, for fentence 3:2); yet are they absolutely necessary to such as converse with the ancient authors.

Clavius observes, that the exponents denote the ratios of the greater inequality, both in deed and name; but the ratios of the lefs inequality, only in deed, not in name: but it is easy finding the name in thefe, if you divide the denominator of the exponent by the numerator.

E. gr. if the exponent be 3, then 5:8 = 1:2; whence it appears, the ratio is called subsuperparticularis quintus. As to the names of irrational ratios, nobody ever attempted them.

Same, or identic ratios, are those whose antecedents have an equal respect to their confequents, i.e. whose antecedents divided by their confequents, give equal exponents. And hence may the identity of irrational ratios be conceived.

Hence, first, as oft as the antecedent of one ratio contains its confequent, or whatever part it contains of its confequent, fo oft, or fuch part of the other confequent does the antecedent of the other ratio contain: or, as oft as the antecedent of the one is contained in its confequent, fo oft is the antecedent of the other contained in its confequent.

Secondly, if A be to B as C to D; then will A : B :: C : D; or A : B = C : D. The former of which is the usual manner of representing the identity of ratios, the latter is that of the excellent Wolthus; which has the advantage of the former, in that the middle character, =, which denotes the fames, is fcientific; i.e. it expresses the relation of the thing represented, which the other, ::, does not. See Character.

Two equal ratios, e. gr. B : C = D : E, we have already observed, constitute a proportion: of two unequal ratios, e. gr. A : B and C : D, we call A : B the greater, if A : B > C : D; or the contrary, we call C : D the hiffer, if C : D > A : B.

Hence, we express a greater and lefs ratio thus: e. gr. 6 to 3 has a greater ratio than 5 to 4; for, 6 : 3 = (2) > 5 : 4 ( = 1 1/2). But 3 to 6 has a lefs ratio than 4 to 5; for = < 4 : 5. Compound ratio is that made up of two or more other ratios, which the fum of the antecedents of two or more ratios has to the fum of their confequents. Thus, 6 to 72 is in a ratio compounded of 2 to 6, and 3 to 12.

Particularly if it be compounded of two, it is called a duplicate ratio; if of three, a triplicate; if of four, quadruplicate; and, in the general, duplicate, if it be composed of several fimilar ratios. Thus 48 : 3 is a duplicate ratio of 4 : 1 and 12 : 3.

RATIO. Additive. See ADDITIVE.
RATIO. Alternate. See Alternate.
RATIO. Ordinate. See Ordinate.
RATIO Modularis and Modulari, were terms introduced into use by Cotes, but more modern authors do not use them always in the same fene: according to Cotes, the modulus in logarithms is that number which connects any fystem of logarithms with the hyperbolic fystem; or that number by which the hyperbolic number of a logarithm must be multiplied, or by the reciprocal of which it must be divided, in order to transform it to another fystem; and this modulus is, therefore, always the reciprocal of the hyperbolic loga- rithm of the radix of that fystem to which the modulus belongs.

This is what Cotes calls the modulus, to whom we owe the introduction of the term; and the reciprocal of it he calls the ratio modularis: but some modern authors, as Lagrange, &c. use the term modulus to denote the ratio modularis of Cotes.

The modulus of the hyperbolic fystem is 1, this being the reciprocal of the hyperbolic logarithm of 2.71828182, the radix of this fystem; and the modulus of the common logarithm
logarithmic system is \( \log_{2} 2 \), which is the reciprocal of the hyperbolic logarithm of \( \log_{2} 2 \), the radix of this system.

It is shown under the article Logarithms, that

\[
\log_{a} \frac{a}{b} = \frac{1}{2} \left( \frac{a - b}{b} \right)^{2} + \frac{1}{2} \left( \frac{a - b}{a} \right)^{2}, \ldots
\]

where \( r \) is the radix, and may be assumed at pleasure, and the reciprocal of this whole denominator is called the modulus. In the hyperbolic system the whole denominator is assumed \( 1 \), which makes \( r = 2 \), and the common system \( r \) is assumed 10, and the whole series becomes \( \log_{10} \frac{a}{b} = \frac{1}{2} \left( \frac{a - b}{b} \right)^{2} + \frac{1}{2} \left( \frac{a - b}{a} \right)^{2}, \ldots \)

where whatever be the value of \( r \); therefore, in every system, the modulus is the reciprocal of hyp. log. of the radix. See Logarithms.

Ratio, Denominator of \( a \). See Denominator.

Ratio, Properties of \( 1 \). Ratios similar to the same third are also similar to one another; and those similar to the same, are also similar to one another.

2. \( a : b :: c : d \); then, inversely, \( b : a :: d : c \).

3. Similar parts \( p \) and \( q \) have the same ratio to the wholes \( T \) and \( t \); and if the wholes have the same ratio, the parts are similar.

4. If \( a : b :: c : d \); then, alternately, \( a : c :: b : d \).

And hence, if \( b = d \), \( a = c \); and hence, also, if \( a : b :: c : d \); and \( a : f :: c : g \); we shall have \( b : f :: d : g \). Hence, again, if \( a : b :: c : d \); and \( f : a :: g : c \); we shall have \( f : b :: d : g \).

5. Those things which have the same ratio to the same, or equal things, are equal; and vice versa.

6. If you multiply any quantities, as \( A \) and \( B \), by the squares of \( A \) and \( B \), the products \( D \) and \( E \) will be to each other as \( A \) and \( B \).

7. If you divide any quantities, as \( A \) and \( B \), by the squares of \( A \) and \( B \), the quotients \( F \) and \( G \) will be to each other as \( A \) and \( B \).

8. The exponent of a compound ratio is equal to the sum of the exponents of the simple ratios.

9. If you divide the antecedents of the consequents of similar ratios, \( A : B \), and \( C : D \), by the same \( E \); in the former case, the quotients \( F \) and \( G \) will have the same ratio to the consequent \( B \) and \( D \); and in the latter, the antecedents \( A \) and \( B \) will have the same ratio to the quotients \( H \) and \( K \).

10. If there be several quantities in the same continued ratio \( A, B, C, D, E, \ldots \); the first \( A \) is to the third \( C \), in a duplicate ratio; to the fourth \( D \), in a triplicate; to the fifth \( E \), in a quadruplicate, &c. ratio of the ratio of the first \( A \), to the second \( B \).

11. If there be any series of quantities in the same ratio, \( A, B, C, D, E, \ldots \); the ratio of the first \( A \) to the last \( F \) compounded of the intermediate ratios \( A : B :: B : C :: C : D :: D : E :: E : F \), &c.

12. Ratios compounded of ratios, of which each is equal to each other, are equal among themselves. Thus the ratios \( \frac{3}{4} : \frac{3}{4} :: \frac{3}{4} : \frac{3}{4} \), compounded of \( 3 : 3 :: 4 : 4 \), and \( 3 : 3 :: 4 : 4 \) and \( 3 : 1 :: 20 : 4 \).

For other properties of similar or equal ratios, see Proportion.

Ratios, Reduction of. It is obvious that there is a variety of cases in which the real ratio of two quantities may be expressed in terms too great to be applied to any useful purpose; of which we have an example in the construction of planetariums, and similar astronomical instruments. The ratios of the times in which the several planets perform their sidereal revolutions, are expressed in very large numbers, far exceeding the number of teeth that can be introduced into the machinery of a planetarium; and it, therefore, becomes necessary to find smaller numbers, which, though they do not express the true ratio, may approximate as near to the truth as the scale of the clock will admit. Another instance, in which a reduction of the ratio of large numbers to others expressed in lower terms becomes necessary, occurs in the calendar; for, according to the common reckoning, the year is supposed to be 365 days, whereas it is known to be nearly 365 days 6 hours; it, therefore, becomes necessary to have some means of expressing the ratio between the true and the assumed length of the years, in order that, by a proper interpolation, we may preserve an uniformity in the feast days, with reference to the month, as we should otherwise find the short day transferred to the middle of June, and the long day to the month of December.

This reduction of ratios is best performed by means of continued fractions, of which a sketch is given under that article, as also under the article Indeterminate Analysis, but which we shall probably treat at greater length in a supplement to the present work, on which account it is not our intention to enter much into the rationale of the theory in this place, but merely to state the rules by which the required reduction is to be performed.

To reduce a ratio expressed as a fraction, to others nearly equivalent, but represented in simpler terms.

Rule 1. Divide the greater of the two numbers by the less; then the divisor by the remainder, and so on, as in finding the greatest common measure of two numbers, and refer the several quotients, which may be denoted by \( a, b, c, d, \&c. \).

2. Write down the several quotients, thus; \( a, b, c, d, \&c. \) from which the series of converging fractions or ratios will be derived as follows; viz. the first fraction will have unity for its numerator, and the first quotient, \( a \), for its denominator; the second will have the second term, \( b \), for its numerator, and for its denominator \( a + b + 1 \); and the numerators of all the succeeding fractions will be found, by multiplying the numerator last obtained, by the succeeding quotient in the above series, and adding to the product the preceding numerator, and the denominators are obtained by precisely the same rule, merely changing the word numerator into denominator.

In this rule we have supposed the ratio to be less than 1, or the numerator less than the denominator; if the denominator be less than the numerator, it must be reversed, making the numerator what we have called the denominator, and the denominator the numerator.

The last fraction of this series will be the same as the original fraction proposed, and the others will be as many approximate or converging fractions, each of which will approach nearer to the original fraction than the preceding one, and nearer than any other fraction whose terms are not expressed by greater numbers. This rule may be exhibited analytically as follows:

Let \( \frac{A}{B} \) be the proposed fraction, and \( a, b, c, \&c. \) the quotients obtained by the divisions as above, then the converging
verging fractions will be
\[
\frac{bc + 1}{a} \frac{b}{ab + 1} \frac{bc + 1}{(ab + 1)c + a} \frac{(ab + 1)c + a}{d + ab + 1},
\]
&c. which will be found to agree with the preceding rule; and these fractions will be alternately greater and less than that proposed, which will be the limit of the series.

Let us illustrate this rule by an example. Required a series of converging fractions towards \( \frac{314159}{100000} \), which is the fraction commonly employed for expressing the ratio of the diameter to the circumference of a circle.

**Operation by Division.**

\[
\begin{array}{c}
100000 \div 314159 = 3 \quad a \\
300000 \div 314159 = 9 \quad b \\
92613 \div 314159 = 3 \quad c \\
28797 \div 314159 = 1 \quad d \\
854 \div 314159 = 33 \quad e \\
825 \div 33 = 29 \quad f \\
29 \div 4 = 7 \quad g \\
4 \div 1 = 4 \quad h
\end{array}
\]

Having thus obtained our quotients, the several fractions will be easily formed by the preceding rule; thus,

\[
\begin{array}{c}
3 & 7 & 15 & 25 & 1 & 7 & 4 \\
\frac{3}{7} & \frac{22}{15} & \frac{335}{25} & \frac{3355}{15} & \frac{33555}{7} & \frac{9208}{4} & \frac{92089}{1} \\
\frac{7}{15} & \frac{3044}{25} & \frac{3044}{15} & \frac{3044}{7} & \frac{9563}{4} & \frac{9563}{1} \\
\frac{15}{25} & \frac{276149}{1} & 106' & 3044 & 106' & 3044 & 106'
\end{array}
\]

the last of which is the same as the original fraction. These fractions are formed according to the preceding rule, which will be understood from one example; thus, the fifth fraction is formed from the two preceding fractions as follows:

\[
335 \times 25 + 335 = 9208 \
113 \times 25 + 106 = 2931
\]

the numerator and denominator of the last fraction add, once, twice, three times, &c. the numerator and denominator of the principal fraction which interpolates between the two, which will form the interpolated fractions required. Thus, because \( \frac{76149}{24239} \) is the principal fraction interpolated between \( \frac{9563}{3044} \) and \( \frac{314159}{100000} \), the intermediate or interpolated fraction will be

\[
\begin{array}{c}
9563 & + 76149 = 85712 \\
3044 & + 24239 = 27283 \\
9563 & + 2 \times 76149 = 161861 \\
3044 & + 2 \times 24239 = 51522 \\
2963 & + 3 \times 76149 = 238010 \\
3044 & + 3 \times 24239 = 75761
\end{array}
\]

And
And in the same manner we may interpolate fourteen fractions between \( \frac{3}{1} \) and \( \frac{333}{106} \); twenty-four between \( \frac{333}{106} \) and \( \frac{9208}{2931} \); and six between \( \frac{9208}{2931} \) and \( \frac{16149}{24339} \).

Having thus explained the nature of the operation, we shall enter into detail in the following example.

Example 2.—According to M de la Caille, the solar year is \( 365\frac{\text{d}}{4} \) and \( 48 \text{m} 49\text{s} \), and consequently longer by \( 48 \text{m} 49\text{s} \) than the common year of 365 days. If this difference were exactly 6 hours, it would make one day at the end of four common years; but if we wish to know exactly at the end of how many years this difference will produce a certain number of days, we must seek the ratio between \( 24\text{b} \) and \( 5\text{h} \), which we find to be \( \frac{20929}{86400} \).

As that at the end of 86400 common years, we must intercalate 20929 days, in order to reduce them to tropical years.

Now as the ratio of 86400 to 20929 is expressed in very high terms, let it be required to find ratios in lower terms, as near this as possible.

For this purpose, we must perform upon these numbers the same operations as in the preceding case; thus:

\[
\begin{align*}
20929 \times 86400 &= 4a \\
2684 \\
\frac{2684}{2931} \times 20929 &= 7b \\
18768 \\
\frac{2141}{2931} \times 2684 &= 1c \\
2141 \\
\frac{543}{2931} \times 2141 &= 3d \\
1629 \\
\frac{512}{2931} \times 543 &= 1e \\
512 \\
\frac{31}{2931} \times 512 &= 16f \\
496 \\
\frac{16}{2931} \times 31 &= 1g \\
16 \\
\frac{15}{2931} \times 16 &= 1b \\
15 \\
\frac{1}{2931} \times 15 &= 1c \\
15 \\
\end{align*}
\]

From which quotients we derive the following converging fractions, \( \text{viz.} \)

\[
\begin{array}{cccccccc}
4 & 7 & 1 & 3 & 1 & 16 & 1 & 1 \\
4 & 29 & 33 & 128 & 161 & 2704 & 2865 & 5569 & 86400 \\
1 & 7 & 8 & 31 & 39 & 655 & 694 & 1349 & 20929 \\
\end{array}
\]

It appears farther, that as the fractions \( \frac{4}{1}, \frac{29}{7}, \frac{33}{8}, \text{&c.} \) are alternately less and greater than the fraction \( \frac{86400}{20929} \), or \( \frac{24\text{b}}{5\text{h} \text{48m} 49\text{s}} \), the intercalation of 1 day in 4 years would be too much of 7 days in 29 years, too little, of 8 days in 33 years too much again, and so on; but each of these intercalations will be the most exact, that it is possible to make in the same space of time.

Now if we arrange in two separate series, the fractions that are less, and those that are greater, than the given fractions, we may infert or interpolate between certain of these fractions, as in the preceding examples.

Taking first those fractions that are less than the given one, and their corresponding quotients, we shall have,

\[
\begin{array}{cccccccc}
1 & 1 & 15 & 4 & 33 & 2865 & 86400 \\
1 & 8 & 694 & 20929 \\
\end{array}
\]

Hence it appears, that the only interpolation that can be performed is between the two fractions \( \frac{2865}{86400} \) and \( \frac{694}{20929} \), which will admit of 14 intermediate fractions; which being supplied, as in the former example, gives the following series of converging fractions, each less than the fraction originally proposed, \( \text{viz.} \)

\[
\begin{array}{cccccccc}
4 & 33 & 161 & 2865 & 8434 & 14003 \\
1 & 8 & 39 & 694 & 2043 & 3392 \\
19572 & 25141 & 30710 & 36279 \\
4741 & 6090 & 7439 & 8788 \\
41848 & 52986 & 58555 & 64124 \\
10137 & 12835 & 14184 & 15533 \\
66633 & 75262 & 80831 & 86400 \\
16882 & 18231 & 19580 & 20929 \\
\end{array}
\]

And as the last fraction is the same as the given fraction, it is evident that this series cannot be carried farther: hence, if we choose to admit those interpolations only in which the error is too much, the simplest and most exact will be that of 1 day in 4 years, or of 8 days in 33 years, or of 39 in 161 years, and so on.

Let us now consider the decreasing fractions:

\[
\begin{array}{cccccccc}
7 & 3 & 16 & 1 \\
29 & 128 & 2704 & 5569 \\
7 & 31 & 655 & 1349 \\
\end{array}
\]

Here it appears, that we may place 6 fractions before the first, 2 between the first and second, 15 between the second and third; but between the third and fourth no such fraction can be inserted.

These interpolations being made, we shall have the following series of decreasing fractions, \( \text{viz.} \)

\[
\begin{array}{cccccccc}
5 & 9 & 13 & 17 & 21 & 25 \\
1 & 2 & 3 & 4 & 5 & 6 \\
29 & 62 & 95 & 128 & 289 & 450 \\
7 & 15 & 23 & 31 & 70 & 109 \\
611 & 772 & 933 & 1094 & 1255 \\
143 & 187 & 226 & 265 & 304 \\
\end{array}
\]
which are all less than the proposed fraction, and expressed in less terms; and each of which is nearer than any other fraction that can be expressed in less terms.

Hence we conclude, that if we only attend to the intercalations in which the error is too small, the simplest and most exact are those of 1 day in 5 years, of 2 days in 9 years, of 3 days in 13 years, of 4 days in 17 years, and so on.

In the Gregorian calendar, only 97 days are intercalated in 400 years; but it is evident, from the preceding table, that it would be much more exact to intercalate 109 days in 450 years.

But it must be observed, that in the Gregorian reformation, the determination of the year given by Copernicus was made use of, which is 355'44° 20'"; and substituting this instead of the fraction we shall have 86400 over 29029, or rather 540; whence we may find, by the preceding method, the quotients 4, 8, 5, 3; and from them the principal fractions

\[
\frac{4}{1}, \frac{33}{8}, \frac{169}{41}, \frac{540}{131},
\]

which, except the two first, are quite different from those before determined. However, we do not find amongst these fractions 400, which is that adopted in the Gregorian calendar; and this fraction cannot even be found among the interpolated fractions, which might be inserted in the two series, \(\frac{3}{4}, \frac{169}{41}, \frac{33}{8}, \frac{540}{131}\); for it is evident that it could only be between the last two fractions, between which, because of the number 3 (the corresponding quotient), there can be but two fractions interpolated, which are \(\frac{202}{49}, \frac{371}{90}\); whence it appears, that it would have been more exact, if, in the Gregorian reformation, they had only intercalated 90 days in the space of 371 years.

If we reduce the fraction \(\frac{400}{37}\), so as to have for its numerator the number 86400, it will become \(\frac{86400}{29052}\), which estimates the tropical year at 365'25° 49'12".

In this case, the Gregorian intercalation would be quite exact; but as observations shew that the year is shorter than this by more than 20', it is evident that, at the end of a certain period of time, we must introduce a new intercalation.

If we adopt the determination of de la Caille, it follows, as the denominator 97 of the above fraction, viz. \(\frac{400}{97}\), lies between the denominators of the fifth and sixth principal fractions already found, that, from what has been stated above, the fraction \(\frac{161}{39}\) will be nearer the truth than 400. But as astronomers are still divided with regard to the exact length of the year, we shall refrain from giving a decisive opinion on this subject. For more on the reduction of ratios, see Lagrange's Additions to Euler's Elements of Algebra.
ratio.

federation of ratios which have limits is difficult, we shall begin with examples of other quantities.

1st. Let there be formed a series, whose first term is 1; second, \( \frac{1}{2} \); third, \( \frac{3}{4} \); fourth, \( \frac{1}{2} \); and so on; every term being half the preceding one, viz.

\[
1, \quad \frac{1}{2}, \quad \frac{1}{4}, \quad \frac{1}{8}, \quad \frac{1}{16}, \quad \frac{1}{32}, \quad \&c.
\]

and let the sum of an indefinite number of terms in this series be considered as continually increased by the ascension of a new term; thus, the sum of the two first is \( \frac{3}{2} \), of three terms is \( \frac{15}{16} \), of four terms is \( \frac{1}{16} \), \&c.

I say then, that the varying sum of the terms of this series continually approaches to the fixed number 2, as its limit. For the difference between 1, 2, 3, \&c. terms, and the number 2, will be the numbers 1, \( \frac{1}{2} \), \( \frac{1}{4} \), \( \frac{1}{8} \), \( \frac{1}{16} \), \&c. successively, in infinitum. Here it is evident, that the terms in this last series, which express the successive differences between the increasing sum of the former series and the number 2, are all continually decreasing; and secondly, no term in this series of differences can become either nothing or negative; and thirdly, we may continue this series of successive differences, till we arrive at a term which shall be a less part of the fixed number 2, than any fractional part of it that can be assigned; or so that this difference shall be less, when compared with the number 2, than any ratio assigned. The number 2, therefore, having the conditions laid down in the definition, is to be called the limit of the sum of the terms of the infinite series 1, \( \frac{1}{2} \), \( \frac{1}{4} \), \( \frac{1}{8} \), \( \frac{1}{16} \), \&c.

And the same is to be understood of any other infinite series; viz. if a number can be found having the above conditions, that series is said to have a limit; and the finding of this limit, is what is to be understood when mathematicians speak of finding the sum of such an infinite series.

No number less than 2, for instance \( \frac{1}{2} \), can be taken for the limit; for, in this case, it will not answer the second condition of the definition. In the above example, the sum of four terms of the series is equal to 1\( \frac{1}{2} \), and the sum of five terms exceeds it; therefore, the difference between this sum and the number 1\( \frac{1}{2} \) proposed as a limit, is, in the former case zero, and in the latter negative. Neither can any number greater than 2, as for example 3, be taken for the limit, because here the last condition will be wanting; for if the sum of any assigned number of terms be less than 2, that sum must always want more than unity of the number 2, and consequently cannot approach nearer to 3, than any assigned quantity, as \( \frac{1}{2} \).

In like manner the sum of the series 1, \( \frac{1}{3} \), \( \frac{1}{9} \), \( \frac{1}{27} \), \&c. continued in infinitum, will be \( \frac{1}{2} \); the series of successive differences being \( \frac{1}{2} \), \( \frac{1}{6} \), \( \frac{1}{18} \), \( \frac{1}{54} \), \&c. in infinitum.

Now, in order to make the preceding example general, let \( \frac{a}{b} \) express the common ratio of any series of numbers in continual proportion, whose first term is unity; I say then, if \( \frac{a}{b} \) be greater than \( \frac{1}{2} \), such a series will have for its limit the quantity \( \frac{a}{a-b} \); or, in other words, the sum of all the terms of such an infinite series will be \( \frac{a}{a-b} \).

For the terms of this series will be \( \frac{1}{a}, \frac{b}{a}, \frac{b^2}{a}, \frac{b^3}{a}, \&c. \)

Whence the sum of 1 term is \( \frac{b}{a} \)

of 2 terms \( \frac{a+b}{a} \)

of 3 terms \( \frac{a^2+ab+b^2}{a^2} \)

of 4 terms \( \frac{a^3+a^2b+ab^2+b^3}{a^3} \)

Let each of these sums be subtracted from the limit \( \frac{a}{a-b} \) and we have the successive differences \( \frac{b}{a-b}, \frac{b^2}{a-b}, \frac{b^3}{a-b}, \&c. \) or if \( n \) be any assigned number of terms, the difference between the sum of that number of terms and the limit \( \frac{a}{a-b} \) will be \( \frac{b}{a-b} \cdot \frac{b^{n-1}}{a^{n-1}} \). Whence we may observe, 1st, that as the number of terms whose sum is required increases, this difference continually decreases, because \( \frac{b}{a-b} \), being a fraction less than unity, its powers continually decrease, 2dly. This difference can never become nothing or negative; the powers of a fraction, though they decrease, being always real and affirmative. 3dly. This difference may become less in respect of \( \frac{a}{a-b} \), than by any assigned ratio.

For \( \frac{a}{a-b} = \frac{b^a}{b^a}, \) \( \frac{b^a}{b^a} \), \( \frac{b^a}{b^a} \), or as \( \frac{a^n}{b^n} \) to 1; or as \( \left( \frac{a}{b} \right)^n \) to 1: and since \( \frac{a}{b} \) is greater than 1, and \( n \) indeterminate, the former term of the ratio may become greater than any assigned quantity, and therefore the ratio itself less than any ratio assigned.

The quantity \( \frac{a}{a-b} \), having, therefore, the required conditions, is the limit of the above series, or is equal to the sum of all the terms continued in infinitum.

What has been proved above may be shewn more concisely by dividing \( a \) by \( a-b \), in the manner of division in algebra, for the quotients will be the very series proposed in the example; for instance, \( \frac{a}{a-b} = (1 + \frac{b}{a} + \frac{b^2}{a^2} + \frac{b^3}{a^3} + \&c. \)

\[ \frac{b}{b-b} \]

\[ \frac{b^2}{b^2} \]

\[ \frac{b^3}{b^3} \]

\[ \frac{b^4}{b^4} \]

\[ \frac{b^5}{b^5} \]

\[ \frac{b^6}{b^6} \]

And
And it may be further confirmed by multiplying the proposed series by \( a - b \), for the product will be \( \alpha \), all the terms except the first destroyed each other.

We may also observe, that if every term of the foregoing series be multiplied by any number \( c \), it will become \( \frac{bc}{a} + \frac{b^2c}{a^2} + \frac{b^3c}{a^3} + \cdots \); a series having the same ratio, but whose first term is \( c \); and it is therefore evident, that, in this case, to find the sum of all the terms, we must multiply the former limit by \( c \), whence it will become \( \frac{ac}{a - b} \).

Before we begin to consider ratios, it may not be amiss to caution the reader against confounding the terms of a ratio with the ratio itself: the terms of a ratio may vary in some cases through all degrees of magnitude, and yet the ratio remain constant or invariable. In other instances, varying the terms in infinitum, likewise varies the ratio in infinitum; while in others, though varying the terms may also vary the ratio, yet the last ratio can never exceed certain limits.

Let \( x \) be any varying quantity; make \( 4x^2 + 3x = A \), and \( 2x^3 + x = B \), then will \( A \) and \( B \) also be varying quantities, as depending upon \( x \); when \( x \) vanishes, and \( A \) and \( B \) will both vanish; when \( x \) is infinite, they will be both infinite. I say then the ratio of \( A \) to \( B \), while \( x \) decreases in infinitum, approaches to the ratio of \( 3 \) to \( 1 \).

For, first, \( A \) is to \( B \), as \( 4x^2 + 3x \) is to \( 2x^3 + x \), or as \( 4x + 3 \) to \( 2x + 1 \); where it is obvious, that as \( x \) decreases, the quantities \( 4x + 3 \) and \( 2x + 1 \) also decrease, and consequently the ratio of \( 4x + 3 \) to \( 2x + 1 \), or of \( A \) to \( B \), approaches to that of \( 3 \) to \( 1 \). Secondly, the ratio of \( A \) to \( B \) can never exceed \( 3 \) to \( 1 \). For the ratio of \( 4x^2 + 3x \) to \( 2x^3 + x \), is \( 3 \) to \( 1 \); but \( 4x^2 + 3x \) becomes a less quantity than \( 6x^2 + 3x \), therefore \( 4x^2 + 3x \) is to \( 2x^3 + x \) as \( 2x^2 + 3x \) to \( 2x^3 + x \); that is, less than the ratio of \( 3 \) to \( 1 \).

Lastly, the ratio of \( A \) to \( B \) will approach nearer to the ratio of \( 3 \) to \( 1 \), than any assigned difference. For in the terms of this ratio, \( 4x + 3 \) to \( 2x + 1 \), the varying parts \( 4x \) and \( 2x \), by diminishing \( x \), may become less than any assigned quantity, while the other parts, \( 3 \) and \( 1 \), remain the same; therefore the ratio of \( A \) to \( B \) will approach nearer to the ratio of \( 3 \) to \( 1 \), than by any assigned difference.

In like manner the ratio of \( A \) to \( B \), while \( x \) increases in infinitum, approaches to the ratio of \( 2 \) to \( 1 \), as its limit.

For since \( A \) is to \( B \) as \( 4x + 3 \) to \( 2x + 1 \), or as \( 4x + 3 \) to \( 2x + 1 \), it is obvious that, as \( x \) increases, the quantities \( \frac{3}{x} \) and \( \frac{1}{x} \) decrease, and consequently the ratio of \( 4x + 3 \) to \( 2x + 1 \), or of \( A \) to \( B \), approaches to the ratio of \( 4 \) to \( 2 \), or of \( 2 \) to \( 1 \). For \( 4x^2 + 2x \) is to \( 2x^3 + x \), as \( 2 \) to \( 1 \); but \( 4x + 3x \), is a greater quantity than \( 4x + 2x \), therefore \( 4x + 3x \) is to \( 2x + x \); or \( A \) to \( B \) always in a greater ratio than \( 2 \) to \( 1 \). Lastly, the ratio of \( A \) to \( B \) will approach nearer to that of \( 2 \) to \( 1 \), than any assigned difference. For in the terms of this ratio, \( 4 \) and \( \frac{3}{x} \) and \( 2 \) and \( \frac{1}{x} \), the variable parts \( \frac{3}{x} \) and \( \frac{1}{x} \), by increasing \( x \), may become less than any assigned fraction, while the parts \( 4 \) and \( 2 \) remain the same; therefore the ratio of \( A \) to \( B \) will approach nearer to the ratio of \( 4 \) to \( 2 \), or \( 2 \) to \( 1 \), than any assigned difference.

Hence then we see that though diminishing \( x \), and consequently diminishing the terms \( A \) and \( B \), we increase their ratio, and on the contrary increasing these terms, by increasing the quantity \( x \), we decrease their ratio, yet there is a limit both to the increase and decrease of this ratio, although there be none to the terms themselves which compose it.

The ratio of \( 3 \) to \( 1 \), which limits the ratio of \( A \) to \( B \), when these terms decrease in infinitum, is called the ultimate ratio of the evanecent quantities \( A \) and \( B \). The ratio of \( 2 \) to \( 1 \), which is their other limit, is called the ultimate ratio of the quantities \( A \) and \( B \) increasing in infinitum.

Another example of a similar kind we have as follows.

Let \( x \) be a varying quantity, and \( d \) a constant one, then will \( x + d \) and \( x \) be two varying quantities capable of all degrees of magnitude, I say that the ratio of \( x + d \) to \( x \), while \( x \) increases, will continually decrease, but not beyond a certain limit, which is the limit of equality. On the contrary, if \( x \) decreases, the ratio of \( x + d \) to \( x \) continually decrease more and more ad infinitum, and never come to a limit. For \( x + d \) is to \( x \), as \( 1 + \frac{d}{x} \) to \( 1 \); now as \( x \) increases, the fraction \( \frac{d}{x} \) decreases, and may become less than any assigned fraction; but the number \( 1 \), which is the other part of the antecedent of this ratio, remains the same, as does likewise the consequent, therefore the ratio of \( 1 + \frac{d}{x} \) to \( 1 \), continually approximates to a ratio of equality. Secondly, it can never reach that ratio, because \( \frac{d}{x} \) has always some magnitude, and consequently \( 1 + \frac{d}{x} \) always greater than \( 1 \). It therefore can never reach the ratio of equality, and much less can it pass it, so as to become a ratio minoris inaequalitatis, or a ratio in which the antecedent is less than the consequent. Lastly, the varying fraction \( \frac{d}{x} \), as \( x \) increases, will become less than any assigned fraction, while the other part of the antecedent, and likewise the consequent of this ratio, remain the same.

Therefore the ratio of \( 1 + \frac{d}{x} \) to \( 1 \), will approach nearer to the ratio of equality, than by any ratio that can be assigned, however small such ratio may be; therefore the ratio of equality is the limit of the ratio of \( 1 + \frac{d}{x} \) to \( 1 \), and consequently the limit of the ratio of \( x + d \) to \( x \), which continually decreases, while the terms which compose this ratio continually increase in infinitum.

If \( x \) decrease then \( \frac{d}{x} \) will increase, and may become greater than any assigned number, while the other part of the antecedent, and likewise the consequent, remain invariable; therefore the ratio of \( 1 + \frac{d}{x} \) to \( 1 \), and consequently the ratio of \( x + d \) to \( x \), as \( x \) decreases, will become greater than any assigned ratio whatever, having no limit to its increase.
We may further observe, that though the terms of this ratio, viz. \( x + d \) to \( x \), never approximate nearer to each other, their constant difference being \( d \), yet the ratio of the terms approximates to the ratio of equality; that is, though the terms get no nearer in their difference, yet, if we may be allowed the expression, they get nearer in their ratio. The difference of the terms, and the ratio of the terms, are ideas very distinct from each other, and in no wise to be so connected, but that one may vary whilst the other is constant. Although the ratio of equality may strictly be called the limit of the varying ratio of the quantities \( x + d \) and \( x \), yet the terms of this ratio can never be strictly said to be equal, nor ultimately equal, as that supposes an ultimate rate in which they are equal; nor equal when they \( \text{vanish into infinity} \), or, when they pass out of finite into infinity. There is no finite quantity next to infinity, no number, for instance, which is the next number to infinity. Nor is there any step from a rate of nothing into finite existence; there is no fraction so small as to be the very next fraction to nothing; no fraction can be aligned so small, but another fraction may be aligned that is smaller. Neither can we say, in strictness, that two infinitely great numbers with a finite difference are equal, it being a proposition obviously absurd and contradictory. There is no such thing in nature as an infinitely great number; and it is contradictory to say of any two numbers, both that they have a difference, and that they are equal. Whoever considers that the idea of infinity is a general or abstract idea, that the idea of number is always particular, that infinity is a property of numbers, a property of extension, &c. itself, will readily perceive that these and such like expressions have no literal meaning. (See Locke, b. ii. ch. 16. and ch. 17.) As to the metaphorical use of them, to avoid circumlocution, or the introduction of new terms, it may be allowed, when once the literal meaning has been explained, in this, as well as on various other occasions both in science and in common life.

When the difference between any two quantities decreases, so as to become a less fractional part of the one of them than any aligned fractional part whatever; or when the difference between the terms of a ratio becomes less in respect of one of them (the greater for example) than any aligned ratio, this may be expressed by saying, that such difference \( \text{vanishes} \) in respect of that greater quantity.

But if the difference between two terms vanishes in respect to one of them, it will also vanishes in respect of the other. It is true that at any aligned time, when the terms have a particular magnitude, the difference between the terms will always be a less fractional part of the greater term than it is of the lesser term; but as this difference continually decreases, it will become the same fractional part of the lesser term that it was before the greater, however small that fractional part of the greater term may be; therefore, if the difference vanishes with regard to one of them, it will vanish all with regard to the other. We may, therefore, instead of the third condition of our definition, say, that “the difference must vanish in respect of either of the fixed or of the varying quantity, since one of these implies the other.”

The above is true as well for the case of two variables, as for one fixed and one variable, though both of such variables increase or decrease without limit. Thus, in the example above given, in which the terms were \( x + d \) and \( x \), and where \( x \) is continually increasing, the terms themselves both continually increase; for in this instance it is obvious, that if the difference vanishes with respect to one of the terms, it will also vanish with respect to the other. Let \( x \) be to \( d \), at any aligned point of time, as \( n \) is to \( 1 \), and \( d \) at that instant of time will be the \( \frac{1}{n+1} \)th part of the greater term, and the \( \frac{n}{n+1} \)th part of the less term: now, though the contemporary \( n \) value of these fractions can never be equal, yet in succession the value of the latter fraction will become whatever the former has been; therefore, if \( \frac{1}{n+1} \) become less than any aligned fraction, so will \( \frac{n}{n+1} \) likewise; and thus, if the difference vanishes with respect to one of the terms, \( x + d \), so will it also vanish with respect of the other, \( x \). And the fame would be true if the terms were \( x \) and \( x - d \), all things else being as before.

Again, if \( x \) by decreasing vanish with respect to some fixed quantity \( n \), then will \( x \), multiplied by a given number \( n \), or \( nx \), vanish in respect of \( a \); or, which is the same, if \( x \) vanish in respect of \( a \), to likewise will the quantity \( nx \); bearing to \( x \) the assigned ratio of \( n \) to 1. For though at any particular point of time \( x \) is a smaller fractional part of \( a \) then \( nx \), yet \( x \) can be no aligned fractional part of \( a \) whatever; but by farther diminishing \( x \), the quantity \( nx \) may become the same fractional part of \( a \) that \( x \) was before. If, then, \( x \) may become equal to, or less than, any aligned fractional part of \( a \), to likewise may \( nx \); that is, if \( x \) vanish in respect of \( a \), to likewise will \( nx \).

For a like reason, if \( x \) vanish in respect of any quantity, it will likewise vanish in respect to that quantity multiplied or divided by any number; or it will vanish in respect of a quantity, bearing to any aligned ratio, as that of \( m \) to 1. Thus, if \( x \) vanish in respect of \( a \), it will also vanish in respect of \( 3a \), or \( 2a \), or \( 2a \), &c. or, if any fraction vanish in respect to the diameter of a circle, it will likewise vanish in respect of the radius. For whatever part of the diameter the line \( x \) may be at any aligned point of time, let \( x \) farther decrease, till it be half what it was at that aligned time, and it will now be the same part of the radius that it was before of the diameter; and the same with various other lines and quantities. We have shewn, in the preceding part of this article, that the ratio which two quantities bear to each other may have a limit, although the terms themselves may increase or decrease perpetually without limit. 1. If the terms approximate towards each other; 2, if the less never passes the greater; and, lastly, if their difference vanish in respect of either term, then the limit of their varying ratio is that of equality; and this, whether the terms themselves are such, as by increasing they both become greater than any aligned quantity, or, which is more common, such as by decreasing become less than any aligned quantity, or as it is called, \( \text{infinitely small} \). Because the idea of the terms of a ratio is less abstruse than that of the ratio itself, it is more usual to say that the terms themselves in this case are ultimately equal, though, strictly, it is the ratio only of the terms that comes to a limit, for the terms themselves are supposed to inerface or decrease without limit, or as we commonly say, \( \text{ad infinitum} \).

Prop.—In a circle whose centre is \( C \), (Plate XIII. Analytis, fig. 9.) radius \( CA \), diameter \( Aa \), let \( AB \) be the chord, \( BF \) the line, and \( AD \) the tangent of the arc \( AB \). I say, that while the arc \( AB \) continually decreases without limit; if, the line \( BF \) ultimately approaches the tangent; 2dly, the line never exceeds the tangent; 3dly, their difference will vanish in respect of either line or tangent.

First; \( BF : DA :: CF : CA \), but while the arc decreases, \( CF \) approaches to \( CA \); \( BF \) approaches to \( DA \).
RAT

**RAT**

D A 2dly. C F can never exceed C A; therefore B F can never exceed D A. 3dly. The arc continually decreasing without limit, vanishes in respect of the diameter, which is fixed; therefore the chord A B, which is less than the arc, likewise vanishes in respect of the diameter A a.

But A a : A B :: A B : A F; therefore, if A B vanishes in respect of A a, A F will vanish in respect of A B; and much more will A F vanish in respect of A a; but if A F vanish in respect of A a, it will also vanish in respect of \( \frac{1}{2} A a \) or C A.

Now C A : C F :: A D : F B, and by division of proportion C A : A F :: A D : A D - F B. Therefore, as A F vanishes in respect of C A, so does A D - F B (the difference of the fine and tangent) vanishes in respect to A D the tangent, and consequently in respect of F B the fine. Whence we see, that while the arc continually decreases without limit, the fine approaches to the tangent; 2dly, the fine never exceeds the tangent; 3dly, although the fine and tangent both vanish in respect of the radius, yet their difference vanishes in respect of these quantities themselves. Therefore the ratio of equality is the limit of the varying ratio which the fine and tangent have to each other, while they both decrease perpetually without limit, or it is their ultimate ratio, or, as we may say, they are ultimately equal.

The fine is less than the chord; for in the right-angled triangle A F B, the side B F is less than the hypothenuse A B; the chord is less than the arc; this is self-evident, the chord being a straight line, and the arc a curve, both terminated by the same points A and B. The arc is less than the tangent; for from the point D draw another tangent to the circle in H; and the lines A B H, A D H, will be terminated by the same points A and H; and will have the concavities turned the same way; therefore the included arc A B H will be less than the sum of the two equal tangents D A and D H; consequently half that arc, or A B, will be less than half the sum of the tangents A D.

Cor. 1. Hence the fine, chord, arc, and tangent, are all ultimately in a ratio of equality. This may appear because the chord and arc are included between the fine and tangent, but perhaps more plainly thus. Of these four quantities, viz. the fine, chord, arc, and tangent, the fine is the least, and the tangent the greatest; therefore, the difference between the fine and the tangent is greater than the difference between any other two of these four quantities. If, therefore, the greatest of all those differences vanish in respect of the least of all those quantities, much more will the difference between any other two of these four quantities vanish in respect of the quantities themselves.

Cor. 2. Join B a, and in the right-angled triangle B F a, the hypothenuse B a is greater than the side F a; therefore A a - B a is less than A a - F a, or than A F; but while the arc A B decreases continually without limit, A F vanishes in respect of A a; much more then does A a - B a, the difference A a and B a, vanish in respect of A a; therefore the ultimate ratio of A a to B a is that of equality; and the ultimate ratio of \( \frac{1}{2} A a \) or B C to B a, is that of 2 to 1. See other applications of these principles in Leland's "Rudiments of Mathematics," from which the preceding article has been abstracted; Newton's "Principia," ib. 1; Smith's "Fluxions;" and Saundersen's "Algebra."

RATIO, in our Law Writers, is used for a judgment given in a cause.

Hence, *ponere ad rationem* is to cite one to appear in judgment. Walsingham, 88.

RATIO Status, Ragione di Stato. See REASON of State. Vol. XXIX.

**RAT**

Ratio Viátus. See VICTUS.

RATIOCINATION, the act of reasoning.

RATION, or RATIN, in the Army, a pittance or proportion of ammunition, bread, drink, or forage, distributed to each soldier for his daily subsistence.

Some write the word ration, and borrow it from the Spanish ratio; but they both come from the Latin ratio. In some parts they call it a rogan.

The horse have rations of hay and oats, when they cannot go out to forrage. See FORRAGE.

The rations of bread are regulated by weight. The ordinary ration of a foot soldier is a pound and a half of bread per day. The officers have several rations, according to their quality, and the number of attendants that they are obliged to keep.

When the ration is augmented on occasions of rejoicing, it is called a double ration.

The ships' crews have also their rations or allowances of biscuit, water, &c. proportioned according to their flocks. The usual ration at sea, particularly among the Portuguese, &c. is a pound and half of biscuit, a pint of wine, and a quart of fresh water per day; and each month an arrobe, or thirty-one pounds of salt meat, with some dried fish and onions.

RATIONABLES EXPENSE, Reasonable Expenses. The commons in parliament, as well as the proctors of the clergy in convocation, were anciently allowed rationables expensas; that is, such allowance as the king, considering the prices of all things, shall judge meet to impose on the people to pay for the subsistence of their representatives.

This in the 15th of Edward II. was settled at ten groats per day for knights, and five for burgesses; afterwards, four shillings a day for knights, and two shillings for burgesses; which was then deemed an ample retribution, both for expenses, for labour, attendance, neglect of their own affairs, &c. See BURGESS, and KNIGHTS OF THE SHIRE.

RATIONABILIS Parte Bonusum, a writ which lies for the wife, against the executors of her husband, denying her the third part of her husband's goods, after debts and funeral expenses paid.

Fitzherbert quotes Magna Charta, and Glanville, to prove, that by the common law of England, the goods of the deceased, his debts first paid, should be divided into three parts; of which his wife is to have one, his children a fecound, and the executors a third: adding, that this writ lies as well for the children, &c. as the wife. Such is the general law of Scotland at this day. And whatever may have been the custom of late years, in many parts of the kingdom, or however it was introduced in derogation of the old common law, the ancient method continued in use in the province of York, the principality of Wales, and the city of London, till very modern times; when in order to favour the power of bequeathing, and to reduce the whole kingdom to the same standard, three statutes have been provided; the one 4 & 5 W. & M. c. 2, explained by 2 & 3 Ann. c. 5, for the province of York; another, 7 & 8 W. III. c. 38, for Wales; and a third, 11 Geo. I. c. 18, for London (see CUSTOM of London); whereby it is enacted, that persons within those districts, and liable to those customs, may, if they think proper, dispose of all their personal estate by will; and the claims of the widow, children, and other relations, to the contrary, are totally barred. Thus is the old common law now utterly abolished throughout all the kingdom of England, and a man may devile the whole of his chattels as freely as he formerly could his third part or moiety. Blackft. Com. b. ii.

Recto de Rationabili Parte. See Recto.

RATIO.
RAT

RATIONABILIBUS Divisio, is a writ that lies where two lords have forgeries joining together, for him that finds his waltie encroached upon, within the memory of man, against the encroacher, thereby to rectify the bounds of the forgeries; in which respect, Fitzherbert says, it is of the nature of a writ of right.

RATIONABILIS Dos, a third part of such lands and tenements as the husband was seized of at the time of the espousals, with which his wife was formerly endowed by the common law, if no specific donation was made at the church-porch. See Dower and Jointure.

RATIONAL, Reasonable. See Reason.

Rational Fables. See Fables.

Rational Fractions, in Arithmetic and Analysis, are those fractions into which no furd or radical quantity enters; as

\[ \frac{m}{a} \]

The decomposition of rational fractions into simple fractions, that is, the decomposition of them into other fractions whose sum is equal to that proposed, is an important problem, as connected with the integral calculus, and inverse method of fluxions, which was first investigated by Leibnitz, but has since been much extended and simplified by the researches of Euler, La Grange, La Croix, and other eminent analysts.

The decomposition of numeral fractions into their partial fractions, is, perhaps, rather a subject of curiosity than utility, yet as connected with, and leading to, the decomposition of rational algebraic fractions, it may not be amiss to give here a sketch of the processes by which it is accomplished, previous to entering upon the latter subject.

On the decomposition of rational numeral fractions, into others having prime denominators.

It is to be observed, that this can only be effected in the case of a composite denominator, or rather, there will be no difficulty in any other case, as it will require only a separation of the numerator into any parts at pleasure, the sum of which is obviously equal to the fraction proposed; we shall therefore only consider those fractions having composite denominators, which are to be resolved into others having prime denominators; and in this case there may be fractions that will not admit of decomposition, as will appear from what follows. This decomposition is effected, when possible, by means of the indeterminate analysis; viz. let \( \frac{m}{a} \) be the given fraction, and suppose, in the first instance, that its denominator consists of two prime factors, or \( a = ab \), it will then be to find \( \frac{m}{ab} = \frac{a}{a} + \frac{b}{b} \), or \( aq + bq = m \); and \( p \) and \( q \) being the required numerators of the two partial fractions, and which values of \( p \) and \( q \) are easily found from the above equation \( aq + bq = m \), on the principles explained under the article Indeterminate Analysis, subject however to the same limitation there mentioned; viz. the above equation is always possible, provided \( m > ab - a - b \), but in other cases it may or may not admit of solution.

If the given fraction be \( \frac{m}{ab} \), then we may first resolve it into two fractions, and one of these into two others; thus, let \( \frac{m}{ab} = \frac{a}{a} + \frac{b}{b} \), then we have \( abq + c = m \), from which equation \( p \) and \( q \) may be found.

Again, let \( \frac{p}{ab} = \frac{r}{a} + \frac{s}{b} \), which gives \( as + rb = p \), whence \( r \) and \( s \) may be determined, and we shall thus obtain

\[
\frac{m}{ab} = \frac{p}{a} + \frac{q}{b}
\]

as required. In all these cases it is obvious, that the fraction may be decomposed into partial fractions, in as many different ways as the indeterminate equation on which it depends admits of different answers.

Example.—Find two fractions, having prime denominators, whose sum shall be equal to \( \frac{19}{35} \), or to \( \frac{19}{35} \).

Let the required fractions be \( \frac{p}{7} + \frac{q}{5} \), then \( \frac{5p + 7q}{35} = 19 \); therefore \( 5p + 7q = 19 \), whence \( p = 1 \), and \( q = 2 \) (see Indeterminate Analysis); and consequently the required partial fractions are \( \frac{1}{7} \) and \( \frac{2}{5} \).

Example 2.—Find three fractions, whose sum is equal to \( \frac{401}{315} \).

The three factors of 315 are 5, 7, 9, which are of necessity the denominators of the required fractions. Suppose then first, that \( \frac{401}{315} = \frac{p}{5} + \frac{q}{7} + \frac{r}{9} \); whence we have \( 9p + 7q + 5r = 401 \), which gives \( p = 29 \), and \( r = 4 \); therefore \( \frac{401}{315} = \frac{29}{5} + \frac{4}{7} + \frac{r}{9} \). Again, let \( \frac{29}{5} = \frac{r}{r} \), or \( 5r + 7s = 29 \); this gives \( r = 3 \) and \( s = 2 \); so that \( \frac{29}{5} = \frac{3}{7} + \frac{2}{9} + \frac{r}{r} \), and consequently \( \frac{401}{315} = \frac{2}{5} + \frac{3}{9} + \frac{r}{r} \), as required. And in the same manner the decomposition may be obtained in any other case, when falls within the limits above stated.

On the decomposition of rational algebraic fractions, and its application to the integral calculus.

Let \( N = \frac{a + bx + cx^2 + dx^3 + \cdots + px^{n-1}}{D} \) be any rational fraction, whose decomposition into simple fractions is required, and whose numerator is at least one degree lower than its denominator, to which form it may always be reduced by division, if it should present itself under a different form.

The denominator of this fraction, from the known theory of equations, may be supposed to be made up of as many simple factors as is equal to the highest power of \( x \) contained in it, and which factors may be found by determining the roots of the equation formed by putting the whole denominator equal to zero. Let therefore \( a + bx + cx^2 + dx^3 + \cdots + px^{n-1} + qx^n \) be any rational fraction, whose decomposition into simple fractions is required, and whose numerator is at least one degree lower than its denominator, to which form it may always be reduced by division, if it should present itself under a different form.

The denominator of this fraction, from the known theory of equations, may be supposed to be made up of as many simple factors as is equal to the highest power of \( x \) contained in it, and which factors may be found by determining the roots of the equation formed by putting the whole denominator equal to zero. Let therefore \( a + bx + cx^2 + dx^3 + \cdots + px^{n-1} + qx^n \) be any rational fraction, whose decomposition into simple fractions is required, and whose numerator is at least one degree lower than its denominator, to which form it may always be reduced by division, if it should present itself under a different form.

And therefore our proposed fraction \( \frac{N}{D} \) may now be put under the form

\[
\frac{N}{D} = \frac{a + bx + cx^2 + dx^3 + \cdots + px^{n-1}}{(x - r)(x - r')(x - r''(x - r^m))}
\]

and these factors are now to form the denominators of

\[
\frac{N}{D} = \frac{a + bx + cx^2 + dx^3 + \cdots + px^{n-1}}{(x - r)(x - r')(x - r''(x - r^m))}
\]
the simple fractions sought. Let \( A, A', A'', A''', \&c. \)
represent their numerators, so that
\[
\frac{N}{D} = \frac{A}{x-r} + \frac{A'}{x-r'} + \frac{A''}{x-r''} + \&c. \frac{A^{(n-1)}}{x-r^{(n-1)}}
\]

Reduce now these several simple fractions to a common denominator by the usual rule, and add their several numerators together; then comparing the co-efficients of the like powers of \( x \) in the numerator of this new fraction, with those in the numerator proposed, we shall obtain sufficient equations for determining the proper values of \( A, A', A'', A''', \&c. \)
and the decomposition will be effected as proposed. This will be better understood from a partial example.

Let us therefore assume the fraction
\[
\frac{6x^2 - 4x - 6}{x^3 - 6x^2 + 11x - 6},
\]
which it is required to resolve into its simple fractions.

Here the roots of the denominator, by making it equal to zero, are 1, 2, and 3, whence the proposed equation may be put under the form
\[
x^3 - 6x^2 + 11x - 6 = (x-1)(x-2)(x+3) = x^3 - x - 2 + (x+3),
\]

Make now this fraction
\[
\frac{6x^2 - 4x - 6}{(x-1)(x-2)(x+3)} = \frac{A}{x-1} + \frac{A'}{x-2} + \frac{A''}{x+3},
\]

which being reduced to a common denominator, and added together, give
\[
\frac{6x^2 - 4x - 6}{x^3 - 6x^2 + 11x - 6} = \frac{A(x-1)(x+3) + A'(x-1)(x+3) + A''(x-1)(x-2)}{(x-1)(x-2)(x+3)}
\]

\[
= \frac{(A + A' + A'')(x^2 - x - 2 + 3x)}{(x-1)(x-2)(x+3)}
\]
whence
\[
A + A' + A'' = 6
\]
\[
6A + 3A' - 2A'' = 6
\]

from which we readily draw \( A = 1, A' = 2, A'' = 3 \); so that the required fractions are
\[
\frac{1}{x-1} + \frac{2}{x-2} + \frac{3}{x+3}
\]

If therefore the fluent of \( \frac{6x^2 - 4x - 6}{x^3 - 6x^2 + 11x - 6} \) were required, we might immediately reduce the problem to finding the fluents of \( \frac{x}{x-1} + \frac{2x}{x-2} + \frac{3x}{x+3} \), which are known, being hyp. log. \( x \rightarrow 1 \) hyp. log. \( x \rightarrow 2 \) hyp. log. \( x \rightarrow 3 \) = hyp. log. \( [(x-1)(x-2)(x+3)] \)

The same method may be employed for all rational fractions, whose denominators are reducible into unequal simple factors, but as this cannot be generally effected when the highest power of the variable quantity exceeds the fourth degree, we are necessarily limited in our application of the rule, in consequence of the imprecision which still attends the general solution of equations. In the case, however, of equal factors in the denominator, a different process is required, which we will explain, after illustrating the above rule by two or three examples.

Required the fluent of \( \frac{(1+x)x}{x-x^3} \) by resolving it into
its simple fractions.

Here the factors of the denominator being \( x \) and \( 1-x \), we make
\[
\frac{(1+x)x}{x-x^3} = \frac{A}{x} + \frac{A'}{1-x} = \left(\frac{A + (A - A)x}{x-x^3}\right) \frac{x}{1-x},
\]

whence \( A = 1 \), and \( A' = 1 \), or \( A' = 2 \), therefore
\[
\text{fluent} \left(\frac{1+x}{x-x^3}\right) + \text{fluent} \left(\frac{A}{x}\right) + \text{fluent} \left(\frac{2x}{1-x}\right)
\]

which are known.

Required the fluent of \( \frac{(x-1)x}{x + 4x + 2x^2} \), or of \( \frac{1}{x-1} \).

Here, by making \( x^2 - 2x + \frac{1}{2} = 0 \), we have \( x = 1 \pm \frac{1}{2} \sqrt{2} \); make therefore,
\[
\frac{(x-1)x}{x - 1 - \frac{1}{2} \sqrt{2}} = \frac{A}{x-1} + \frac{A'}{x-1 + \frac{1}{2} \sqrt{2}}
\]

\[
\frac{1}{x - 1 - \frac{1}{2} \sqrt{2}} = \frac{A}{x-1} + \frac{A'}{x-1 + \frac{1}{2} \sqrt{2}}
\]

Here we have \( A + A' = - \frac{1}{2} \left( 1 - \frac{1}{2} \sqrt{2} \right) A + (1 + \frac{1}{2} \sqrt{2}) A' = - \frac{1}{2} \) whence we have \( A = - \frac{1}{2} \), and \( A' = - \frac{3}{2} \), therefore fluent of \( \frac{(x-1)x}{x-x^3} \) = fluent \( \frac{1}{x-1} \), which leads us to no useful result.

In case of equal factors, therefore, we must proceed as follows: let the proposed fraction be
\[
\frac{a + bx + cx + dx^2 + \cdots q x^{m-1}}{(x-p)^n (x-r)^n (x-s)^n} \quad \&c.
\]

Assume it equal to
\[
\frac{A}{x-r} + \frac{A'}{x-r'} + \frac{A''}{x-r''} + \cdots \frac{B^{n-1}}{x-p} + \frac{A}{x-r} + \frac{A'}{x-r'} + \frac{A''}{x-r''} + \&c.
\]

Where the upper line represents the fractions due to the \( n \) equal factors, and the lower those due to the \( m \) unequal factors.

Let now these fractions be reduced to a common denominator, and the co-efficients equated as before, which will give us the required values of the several numerators sought.

Example.—It is required to convert \( \frac{1 - 5x}{(1 + x) (1 + x)^4} \) into its equivalent simple fractions.

Assume \( \frac{1 - 5x}{(1 + x)^4} = \frac{B}{(1 + x)^3} + \frac{B'}{(1 + x)^2} + \frac{A}{(1 + x)^1} \)

\[
= \frac{B + (1 + x)B'}{(1 + x)^3} + \frac{A}{1 + x} = \frac{B + B' + A + (2 A - B)x + (A - B)x^3}{(1 + x)^3 (1 - x)}
\]

whence
RATIONAL FRACTIONS.

whence \[ B + B' + A = 1 \]
\[ 2A - B = -5 \]
\[ A - B' = 0 \]

therefore \[ B = 3, B' = -1, \text{ and } A = -1, \]
consequently
\[
\frac{1 - 5x}{(1 + x)^2 (1 - x)} = \frac{3}{1 + x} - \frac{1}{1 + x} - \frac{1}{1 + x} - \frac{1}{1 + x}.
\]

We have in both the preceding cases extended the calculation to a greater length than it is necessary to observe in practical cases, in order that the reader may see distinctly the principles on the decomposition depends. We shall now furnish him with an easier practical method, which we have extracted from Bonyycastle's Algebra, vol. i.

1. When the factors of the denominator of the given fraction are all unequal, or of the form

\[
\frac{N}{D} = \frac{A}{x - r}, \frac{A'}{x - r'} + \frac{A''}{x - r''} + \frac{A'''}{x - r'''}, \ldots
\]
note that which constitutes the denominator of the simple fraction which is to be found, and let \( S \) denote the product of all the remaining fractions; then if the root or value of \( x \), in that factor, be substituted for \( x \) in the formula \( S \), it will give the numerator of the fraction required.

2. If some of the factors are equal and others unequal, or of the form

\[
\frac{N}{D} = \frac{A}{x - r}, \frac{A'}{x - r'} + \frac{B}{x - p} \frac{B'}{x - p'}, \ldots
\]
let \( S \) denote the product of all the factors in the denominator, except one, as before ; then find the simple fractions due to the unequal fractions as above, and for those of the equal factors proceed as follows:

1. \[ B = \frac{N}{S}, \text{ taking } x \text{ in } N, \text{ and } S = p. \]

Let \[ Q = \frac{N - BS}{S}, \text{ then } \]

2. \[ B' = \frac{Q}{S}, \text{ taking } x \text{ in } Q, \text{ and } S = p. \]

Let \[ Q' = \frac{Q - B'S}{S}, \text{ then } \]

3. \[ B'' = \frac{Q'}{S}, \text{ taking } x \text{ in } Q', \text{ and } S = p. \]

Let \[ Q'' = \frac{Q' - B''S}{S}, \text{ then } \]

4. \[ B''' = \frac{Q''}{S}, \text{ taking } x \text{ in } Q'', \text{ and } S = p. \]

\&c.

Which operation being performed, the sum of the fractions thus obtained, together with the former, will give all the simple fractions into which the given fraction is resolvable.

Example 1.—It is required to convert the rational fraction \( \frac{1 + x^3}{x - x^3} \) into its equivalent simple fractions.

Here \( \frac{1 + x^3}{x - x^3} = \frac{A}{0 + x} + \frac{A'}{1 - x} + \frac{A''}{1 + x}; \) whence, by the preceding rule,

\[
\frac{A}{S} = \frac{1 + x^3}{x - x^3} = 1; \text{ being } a = x
\]

\[
A' = \frac{N}{S} = \frac{1 + x^3}{x + x^3} = 1; \text{ being } 1 = x
\]

\[
A'' = \frac{N}{S} = \frac{1 + x^3}{x - x^3} = -1; \text{ being } 1 = -x.
\]

The required fractions are therefore

\[
\frac{1}{x} + \frac{1}{1 - x} - \frac{1}{1 + x} = \frac{1 + x^3}{x - x^3}
\]

Example 2.—It is required to convert the rational fraction \( \frac{1}{x^3 (1 - x)} \) into its equivalent simple fractions. Here

\[
\frac{N}{D} = \frac{1}{x^3 (1 - x)} = \frac{A}{x - r} + \frac{B}{x - r'} + \frac{C}{x - r''} + \frac{C'}{x - r'''}, \text{ &c. }
\]

whence for \( 1 + x \), the first factor, we have

\[
A = \frac{N}{S} = \frac{1}{x^3 - 2x^3 + x^3} = \frac{1}{4}, \text{ for } 1 + x = 1
\]

\[
B = \frac{N}{S} = \frac{1}{1 - x - x^3 + x^3} = 1, \text{ for } 1 + x = 0.
\]

Let now \( Q = \frac{N - BS}{S}, \) for \( 1 + x = 2 \)

\[
Q' = \frac{Q}{S}, \text{ for } 1 + x = 0.\]

Again, for \( 1 - x \)

\[
C = \frac{N}{S} = \frac{1}{x^3 + x^3} = \frac{1}{2}, \text{ for } 1 - x = 1
\]

Let now \( R = \frac{N - CS}{S}, \) for \( 1 - x = 2 \)

\[
R' = \frac{R}{S}, \text{ for } 1 - x = 0.
\]

Therefore

\[
\frac{1}{x^3 (1 - x)^3 (1 + x)} = \frac{1}{x^3 + 1 + x} + \frac{1}{x^3 + x^3} + \frac{1}{x^3 + 2x^3} + \frac{1}{x^3 + 3x^3} = \frac{1}{x^3 + 1} + \frac{1}{x^3 + x^3} + \frac{1}{x^3 + 2x^3} + \frac{1}{x^3 + 3x^3} = \frac{1}{x^3 + 1} + \frac{1}{x^3 + x^3} + \frac{1}{x^3 + 2x^3} + \frac{1}{x^3 + 3x^3}, \text{ as required.}
\]

It is obvious, as we have before stated, that this decomposition of rational fractions must necessarily be affected as to its general application, by the imperfection of the theory of equations, which will not admit of a practical resolution of the denominator into its simple factors in all cases. It will also further appear, that, in case of any of the roots being imaginary, the same will necessarily enter into the numerators of the simple fractions. But this difficulty may be avoided : for since the imaginary roots of equations always enter in pairs, and the product of such pairs of roots being always real, being of the form \( x + 2 \alpha x + \alpha^2 + \beta \), we may, instead of resolving the fractions into simple fractions

\[
\frac{A}{x - r} + \frac{A'}{x - r'} + \frac{A''}{x - r''}, \text{ &c. }
\]

resolve it into as many of these fractions as it has rational simple factors, and into as many fractions of the form \( \frac{Bx + C}{x^2 + x + \alpha^2 + \beta} \) as it has pairs of imaginary factors, and then proceed as before. We
RAT

We cannot extend our remarks to a greater length in this article; we must, therefore, refer the reader who wishes to see these principles more completely developed, to Euler's Analytis Infinitorum, vol. i. ch. 2 and 11; to La Croix's Algebra, and his Calcul Differentiel et Calcul Integral. See also Bonycastle's Algebra, and Simpson's Fluxions.

RATIONAL or true horizon, is that whole plane is conceived to pass through the centre of the earth, and which therefore divides the globe into two equal portions, or hemispheres. See Horizon.

It is called the rational horizon, because only conceived by the understanding; in opposition to the sensible or apparent horizon, which is visible to the eye.

RATIONAL integer, or whole number, is that of which unity is an aliquot part. See Number, and ALIquot part.

RATIONAL MIXT number is that consisting of an integer, and a fraction; or of unity, and a broken number.

Commensurable quantities are defined by being one to another as one rational number to another.

For unity is an aliquot part of a rational number; and a fraction has some aliquot part common with unity; in things, therefore, that are as a rational to a rational number, either the one is an aliquot part of the other, or there is some common aliquot part of both; therefore they are commensurable.

Hence, if a rational number be divided by a rational, the quotient is always a rational.

RATIONAL Physicians, in ancient medical history, the physicians of the dogmatic sect, who stood in opposition to the empiric sect; the former appealing to certain theoretical principles in the application of remedies, while the latter relied entirely upon experience, and disclaimed all knowledge of first principles. The tenets of both these sects have been handed down to us by a classic author, Celsus, and have been given at length under a former article. See EMPHIC.

RATIONAL Quantity, or number, a quantity or number commensurable to unity.

Subposing any quantity to be 1, there are infinite other quantities, some of which are commensurable to it, either simply, or in power; these Euclid calls rational quantities.

The rest, that are incommensurable to 1, he calls irrational quantities, or jurels.

RATIONAL Ratio. See RATIO.

RATIONAL Soul. See SOUL.

RATONALE, a solution or account of the principles of some opinion, action, hypothesis, phenomenon, or the like. Hence.

RATONALE is also the title of several books. The most considerable is the "Rationale of Divine Offices," by Guil. Durandus, a celebrated school-divine, bishop of Mende, martyred in 1286, as he himself tells us. See PRINTING.

RATONALE also denotes an ancient furred tippet, worn by the high-priest under the old law; and called by the Hebrews, הָרָתָּה, hophesh; by the Greeks, ἡπεθος; by the Latins, rationale, and pelorale; and by the English translators, breast-plate.

The rationale was a piece of embroidered stuff worn on the breast, about a span square. Du-Cange describes it as a double square of four colours, interwoven with gold, and set with twelve precious stones in four rows, on which were engraved the names of the twelve tribes, and fastened to the shoulder by two chains and two hooks of gold. The form of the rationale was prescribed by God himself, Exod. xxviii. 15—29.

A rationale appears also to have been anciently worn by the bishops under the new law. But authors are in doubt about its form; some will have it resembal of that of the Jews; others take it to be only the pallium.

RATIONALIS, an officer mentioned in several ancient inscriptions.

Laenepius, in the life of Alex. Severus, uses rationalis as synonymous with procurator.

The rationales were intendants or surveyors under the emperors; and though Laenepius pretends they were first established by Severus, it is evident there were some under Augustus.

RATIONALIUM, among the Romans, a book which contained the accounts of the empire. It was otherwise called breviarium. See BREVIARY.

RATIONIS ENS. See Ens.

RATIONIS Dificitio. See DISTINCTIO.

RATONIS OS, in Anatomy, the bone of the forehead, otherwise called os frontis.

RATIBON, or REGENSPURG, in Geography, an imperial city of Germany, in the circle of Bavaris, and capital of a bishopric of the same name, situated at the confluence of the Regen and of the Danube. The town is large, populous, and fortified; and was anciently the capital of Bavaria, and the residence of its dukes. The emperor Frederic I. annexed it to the empire. This town is a staple, but neither its manufactures nor trade are very considerable; corn, wood, and provisions, are sent by the Danube to Vienna. The number of inhabitants is about 24,000; 62 miles N.E. of Augsburg. N. lat. 48° 55'. E. long. 12° 50'.

The bishopric of Ratibon comprehends about 1383 parishes; and was founded, as it has been supposed, by St. Boniface, in the year 736. The seat of the bishop is at Ratibon, where, however, he has no jurisdiction.

RATISKA, a town of Immervia; 35 miles N.E. of Cotatis.

RATKAI, George, in Biography, born in 1613, of a noble family, in Hungary, entered into holy orders, and was made canon of the church of Zagrab. He obtained the see of the vicar of Croatia, John Drakovitz, who engaged him to compose the history of that province, and gave him free access to its archives. He accordingly published, in 1652, a very learned work, entitled "Memoria Regum et Banorum regnorum Dalmatiae, Croatia, Slavonie, inchoata ab origine sua ulque ad annum," Gen. Biog.

RATLINES, or, as the seamen call them, Rutlins, or Ratlings, are certain small lines which traverse the throns of a ship horizontally, at regular distances above the dead-eyes upwards, and forming a variety of ladders, whereby to climb to any of the masts, or ascend from them. Hence the term seems to be derived from ratb, an obsolete word, signifying a hill. In order to prevent the ratling from slipping down by the weight of the sailors, they are firmly attached by a knot, called a close-bitch, to all the throns, except the foremost or aftermost; where one of the ends, being fitted with an eye-splice, is previously fastened with twine-thread or pack-thread. Falconer.

RATNO, in Geography, a town of Lithuania, in the palatinate of Brzefz; 50 miles S.E. of Brzefz.

RATTOATH, a poor village of the county of Meath, Ireland, which, before the union, had its representatives in parliament. It gave name to a barony, and is 12 1/2 miles N.W. by N. from Dublin.

RATOLY, a town of Hindoostan, in the circar of Gohud; 25 miles S.E. of Ratt.

RATONES, a small island in the river La Plata, near Monte Video.

RATSCHA,
RAT

RATSCHA, or Retzka, a fortress of Sclavonia, on the N. side of the Save, opposite to the mouth of the Drin; 35 miles S.W. of Peterwardein.

RATSCHZ, a town of Moravia, in the circle of Brunn; 10 miles N.E. of Brunn.

RATURZ, a town of Hindooftan, in the circle of Aurungabad; 65 miles E. of Aurungabad.

RATTAK, a town of Bengal; 14 miles S.S.E. of Curquckpou.

RATTAN. See Ruatan.

Rattan Canes. See Canes.

RATTELS DORF, in Geography, a town of Bavaria, in the bishopric of Bamberg; 9 miles N. of Bamberg.

RATEN. See Ratzen.

RATTEN, in Rural Economy, a provincial word, used to signify a rat.

RATTENBERG, in Geography, a town of the county of Tyrol, with a citadel on the Inn; 16 miles E.N.E. of Innsbruck.

RATTEN, a town of the duchy of Holstein; 6 miles N.N.W. of Lubeck.

RATTLE, among the Ancients, a musical instrument called by the Romans crupitaclum. Mr. Malcolm takes the tintinnabulum, crotalum, and sistruum, to have been only so many different kinds of rattles. The invention of the rattle is ascribed to the famous mathematician Archytas; whence Aristotle calls it Archytas puellae, Archytas's rattle. Diogenianus adds the occasion of the invention; viz. that Archytas, having children, he contrived this instrument to prevent their tumbling over things about the house. So that how much fower some instruments have changed their uses, the rattle, we are sure, has preferred its original application.

RATTLE, or Rattel, in Commerce, a weight in Arabia; a rattle of coffee contains, at Betelagus, 14½ vikas, and a farcel, or frazil, of 10 maunds, or 20 rattles, contains 290 vikas; a farcel weighs 20 lb. 6 oz. 4 dr. avoirdupois, and a bahar of 40 farcelles = 815½ lb. avoirdupois; 10 farcelles in Betelagus are equal to 7 in Mocha; 16 vikas of dates, candles, and iron, are reckoned to a rattle; but of all other forts of goods 15 vikas make a rattle. The rattle is used in the bazar, or market, only. At Jiddah, another sea-port of Arabia, in the Red sea, the bahar contains 10 frazils, 100 maunds, or 500 rattles, and the rattle 15 vikas. The bahar weighs 222½ lb. English troy, or 183 lb. avoirdupois; and the maund 29 oz. 4½ dr. avoirdupois. Kelly's Un. Cambil.

RATTLE-Gra.S. See Rhinanthus.

RATTLE-N. See Wolf Net.

RATTLE, Red. See Pedicularis.

RATTLE, Yellow. See Rhinanthus.

RATTLE-SNAKE. See Snake.

RATTLE-SNAKE Root. See Snake-root.

RATTLE-SNAKE Root, Dr. Witt's, a species of Prenanthes; which fee.

RATTLE-SNAKE Weed, a species of Erygium; which fee.

RATTLE-SNAKE Islands, in Geography, a cluster of small islands at the western extremity of lake Érie.

RATTLE-SNAKE Mountains, mountains of New Hampshire; 38 miles N. of Concord.

RATTLING in horses, a term applied to a disagreeable noise produced in them by the entrance of the air between the internal parts of the sheath and the prepuce or covering, principally taking place in trotting or going fast.

RATTOONEAU, in Geography, a small island at the entrance of the harbour of Marseille, which has a fortress erected in the 17th century by the duke of Guise.

RATTREY HEAD, a cape of Scotland, on the N.E. coast of the county of Aberdeen; 7 miles N. of Peterhead. N. lat. 57° 12'. W. long. 1° 44'.

RATULAH, a town of Hindooftan, in Oude; 15 miles N.E. of Fyzabad.

RATWAH, a town of Hindooftan, in the circle of Gohud; 27 miles E. of Gwalior.

RATZER, in Commerce, the name of a small coin, struck at Frifburgh, &c. nearly of the same value with the blare, which, in France, is worth two fols and a denier.

RATZEBURG, in Geography, a town of Hinder Pomerania; 14 miles S. of New Stettin. N. lat. 53° 30'. E. long. 16° 14'.

RATZBURG, a town of Germany, which gives name to a principality, situated on an island in a large lake; the lake is 30 miles long, and 9 broad, and boats pass by it to Lubeck with goods and passengers. It was burnt by the Danes in 1693, and since that danger the streets have been regularly laid out, and the houses are built after the Dutch manner. In the market-place is the registry-office, and here is held the chief court of justice and the consistory; the garrison is quartered in barracks; 20 miles S. of Lubeck. N. lat. 53° 45'. E. long. 15° 46'. The principality of the same name is situated between Mecklenburg and Saxe-Lauenburg, and extends about 10 miles each way. The soil is fertile, and produces a considerable quantity of wheat, besides feeding a number of cattle. It was converted from a bishophoi into a principality by the peace of Westphalia. It belongs to Mecklenburg-Strelitz.

RATZENSTEIN, a town of the duchy of Styria; 5 miles S. of Windisch Gratz.

RATZKUTZCHA, a town of Hungary; 10 miles N.N.W. of Cakathurn.

RAVA. See Rawa.

RAVALEMENT, Fr. equivalent, among organ-builders and harpsichord-makers, to compass as English. The complete set of keys, or whole system of musical sounds, (said Roussel in 1768,) instead of confining itself to four octaves, like common keyed-instruments formerly, extends now to five octaves, adding a fifth below double C, and a fourth above C in alt., including five octaves between the lowest F and the highest. (This was the common compass of our harpsichords made by Tabel, Kirckman, and Shudi, long before 1768.) The word ravalement is confined to keyed-instruments; there are no others of so extensive a compass as five octaves. But in the year 1777, when Dr. Burney first composed and published duets “a quatre mains,” or for two performers on one instrument, the ladies, at that time wearing hoops, which kept them at too great a distance from each other, had a harpsichord made by Merlin, expressly for duets, with five octaves; extending from the octave below double C in the base, to the octave above C in alt. in the treble. And as duets a quatre mains have been composed by all the great masters in Europe since that time, instruments with additional keys are now become general. At first it was only in the treble that the compass was extended, except in the instrument above-mentioned by Merlin; but at present notes are added in the base to complete the five octaves, and, indeed, the additional notes in the base are better worth having for particular effects, than those in the treble; which often, from the shortness of the strings and feeble vibration, more resemble the tone of wood than wire; whereas the tone of those in the base of large piano fortés, by the bell makers, is so rich and full, that
RAV

that each found below double F resembles that of an organ-pipe in flow notes, more than the transient tone of a string.

Roufleau very justly observes, that almost all instruments are limited in their compass below, except harps and instruments with keys. The violoncello can go no lower than double C, its 4th string, nor the violin below G. The flute and hautbois descend only to D and C. But the notes in alt. have been extended in the acute to founds that are seldom in tune, and never pleasing. Like rapid notes of difficult execution, they surprize, and the performer's dexterity is applauded; but neither the harmony nor the melody of very high or rapid founds can excite rapture like those of moderate quickness, when produced with feeling and expression, in the middle of the scale.

RAVALSHE, in Geography, a town of Sweden, in Weft Gothland; 24 miles N.W. of Uddevalla.

RAVANA, in Hindo Mythology. See RAVENA.

RAVANAK, in Geography, a town of European Turkey, in Macedonia; 16 miles E.S.E. of Saloniki.

RAUAND, a town of Persia, in the province of Kerman; 105 miles E. of Sirgan.

RAVA-POU, in Botany, Rheede Hort. Malab. v. 4. 99 t. 48; a plant erroneously cited by Linneus for his very different Nyctanthes bifiuta. See GUETTARDA Speciosa.

RAUCA AVIS, in Ornithology, the name of a bird described by Nieremberg, as common about the lakes and rivers of America, and of the kingfisher kind, but nearly as large as a duck, and black on the crown, and white on the breast and belly. Its neck is naturally very long in proportion to its body, yet it can occasionally contract and shorten it in a very wonderful manner. It is a native of Mexico, and is esteemed very good for the table. Mr. Ray has placed this among the birds, the accounts of which he is distrustful of.

RAUCH, in Geography, a town of Germany, in the lordship of Schwarzenberg; 10 miles S.W. of Scheinfeld.

RAUCHENEGG, a town of Austria; 2 miles W. of Baden.

RAUCHT, a town of Russia, in the government of Viborg, near lake Ladoga; 44 miles S.E. of Viborg.

RAUDANAGUR, a town of Bengal; 50 miles E. of Ramgar.

RAUDEHN, a town of Prussia, in the palatinate of Culm; 10 miles N.E. of Culm.—Alfo, a town of Silesia, in the principality of Ratibor; 12 miles N.E. of Ratibor.

RAUDNIZ, a town of Bohemia, in the circle of Schlan; 12 miles N.N.E. of Schlan.—Alfo, a town of Bohemia, in the circle of Chrudin; 16 miles N.N.W. of Chrudin.

RAUDRI, a name of the Hindo goddess Parvati, confort of Siwa, the destroying power. In this character she may be considered as Sakti, or energy in her form of Rudra, or Fate. Rudri, and Rudrani, are other modes of writing this name of the goddess in her avenging character, in which she does not apparently differ much from her attributes, as Sakti of Mahakala; under which name, and the others occurring in this article, distinguished by italics, farther and sufficient information may be sought. See also TRISAKTI-DEVI, and TAMAS.

RAUDTEN, in Geography, a town of Silesia, in the principality of Wohlan; 18 miles N.W. of Wohlan. N. lat. 51° 30'. E. long. 16° 15'.

RAVEL BREAD, a sort of bread, called also black wheat; as being of a middle fineness between white and brown.

RAVELIN, in Fortification, was anciently a flat bastion, placed in the middle of a curtain.

RAVELIN is now a detached work, composed only of two faces, which make a salient angle, without and sometimes with flanks; and raised before the curtain on the counter-fearp of the place; serving to cover it and the joining flanks from the direct fire of an enemy.

A ravelin is a triangular work, resembling the point of a balloon, with the flanks cut off. (See Plate V. Fortification, fig. 4. lit. i. i. &c.) Its use before a curtain is, to cover the opposite flanks of the two next bastions. It is used also to cover a bridge or a gate, and is always placed without the moat.

What the engineers call a ravelin, the soldiers generally call a demi-lune, or half-moon. See DEMI-LUNE.

There are also double ravelins, which serve to defend each other. They are said to be double when they are joined by a curtain.

Ravelins, or half-moons, are constructed by setting off 50 toises from the re-entering angle O of the counter-fearp (Plate VII. Fortification, fig. 4.) on the capital O L of the ravelin, or on the perpendicular produced, and from the point L drawing lines to the shoulders A, B; whole parts L M, M N, terminated by the counter-fearp, will be the faces M O, O N, the semi-gorges of the ravelin required.

Others will have the faces of the ravelin to terminate on tofe of the bastions within three toises of the shoulders, in which case the ravelins cover the flanks better than the others. The ditch before the ravelin is 12 toises, and its counter-fearp parallel to the faces of the ravelins, and made in a circular arc before the salient angle. When the ravelins are made with flanks, the faces should terminate two of the bastions, at least 5 toises from the shoulders. These flanks are made by setting off 10 toises from the extremities of the faces, and from the points thus determined, the flanks are drawn parallel to the capital of the ravelin. When redoubts, or keeps, are formed in the ravelin, this is done by setting off 16 toises from the extremities of the faces, on the semi-gorges from M to b, and from M to a; and from the points b, a, the faces are drawn parallel to the face of the ravelin; the ditch before this redoubt is 6 toises, and its counter-fearp parallel to the faces. This work should be covered in the faces of a wall, a foot or two thick, furnished with loopholes for the musketry to fire through; and it will serve to secure a retreat for the troops who defend the ravelin; they may thus prevent the enemy from making a lodgment in the outward part of the ravelin, or at least greatly obstruct their attempts for this purpose. Nor can they be drove from this place, until the enemy has erected a battery, and brought cannon on the ravelin to batter the redoubt. When the counter-gate (which fe) is placed before the ravelin, 40 toises are set off on the capital of the ravelin from its salient angle to the salient angle of the counter-guard, and 10 on the counter-fearp of the ditch. For the construction of crown-works before the ravelin, see HORN-work. Within the ravelin are constructed a rampart of about 16 or 20 yards, and a parapet of about 6 yards; ramparts are also annexed in the slope of a rampart, and a barbette, when it is proper, is constructed in a salient angle. In wet ditches, where the troops pass from the town to the ravelin in boats, it is proper to make, in the gorge of the ravelin, a kind of harbour, where the boats may be covered from the fire of the enemy. In dry fosses, there should be ramps or stairs in the gorge of the ravelin, to preserve a free communication, if the bridges should be broken down by the enemy's shot. The celebrated general Cochon, in the ravelins which he built at Bergen-op-zoom, contrived a very good defence for the covered way before the faces of the bastions, by making retired flanks in the breasts of the ravelin, where
R A V

one or two cannon might be placed as secure from the enemy's fire as those behind the orillon of a bastion. See Military Construction.

Ravello, in Geography, a sea-port town of Naples, in Principality Citra, the fee of a bishop, united to Scala; 11 miles W.S.W. of Salerno. N. lat. 40° 39'. E. long. 15° 10'.

RavelWater, a river of the county of Antrim, Ireland, rising in the mountains in the northern part, and flowing through Ravel Glen to the river Main.

Raven, Corvus corax of Linnaeus, in Ornithology, a large bird of the crow kind, well known throughout the world, as being found in all climates, and all regions. The colour of the whole bird is black, finely glossed with a rich blue, the belly excepted, which is dusky. The ravens build in high trees, or upon the ruins of lofty buildings in the neighbourhood of great towns, being held in the same veneration as the vultures are in Egypt, and for the same reason; for, to devour the carcasses and filth that would otherwise prove a nuisance. They lay five or six eggs, of a pale greenish colour, marked with small brownish spots. There are many fabulous stories of the longevity of the raven; but birds are in general long lived, and the crow kind not less so than the raven. The raven is a very docile bird, and may be taught to speak, as well as to fetch and carry. In clear weather, ravens are remarked to fly in pairs at a great height, making a deep loud noise, different from the common croaking; and their crient is remarkably good. See Corvus Corax.

The quills of a raven are used in tuning the lower notes of a harpsichord, when the wires are set at a considerable distance from the fiddles. It is rare to find this creature white, yet it happens sometimes. Boyle mentions one. There was also one shewn to the Royal Society some years ago. Boyle's Works Rbr. vol. ii. p. 46.

Raven, Night, an English name for a heron, which flies in the night, and makes a very odd and hoarse noise. It has been applied to some to the bittern, or ardea balearis, but improperly, belonging of right to the smaller grey heron, called nitrogen. See Nitrogen.

Raven, Sea, or Corvus marinus. See Corvus Aquaticus.

Ravena, in Hindu Mythology, is the name of a celebrated king of Lanka, or Ceylon. Such was his prowess, and the oppression which he exercised over his subjects, that he became necessary for Vishnu, the preserver of the deity, to defend on earth for his destruction, and the relief of the suffering world. He accordingly became incarnate in the person of Rama, and the wars that ensued between the forces of the tyrant and the divine general, for the recovery of Sita, his ravished spouse, are the subject of the fine epic poem, the Ramayana; under which article of this work, and under Ranya, and others thence referred to, the poem, and the historical traditions connected with these points, are sufficiently described and discussed.

Although obscured by mythological fables, these perfons and wars are admitted to have had historical existence; and some important points of chronology hinge upon them. We have, therefore, in this and other articles, noticed at some length the legends connected with these subjects.

In the Hindu theogony, the origin of Ravena is thus related. Two ethereal warders of Vishnu's palace carried the pride of office so far as to inflit the seven Maharthis, (see Maharthis, or Rishis,) who had come to offer their adorations. The offended deities pronounced an imprecation on the insolent warders, condemning them to be adhe-

yoni, or born below, thrice in mortal forms, before they could be re-admitted into the divine prehence. The imprecation of a Rishi, even if provoked by a god, is scarcely to be averted; and the offenders, in consequence, appeared in their first birth as Hiranayaka, or golden-eyed, and Hiranayakipuro, or clad in gold; secondly, as Ravena and Kumbhakarna; and lastly, as Kansa and Sipulora.

The history, if such it may be called, of Ravena, Rama, &c, is perpetually alluded to in Hindu writings; the Ramayana, containing an infinity of such legends being one of the most popular works of the East. Ravena, or Ravana, has become a generic name for a tyrant. He is also called Dasagriiva, or the ten-necked; he being usually represented with that number of heads, and twenty hands, symbolical of suppliance and prowess. A couplet in the Ramayana may be thus translated. Where Ravana is, the fun lores his forces, the winds cease to blow, the fires cease to burn; the rattling ocean, seeing him, flulls its waves. Such are the hyperbolical relations of his potency, obtained by the usual process of self-inflicted austerities. So ardent was he in this irrefrangible species of merit, that he offered to Siva nine of his ten heads successively; and thus extorting the favour of the condescending deity, pleased with such an important sacrifice, he obtained a promise, with some equivocal stipulations, of whatever he should desire.

This sort of austerity is called Tapas, under which word some account is offered of various modes of practising it. The gods and demi-gods, alarmed at Siva's promise, besought him to recall it. But such conduct is deemed unbecoming in deities, who, however, do not scruple to evade the performance of their promises by deceit or prevanation: and, on this occasion, Nareda was deputed to found Ravena as to what he would demand, which, as usual, was universal dominion, &c. Nareda artfully persuaded Ravena that Mahadeva, or Siva, his promised, was drunk, and had pronounced him what he could not perform; whereupon the vindictive giant tears up Kailasa, the pantheon of Siva, which, being contrary to the stipulations, releashes Siva from his promise, and he confines to the destruction of Ravena, which is brought about by the avatars or deyants, of Vishnu in the person of Rama. From this story we are told to learn that all worldly affairs are the predestined ordinances of providence; whose will, that any event should take place on earth, includes sufficiently all the routine and detail of its accomplishment; although we only see the links of a chain of causes leading naturally to its effect.

We will here add an extract from the Hindu Pantheon, whence a considerable part of this article is taken, shewing how unceasingly the mythological machinery of that poetical people is introduced into their popular works. The names distinguished by capital imply that articles are given under those words, in this work; and a reference may be made to them for any defined information.

"Respecting Ravena," says the author of the publication adverted to, "I will notice but one more tale, as related to me by a Brahman; who, unable fully to make me feel the poetical beauties, or comprehend the morality of the Ramayana, bluffed while he developed its follies; which, in conformity with popular taste, or if taken separately, are apparently very numerous; although it must be confessed, they are so contrived as to be intimately connected with the main action of the poem. The following idle tale is of this description; but shall not here explain the causes that led to the predication, or the consequences that ensued."

"Ravena, by his power and infernal arts, had subjugated all
all the gods and demi-gods, and forced them to perform menial offices about his person and household. Isyra made garlands of flowers to adorn him withal. Agni, or Parvaka, was his cook. Sukra, regent of the sun, supplied light by day; and Soma, regent of the moon, by night. Varuna, the Hindoo Neptune, purveyed water for the palace. Kuvera, their Pluto, furnished cash. The whole nine planets (the nine planetary spheres, including Rahu and Ketu) sometimes arranged themselves into a ladder, by which, they serving as steps, the tyrant ascended his throne. Braha (for the great gods were there also, and I give this anecdote as I find it in my memoranda, without any improved arrangement) was a herald, proclaiming the giant's titles, the day of the week, month, &c. daily in the palace; a sort of speaking almanac. Mahadeva, in his character or incarnation of Kandeh-Rao, performed the office of barber, and trimmed the giant's beards. Vishnu had the honourable occupation of instructing and drilling the dancing and singing girls, and selecting the fairest for the royal bed. Ganea, or Pollear, had the care of the cows, goats, and herds. Vayu swept the house. Yama washed the linen. And in this manner were all the gods employed in the menial offices of Ravena, who reburked and flogged them in default of industry and attention. Nor were the female divinities exempted: for Parvati, in her form of Sati, was head Aya, or nurse, to Ravena's children. Lakshmi and Saraswati were also among them, but it does not appear in what capacity. Earthly kings and queens were also forced into this degrading servitude, to the number of ninety-six royal families; as is said to be detailed in the Ramayana. But I have some doubt if such a relation be actually in this shape, in that poem: this we shall see, when its other books are translated and published. In my abstract of it, however, such a godly predication seems essential to the main action; Rama being thereby impelled by every consideration of piety and duty to immediate and immediate energetic measures, for the relief and liberation of the degraded divinities.

Ravana, as we have noticed, is surnamed Dala-griva, or the ten-headed. He is also called Vifrvana, or fon of Vifrava, the father likewise of Kuvera. The brothers are sometimes named Pulafja, or Pualafja. (See these articles.) Another of his names is equivalent to lord of Rakhasas, a race of malignant beings, common agents in the hands of superhuman tyrants for the annoyance of the virtuous portion of mankind, or thwarting the benificent views of the gods. Many specific varieties of these demons are enumerated in the first book of the Ramayana, as aiding Ravena in defence of himself and his kingdom of Lanka. In pictures illustrative of the Ramayana, which are very common throughout India, they are depicted especially ill-favoured, painted green, red, blue, &c. and engaged in fierce contortions with Rama's humanfoldery. Several generations of these Rakhas, each of 14,000, were destroyed by Rama. See Raksha.

RAVENALA, in Botany, Adans. Fam. des Plantes, v. 2. 67. See Uranka.

RAUENBACH, in Geography, a town of Germany, in the principality of Ansbach; four miles S.S.W. of Ansbach.

RAVENGLASS, a market-town and sea-port in the parish of Muncaster, Allerdale ward, above Darwent, county of Cumberland, England, is situated on the Solway Frith, near the confluence of the rivers Esk, Mite, and Irri. Though possessing many advantages for trade, it is but a poor place, and chiefly supported by its oyster fishery, for which it is much celebrated. This town stands at the distance of 57 miles S.S.W. from Carlisle, and 287 N.W. by N. from London. The manor originally constituted part of the barony of Egremont, but was granted to Richard Lucy to the Penningtons, from whom the present owner, Lord Muncaster, is lineally descended. The market day is Saturday, weekly; and there are two annual fairs, one of which is held on the eve, day, and morrow, of St. James, and is remarkable for the ceremonies attending its proclamation and continuance. On the first day, the earl of Egremont, or his proxy, attends, accompanied by the fequeant of the borough of Egremont, with the insignia, called the Bow of Egremont; by the foresters, with their bows and arrows; and by all the tenants of the forest of Copeland, who hold their confirmations by the special service of attending the earl, or his representative, during the fair. On the third day, at noon, the earls, officers, and tenants of the forest, depart, after profession; and lord Muncaster, and his tenants, take formal possession of the place, and the day is concluded by horse-racing, and various rustic diversions.

Near Ravenglas, on the northern bank of the river Esk, stands Muncaster-houfe, the seat of lord Muncaster; and eft from it, on the opposite side of the river, are seen ruins of considerable magnitude, respecting which no historical documents are known to exist. They are now called the city of Barnsley; and its foundation is ascribed, by tradition, to the Danes, who are said "to have gathered for its inhabitants the men of Drig, and the women of Becket" from the popular saying, "let us go together like lads of Drig and lasses of Becket." These ruins extend about three hundred yards in length from east to west, and 100 in breadth, from north to south; and are enclosed, except at the east end, by a wall, nearly three feet in height. "There appears," says Hutchin, "to have been a long street, with several crofs ones; the remains of the house-heads within the walls are not very numerous; but on the outside they are innumerable, especially at the south side and west end. The circumference of the city, and suburbs, is nearly three computed miles; the figure is an oblong square. There is an ancient road through the city, leading from Ulpha to Ravenglas. About the year 1730, a considerable quantity of silver coin was discovered in the ruins of one of the houses, concealed in a cave formed in a beam." A History of the County of Cumberland, &c. by William Hutchin, F.S.A., two vols. 4to. Beauties of England and Wales, vol. iii., 1802, by John Briton and Edward Wedlake Brayley.

RAVENNA, a very ancient city of Italy, in the department of the Amone, seated on the river Mentone, near the Adriatic. This city, as Strabo informs us, was built by the Thessalians, on several islands, long before the war of Troy, and they were driven out by the Trojans. In the time of this Greek writer, it was situated in the midst of a marsh, and attached to the continent, and in process of time the Po accumulated mud and sand, so that the land was raised and the sea removed to a greater distance. The same writer informs us, that it was made a Roman colony by Augustus; and Dion says, that a fleet of 250 vessels was stationed in this port by that prince, from which circumstance it was called "portus classis." or the port of the fleet. He stationed, lays Suetonius, one fleet at Milemum, and another at Ravenna, for guarding the upper and lower sea. Tiberius repaired its walls, and erected some new gates, which fill bear an inscription to this purpose. Trajan also contributed towards embellishing this city. Honorius made it the place of his residence, both before and after Alaric had captured and burned Rome. When Odoacer made a conquest of Italy, he refided at Ravenna, and dallustrated here a siege.
of three years, at the termination of which he was taken and slain by Theodoric. Theodoric fixed the seat of his empire in this place, and adorned it with magnificent churches and palaces, and re-constructed the aqueduct of Trajan. His daughter Amalaetha, and his grandson Athalaric, contributed towards the improvement of this city. When the Goths were driven from Italy by Narves, general of the emperor Julianus, he was made governor of Ravenna; and having continued in this station for 16 years, he was recalled by Julian II., successor to Julianus; and in the year 567 he was succeeded by Longinus, who took up his residence at Ravenna, under the title of exarch. (See Exarch.)

The famous battle of Ravenna was fought near this town between Gafon de Foix, duke of Nemmas, and nephew of Louis XII., and the army of pope Julius II., Ferdinand, king of Spain, and the Venetians, in which the former young general, being only 24 years of age, having killed between 16 and 18,000 of the enemy, proved victorious, though he himself was killed by too ardently following the pursuit. This happened on Easter-day 1512. The French, enraged by the loss of their brave general, took Ravenna by storm, and pillaged the city with such severity that it has never recovered. On the road to Forli, by the banks of the little river Rocco, three miles from the city, a crofs shews the spot where Gafon de Foix was killed. Fresh water has always been focarce at Ravenna, that it has occasioned a pleasant epigram by Martial. This city was of late the capital of Romagna, with the title of an archbishopric. It has produced several perfons of eminence, as Faufinus, often mentioned by Martial; the bishop Alpafius, who lived under the reign of Alexander Severus; Caifiodorus, chancellor to Theodoric, king of the Goths in Italy; pope John XVII.; Peter Damien, cardinal of Ofa, and several others. Ravenna was also the seat of many councils at Succesive periods. The three last councils, in 1311, 1314, and 1317, were summoned for the purpose of reforming the corrupted manners of the ecclefastics, which were, in those days, very debauched. It is now a mean and inconsiderable town; the houses are old and in a ruined state, and the number of inhabitants scarcely amounts to 14 or 15,000. In the time of the Romans, it was seated on a kind of bay formed by the Adriatic, and its harbour was celebrated; but it is now three miles from the sea. The mud thrown up by the tide having formed a tract of land, which is cultivated, and on which the city itself has been enlarged towards the sea. The air is infalubrious; but has been somewhat amened by conveying along the sides of the city the rivers Mentone and Ronco, which carry off the fetid water from the marfy grounds. It contains several churches, and 24 convents; 42 miles E. of Bologna. N. lat. 44° 27'. E. long. 11° 5'.

RAVENPOINT, a headland of the county of Wexford, Ireland, at the N. side of the entrance into Wexford haven. N. lat. 52° 23'. W. long. 6° 18'.

RAVENSARA, in Botany, a barbarous appellation, altered by Sonnerat from the Madagafcar name of the plant, Raven-fara, or Varavensara, meaning, it feems, a good leaf, and applying to the aromatic qualities, and economical uses, of the leaves. Hence Juffieu was induced to contrive the apt generic name Agathophyllum, from Agathos, good or profitable, and Phillos, a leaf; under which this genus ought to have been described in its proper place, in our firft volume. But one of our predeceffors has, by mistake, referred the reader to Ravenfara, as a genuine Linnean name, attributing Agathophyllum to professor Martyn; see that article. To correct this error, and supply the confquent deficiency, we subjoin an account of the tree in question, under its proper and received denomination.
Weilphalia. The approaching congress (1814) may possibly fix its future destination.

RAVENSBURG, a town of Bavaria, which anciently belonged to the Guelphs, counts of Altorf; but it was an imperial town before the time of king Rodolphus, and continued such till the year 1802, when it was given, among other indemnities, to the elector of Bavaria. The Roman Catholics and Lutherans are united with regard to the temporal and spiritual concerns of the place, and the magistracy is shared betwixt them. They have one church in common; but the Lutherans are exclusively poleved of another, and the Roman Catholics have also two parih-churches; 21 miles N.E. of Constance. N. lat. 47° 41'. E. long. 9° 38'.

RAVENSBURN, a small stream of England, which runs into the Thames between Greenwich and Deptford.

RAVENSCHROFT, Thomas, in Biography, an active English musician and publisher, who flourished from the beginning of the 17th century to 1653. He was the editor and compositor of the best collection of psalm tunes in four parts, which had till then appeared in England. He was a bachelor of music, and a professor not only well acquainted with the practice of the art, but seems to have bestowed much time in the perusal of the best authors, and in meditation on the theory.

This book, published in small octavo, 1621 and 1633, contains a melody for every one of the hundred and fifty psalms, many of them by the editor himself, of which a considerable number is still in use; as Windor, St. David's, Southwell, and Canterbury. There are others, likewise, which are sung by the German, Netherlandish, and French Protestants. To these the bafe, tenor, and counter-tenor parts have been composed by twenty-one English musicians: among whom we find the names of Tallis, Dowland, Morley, Bennett, Stubbs, Farmery, and John Milton, the father of our great poet. The tunes which are peculiar to the measure of the 100th psalm, the 113th, and 119th, were originally Lutheran, or perhaps of still higher antiquity. And though Ravencroft has affixed the name of Dr. John Dowland to the parts which have been set to the 100th psalm, yet, in the index, he has ranked the melody itself with the French tunes; perhaps from having seen it among the melodies that were set to the French version of Clement Marot and Theodore Beza's Psalms, by Goudemel and Claude le Jeune. Ravencroft, in imitation of these harmonists, always gives the principal melody, or, as he calls it, the play-song, to the tenor. This part, indeed, he sometimes erroneously terms Fa-burden. This is a corruption of fauxbourdon, and false-bourdons, which originally implied such simple harmony as arises from a series of thirds and sixths to the base. His publication is, in some measure, historical: for he tells us not only who composed the parts to old melodies, but who increased the common stock, by the addition of new tunes; as well as which of them were originally English, Welsh, Scotch, German, Dutch, Italian, French, and imitations of these.

No tunes of triple time occur in Claude le Jeune, and but five in Ravencroft: the principal of which are Cambridge, Martyrs, Marcheller, and the 8İst. This last is still much used, and often played by chimies: it is called an imitation of a foreign tune, and has the name of Richard Alliton prefixed to it. Muller's German edition of the psalm tunes at Frankfort is exactly that of Claude le Jeune, in two parts only; except that he has tranposed some of the melodies, and inserted easy leading and connective notes, to assist, not only the finger, but sometimes the tunes them-
RAVILLY, a small town of the county of Carlow, Ireland, in the barony of the same name. It is situated on the river Slaney, 3 miles S. from Baltinglas, and 32 S. by W. from Dublin.

RAVINA, a town of European Turkey, in Albania; 32½ miles E. of Valona.

RAVINE, in Field Fortification, a deep hollow, usually formed by a great flood, or long continued running of water, frequently turned to good purposes in the field.

RAVIS, the fame with ravoedo. See Hoariness.

RAVISHMENT, in Law, denotes an unlawful seducing either a woman, or an heir in ward; for which there is a remedy by a writ of ravishment, or action of trespas sui & armis, de filio vel fillâ rapto vel adultero, in the same manner as the husband may have it de uxore rapitâ et adulâta, on account of the abduction of his wife. This action lay at the common law; and thereby the husband shall recover, not the possession of his wife, but damages for taking her away; and by statute Wilm. I. 3 Edw. I. c. 13. the offender shall also be imprisoned two years, and fined at the pleasure of the king. Both the king and the husband may, therefore, have this action; and the husband is also entitled to recover damages in an action on the cafe against such as persuade and entice the wife to live separate from him, without a sufficient cause.

Sometimes it is also used in the same sense as rape; which fee.

RAVISHMENT de Gard, is a writ which anciently lay, and still lies, for the guardian in toage against him who took from him the body of his ward, or pupil: but then he must account to his pupil for the damages he so recovers. It is expressly provided by statute 12 Car. II. c. 24. that testamentary guardians may maintain an action of ravishment, or trespas, for recovery of any of their wards, and also for damages, to be applied to the use and benefit of the infants.

RAVITZ, or Rawisch, in Geography, a town of the duchy of Warsaw, most of the inhabitants of which are Lutherans: it has a considerable manufacture of cloth; 24 miles S. of Posen.

RAVIUS, or Rave, Christian, in Biography, a learned German Orientalist, was born at Berlin in the year 1613. From a very early period he was attached to the study of the eallern languages, and after spending eight years in different universities on the continent, he came over to England in the year 1658, and took up his residence at the university of Oxford. He brought with him recommendations from Vossius, and other learned men; and was invited to Dublin by archbishop Usher, primate of Ireland, who settled upon him a handsome stipend, and engaged him to take a voyage into the East, for the purpose of collecting ancient manuscripts. About the same time he was invited by cardinal Richelieu to enter into his employment for a similar purpose, which he declined, having already accepted the proposals of Usher. In 1639 he became acquainted with our countryman, the learned Edward Pococke, at Conflantinople, where he improved himself in many languages, to which he had already applied his talents; and made himself master of the Turkish, Arabic, and Persian languages. In the mean time he did not neglect the main object of his mission, but collected more than 300 choice manuscripts. For this service he was, on his return, amply rewarded. In 1642 he taught the Oriental languages at Gresham college, in London. During the following year he went to Holland, and was appointed professor of the Oriental languages at Utrecht. We find him again in England in 1648, when he took the covenant, and was made fellow of Magdalen college, Oxford, by the parliamentary visitors. In the course of a few months he left England, and went to Sweden, where he obtained the appointment of professor of the Oriental languages at the university of Upfal. This place he was obliged to leave about the year 1657; the revenues, that ought to have been devoted to the Upfal professors, having been applied towards defraying the expences of the war between Sweden and Denmark. After this he for some time filled the chair of Oriental literature at the university of Kiel, and from thence he removed to occupy the same professorship at Frankfurt on the Main. He died in 1677, about the age of 64. His works are very numerous, of which the following are titles of the principal: "Observatio ad univerfam Europam pro dicendis Rebus et Linguas Orientalibus, ac conjugandae Africa atque Asia Eruditiones," 1644; "Orthographiae et Ana logiae vulgo Etymologiae Ebraicae Delinarum, juxta voces partes abractas;" "A Dicource of the Oriental Tongues, viz. Hebrew, Samaritan, Chaldee, Syriac, Arabic, and Ethiopic," 1649; "Concordiarius Hebraicarum et Chaldaicarum Epitome;" "Chronologia Biblica nova;" "Epitome varia 22 doct. Viro." He gave also to the world a translation, from the Arabic language, of Apollonius's Conic Sections. He had a brother, named John Ravis, who was professor of philosophy at Rostock, about the year 1638. In 1664-5 he was appointed counsellor and librarian to the elector of Brandenburg. He was author of "Commentarius in Cornelium Nepoten;" 1655; "Summa Studiorum pro Nobilitate Danica;" "Aphorismi Mili tares, and other learned works.

RAULIN, John, a French writer in the 15th century, was born at Toul in the year 1443. He pursued his studies at the university of Paris, where he obtained the degree of D.D. in 1480, and afterwards filled the professor's chair in theology with great distinction. He was elected grand master of the college of Navarre, and founded a good library in that seminary. Becoming dissatisfied with the world, he embraced the monastic life at the abbey of Cluny, in Burgundy, in 1497. He died in 1514, at the age of 71. He attracted much attention as a preacher, and several of his sermons have been published, which exhibit flinking specimens of the bad taste which prevailed in France in the 15th century. The works of this author were collected, and published at Antwerp, in 6 vols. 4to., 1612. They are accompanied with a curious and valuable collection of "Letters," that illustrate the history, manners, and sentiments of the age in which he lived. They were first published after his death, in quarto, in 1521, under the title of "Joannis Raulini Epistolae Illustrium Virorum." Moreri.

RAULT, Felix, the favourite performer on the German flute at Paris, in 1770; where we heard him ourselves with as much pleasure as a flute can give, by next execution, perfect intonation, and a mellifluous embouchure. M. Laborde has rendered his biographical article interesting by a detail of his professional merits and private character.

"M. Felix Rault was born at Bourdeaux, in 1736. He was the son of Charles Rault, of the king's band, and first balloon at the opera. Felix was received there in 1753, and in the king's band in 1768. His talents are so well known at Paris, as to be above praise. Since Blavet's time, no one has brought the art of playing upon the German flute to such perfection, especially in accompanying the voice; a much more difficult art than playing concertos of great execution, generally well studied at home previous to performance. But such study is useless to Rault; for no
one reads music more readily and with more facility, or gives it more meaning, than this performer. The beauty of his tone, the precision of his execution, the richness of his embouchure, however extraordinary, merit still less praise than his personal qualities, which endear him to all his acquaintance.” Laborde.

RAUMO, in Geography, a sea-port town of Sweden, in the province of Finland, on the E. coast of the gulf of Bothnia; 50 miles N. of Abo.

RAUNPIED, in Rural Economy, a provincial word used to signify flag-headed, and a name of one of the Hindoo hells; they reckoning twenty-one of these receptacles for sinners. Naraka is called Maharaurava, or moist dreadful.

RAURIS, in Geography, a town of the archbishopric of Salzburg; 32 miles S. of Salzburg.

RAUSCHENBERG, a town of Heife; 4 miles N. of Marburg. N. lat. 50° 53'. E. long. 8° 53'.

RAUSHENBERG, a town of Germany, in the principalcity of Culmbach; 7 miles N.N.E. of Neustadt.

RAUSNITZ, a town of Moravia, in the circle of Brunn; 10 miles E. of Brunn.

RAUTA LAMBI, a town of Sweden, in the government of Kuopio; 27 miles S.W. of Kuopio.

RAUTENBURG, a town of Prussian Lithuania; 27 miles W. of Tilsit.—Alfo, a town of Prussia, in the province of Samland; 36 miles N.E. of Königsberg.

RAUTERN, a town of Austria; 6 miles W.N.W. of Droffendorf.

RAUTIO, a town of Sweden, in the government of Ule; 56 miles S. of Braheлад.

RAUTPOUR, a town of Hindoostan, in Allahabad; 18 miles N.W.W. of Corah.

RAUTY DUNGEER, a town of Hindoostan, in Guzerat, on the coast; 50 miles S.W. of Noamagur.

RAUTY-Mummy, or Rauty-madder, bone-mummy, a name given by the people of the East Indies to a kind of foifie flower, much valued for its medicinal virtues. It is of the nature of the fucasies, and is found upon the high rocks, and supposed to be generated of the dew which falls from the heavens; but this is an idle opinion, and the formation of it is evidently the fame with that of the European rhomboidal seelentas. They beat it to powder, and after boiling it in milk, they give it in cafes of the venerable kind. In a common clap, they give half a scruple, night and morning.

RAUVEE, in Geography, a river of Asia, which rises on the borders of Thibet, and joins the Chunaub in the country of Lahore, 28 miles N.E. of Moultan. The Ravee is the "Hydroses" of Alexander, and though it is represented as a noble river, it is somewhat inferior in bulk to the Chunaub. Its sources are in the mountains near Nagorkote, a famous place of Hindoo worship; and it enters the plains near Shapour (called alfo Rajapour), from whence the famous canal of Shah Nahr was drawn to Lahore. 483 common cofles in length. The space between the Ravee and Chunaub, at their entry on the plains, is about 54 geographical miles; and they gradually approach each other during a course of 170 miles. The junction of the Ravee with the Chunaub (or rather the Chunaub and Behut collectively) is effected nearly midway between Teoulumba and Moutan. The Ayin Acbaree allows 27 cofles between the junction of the Behut and Chunaub, and that of the Ravee with the Chunaub; but this distance must be applied to the course of the river, not to the road by land. When these three rivers are united, they form a stream equal to the Indus itself, at the place of confluence; which is from 20 to 30 miles below Moutan. Reidell.

RAUWOLFIA, in Botany, was fo named by Plumer, in memory of Leonard Rauwolf, a native of Augsburg, and a pupil of Rondelet. He failed from Magdeburg in 1573, for the Levant, and performed a laborious and dangerous journey through Syria, Mesopotamia, Paletine and Egypt; of which he has left an account in German, full of curious information relative to medical and other rare plants, with several wooden cuts. He died physician to the Austrian army, at Havany, in Hungary, in 1606, according to Dryander, Bibl. Banks. v. 395, though Haller says 1596. The latter writer mentions his being obliged to quit his country on account of his religion, which was Protestant. His Splendid herbarium, once the property of queen Chriftina, and of Isaac Voffius, is preferred in the university of Leyden. From it Gronovius composed his Flora Orientalis.—Linn. Gen. 115. Schreb. 160. Willd. Sp. Pl. v. 1. 1217. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 2. 64. Juff. 148. Plum. Gen. 19. t. 40. Lamarck Illutr. t. 172. Gaertn. t. 52.—Clas and order, Pentandria Monogynia. Nat. Ord. Contorta, Linn. Apocin., Jull.

Gen. Ch. Cal. Perianth inferior, minute, with five segments, permanent. Cor. of one petal, falver-shaped; tube cylindrical, globose at the base; limb in five deep, rounded, emarginate, oblique segments. Stam. Filaments five, shorter than the tube; anthers erect, fimple, acute. Pet. of the middle roundifh; fhyly very short; fligia capitata. Peric. Berry nearly globose, marked with a furrow along one fide, of one cell. Seed two, convex at the base, tapers at the fummit, compressed, divided, more or less completely, into two cells.

Efl. Ch. Corolla oblique, falver-shaped. Stamens included. Berry globose, with two fefts, each of two cells.

1. R. nitida. Shining Rauwolfia. Linn. Sp. Pl. 303. Hort. Chiff. 75. t. 9. Willd. n. 1. Ait. n. 1. (R. tetraphylla angustifolia; Plum. Ic. 232. t. 236. f. 1.)—Leaves in fours, lanceolate, pointed, very smooth and fhiming. Flowers axillary, terminal, or umbellate, with a fmall umbel. Flowers axillary, terminal, or umbellate, with a fmall umbel. Stamens five. Perianth five. berry, a little bigger, rounder, and fower-shaped. Stamens five, dotted, shortly ovate, obtusely fide, of one cell. Seed two, convex at the base, tapering at the summit, compressed, divided, more or less completely, into two cells.

Native of New Spain. The whole plant is smooth. Stem fhruppy, a yard high, with plant, round, leafy branches. Flowers scattered, rounded at the base, rather pointed, single-ribbed, two or three inches long, on fhortifh ftofalks. Flowers scattered, rounded at the base, rather pointed, single-ribbed, two or three inches long, on fhortifh ftofalks. Flowers scattered, rounded at the base, rather pointed, single-ribbed, two or three inches long, on fhortifh ftofalks. Flowers scattered, rounded at the base, rather pointed, single-ribbed, two or three inches long, on fhortifh ftofalks. Flowers scattered, rounded at the base, rather pointed, single-ribbed, two or three inches long, on fhortifh ftofalks. Flowers scattered, rounded at the base, rather pointed, single-ribbed, two or three inches long, on fhortifh ftofalks. Flowers scattered, rounded at the base, rather pointed, single-ribbed, two or three inches long, on fhortifh ftofalks. Flowers scattered, rounded at the base, rather pointed, single-ribbed, two or three inches long, on fhortifh ftofalks. Flowers scattered, rounded at the base, rather pointed, single-ribbed, two or three inches long, on fhortifh ftofalks. Flowers scattered, rounded at the base, rather pointed, single-ribbed, two or three inches long, on fhortifh ftofalks. Flowers scattered, rounded at the base, rather pointed, single-ribbed, two or three inches long, on fhortifh ftofalks. Flowers scattered, rounded at the base, rather pointed, single-ribbed, two or three inches long, on fhortifh ftofalks.
clutters, opposite to the leaves. Berry obovate, with only one seed; at least in garden specimens, which very probably differ in those respects from wild ones. This species flowered at Madrid from August to October.

3. R. canescens. Hoary Rauwolfa. Linn. Sp. Pl. 303. Wild. n. 3. Ait. n. 2. (R. hirsuta; Jacq. Amer. 47. R. tetraphylla latifolia; Plum. Ic. 232. f. 256.)—Leaves in fours, elliptic-obovate, acute, downy. Flowers axillary or terminal. Segments of the corolla obtuse.—Native of dry, funny, bushy places in the West India islands, as well as on the neighbouring continent. It was cultivated by Miller at the same time with the first species. We received a specimen in flower, from the Iloalo at Kew, in June 1807. Jacquin says this species varies greatly in the size of all its parts, according to soil and situation, and in the height of its stem from one to eight feet. The young branches, flower-flats, flower-flats, and both sides of the leaves, are clothed with short dense pubescence, which almost entirely disappears by culture, though the upper side of the flower-flats continues rough with slightly glabrous. The leaves are from one and a half to two inches long, obovate, more or less inclining to elliptic, acute, unequall. Flowers in small, axillary, downy, flaked tufts, or umbels. Corolla green with a tinge of red, its segments obtuse. Fruit cloven at the top, first red, then black, containing two seeds, as Jacquin well describes it. One cell of each seed is usually, according to him, abortive.

4. R. tomentosa. Downy Rauwolfa. Jacq. Amer. 48. Obs. fasc. 2. g. t. 35.—Leaves in fours, obvato-lanceolate, downy, tapering at each end. Flowers axillary or terminal. Segments of the corolla acute.—Native of rocky places about Carthagena; sometimes on the ilone walls of the town. Jacquin alone seems to have known this species, which principally differs from the last, as far as we can judge, in having white flowers, the segments of whose corolla are acute and acute. The leaves moreover are rather tapering at each end; but that circumstance varies. Fruit the size of a pea, first red, then black. We have seen no specimen.

5. R. Pulaparia. East Indian Rauwolfa. Roxb. MSS. —Leaves in threes, elliptical, bluntly pointed, smooth and shining. Flowers terminal, in forked panicles. Corolla many times longer than the calyx. Sent by Dr. Roxburgh, from Calcutta, with the above name. We rely on him for the genus, having seen no fruit. This shrub is smooth in nearly every part, with round branches. Leaves about three inches long, and above one broad, coriaceous and shining; their transverse veins very fine and numerous. Flower-flats very minutely downy, as well as the imbricated bracteas, and keeled pointed segments of the calyx. Corolla apparently white, with a red tube, which is near three quarters of an inch long, cylindrical, swelling at the top; segments of the limb rounded.

Rauwolfa, in Gardening, contains plants of the tender, exotic, shrubby kind for the hove, of which the species cultivated are: the shining rauwolfa (R. nitida); and the hoary rauwolfa (R. canescens).

Method of Culture.—These may be increased by the seeds or berries, which should be sown in pots filled with light mould, in the autumn or spring, plunging them in a mild hotbed. When the plants have attained some growth, they should be removed into separate pots, and have the management of other exotic hove plants. They may likewise be raised by layers and cuttings, laid down or planted out in pots, plunged in the hot-bed in the spring and summer months, till they have intricate root, being afterwards managed as above from seed.

They afford much ornament and variety in hot-house collections, both in their foliage and flowers. RAUZAN, in Geography, a town of France, in the department of the Gironde; 9 miles S.S.E. of Libourne. RAUZZINI, VENAZIO, in Biography, a native of Italy, who, when he arrived here in 1774, to succeed Mil-lico at the opera, was a beautiful and animated young man, with a sopran voice. He was an excellent musician, having studied counterpoint with as much application as the art of fingering; so that he might truly be said not only to know his own business, but that of a maestro di cappella; having been as able to compose an opera as to perform a principal part in it. "Piramo e Tibbe," and "La Vertale," may be inflamed in proof of this assertion.

His voice was not very powerful when he came hither from Munich, where we first knew him; and where he had enjoyed the highest favour several years. His taste, governed by science, was correct and exquisite. His voice, though not of great volume, was sweet, clear, flexible, and extensive; being in compass more than two octaves. But he is supposed to have injured his cheek in early youth by a rage for counterpoint. He played the harpsichord neatly, accompanied well, and had real genius for composition, which inclined him to devote that time to the pen and the improvement of his hand, which, perhaps, in his ilation, would have been more usefully bestowed in nursing and exercising his voice.

It was some time before the extent of his merit and science were known in this country, and favoured by the public. Nothing can fo speedily convey the merits of a finger to an audience, as a great and powerful voice. However, his taste, fancy, knowledge, and delicacy, together with his beautiful person, and spirited and intellectual manner of acting, before the first feaon was over, gained him general approbation and favour. And since he has quitted the stage, and made Bath his residence. Though he has been long obliged to discontinue finging in public, it is not too much to say that he has dished as a taste throughout the kingdom, by the numerous scholars he has taught among the nobility and gentry, as well as by those whom he has prepared for public patronage, professedly.

RAW, in Agriculture, any sort of plant, sublimate, or material, which is in a green, unripe, or undigested condition, or which is employed in its more fresh and crude state; as, for instance, dung before it has been much reduced, and lost many of its nutrient principles or properties by the process of fermentation. See Dung.

RAW Cream, in Rural Economy, such as is raised in the natural way, not killed or clouted.

RAW Hide. See Hide.

RAW Lands, in Agriculture, a term applied to wet, cold, heavy lands, which are unfit to receive the seed.

RAW Silk. See Silk.

RAWA, or RAWA, in Geography, a town of the duchy of Warsaw, late capital of a patinate of the same name. The castle is appropriated for the confinement of state prisoners; 45 miles S.W. of Warsaw. N. lat. 51° 55'. E. long. 20° 17'.

RAWA, a town of Poland, in the patinate of Belz; 18 miles S.W. of Belz.

RAWA. See RAWA.

RAWAK, a small island in the Pacific ocean, near the N. coast of the island of Waygoo, with which it forms a harbour. E. long. 131° 15'.

RAWAPSKITCHWOCK, a small westerly branch of Machias river. See Machias.

RAWAY, or Bridge-town, a truly commercial village of Middlesex county, New Jersey, on Raway river, four or five miles S.W. of Elizabeth-town, and 75 from Philadelphia.
RAY

It contains a post-office, a presbyterian church, and about 50 or 60 houses.

RAWDON, a town of Nova Scotia, 40 miles from Halifax, containing about 50 or 60 houses.

RAWDON, a township of the county of Hants, in Upper Canada, N. of Sidney.

RAWLINSON, Christopher, in Biography, of Cork-Hall, in Lancashire, was born in 1677, educated in Queen's college, Oxford, and died in 1753; he was much attached to Saxon and Northern literature, and published an edition of “King Alfred's Translation of Boethius de Consolation,” 8vo. 1698.

RAWLINSON, Richard, a distant relation of the preceding, a learned antiquarian, was the son of Sir Thomas Rawlinson, knight, and once lord mayor of London. He was educated at St. John's college, Oxford, and was admitted to the degree of doctor of the civil law in 1719. He devoted himself to antiquarian pursuits, and made large collections for a continuation of Wood's Athenae Oxonienses, and History of Oxford, and published the life of that industrious antiquary. The principal work of Mr. Rawlinson was “The English Topographer,” or, An historical account of all the pieces that have been written relating to the ancient natural history or topographical description of any part of England, 1729. He published the “Latin Letters of Abelard and Heloïse,” and “A Translation of Du Fresnoy's New Method of Studying History,” 2 vols. 8vo. He died at Ilston in 1755; and by his will ordered that his heart should be deposited in the chapel of St. John's college, Oxford. That university was indebted to him for various benefactions of books, manuscripts, medals, &c. as well as landed property, and an endowment for an Anglo-Saxon lecturer.

RAWLLOW, in Geography, a town of Hindoostan, in Palnau; 27 miles W.S.W. of Timerycotta.

RAY, John, in Biography, whom Haller terms the greatest botanist in the memory of man, and to whose transcendent merits we have already briefly adverted, in treating of the genus dedicated by Plu-mer to his name, see RAJAMIA; was born at Black Notley, near Braintree, in Essex, Nov. 29, 1628. His father, Roger Ray, though in the humble lotation of a blacksmith, gave him a learned education; first at the grammar-school of his native town, at that time not very well conducted; and subsequently at Cambridge, where he entered at Catharine Hall, in his 16th year, June 28th, 1644, being designed for holy orders. In about a year and three quarters afterwards, he removed to Trinity College, where he found the young men occupied in a more liberal train of studies, with less of scholastic disputes and quibbles. Ray was fortunate in having for his tutor at Trinity, Dr. Duport, an eminent Greek scholar, under whose护照ing and partial care, he soon made up for all the deficiencies of his early education, in the learned languages, including Hebrew. By this gentleman he was always mentioned with peculiar regard. He was no less happy in a youthful literary friend and fellow-student, afterwards the celebrated Dr. Isaac Barrow. Even at this early period, Ray began to cultivate natural history; and distinguished himself by many school exercises as an orator, no less than by his general taste for study, his love of virtue, and his gentlemanly manners, qualities which shine brighter and brighter to the latest period of his life. His merit occasioned him to be chosen a Minor Fellow of Trinity, along with his friend Barrow, September 8th, 1649. On taking his degree of Master of Arts, he became a Major or Senior Fellow; and afterwards, October 18, 1651, Greek Lecturer of the college. At the end of two years he was appointed Mathematical Lecturer, and in two years more, October 2d, 1655, Humanity Reader. He subsequently filled several respectable offices in his college, as Junior Dean, College Steward, &c., and during his residence in the university, became tutor to many gentlemen of rank and fortune, who were sensible of their obligations to him; amongst whom the most eminently distinguished by personal worth, and congeniality of talents with himself, was Mr. Francis Willughby, of Middleton-hall in Warwickshire, so well known by his posthumous works on Birds and Fishes, edited by the affectionate care of Ray.

At this period it was usual for young men of ability and learning, though not in orders, to deliver sermons, and common-place readings, as they were called; not only in the chapels or halls of their own colleges, but even before the university body, at St. Mary's church. In these Ray eminently distinguished himself. He was among the first who ventured to lead the attention of his hearers, from the unprofitable subtleties of scholastic divinity, and the trammels of Arilotelian philosophy, to an observation of nature, and a practical investigation of truth. The rudiments of many of his subsequent writings originated in these juvenile effays, particularly his celebrated book on the “Wisdom of God manifested in the Works of the Creation,” known all over the world by its numerous editions and translations, and universally admired for its rational piety, found philosophy, and solid instruction. This book is the basis of all the labours of following divines, who have made the book of nature a commentary on the book of revelation; a confirmation of truths, which Nature has not authority, of herself, to establish. In it the author inculcates the doctrine of a constantly superintending Providence; as well as the advantage, and even the duty, of contemplating the works of God. This, he says, is part of the business of a sabbath day, as it will be, probably, of our employment through that eternal rest, of which the sabbath is a type. Archbishop Tenison is recorded to have told Dr. Derham, that “Mr. Ray was much celebrated, in his time, at Cambridge, for preaching solid and useful divinity, instead of that enthusiastical stuff, which the sermons of that time were generally filled with.” Two of his funeral discourses are mentioned with particular approbation; one on the death of Dr. Arrowsmith, master of his college; the other on that of one of his most intimate and beloved colleagues, Mr. John Nid, likewise a Senior Fellow of Trinity, who had a great share in Ray's first botanical publication, the “Catalogus Plantarum circa Cantabrigiam nataleum, printed in 1665;” which may be considered as the prototype of his Synopsis, hereafter mentioned. Indeed before this little volume appeared, its author had visited various parts of England and Wales, for the purpoze of investigating their native plants, as he did several times afterwards; nor were his observations confined to natural history, but extended to local and general history, antiquities, the arts, and all kinds of useful knowledge. His amusing Itineraries were published, along with his life, by Dr. Derham, and a few letters to that gentleman, by the care of Dr. George Scott, F.R.S., in 1670, under the title of “Select Remains of the learned John Ray, M.A., &c.” Ray's first botanical tour occupied nearly six weeks, from August 9th to September 18th, 1658. On the 23d of December 1663, he was ordained, both deacon and priest at the same time, by Dr. Sanderson, then bishop of Lincoln. In 1661 he travelled with Mr. Willughby into Scotland, returning by Cumberland and Weftmoreland; and the following year, with the same companion, he accomplished a more particular investigation of Wales. How critically he studied the botany of the countries
countries he visited, is evident from the different editions of his *Catalogus Plantarum Angliae*, and *Synopsis Methodica Stirpium Britannicarum*.

All this while Mr. Ray continued to enjoy his fellowship, and to cultivate his Cambridge connections; but in September 1662, his tranquility was disturbed by the too famous Bartholomew act, by which 2000 confessional divines were turned out of their living, and many fellows of colleges deprived of their maintenance, and means of literary improvement. Among the latter was the subject of our memoir, with thirteen honest men at Cambridge besides, of whose names he has left us a lift. One of them, Dr. Dillingham, was master of Emanuel college; but Ray was the only person of his own college who suffered this deprivation. The reader must not suppose that he, or perhaps any other person in this illustrious catalogue, was, in the least degree, deficient in attachment to the doctrine or discipline of the church of England, or that they had taken the oath called the Solemn League and Covenant; which Ray certainly had neither taken nor ever approved. They were required to swear to the infamous proposition, that the said oath was not binding to those who had taken it, and on this ground Sir Robert cautiously gave up their preferment. It is curious to read the apology made for Ray to Dr. Derham, on this subject, by a Mr. Brokeby — that he was at that time absent from his college, where he might have met with satisfaction to his feruples; and was among some zealous non-conformists, who too much influenced him, by the addition of new feruples. And we may also ascribe somewhat to the prejudice of education in unhappy times." By this it appears, that the "feruples" of non-conformists were most favourable to the sanctity of an oath; and that the "unhappy times" alluded to, were more advantageous to principle, than the golden days of Charles II.; whose ministers doubletely valued the obedience, far more than the honesty, of any man; nor is this tate, by any means, peculiar to them or their profligate master.

Mr. Ray, or, as he wrote his name, for a while, about this period, Wray, having thus the world before him, made an arrangement with Mr. Willughby for a tour on the continent; and in this plan two of his pupils were included, Mr. Nathaniel Bacon, and Mr., afterwards Sir Philip, Skippon. They failed for Calais in April 1663, but being prevented, by the state of political affairs, from prosecuting their journey through France, they traversed the Low Countries, Germany, &c. Proceeding by Venice into Italy; most of whose cities they visited, either by sea or land; as well as Malta and Sicily; and returned, by Switzerland, through France, into England, in the spring of 1666. Mr. Willughby indeed separated from the rest of the party at Montpelier, and visited Spain. An ample account of their observations was published by Ray, in 1673, making a thick octavo volume. The travellers appear to have been diligent and acute in every thing relative to politics, literature, natural history, mechanics, and philosophy, as well as antiquities and other curiosities; but in the fine arts they assume no authority, nor display any considerable taste or knowledge. Mr. Willughby's account of Spain makes a part by itself, and a rich critical catalogue of such plants, not, for the most part, natives of England, as were observed in this tour, concludes the volume. Haller gives to Ray the credit of having discovered several species in Switzerland, previously not known as natives of that country.

Ray palled the summer of 1666 partly at Black Notley, and partly in Sussex, studying chiefly the works of Hook, Boyle, Sydenham on Fevers, and the Philosophical Transactions, "making few discoveries," says he, "fave of mine own errors." The following winter he was employed at Mr. Willughby's, in arranging that gentleman's museum of natural history and coins, and in forming tables of plants and animals for the use of Dr. Wilkins, in his famous work on a Universal Character. He now also began to arrange a catalogue of the English native plants, which he himself had gathered; rather for his own use, than with any immediate view of publication; "at present," as he wrote to Dr. Lister, "the world is glutted with Dr. Merret's bungling Pindar. I resolve never to put out any thing which is not as perfect as is possible for me to make it. I wish you would take a little pains this summer about grafts, that so we might compare notes." The above resolution of our author is, no doubt, highly commendable, but the world has rather to lament that so many able men have formed the fame determination, at least in natural science. If it were universally adhered to, scarcely any work would see the light; for few can be so sensible of the defects of any other person's attempt to illustrate the works of nature, as a man of tolerable judgment must be of his own. This is especially the case with those who, like Ray, direct aspiring views towards, system, and philosophical theory. Happily for the world, Willughby was in the course of his life trained himself by wholesome practical discipline, in observation and experience. His first botanical works assumed the humble form of alphabetical catalogues. His and Mr. Willughby's labours in the service of bishop Wilkins, were indeed of a systematical description; and accordingly the authors themselves were, more than any other person probably, dissatisfied with their performance. They relaxed from these labours in a tour of practical observation through the west of England, as far as the Land's End, in the summer of 1667, and returning by London, Mr. Ray was invited to become a Fellow of the Royal Society, into which learned body he was admitted November 7th. Being now requested by his friend Wilkins to translate the "Real Character" into Latin, he undertook, and by degrees accomplished, that arduous performance, depositing his manuscript in the library of the Royal Society, where it has ever since reposed. The following summer was agreeably spent, in visits to various literary friends, and in a solitary journey to the north; for his former companion Willughby, being just married, layed at home; there Ray joined him in September 1668, and remained for most part of the ensuing winter and spring.

The felicities and leisure of the country, with the converse and affluence of such a friend, were favourable to the prosecution of a new subject of enquiry, which now strongly attracted the attention of our great naturalist, the theory of vegetation. The frist step of the two philosophers, in this little-explored path, was an examination of the motion of the sap in trees; and the result of their enquiries, communicated to the Royal Society, appeared soon after in the Philosophical Transactions. Their experiments clearly prove the ascent of the sap through the woody part of the tree; which is easily detected by boring the trunk, at different depths, before the leaves are unfolded; and they observed also the mucilaginous nature of the flowing sap, "precipitating a kind of white coagulum or jelly, which," says Ray, in a note preferred by Derham, "may be well conceived to be the part which, every year, between bark and tree, turns to wood, and of which the leaves and fruit are made. It seems to precipitate more when the tree is just ready to put out leaves, and begins to cease dropping, than at first bleeding." The accuracy of the leading facts recorded by these ingenious men, is confirmed by subsequent observers, who have further purified the same subject, which is now sufficiently
sufficiently well understood. They indeed, like the rest of the world till lately, seem not to have suspected, that the sap was quietest till their perforations in the tree were made; nor did they advert, as they ought, to phenomena dependent on the principle of life, in the vegetable body. See *Circulation of the Sap*.

At this time Ray began to prepare for the press his "Collection of Proverbs," a curious book in its way, by which he is perhaps better known to the generality of his countrymen, than by any other of his literary labours. The first edition was published in 1672; but the work was subfequently much enlarged, and the author may almost be said to have exhausted his subject. From its very nature, delicacy and refinement must often be dispensed with; but this is evidently not the fault, or the aim, of the writer. His learning and critical acuteness diffuse light over the whole, and make us overlook the coarse vehicle of our instruction.

The first edition of the Catalogue of English Plants, already mentioned, came out in 1670, and the second in 1677. Their great author gave his work to the world with that diffidence, for which he alone perhaps could perceive any just foundation. We pollute our remarks till we speak of the fame work in its systematic form hereafter.

About this period the health of Mr. Ray seems to have been considerably impaired. He refused a tempting offer to travel again on the continent, as tutor to three young noblemen; nor could the powerful attractions of alpine botany, which made a part of his prospect, overcome the reluctance to leaving home, which arose from a feeble state of body. Indeed this very reluctance, or little-steps, is accounted for, by the turn which his disorder took, as it terminated in the jaundice. After this depressing complaint had left him, he refrained, with fresh alacrity, his botanical travels at home, visiting the rich florists of the north of England, with a companion named Thomas Williscroft, whole name and discoveries he afterwards, on many occasions, has gratefully commemorated. Nothing forms a more striking feature in Ray's character, than the unrelished and abundant commendation, which he always gave to his friends and fellow-labourers. We are about to narrate an event, which called forth all his affectionate feelings of this kind, as well as his most important and beneficial exertions; when, even to this own prejudice, he fulfilled the sacred duties of friendship, and delighted in adorning the built of his friend with wreaths, that he himself might justly have assumed. On the 3d of July 1672, Mr. Williscroft was unexpectedly carried off by an acute disorder, in the 37th year of his age. The care of his two infant sons was confided by himself to Mr. Ray, who was also appointed one of his five executors, and to whom he left an annuity of 60l. for life. The eldest of these youths was created a baronet at the age of 10 years, but died before he was 20. Their father Cassandra afterwards married the duke of Chandos. Thomas, the younger son, was one of the ten peers created, all on the same day, by queen Anne, and received the title of lord Middleton. His early youth was much indebted to the care of his faithful guardian, who composed, for his and his brother's use, and published in 1672, a *Nomenclator Classicus*, far more exact, especially in the names of natural objects, than any that had previously appeared. The care of his pupils, and of the literary concerns of their deceased parent, now interrupted Mr. Ray's botanizing excursions, and caused him also to decline the offer of Dr. Liller, then a physician at York, to settle under his roof. Bishop Wilkins did not long survive Mr. Williscroft, and his death made another chasm in the scientific and social circle of our great natural philosopher, who felt these losses as deeply and tenderly as any man. He sought consolation in a domestic attachment, fixing his choice on a young woman, of good parentage, whose name was Margaret Oakeley, and who resided in the family at Middleton-hall. He was married at the parilh church, June 5th, 1673, being then in the 45th year of his age, and his bride about 20. This lady took a share in the early education of his pupils, as far as concerned their reading English. She is said to have been recommended by her character, as well as her person, to the regard of her husband. She bore him three daughters, who, with their mother, survived him.

Ray's communications to the Royal Society became now very frequent, and extended to various subjects relative to the natural history of animals, as well as to the physiology, and even the botanical characters, of vegetables. He was, at the same time, in the course of the years 1674 and 1675, much occupied in digesting Mr. Williscroft's zoological papers. Thes e were composed in Latin, in which language the Ornithology first appeared in 1676, making a full volume, accompanied by 77 plates, engraved, at the expense of the author's widow, from his own drawings. An English translation by Ray, with still more additions than he had supplied to the former publication, and one more plate, issued from the press in 1678. The account which Dr. Derham received from the lips of Mr. Ray, about eight months previous to his decease, respecting the primary intentions of himself and his late friend, and which is recorded in his life, p. 48, is too curious to be omitted here, as their project and its execution form an epocha in the history of natural science. "These two gentlemen," says Derham, "finding the history of Nature very imperfect, had agreed between themselves, before their travels beyond sea, to reduce the several tribes of things to a method; and to give accurate descriptions of the several species, from a strict view of them. And forasmuch as Mr. Williscroft's genius lay chiefly to Animals, therefore he undertook the Birds, Beasts, Fishes, and Insects, as Mr. Ray did the Vegetables.* Derham adds, that Mr. Williscroft, during his short life, "prosecuted his design with as great application, as if he had been to get his bread thereby." The writer of the present article has elsewhere observed, (Introductory Discourse, Tr. of Linn. Soc. v. 1.) that "from the affectionate care with which Ray has cherished the fame of his departed friend, we are in danger of attributing too much to Mr. Williscroft, and too little to himself." His own statement, no doubt, was correct, as to their original aims; but it is impossible not to perceive that the survivor executed or perfected what his friend, in many instances, could only have projected, or fearfully begun. Had Williscroft lived, there can be little doubt of his career being as glorious in the sequel as that of his friend; and possibly, from the advantages of fortune which he enjoyed, even more widely beneficial to science. Yet who can tell that he might not have thickened his course? Though he gloriously avoided the fames of luxury and folly in his youth, who shall say that politics or ambition might not have dazzled his riper age? or that he would always have escaped that ruinous vanity, which grasps at universal knowledge, or rather at universal fame; and knowing nothing deeply, is most flattered with any praise which is least deserved. So often has this last been the case with literary men, that one cannot but mildly regard a character of the fairest promise. What Ray has done, we know and can appreciate, Equal to his friend in learning, talents, and zeal, the advantages of ample fortune were compensated by the leisure and tranquillity of a sequestered country life. His duties went
Ray went hand in hand with his studies and recreations, and he enjoyed, as Haller observes, the rare felicity of giving 50 years uninterruptedly to his favourite science. His long-protrayed studies, and ripened experience, enabled him to achieve what at first he could but regard at a distance, as the great object of his wishes, a systematic arrangement of the animal as well as vegetable kingdoms. Every body had, hitherto, been content with Aristotle's classification of animals, of whose imperfections Ray, daring to think for himself, could not but be aware. He invented a new one, founded on the structure of the heart. "The Harvian experiments, and doctrine of the circulation, had called the peculiar attention of philosophers to every organ which has a share in that phenomenon; and to this cause, probably, we owe the method of Ray." The mode of breathing in animals, whether by lungs or by gills, and the single or double structure of the heart, in the former case, constitute the basis of his system; which, in these particulars at least, succeeding naturalists have adopted. His subordinate characters of the principal classes excite great skill and sagacity, and the Linnean system of Quadrupeds is highly indebted to that of our illustrious countryman.

His zoological publications indeed did not follow each other in rapid succession; for after the Ornithology had come forth in English, eight years elapsed before the Historia Pflanzen of Willughby was given, by his care, to the world. This was printed in folio, with 188 plates of figures, in 1686, at Oxford, owing to the interest of bishop Fell, and the pecuniary assistance of the Royal Society. It does not appear why the record of Mr. Willughby witheld, in this instance, the contributions which had to much benefited her husband's former work, and which she justly owed to his fame. It seems that the intimate connexion of Ray with this family, was much impaired by the death of lady Caffandra Willughby, the mother of his friend, about the year 1675 or 1676; when the children were taken from his tuition, and he left Middleton-hall, fixing for a short time at Sutton Coldfield, four miles distant. At Michaelmas 1677 he removed from thence to Falborne-hall, in Elysh, not far from his native village. On the 15th of March following, his mother, at the age of 78, died at Black Notley, "in her house on Dowlands," of whom he speaks with that reverence and regret, which has peculiarly marked the characters of some of the greatest and best men on the same occasion. At Midsummer 1679, he finally settled at Black Notley, for the remainder of his days, or "for the short pittance of time he had yet to live in this world," as he himself expressed it; which pittance, however, extended to more than twenty-five years.

The first fruit of our author's leisure and retirement was his Methodus Plantarum Nova, published in 1682, making an octavo volume. "His principles of arrangement are chiefly derived from the fruit. The regularity and irregularity of flowers, which take the lead in the systeim of Rovinius, make no part of that of Ray. It is remarkable that he adopts the ancient primary division of plants, into trees, shrubs, and herbs, and that he blamed Rovinius for abolishing it, though his own prefatory remarks tend to overfect that principle, as a vulgar and casual one, unworthy of a philosopher. That his system was not merely a commodious artificial aid to practical botany, but a philosophical clue to the labyrinth of Nature, he probably, like his fellow-labourers, for many years, in this department, believed; yet he was too modest, and too learned, to think he had brought this new and arduous design to perfection; for whatever he has incidentally or deliberately thrown out, respecting the value of his labours, is often marked with more difference on the subject of classification, than any other. He first applied his system to practical use in a general Historia Plantarum, of which the first volume, a thick folio, was published in 1686, and the second in 1687. The third volume of the same work, which is supplementary, came out in 1704. 'This vast and critical compilation is full in use as a book of reference, being particularly valuable as an epitome of the contents of various rare and expensive works, which ordinary libraries cannot pollute, such as the Historia Universalis. The defacement of species is faithful and instructive; the remarks original, bounded only by the whole circuit of the botanical learning of that day; nor are generic characters neglected, however vaguely they are assumed. Specific differences do not enter regularly into the author's plan, nor has he followed any uniform rules of nomenclature. So ample a transcript of the practical knowledge of such a botanist, cannot but be a treatise; yet it is now much neglected, few persons being learning enough to use it with facility, for want of figures, and a popular nomenclature; and those who are, seldom requiring its assistance. A mere catalogue or index, like the works of Tournefort and Calgar Btuthin, which teach nothing of themselves, are of lesser use. The Species Plantarum of Linnaeus unites the advantages of the clearest most concise specific definition, and, by the help of Btuthin, of an universal index.

But if the fame or the utility of Ray's great botanical work has, neither of them, been commensurate with the expectations that might have been formed, a little octavo volume, which he gave to the world in 1690, amply supplied all such defects, and proved the great corner stone of his reputation in this department of science. We speak of the Synopsia Methodica Stirpium Britannicarum. The two editions of his alphabetical catalogue of English plants being fold, and some pettifogging reasons of his book-feller's standing in the way of a third, with any improvements, he re-modelled the work, throwing it into a systematic form, reviving the whole, supplying generic characters, with numerous additions of species, and various emendations and remarks. The uses and medicinal qualities of the plants are removed to the alphabetical index at the end. A second edition of this Synopsia was published in 1696, nor did its author ever prepare another. The third, now molder in use, was edited twenty-eight years afterwards by Dilhensius. (See that biographical article.) Of all the systematical and practical Floras of any country, the second edition of Ray's Synopsia is the most perfect that ever came under our observation. He examined every plant recorded in his work, and even gathered molder of them himself. He investigated their synonyms with consummate accuracy; and if the clearness and precision of other authors had equalled his, he would scarcely have committed an error. It is difficult to find him in a milakle or misconception respecting Nature herself, though he sometimes misapprehends the bad figures, or lame descriptions, he was obliged to consult. 'The of Linne. Sec. c. 4. 277. Above 1500 species are added, in this second edition, and the cryptogamic plants, in particular, are more amply elucidated. A controversial letter from Rovinius to Ray, and its answer, with remarks upon Tournefort, are subjoined to this second edition. Much of the dispute turns upon the now obsolete distinction of plants, in a methodical system, into trees, shrubs, and herbs, &c. The letters are well written, in Latin: and liberal, though perhaps hypercritical, in their style. Ray took no delight in controversy. Its inevitable
evitable asperities were foreign to his nature. We must not omit to notice that, in the preface to both editions of his *Synopsis* of the learned author, venerable for his character, his talents, and his profession, as well as by his noble adherence to principle in the most corrupt times, has taken occasion to congratulate his country, and to pour out his grateful effusions to Divine Providence, in a style worthy of Milton, for the establishment of religion, law, and liberty, by the revolution which placed King William on the throne. An honest Englishman, however retired in his habits and his pursuits, could not have withheld this tribute at such a time; nor was any loyalty ever more personally disinterested than that of Ray.

The year 1690 was the date of the first publication of his noble work on "The Wisdom of God in the Creation," of which we have already spoken, and whose sale, through many editions, was very extensive. In 1700 he printed a book, more exclusively within the sphere of his sacred profession, called "A Persuasive to an Holy Life;" a rare performance of the kind, at that day, as it would be at the present; but being devoted to enthusiasm, mysticism, or cant, as well as of religious bigotry or党的 spirit, and employing the plain and solid arguments of reason, for the benefit of purposes." His three "Physico-Theological Discourses, concerning the Chaos, Deluge, and Disolution of the World," of which the original materials had been collected and prepared formerly at Cambridge, came out in 1692, and were reprinted the following year. A third edition, superintended by Derham, was published in 1713. This able editor took up the same subject himself in a similar performance, the materials of which, like Ray's, were first delivered in sermons, at Bow church, he having been appointed reader of Mr. Boyle's lectures.

While Ray was from time to time intent on these moral and religious performances, in which he laboured equally to impress and elucidate the truths of natural and revealed religion, as well as to enforce its precepts and duties, he was no less attentive than formerly to his systematical studies. Dr. Tancred Robinson is recorded by Derham, as having first prompted our great naturalist to undertake a *Synopsis* Methodica, or checkly arrangement, of the whole animal, as he had done of the vegetable, kingdom. He even wished him to extend his attention to fossils, anticipating, in short, what Linnaeus afterwards performed. Nor did he think from the talk. Though now for some time oppressed with bodily infirmity, and particularly with very troublesome ulcers in his legs, his mind was tranquil and unimpaired. He soon finished his *Synopsis Methodica Animalium Quadrupedum et Serpentina Generis*, which came out in 1693, making a thin, but closely printed, octavo volume. We have already spoken of the originality of his method. The volume in question, however, is not confined to dry systematical arrangement. It enters deeply into the general and particular history of animals, their external forms, and internal structure, with abundance of entertaining and curious facts and observations. Linnaeus was so pleased of this book from the year 1734, and appears to have studied it well. A similar volume on birds, and another on fishes, were prepared by the author; but the manuscripts of these lay neglected in the hands of some careless or ignorant book-seller, till they were discovered by Dr. Derham, and published in 1713. They contain more of particular descriptions and histories, than of general remarks; but otherwise accord with the plan of the *Synopsis* of Quadrupeds. Many things are supplied from materials obtained since the publication of Willughby's *Ornithology* and Ichthyology, and several figures of fishes were added by Derham, at the persuasion of Petiver, whose works they somewhat resemble. Having accomplished so many great and laborious publications, our venerable naturalist began, as Dr. Derham informs us, to enjoy the thoughts of repoling from his labours. He was nevertheless ready, at the call of his friends, to revile a translation of Rauwolf's Travels, the original having even then become very scarce, besides being unintelligible to mere English readers. This translation, with some other rare tracts annexed, and a catalogue of Greek, Syrian, Egyptian, and Cretan plants, drawn up by Mr. Ray, illumed from the press in 1693. See Rauwolf.

Possibly the *Stirpium Europaeorum extra Britannias nascientes Syllae*, which appeared in 1694, originated in the author's attention being recalled, by the last-mentioned publication, to the contemplation of exotic plants. In this volume he collects from Clusius, Bauhin, Colonna, and others, various additions to his own discoveries, and the whole are disposed in alphabetical order. A geographical arrangement of the plants, which he had himself gathered in his foreign travels, is founded; and the volume concludes with alphabetical catalogues, selected from Boccone's Sicilian plants, and other recent authors. It is in the preface to this book, that he first adverts to the fyxlem of Rivinlus, not without just applauses of that author's work, a copy of which had been presented to Ray. He commends the apt distribution of the genera, the clearness and conciseness of the fylfe, the purity of the Latin, and the beauty as well as exactness of the plates. He, however, contends for the ancient distinction of plants into trees and herbs, which, as we have seen, he had himself mentioned as unphilosophical. In the rest of his criticisms, though much may be said on both sides, and though these controversy like others, profit of the intricacies and anomalies of Nature, to make good their arguments, concealing themselves, like the cuttlefish, in their ink; still we cannot but give our testimony to the greater solidity of Ray's principles, as derived from the fruits and seeds of plants, than to the seemingly more elegant ones of Rivinlus, deduced from the flower; which faith undoubtedly lead, in their practical application, to some paradoxical combinations. But on this subject we may say more in its proper place. (See Rivinus.) In this preface Ray points out the importance and use of the flaments and piliils, facetiously explaining the sexual doctrine, as now universally admitted.

One advantage arose from the epistolary alteration of Rivinus and Ray, that it led the latter to revile his own system, and to republish it, in an improved state. Happy if such were more generally the fruit of contention, that each party should correct himself, instead of aggravating the defects of his adversary. Some notice is taken, in the preface to this edition, both of the system of Tournefort and that of Hermann, which last was most congenial to the principles of Ray. The work was finished in 1698, but not given to the public till 1703, recourse having been had to a Dutch bookseller, who thought it for his interest to place an English publisher's name in the title-page; a proceeding which, however harmless, shocked the honest feelings of the author; and this perhaps excited the thrifty Hollander's fuiprize. By his exertions, however, the book, and the fame of his author, became more widely diffused, and continental botanists were much further initiated into Ray's system than they had previously been.

But now the mortal career of this eminent man was drawing towards a close. He complained in his letters, that so far from being able to visit the London gardens, as he wished,
RAY.

William Coyte, M.A., father of the late Dr. CoYTE of Ipswich, and the original manuscript is now before us, containing the information that Ray was interred in the church-yard. In 1737, the monument in question, which seems to have been a foot of altar tomb, being nearly ruined, was reflored at the charge of Dr. Legge, and removed for shelter into the church; where therefore it became a centograph as an inscription added on this occasion terms it. Forty-five years afterwards the tomb again underwent a repair, by the care of the present Sir Thomas Gerry Cullum and others, who subjoined a third inscription, as follows:

Tumulum hunc, a nonnullis humanitati, et scientiae naturali, faveaturhus, ohim conditum, et aliorum boni diligentiae poletam redditurum, 1737, nume e vetustatis fine et foribus paxci de novo revocantur, 1792.

A more laffing monument was dedicated to the memory of our great English naturalist, in the genus of plants which bears his name. (See RALANIA.) The opinion we have there, in few words expressed, of his high rank in botanical science, it is hoped the present more diffuse account will justify. It must be lamented that he made, as far as we can learn, no collection of dried plants, which might serve to ascertain, in every case, what he described. The great Herbariums of Buckle, Uvedale, &c. still kept in the British Museum, are indeed supposed to supply, in a great measure, this defect; they having been collected by persons who had frequent communication with Ray, and were well acquainted with his plants. Whatever he had preferred relative to any branch of natural history, he gave, a week before his death, to his neighbour Mr. Samuel Dale, author of the Pharmacologia. Nothing is said of his library, which was probably considerable. His pecuniary circumstances were very limited, for he merely conformed as a layman to the church of England, and was unwilling to subscribe what was requisite for receiving prebend. He is recorded nevertheless to have disapproved of separatists from the national church; justly disgusted, probably, by the contentions and fanaticism he had seen throughout the greater part of his life. His principles and feelings feared far above the foolish distinctions, which marked the orthodox or the heterodox of those times, and his mind was uncontaminated with their passions. His good sense might well lead him to regret, that those who had so lately escaped a most tremendous common enemy, should be so prone to quarrel amongst themselves. It is an honour to both these parties that they have been emulous to claim him as their ally.

In the preceding review of the literary productions of Ray, more numerous, as Haller says, than those of any other botanist, Linnæus excepted, we have been obliged to pass over several things of lefs note; such as his lists of native British plants, for Gibbon's edition of Camden's Britannia; and even a variety of communications to the Royal Society. Neither have we touched on the principles of his botanical system, that subject being explained at length by our predecessor, the late Rev. Mr. Wood, under the article Classification. Those who are anxious to peruse a more full and critical investigation of his works and studies, than it has been possible to give in this place, will do well to consult Dr. Pulteney's "Sketches of the Progress of Botany in England." The "Philosophical Letters," collected and published in 1718, by Dr. Derham, containing 68 written by Ray, and many
RAY

many more by his correspondents, throw much light on his character and pursuits. We cannot help remarking that this hand-writing was peculiarly fair and elegant. A specimen of it exists among Sir Henry Spelman's valut and curious collection of manuscripts, now in the possession of John Patterson, esq. late M. P. for Norwich.

The portraits of Ray are not numerous. One in oil, taken at an advanced period of his life, remains in the British Museum, and Dr. John Sins is pollied of a miniature, of an earlier date, of which its owner has given an engraving, by way of frontispiece to the first volume of the "Annals of Botany," published in 1805. The latter is rather deficient in that strength of character which appears in the more common prints, after a picture by Faithorne, often prefixed to the third edition of the Synopsis, and sometimes to the Historia Plantarum. One of these prints was engraved by Elder; the other by Vertue. Neither of them is strictly appropriated to any particular hook. That in the German edition of his "Wisdom of God in the Creation," published at Leipsic in 1732, appears to be copied from one of thefe, and yet is so unlike them in expression, that if it were possible, one would suppose it taken from some other portrait of the fame perfon. Ray's Works. His Life by Dr. Derham. Haller's Bibl. Bot. Pulteney's Sketches. Akin's General Biography. S.

RAY, in Geography, a town of France, in the department of the Upper Saone; 12 miles E. of Champlite.

RAY, in Geometry. See Radius.

RAY, Radius, in Optics, a beam or line of light, propagated from a radiant point, through any medium.

Sir Isaac Newton defines rays to be the least parts of light, whether visible in the fame line, or contemporary in several lines.

For, that light consists of parts of both kinds, appears hence, that one may ftep what comes this moment in any point, and let pafs that which comes the next; and again, one may ftep what comes in this point, and let pafs that in the next. Now, the least light, or part of light, which may be thus ftepped alone, he calls a ray of light.

A ray of light is, therefore, confidered as an infinitely narrow portion, or an evanescent element of a fream of light; and a pencil, as a small detached fream, compofed of a collection of fuch rays accompanying each other. As we cannot exhibit to the fenes a fingle mathematical expefion, except as the boundary of two furfaces; in the fame manner, we cannot exhibit a fingle fream of light, except as the confine between light and darkmess, or as the lateral limit of a pencil of light.

If the parts of a ray of light do all lie straight between the radiant and the eye, which is the cafe when it moves through the fame uniform fubfance or a vacuum, called a medium, the ray is faid to be direct: the laws and properties of which make the fubjeet of optics. If any of them be turned out of that direfion, or bent in their paffage, the ray is faid to be refracted: and that branch of optics which treats of thefes refracted rays, is called dioptries; which fee. See also Refraction.

If it strike on the furface, or medium attached to the furface, of any body, and be driven back, it is faid to be reflected: and that branch of optics which treats of thefes refracted rays, is called cateoptics; which fee. See also Reflection.

In each cafe, the ray, as it falls either directly on the eye, or on the point of reflection, or of refraction, is faid to be incident: and the angle which the incident ray makes with the perpendicular to the reflecting surface at the point of incidenfe, is called the angle of incidence; and the angle which the refracted ray makes with the fame perpendicular, is called the angle of refraction; and alfo, the angle which the refracted ray makes with a perpendicular to the refracting surface produced, is called the angle of refraction.

Again, if feveral rays be propagated from the radiant equidiftantly from one another, they are called parallel rays. If they come inclining towards each other, they are called converging rays. And if they go continually receding from each other, they are called diverging rays.

It is evident that the rays of light, which come from a luminous point, must fall divergingly upon any given surface; yet when the object is very diftant, compared with the interval that separates these rays, the divergency of the rays becomes infensible; hence the rays of the sun, of the moon, of the stars, &c. are deemed parallel rays. When the luminous point is near, then the rays are fensibly diverging.

It is from the various circumstances of rays, that the fveral kinds of bodies are diftinguished in optics. A body, e. g. that diffuses its own light, or emits rays of its own, is called a body. If it only refects rays which it receives from another, it is called an illuminated body.

This definition, however, is not always obferved; for a luminous body, in common language, means any visible object, whether it be visible by the emifion of original light, like the sun, a candle, &c. or by reflected light, like the moon, or any other celestial or terrestrial object that has no native light, or that does not emit its own light.

If an object only transmit rays, it is called a transparent body. So that transparent bodies, such as water, glafs, &c. are thofe through which light will pafs, or through which our eyes can perceive objects situated on the other fide, and alfo bodies, as alfo a vacuum, are denomminated mediums in optics.

If it intercepts the rays, or refufe them paffage, fo that nothing can be feeen through it, it is called an opaque body.

Hence no body radiates, i. e. emits rays, unlefs it be either luminous, or illuminated.

It is by means of rays reflected from the feveral points of illuminated objects to the eye, that they become visible, and that vision is performed; whence fuch rays are called visual rays.

When an eye views any object directly, fome of the rays, which proceed from every perceivable point of the object, enter the eye, and the whole number of rays, or quantity of light, which thus enters the eye, is circumfcribed by the rays which proceed from the extreme points of the object: and the angle which these extreme rays from at the eye is called the visual angle, from the magnitude of which we principally judge of the distance of a known object. Thus, if the fame object is represented at different distances, it is evident that the farther the object is from the eye, the smaller will the visual angle be. Supposing also the distance between the eye and the object to remain the fame, if by any means the rays of light are bent fo as to enlarge the visual angle, then the object will appear larger, or it is faid to be magnified; and on the contrary, if the visual angle be diminished, then the object will appear smaller, in which cafe it is faid to be diminished.

In effect, we find that any point of an object is seen in all places to which a right line may be drawn from that point; but it is allowed, nothing can be seen without light; therefore every point of an object diffuses innumerable rays every way. Again, from other experiments it appears, that the images of all objects, whence right lines may be drawn to the
The eye, as painted in the eye, behind the crystalline, very small, but very distinct.

And lastly, from other experiments, that each ray produces an image of the radiating point: and that the several rays emitted from the same point are again united in one point, by the crystalline, and other humours of the eye, and thus thrown on the retina.

It is the spiffitude or clofenefs of the rays emitted from a luminous body, that constitutes the intenfenes of the light. Yet the direction in which the rays strike the eye, has a considerable influence. In effect, a perpendicular ray, striking with more force than an oblique one, in the ratio of the whole line to the fide of the angle of obliquity (as follows from the laws of refraction, which see), a perpendicular ray will affect the eye more vividly than an oblique one, in that ratio.

If then the spiffitude of the rays be equal, the intenfity will be as the direction; if the direction be the fame, the intenfenes will be as the spiffitude: if both differ, the intenfenes will be in a ratio compounded of the direction and the spiffitude.

Hence, first, if light be propagated in parallel rays through an unrefiiling medium, its intenfity will not be varied by dilance.

Secondly, if light be propagated in diverging rays through an unrefiiling medium, its intenfity will decrease in a duplicate ratio of the distances from the radiant point, reciprocally.

Thirdly, if light be propagated in converging rays through an unrefiiling medium; its intenfity will increase in a duplicate ratio of the distances from the point of concourse, reciprocally.

Fourthly, if the breadth of an illuminated plane be to the distance of the radiant point as 1 to 2,000,000, it is the fame thing as if the ray struck upon it parallel; and hence, since the diameter of the pupil of the eye, when large, fearcely exceeds 8th or 10th of an inch; the rays will fall upon it parallel as to lefle, at the distance of 3860 English feet, which is nearly fix furlongs. See Light.

The effect of concave lefles, and convex mirrors, is to make parallel rays diverge; converging rays become parallel; and diverging rays to become more divergent.

The effect of convex lefles, and concave mirrors, is to make diverging rays become parallel; parallel rays become convergent; and converging rays to converge the more. See Lenses.

The rays of light are not homogeneous, or similar, but differ in all the properties with which we are acquainted; viz. refrangibility, refle&ibility, and colour.

It is probable that from the different refrangibility the other differences have their rife; at leat it appears, that those rays which agree or differ in this, do fo in all the reft. Thus, from the different fentiments the differently difpofed rays excite in us, we call them red rays, yellow rays, &c.

The effect of the prin is to separate and fort the different kinds of rays, which come blended promifcuoufly from the fun; and to throw each kind by itself, according to its degree of refrangibility and colour, red to red, blue to blue, &c.

Besides refrangibility, and the other properties of the rays of light already ascertained by observation and experiment, sir Ifaac Newton fupposes they may have many more; particularly, a power of being inflected, or bent, by the action of distant bodies: and those rays which differ in refrangibility, he conceives likewife to differ in this refle&ibility.

In paffing by the edges and sides of bodies, he conceives that the rays may be bent several times backwards and forwards, with a motion like that of an ell; and that those rays which appear to fall on bodies are reflected or refracted before they arrive at the bodies: and adds, that they may be reflected, reflected, and inflected, all by the fame principle acting in different circumftances. See Reflection and Light. See also Reflection and Refraction.

Again, do not the rays, falling on the bottom of the eye, excite vibrations in the retina; which, being propagated along the fibres of the optic nerve into the brain, cause vision? and do not several forts of rays make vibrations of several bignefses, which excite fentiments of several colours, much after the manner as the vibrations of the air, according to their several bignefses, excite fentiments of several sounds?

Particularly, do not the moft refrangible rays excite the fhortest vibrations, to make a fentiment of a deep violet; and the leaft refrangible the largelf, to make a fentiment of a deep red? and the feveral intermediate kinds of rays, vibrations of intermediate bignefses, to make fentiments of the intermediate colours?

And may not the harmony and difcord of colours arise from the proportion of these vibrations; as thofe of longt depend on the vibrations of the air; for fome colours, if viewed together, are agreeable, as gold and indigo; others difagreeable. See Colour.

Again, have not the rays of light feveral fides ended with feveral original properties? It is certain we find, that every ray of light has two oppofite fides, originally ended with a property, on which the unufual refraction of illand cryftal depends, and other two oppofite fides ended with that property.

Laftly, are not the rays of light very small bodies emitted from fiihing fubfances?

Such bodies may have all the conditions of light: and there is that action and reaction between transparent bodies and light, which very much refigures the attractive force between other bodies. Nothing more is required for the production of all the various colours, and all the degrees of refrangibility, but that the rays of light be bodies of different fizes; the leaf of which may make violet the weakfet, and darkelf of the colours, and be the moft easily difturbed by refraction from its refilinear courfe; and the reft as they are bigger and bigger, may make the ftronger and more lucid colours, blue, green, yellow, and red. (See Colour and Light.) Nor is any thing more requisite for the putting of the rays into fits of easy refle&ion, and easy tranfmi&ion, than that they may be small bodies, which, by attraction, or some other force, excite vibrations in the bodies they act upon; which vibrations, being twifter than the rays, overtake them successively, and agitate them fo as by degrees to increafe and diminish their velocity, and thereby put them into thofe fits. Laftly, the unufual refraction of illand cryftal appears very much as if it were performed by fome attractive virtue lodged in certain fides both of the rays, and of the cryftal.

Rays of Heat denote separate portions of that emanation, which proceeds from an heated body, when placed in a colder temperature, and which expands itself in every direction, provided it be not prevented by the interposition of particular fubfances. This appellation is adopted and thus applied, not becaufe that emanation is certainly known to consist of separate streams, but merely for the convenience of explanation. The rays of heat are not the fame with the rays of light. If this were the fale, a certain quantity of
of heat ought to be accompanied with the same quantity of light; whereas it is found, that several substances emit a considerable quantity of light without any sensible heat, and others give out a considerable portion of heat without any light. But that there are two distinct powers of nature is a proposition, that has been amply illustrated, and most satisfactorily established by the discoveries and experiments of Dr. Herschel. This celebrated astronomer cautioneth those, who peruse the account of his experiments and observations upon them, from concluding, that in using the word rays, he means to oppose, much less to countenance, the opinion of those philosophers, who still believe, that light itself comes to us from the sun, not by rays, but by the supposed vibration of an elastic ether, every where diffused through space: he merely claims the fame privilege for the rays that occur in heat, which they do not scruple to allow to those that illuminate objects. For in what manner forever this radiance may be affected, he undertakes to prove, that the evidence, either for rays, or for vibrations, which occasion heat, stands on the same foundation on which the radiance of the illuminating principle, light, is built.

Proposing to give a comparative view of the operations that may be performed on the rays that occasion heat, and of those which are known to have been effected on the rays that occasion light, he selects such facts as are well known with regard to the latter. Light, he says, both solar and terrestrial, is a sensation occasioned by rays emanating from luminous bodies, which have a power of illuminating objects; and, according to circumstances, of making them to appear of various colours. The rays of light are subject to the laws both of reflection and of refraction; but they are of different refrangibility. They are liable to be stopped in certain proportions, when transmitted through diaphanous bodies; and also to be scattered on rough surfaces. They are also supposed to have a power of heating bodies; but this is a subject "sub judice." The similar propositions, which it is his design to prove, and which by a variety of curious and well-conducted experiments he has confirmed, are such as follow. Heat, both solar and terrestrial, is a sensation occasioned by rays emanating from compound substances, which have a power of heating bodies. These rays are subject to the laws of reflection and of refraction; and they are of different refrangibility. They are liable to be stopped in certain proportions, when transmitted through diaphanous bodies; and also to be scattered on rough surfaces; and in a certain state of energy, they may be supposed to have a power of illuminating objects, which latter property remains to be examined.

In the examination of the illuminating and heating power of the prismatic colours, our author observes, that the red-making rays are very far from having the former in an eminent degree: the orange surpasses more of it than the red; and the yellow rays illuminate objects still more perfectly. The maximum of illumination lies in the brightest yellow, or palest green. The green itself is nearly equally bright with the yellow: but from the full deep green, the illuminating power decreases very sensibly; that of the blue is nearly upon a par with that of the red; the indigo has much less than the blue; and the violet is very deficient. Our author infers from other experiments, that the heating power of the prismatic colours is very far from being equally distributed; and that the red rays are chiefly eminent in this respect. Allowing that the power of heating is chiefly lodged in the red-making rays, it accounts for the comfortable warmth that is thrown out from a fire, when it is in the state of a red glow, and for the heat which is given by charcoal, coke, and balls of small coal mixed up with clay, used in hot-houses; all which throw out red light. It also explains the reason, why the yellow, green, blue, and purple flames of burning spirits mixed with salt, occasion so little heat that a hand is not materially injured, when passed through their corruptions.

Having ascertained, that radiant heat is subject not only to the laws of refraction, but to those also of the different refrangibility of light, Dr. Herschel is led to surmise, that this heat consists of particles of light of a certain range of moments, which range may extend a little farther, on each side of refrangibility, than that of light. In a gradual exposure of the thermometer to the rays of the prismatic spectrum, beginning from the violet, he found that he arrived at the maximum of light long before he came to that of heat, which lies at the other extreme. By several experiments, it appears, that the maximum of illumination has little more than half the heat of the full red rays; and from other experiments our author concludes, that the full red falls still short of the maximum of heat, which perhaps lies even a little beyond visible refraction. In this case, radiant heat will at least partly, if not chiefly, consist, if the expression may be allowed, of invisible light, that is, of rays coming from the sun, that have such a momentum as to be unit for vision. Admitting it as highly probable, that the organs of light are only adapted to receive impressions from particles of a certain momentum, this will explain why the maximum of illumination should be in the middle of the refrangible rays, as those which have greater or less momenta, are likely to become equally unfit for impressions of light. Whereas, in radiant heat, there may be no such limitation to the momentum of its particles. From the powerful effects of a burning lens, however, we derive information, that the momentum of terrestrial radiant heat is not likely to exceed that of the sun; and that, consequently, the refrangibility of caloric rays cannot extend much beyond that of coloured light. Hence we may also infer, that the invisible heat of red-hot iron, gradually cooled till it ceases to shine, has the momentum of the invisible rays, which, in the solar spectrum viewed by daylight, go to the confines of red, and this will afford an easy solution of the reflection of invisible heat by concave mirrors.

Our author deduces from various experiments with the thermometer abundant evidence, that there are rays coming from the sun, which are less refrangible than any of those that affect the light. They are invested with a high power of heating bodies, but with none of illuminating objects; and on this account they have hitherto escaped notice. At the distance of fifty-two inches from the prism, there was still a considerable heating power exerted by the invisible rays, an inch and a half beyond the red ones, measured upon their projection on a horizontal plane. Moreover, the power of heating is extended to the utmost limits of the visible violet rays, but not beyond them; and it is gradually impaired, as the rays become more refrangible. The maximum of this heating power is found to be vested among the invisible rays, and it is probably not less than half an inch beyond the last visible ones. It is also shown, that the sun's invisible rays, in their least refrangible state, and considerably beyond the maximum, still exert a heating power fully equal to that of red-coloured light; and consequently, if we may infer the quantity of the efficient from the effect produced, the invisible rays of the sun probably far exceed the visible ones in number. The general conclusion with which Dr. Herschel closes his account of one series of
of experiments and his reasoning upon them, is in the following manner: "If," says he, "we call light those rays which illuminate objects, and radiant heat, those which heat bodies, it may be inquired whether light be essentially different from radiant heat? In answer to which I would suggest, that we are not allowed by the rules of philosophy to admit two different causes to explain certain effects, if they may be accounted for by one. A beam of radiant heat emanating from the sun, confits of rays that are differently refrangible. The range of their extent, when diffused by a prism, begins at violet-coloured light, where they are most refracted, and have the heat efficacy. We have traced these calorific rays throughout the whole extent of the prismatic spectrum, and found their power increasing, while their refrangibility was lessened, as far as to the confines of red-coloured light. But their diminishing refrangibility, and increasing power, did not stop here: for we have pursued them a considerable way beyond the prismatic spectrum into an invisible state, still exerting their increasing energy, with a decrease of refrangibility up to the maximum of their power; and have also traced them to that state, where, though still less refracted, their energy, on account, we may suppose, of their now falling density, decreased pretty fast; after which the invisible thermometrical spectrum, if I may call it, soon vanished."—If this," continues our author, "be a true account of solar heat, for the support of which I appeal to my experiments, it remains only for us to admit, that each of the rays of the sun as have the refrangibility of those which are contained in the prismatic spectrum, by the construction of the organs of sight, are admitted, under the appearance of light and colour; and that the red, being stopped in the coats and humours of the eye, acts upon them, as they are known to do upon all other parts of our body, by occasioning a sensaion of heat."

Although, as we have above stated, the rays of light and those of heat, posses many similar properties, yet Dr. Herschel has shewn, that there are some striking and substantial differences between them. The rays of heat are of a much more extensive refrangibility than those of light, as our author has clearly and incontrovertibly demonstrated both by reasoning and experiment: nor do these rays agree either in their mean refrangibility, nor in the situation of their maxima. Where we have most light, there is but little heat, and where we have most heat, we find no light at all. (See Refrangibility.) It is found, that the lines of refraction of the heat-making rays are in a constant ratio to the lines of incidence; but that the focus of the rays of heat in burning glasses is different from the focus of the rays of light; that of heat being farther removed from the lens than the focus of light, probably not less than a quarter of an inch: the heat at half an inch beyond the focus of light being still equal to that in the focus. Although light and heat are both refrangible, the ratio of the lines of incidence and refraction of the mean rays is not the same in both. Heat is evidently less refrangible than light. From experiments relating to the transmission of light and heat through diaphanous bodies it appears, that no kind of regularity takes place in the proportion of rays of one sort and of another, which are stopped in their passage. Heat and light seem to be entirely unconnected, and the rays that occasion them are different. We have several tables, formed from the author's experiments, and shewing the quantities of light and heat intercepted by different substances. The blueish-white and flint-glasses, e. gr. stop nearly three times as much heat as light, whereas the greenish crown glasses stop only about one-fourth more of the former than of the latter.

From a table exhibiting the effects of coloured glasses, it appears, that a yellow glass stops only 335 rays of heat, but stops 819 of light; on the contrary, a pale blue stops 812 rays of heat, and but 634 of light. Again, a dark blue glass stops only 362 rays of heat, but intercepts 801 of light; and a dark red glass stops no more than 606 rays of heat, and yet intercepts nearly all the light, fearfully one ray out of 5000 being able to make its way through it. For the conclusions deduced from these tables, as they evince the non-identity of the rays of heat and those of light, and for the tables themselves, we must refer to the author's own paper, ubi infra. We are restrained by our limits from pursuing this curious subject, and from entering upon a detail of Dr. Herschel's experiments, illustrating and confirming principles, the discovery of which must be allowed to be one of the greatest that has been made since the days of Newton, although the theories of some speculative philosophers might have led to it a few years earlier. Dr. Herschel was occupied in determining the properties of various kinds of coloured glasses, which rendered them more or less fit for enabling the eye to view the sun through a telescope; and for this purpose it was necessary to inquire which of the rays would furnish the greatest quantity of light, without subjecting the eye to the inconvenience of unnecessary heat. He first observed that the heat became more and more considerable as the thermometer approached the extreme red rays in the prismatic spectrum; and pursuing the experiment, he found not only that the heat continued beyond the visible spectrum, but that it was even more intense where the thermometer was at a little distance without the limits of the spectrum, than in any point within it: as we have already stated. For Dr. Herschel's communications to the Royal Society on this subject, we refer to the 90th volume of the Philosophical Transactions for the year 1800, part ii. p. 255, &c. p. 284, &c. p. 293, &c. part iii. p. 437, &c.

Sir Henry Englefield has repeated Dr. Herschel's experiments with many precautions, and Mr. (Sir H.) Davy was a witness of their perfect accuracy. The excess of heat beyond the spectrum was even considerable enough to be ascertained by the sense of warmth occasioned by feeling it on the hand. It was first observed in Germany by Ritter, and soon afterwards in England by Dr. Wolfallon, that the muriate of silver is blackened by invisible rays, which extend beyond the prismatic spectrum, on the violet side. It is therefore probable, that these black or invisible rays, the violet, blue, green, perhaps the yellow, and the red rays of light, and the rays of invisible heat, constitute several different degrees of the same force, distinguished from each other into this limited number, not by natural divisions, but by their effects on our senses; and we may also conclude that there is some familiar relation between heated and luminous bodies of different kinds. See Young's Phil. Lect. vol. i. p. 639. See Heat and Refraction.

M. Delaroche has found, that the rays of invisible heat traverse glasses with difficulty at a temperature below that of boiling water; but that they traverse it with a facility, always increasing with the temperature, as it approaches the point when bodies become luminous, and from these experiments it would appear, that the modification, whatever it be, which must be impressed upon the invisible rays to render them more and more capable of passing through glass, makes them approach more and more to the state in which they must be when they penetrate our eyes, and occasion the sensation of vision. The same ingenious philosopher has likewise found, that the rays of heat which have passed through
through a plate of glass are proportionably more adapted to pass through a second plate; and from this circumstance we deduce a new proof of the peculiar state of these rays, and of the modification which they acquire. Mehrs. Gay-Lussac and Thenard have proved that all the changes of colour produced by light may be imitated and produced by heat, and by an elevation of temperature not exceeding 312°. Other phenomena previously observed indicated, that in the comparison of the actions of heat and light in heating bodies, or producing chemical changes in them, there is a great difference in the rays of different colours. M. Rochon announced the fact amply confirmed by Dr. Herschel, that the heat produced by the different rays of the prismatic spectrum was unequal. As Dr. Herschel fixed the maximum effect beyond the red rays, and theed, as we have already stated, that the most heating rays of the spectrum were entirely, or nearly, invisible; Dr. Wollaston, and Miers. Ritter and Beckmann, having examined the opposite, or violet end of the spectrum, found that this likewise produced peculiar properties, and that, beyond the violet, there are invisible rays, which form, in greatest perfection, the power of determining chemical combinations. It has been a subject of interesting research, whether the invisible, or almost invisible rays, situated beyond the extremities of the spectrum, poffefs any other properties of light. *E. gr. If the reflection of them from polished glass can give them that modification which Malus has distinguished by the name of 'polarization.' [See Light.] M. Berthollet engaged Mehrs. Malus and Berard to undertake this double object. M. Malus's death prevented his prosecution of the subject; but what he began M. Berard accomplished with the utmost possible exactness. By means of the heliotrope, which Malus caucled to be constructed for the philosophical cabinet of M. Berthollet, he obtained a ray of light, perfectly fixed, on which he could make experiments at pleasure. By decomposing this ray with a prism, he obtained an immovable coloured spectrum; and by placing very few sensible thermometers in the spaces occupied by the different colours, he was enabled to compare their calorific effects with the utmost certainty. He also ascertained their chemical properties by submitting, in place of the thermometer, chemical compounds easily altered. He first of all observed the calorific power of the different rays, which, it is known, are in this respect unequal. M. Rochon, who is said to have first observed this inequality, placed the maximum of heat in the yellow ray, where the illuminating power is the greatest. Dr. Herschel, as we have before shown, placed it out of the spectrum, and beyond the red ray. The experiments of Herschel have been confirmed by those of Berard, as far as they respect the progressive heating power of the rays from the violet to the red; but he found the greatest heating power at the extremity of the spectrum itself, and not beyond it. He fixed it at the point, where the bulb of the thermometer was still entirely covered with the red ray; and he found that the thermometer sunk progressively, in proportion as the distance of its bulb from the red ray increased. When he placed the thermometer quite beyond the visible spectrum, on the spot where Herschel fixed the maximum of heat, its elevation above that of the ambient air was only one-fifth of what it had been in the red ray itself. The absolute intensity of the heat produced was likewise less in the experiments of Berard than in those of Herschel.

M. Berard wished to know if these properties would exist in each of the pencils into which the ray divides itself, passing through a rhomboid of Iceland spar. In this case each of the two spectra exhibited the same properties. In both, the calorific power diminished from the violet to the red end; and it extended beyond the last visible red rays. In this operation the luminous molecules are polarized by the crystal. In order to determine whether the invisible rays of heat experience the same effect, M. Berard received the solar ray upon a polished and transparent glass, which polarized a portion of it by reflection. This reflected ray was then received upon a second glass, fixed in an apparatus, which permitted it to be turned round the ray under a constant incidence, and this incidence itself was determined in such a manner, that in a certain position of the glasses the reflection ceased to take place. We know, from the experiments of Malus, that a glass may be always disposed in such a manner that this condition is fulfilled. Things being thus disposed, by collecting with a mirror the calorific and luminous rays reflected from the second glass, and directing them upon a thermometer, M. Berard found, that as soon as light was reflected the thermometer was elevated, and of course the heat was reflected likewise; but when, from the position of the second glass, the light was totally transmitted, the heat was transmitted at the same time, and the thermometer was not elevated. In this experiment, then, as well as the preceding, the calorific principle, whatever it may be, never separates from the luminous molecules.

To the ray of solar light employed in this experiment, M. Berard substituted a pencil of radiant heat proceeding from a body hot, but not red, and even not luminous. The effect was the same as before. The thermometer rose when the second glass was so situated as to reflect light, and it did not rise when the second could not reflect light. Therefore the particles of invisible radiant heat are modified by reflection, precisely like light.

After having thus determined the calorific properties of the different rays of the spectrum, M. Berard examined their chemical properties. When muriate of silver, or other white salts of silver, are exposed to light, they become dark coloured very speedily. Guaiac thus exposed to light passes from yellow to green, as Dr. Wollaston observed. Gay-Lussac and Thenard discovered another action of this light still more prompt and energetic. When a mixture of oxygenated acid gas and hydrogen gas are exposed to the action of solar light, decomposition takes place, and water and muriatic acid are formed. These different phenomena enabled M. Berard to examine the chemical powers of the different rays of the spectrum. By exposing to the different coloured rays, pieces of card impregnated with muriate of silver, or small phials filled with the detoning mixture, he was enabled to judge of the energy of each by the intensity or rapidity of the chemical change which it produced. He found that the chemical intensity was greatest at the violet end of the spectrum, and that it extended, as Ritter and Wollaston had observed, a little beyond that extremity. When he left substances exposed for a certain time to the action of each ray, he observed sensible effects, though with an intensity continually decreasing in the indigo and blue rays. Hence we must consider it as extremely probable, that if he had been able to employ re-actives still more sensible, he would have observed analogous effects, but still more sensible, even in the other rays. To shew clearly the great disporportion which exists in this respect between the energies of the different rays, M. Berard concentrated, by means of a lens, all that part of the spectrum which extends from the green to the extreme violet; and he concentrated, by means of another lens, all that portion which extends from the green to the extremity of the red. This last pencil formed a white point so brilliant that the eyes were scarcely able to endure it; yet the muriate of silver remained more than two hours exposed to this brilliant light without undergoing any sensi-ble
ble alteration. On the other hand, when exposed to the other pencil, which was much less bright, and less hot, it was blackened in less than six minutes. M. Berard concluded, from this experiment, that the chemical effects produced by light are not solely owing to the heat developed in the body by its combining with the sublimate of the body; because, on such a supposition, the faculty of producing chemical combinations ought to be greater in those rays which possess the faculty of heating in the greatest perfection; but perhaps we should find less opposition between these two opinions, if we attended to the different results which may be produced by the same agent placed in different circumstances, and if we considered that agents of a nature quite dissimilar may determine the same combinations when they are employed.

Various hypotheses have been suggested in order to account for the properties above stated. If we wish to consider solar light as composed of three distinct sublimates, one of which occasions light, another heat, and the third chemical combinations; it will follow that each of these sublimates is separable by the prism into an infinity of different modifications, like light itself; since we find, by experiment, that each of the three properties, chemical, coloring, and calcining, is spread, though unequally, over a certain extent of the spectrum. Hence we must suppose, on that hypothesis, that there exist three spectrums one above another; namely, a calcining, a coloring, and a chemical spectrum. We must, likewise, admit that each of these sublimates which compose the three spectrums, and even each molecule of unequal refrangibility which constitutes these sublimates, is endowed, like the molecules of visible light, with the property of being polarized by reflection, and of escaping from reflection in the same potions as the luminous molecules, &c.

Instead of this complication of ideas, let us conceive simply, according to the phenomena, that light is composed of a collection of rays unequally refrangible, and of course unequally attracted by bodies. This supposes original differences in their size and velocity, or in their affinities. Why should those rays, which differ already in so many things, produce upon thermometers, or upon our organs, the same sensations of heat or light? Why should they have the same energy to form or separate combinations? Would it not be quite natural that vision should not operate on our eyes, except within certain limits of refrangibility; and that too little or too much refrangibility should render it equally incapable of producing that effect. Perhaps these rays may be visible to other eyes than ours, perhaps they are so to certain animals, which would account for certain actions that appear to us marvellous. In a word, we may conceive the calcining and chemical faculty to vary through the whole length of the spectrums, at the same time with the refrangibility, but according to different functions; so that the calcining faculty is at its maximum at the violet end of the spectrums, and at its minimum at the red end; while, on the other hand, the chemical faculty expressed by another function is at its minimum at the red end, and at its maximum at the violet end, or a little beyond it. This simple supposition, which is only the simple statement of the phenomena, equally agrees with all the facts hitherto observed, and accounts for those established by M. Berard, and even enables us to predict them. In fact, if all the rays, which produce these three orders of phenomena, are rays of light, they must of course be polarized in passing through Iceland crysal, or in being reflected from a polished glass with a determined incidence; and when they have received these modifications, they must be reflected by another glass, if it is properly placed, to exert its reflecting energy on the luminous molecules. On the other hand, if that force is null on the visible luminous molecules, the invisible light will not be any longer reflected: for the cause which occasions or prevents reflection appears to act equally upon all the molecules, whatever their refrangibility may be. It ought, therefore, to act upon the molecules of invisible light, the condition of visibility or invisibility relating merely to our eyes, and not to the nature of the molecules which produce these sensations in us.

This mode of viewing the facts appeared to Meffrs. Berthollet, Chaptal, and Biot, who made a report to the Institute on the Memoire of Berard, the most natural and simple; though the mode of refere of Berard restrained him from deciding in a cafe, not sufficiently examined by the test of experiment. Annal. de Chimie, vol. xxxv. p. 369. of Thomson's Annals of Philosophy, No. 9.

Ray, Common, in Optics, is sometimes used for a right line drawn from the point of concourse of the two optical axes, through the middle of the right line which pæflies through the middle of the centres of the pupils of the two eyes.

Rays, Cone of. See Cone.
Rays, Deflection of. See Deflection.
Rays, Inclination of incident. See Inclination.
Rays, Optic. See Optic.
Rays, Reflectivity of. See Reflectivity.
Rays, Principal, in Perspective, is the perpendicular distance between the eye and the vertical plane or table, as some call it. See Perspective.
Rays, Pencil of. See Pencil of Rays.
Rays, Pyramid of. See Optic Pyramid.
Ray of Curvature, in Geometry, is used to signify the demi-diameter of the circle of curvature. See Radius and Curvature.
Ray, Clavated. See Raia Clavata, and Thornback.
Ray, Eagle. See Raia Aquila.
Ray, Electric or Smooth, a species of the Raiu. See Raia, Torpedo, and Anatomy of Fish.
Ray, Fuller, Raia fullonica, a species of ray, deriving its name from the instrument which fullers use in smoothing cloth, the back being rough and spiney. See Raia Fulonica.
Ray, Oblong. See Raia and Rhinobatos.
Ray, Oceluted. See Raia and Miraletus.
Ray, Rough. See Raia Rubus. At Scarborough, where it is common, it is called the white hants or gullet.
Ray, Shagreen, called at Scarborough the French ray, is about the size of the skate, but narrower in its form than the common kinds. The upper part of the body is covered closely with small thorn-like tubercles, resembling the skin of the dog-fish; and from the nofe to the beginning of the pectoral fins is a tuberculated space. Pennant.
Ray, Sharp-nosed. See Raia Oxyspinus. This fish makes a snotting noise, and is suppos'd to be the bos of the ancients, which Oppian describes as the broadest among fishes, and fond of human flesh; adding, that the method it takes of delirying men is by overlaying and keeping them down by its vail weight till they are drowned. Pennant.
Ray, in our Old Writers, a word appropriated to cloth never coloured, or dyed, 11 Hen. IV. c. 6. Blount, Cowell.
Rays, in Botany, the spreading marginal foliis of a compound flower; see Radius. The same term is applied to the sub-divisions of an umbel, more properly denominated
Ray-Grafs, in Agriculture, an useful sort of early graves that has long been, and still is, much cultivated by the farmer in some districts. There are said to be different varieties of this geese, but that grown by Mr. Peacey, of Devonshire, has been found, on experience, much superior to the common sort. This geese has sometimes the title of ray-graves. See Loliwm Perenne.

It has been remarked by the Rev. Mr. Duncan, of Kilmarrock, in the fourth volume of Communications to the Board of Agriculture, that it has been found of late that there is an annual and perennial kind; that the latter should only be sown; but that the annual, he thinks, affords the greatest and most palatable crop of hay, and may be sown on those light soils which more readily tend to geese, at least a considerable proportion of it should be blended with the perennial geese. He adds, that the two kinds of geese are readily distinguished by a careful observer, as the perennial is smaller, and fairer in colour, than the annual, and likewise much lighter. Good annual geese weighs from 21 to 24 lbs. avoirdupois weight per bushel, but the perennial only from 16 to 18 lbs. As no distinction of these geese was formerly made by farmers, he suggests it as probable that they have come to be known and distinguished, from the circumstance of no ray-graves disappearing wholly the first year, by which fome perons have been tempted, from the high price of the geese, to allow what remained in the second year to advance to maturity, though to the great injury of the pasture. It is therefore from the seed of the second year's crop that he supposes the perennial geese has gradually originated; and its inferiority in point of substance feems, he thinks, to prove the supposition. By this means the farmer may, by allotting a small portion of good land for the purpose, supply himself with what is faid to be the perennial geese, without submitting to the imposition of an extravagant price, and may probably enjuice or improve upon the durability of it, by collecting geese from the third or fourth year's growth.

It is found to be an excellent geese for pasture as well as hay. It has an early, but not very abundant, foliage. It is highly relished by cattle and sheep. From its being apt to run up into flowering items, it should be kept well fed down. From its secreting and depositing much fecharine matter in the joints of the items, it affords a large proportion of nutritious matter for the support of animals, both in its green state and when made into hay. And it is said not to affect the wind of horsesh, which renders it particularly valuable for hunting and racing horses.

It has, however, been objected to by some, from the quantity of flower items which it yields up; but this is allayed by others to be only the cafe when it grows in dry upland situations. It is found, of course, to vary much under different circumstances and situations.

The items that are most suitable for it are those of the loamy and sandy kinds, but it is capable of being grown on those of the clayey sorts when not too stiff. On the two stiff sorts, a mixture with other geese, it frequently becomes permanent, and affords an useful spring food, especially for sheep rook.

As it is found to produce a thick well-connected sward in items of the rich fertile sorts, it has been suppos'd only suited to them, though occasionally met with in those of the poorer descriptions.

In Essex it is found very bad for the strong wet heavy lands.

But in other districts it is most sown in light clayey soils, where clover is liable to fail in coming up well. Some, however, find that a light soil is quite as suitable for it as one of a clayey nature; and that though it may be most sown in light heavy lands, it is not from the notion that lighter soils are less suited to it, but that such lands may be covered with this geese, should the clover crop not turn out well in consequence of the great richness of these clayey soils.

On the light clayey soils the proportion of feed is usually from one bushel to one bushel and a half of ray-graves, with eight or ten pounds of red clover feed, to the acre. On other soils from fix to ten gallons of ray-graves, with from five to eight pounds of red clover feed, and from two to four pounds of trefoil feed, are used to the acre; some adding to these, two, three, or more, pounds of white clover feed.

In Sussex, for a layer for one or two years, they employ of ray-graves feed three gallons, and of red clover and trefoil feed each one gallon, to the acre.

But for permanent pasture the proportion is this. Of ray-graves feed four gallons, Dutch clover and trefoil feed, of each two gallons to the acre. Other different proportions are made use of in different cases.

It has been well remarked by Dr. Campbell, in the third volume of Communications to the Board of Agriculture, that when land is in a proper state of manure, ray-graves united with white clover, will form a perfect sward the latter end of the second year after it is sown. A particular field, of about five acres, that was sown with these two geese only, was, he says, more perfectly grassed over, than others, which had the addition of trefoil and rib-graves, and which were sown at the same time. A neighbour of his, the only man in the county that had tryed ray-graves, told him it would not answe, and referred him to a particular field where some had been sown. The fact was, the doctor says, that he had cropped his field with oats until it was no longer worth ploughing, and then, with his last feed, he sowed ray-graves, which certainly did not flourish. But his argument would, he thinks, have been equally conclusive against any geese or grain whatever. The ray-graves languished, and finally died away, giving place to the vegetation suited to the state of the land. If it be expected that ray-graves, or any other good geese, should thrive and produce abundant crops on exhausted or poor land, it must not, he says, be in the soil which occurs here. And he adds the following useful remarks, on converting ray-graves into hay; it is necessary to cut it at a period previous to its being so ripe as to have perfefted its feed, and changed to a yellow colour; or in this case a great part of the juices of the plant, which constitute a principal part of the nutriment it is to afford, will be converted into a species of flaw, and its nutritive properties be proportionally diminished. When it is made into hay, perons not acquainted with its qualities are apt to object to its apparent coarfeness, which proceeds from its confilling almost entirely of flowering-items, the ray-graves having a comparatively smaller proportion of leaves than any other geese. Whether this be a defect or a merit will, he thinks, depend upon a solution of this question: Do the items and flowering parts of geese, or the leaves taken weight for weight, contain the greater proportion of nutriment? It does not appear, he says, that this has been determined by experiments instituted for the purpose; but it seems probable, from the items being so much sweeter than the leaves, (which is particularly perceptible upon chewing them when about half dry,) and from those vegetables which contain much fcharrine matter being particularly nutritious, that the greater proportionate quantity of
nutriment will be found to reside in the salks; and if so, the advantages of ray-grafs will be decisive. But, however this may be, it is certain that, supposing wet weather comes during the process of hay-making, the first part of the grafs that decays is the leaf, which soon becomes yellow, and then black, losing all pretensions to nutritive properties; in which case it is evident that almost the whole nutriment contained in the hay must reside, exclusively, in the flowering-salks. Ray-grafs then has, in unfavourable hay-salfons, an advantage, he thinks, over all others, insomuch as from having fewer leaves it is not so apt to be injured by a continuance of rain; and it is, besides, when in the soks, more acces-
sible to the air and wind from lying more open and light; and consequently not so apt to heat and mould as other grafses in similar situations and salfons. And he concludes that it certainly possesses the following valuable properties.

1. That there are few grafses so early in the spring.

2. That there are none better suited by cattle, or more nutritive.

3. That it has the power of refilling the effects of bad weather, in tickish salfons, in a greater degree than other grafses.

4. That there is a greater facility in collecting its feed than of any other grafses.

It is supposed that the prejudices against it have proceeded, 1. From its having been found in land not capable of producing a full crop of any good vegetable. 2. From allowing it to shoot up so far, as to have formed the feed in the flowering-salks, before cattle have been turned into paffure, or that it has been cut for hay. Ray-grafs appears, he thinks, to partake more of the nature of grain than any other grafs. Hence, when it has perfected its feed, it shoots out no more salks, and but few leaves that salfon, as lord Kaines has juftly observed. Hence it is neccessary to turn cattle into a field of this grafs early in the spring, and to keep it well under by a sufficiens quantity of slock; in which cafe it will continue to put out fresh flowering-salks and leaves during the whole salfon. 3. The hay, for the reafon just alined, should be cut before it becomes a mere sraw. Common hay-grafs, being composed of grafses in various fages of growth and ripeness, admits of greater latitude than a field of ray-grafs, because many of them will generally be in a proper flate for cutting, although others may have palled their prime.

He adds the following facts in support of its nutritious properties. No hay, says he, could be better refilled by my horses than this was; not a particle of it was walled by them, or left in the rack; no animals could thrive, coat, or do their work better, than they did, whilst they had this ray-
grafs hay to take to. Never was there a greater contrast than when they were put to the natural hay-grafs of the country, after they had refilled the other. They were literally starved into the eating of it; and in spite of an addi-
tional quantity of corn, they fell away (agreeable to his farming man’s mode of expreffion) a limb a-piece. This year nothing can look better than his horses do upon this hay, (with some red clover mixed,) and this, with the adfion of very little corn, and that mostly light, the tailings of oats and barley.

These facts place the utility of this grafs in a very striking point of view. And the following, given by Mr. Duncan, are of the fame tendency, as he found in a comparative ex-
periment of pieces of ground laid to paffure with it, and meadow soft-grafs alone and in mixture, that the ray-grafs portion was not only more early ready for the fcythe by nearly three weeks, but the hay of it always more greenly eaten by the horses and cattle, as well as the paffure in suc-
ceeding years, on the ray-grafs divifion, contantly eaten bare before the cattle flock would touch that of the foit grafs.

In the county of EfleEf the farmers in many places have, however, a very indifferent opinion of ray-grafs, believing it to do great injury to the land, especially when of the better kind. When fown with red clover, it does not do so well or is so good as a preparation for wheat, but it answers well for peafe. In trying it mixed and unmixed with clover, fome have found that when without it, it is all the better for the wheat; and that the wire-worm after ray is sure to destroy the wheat.

In weaning calves it is found extremely useful and ad-

tractive, as it agrees very well with them, far better than tares, which are liable to run through them, or foour.

In EfleEF this grafs is employed in mixture with others, as a fheep-feed, with great benefit and fecceeds.

The farmers in the tillage parts of Oxfordshire also con-

ider ray-grafs as preparing badly for wheat; they conceive that the wheat which follows will never be found so good where it is fown as where there is none. It is thought far from having any ameliorating effects on the land, as it draws too much. It is never fown alone by fome. It makes the very worth hay, unlefs cut at an early period, or very young, in the opinion of many.

In Berkshire this grafs is fown in the chalk district, and found to a certainty less nutritious than many other forts, as well as more exhaufing in its nature. When intended for permanent paffure, it is found, in general, to fail in a very few years; and, unlefs the feed is changed, it will degenerate under any mode of management. It, however, pos-
fefes the advantage of being cheap, and of producing early feed, which are objects of no inconfiderable importance on a farm. Some find that the Peacey variety furnifhes feed a fortnight or three weeks fooner than the common fort. It is seldom fown finely, but in mixture with many other artifi-
cial grafses, in proportions to fuit the difference of foil. In fome places it is fown with different other artificial grafses in variety, every four years, on different parts of the land, as to prevent it getting fick of the fame kind of feeds.

In the intention of hay, it should be cut early, or its juices will be much exhausted. Horses fed on this fort of hay are found to preferve their wind better than on hay of other grafses.

In Cheshire the dairy farmers do not consider it a good grafs for producing milk, on which account it is not so much cultivated; its earlines, however, has made it esteemed by many; as on almoft any foil, fome suppofe it will be a paffure a week or ten days sooner than any other kind. And its having the property of correcting the tendency of clover to produce flatulence, renders it also highly worthy of the farmer’s attention.

When for hay, if not cut early, the produce is scarcely so nutritious as sraw.

This grafs-feed is sometimes fown alone, and the quantity of feeds which the plants afford, and the facility of collecting it, are probably the reafons of its being very common; while the advantages of its earlines have led to its more frequent cultivation. It is fuggfed, however, that several grafses, as the vernal, the foz-tail, the meadow poa, and fome others, are equally as early as this grafs, and that the meadow fescue, the oat-grafs, and fome others, feem to be as well deferving of the attention of the farmer.

According to the ingenious experiments on this grafs, made under the direction of the duke of Bedford, as flated in the appendix to Sir Humphry Davy’s Agricultural Chemicly, the refults were as follow.
The quantity of produce from a rich brown loam, taken at the time of the plant's flowering, was

\text{Raymond de Pegafour, in Biography, a faint in the Roman calendar, was a Spaniard by nation, and born at the castle of Pegafour, in Catalonia, in the year 1175. He received the early part of his education at Barcelona, from whence he removed to the university of Bologna, where he studied the law, took his degrees, and afterwards taught the canon law for some time with great reputation. He was afterwards called to Barcelona, by Berenger, bishop of that city, who made him his canon, and provost of his cathedral church. He held these polls in the year 1218, when he established an institution which led the way to the foundation of the Order of Mercy, (see that article.) In 1222 he resigned his dignities, and became a member of the Dominican order of preaching friars at Barcelona. In 1230, pope Gregory IX. sent for him to Rome, appointed him his chaplain and confessor, and devoted on him the care of carrying on the compilation of the "Decretals." The pontiff would willingly have recommissioned him for his labours by presenting him with very considerable church preferment, but he chose rather the quiet of a monastery to the honours and emoluments of the richest fees in Spain and Portugal, which were offered to him. In 1235 he was called to assume the pontiff of general of his order; but upon the plea of his infirmities, he was sufferered, in about two years, to return to his monastery, where he spent the remainder of his long life. He died in 1275, having entered on the 100th year of his age. To his everlasting disgrace, he is said to have been principally instrumental in introducing the Inquisition in the kingdom of Arragon, and into Languedoe, a circumstance which probably was the means of his canonization in the year 1601. He was author of "Summa de Caflibus potentiulis, seu de Peuententia et Matrimonio," which was long popular in the Catholic world, and went through numerous impressions. The best edition of it is that published by father Laget, at Lyons, in 1708. Raymond's chief work is "Lib. V. Decretalium," commencing with the papacy of Alexander III., where the decrees of Gratian terminate, which was approved by pope Gregory IX., and constitutes the second volume of the papal canon law. Moreri. Raymond Lully, a philospher of much celebrity in the dark ages, was born at Majorca in 1234. He was brought up a sinner, and led the life of a man of pleasure. Falling in love with a young woman, who was deaf to his addresses, on account of a cancer with which she was afflicted, and which the exhibited to his view, in order to make him deaf from his importunities, he was so much afflicted with the light, that he retired from the world, devoting himself to pious pursuits, and in the search of a remedy for the dis ease with which the object of his affection was afflicted; this was the chief motive for the chemical labours for which he became so famous. He undertook a course of travels into the East, for the purpose of converting the Mahometans to the Christian faith, and incurred very great hardships, and the most serious dangers. So great was his zeal for this object, that being unable to persuade certain Christian princes to engage in it, he entered into the Franciscan order, and returned to Africa, with the hope of obtaining the honour of dying a martyr. He was accordingly thrown into prison, and after suffering much torture, and long imprisonment, he was freed through the interest of some Genoese traders, who took him on board their ship to convey him home. He died just when he had arrived within sight of his native land, in the year 1315. As a chemist, his chief object was the pursuit of the philosopher's stone, and the universal remedy for all disorders. Boerhaave, who had perused the works of Lully, speaks highly of their merit; he finds them, he says, "beyond all expectation, excellent, so that he doubted whether they could be the work of that age. So full are they of the experiments and observations which occur in later writers, that either they must be suppos itious, or the ancient chemists must have been acquainted with many things which pass for modern discoveries." Lully is supposed to have derived his chemical knowledge from his travels in the East, particularly from the writings of Geber. A complete edition of all the writings attributed to him, was printed at Mentz. Raymond Lully is chiefly celebrated for an invention by which he pretended to enable anyone, mechanically, to invent arguments and illustrations upon any subject, and thus to reach the summit of science at a small expense of time and labour. This "Great Art" professes to furnish a general instrument for affording invention in the study of every kind of science. For this purpose, certain general terms, which are common to all sciences, are collected and arranged, not according to any natural division, but merely according to the caprice of the inventor. An alphabetical table of such terms was provided, and subjects and predicates taken from these were inscribed in angular spaces, upon circular papers. The sciences, qualities, affections, and relations of things, being thus mechanically brought together, the circular papers of subjects were fixed in a frame, and those of predicates were so placed upon them as to move freely, and in their revolutions to produce various combinations of subjects and predicates; whence would arise definitions, axioms, propositions, varying infinit ely, according to the different application of general terms to particular subjects. Such is the general idea of the Lullian art, which, however applauded by certain writers of
that period, may be pronounced as unworthy of notice, except as a specimen of the artifice with which men frequently impose upon vulgar credulity. Enfield's History of Philosophy.

Raymond, in Geography, a township of America, in Rockingham county, New Hampshire, incorporated in 1764, containing 898 inhabitants; 12 or 14 miles W. of Exeter.

Raymond, or Raymam-town, a post-town in Cumberland county, and district of Maine, containing 825 inhabitants; 142 miles N.N.E. of Boston. The land is generally level, excepting one large hill, called Rattlekake-hill, from its abounding with those reptiles. The greater part of the growth is pine and white oak, and the soil is difficult of culture.

Raynal, William-Francis, in Biography, a French writer of celebrity, was born at St. Genes, in the Bourbon, in 1713. He entered at a very early age among the Jesuits, and by his abilities excited high expectations of his future celebrity. His dislike of restraint induced him to quit the society in the year 1748, although he had made his profession, and had been ordained priest. He now entered his career of authorship, and distinguished himself as a political, historical, and miscellaneous writer. His first piece, published the same year in which he quitted the society, was entitled "Histoire du Stad Thonderat"; he next published "Histoire du Parlement d'Angleterre," which gained him much reputation, though it had little claim to the dignified title of history, and was, moreover, tinged with many prejudices, religious and political. He also compiled "Anecdotes Literaires," in three vols. 12mo.; and "Memoires de Ninon de l'Enclos," and was much employed in the "Mercure de France." The great work of the abbe Raynal was entitled "Histoire Philopolique et Politique des Etablisemens et du Commerce des Europeens dans les deux Indes," to the composition of which he was led by his engaging in some commercial speculations, thinking them likely to turn more profitably than literary pursuits.

His history was published in 1770, and as it contained history, description, and calculation, intermixed with political and philosophical reflections, and was, through the whole, animated by an ardent spirit of philanthropy, and hatred of tyranny, civil and religious, it became popular, and the author was looked up to as one of the reformers of the age. Critics, however, soon found that, as a literary and philosophical work, it would not bear the test of examination. The fyle, though rich, was exceedingly declamatory; the images were frequently inalining; and his principles vitiated by the licentiousness of his country; and the facts upon which the whole was founded were derived from incorrect or dubious documents. The author, it should seem, was soon made sensible of the imperfections of his work, and determined to improve it by travel; with this view he visited the principal commercial towns in France, and passed into England and Holland, at every place making inquiries among travellers and merchants with the most unremitting industry. On his return, he published at Geneva an improved edition of his work, in 10 vols. 8vo., containing many additions and corrections. Its tone was unaltered, and its attacks upon existing authorities were fo bold, that the parliament of Paris ordered it to be burnt, and issued a decree for apprehending the author. He retired to Spa, whence he travelled through Germany, and after having visited all the principal places, he returned to France, and lived some time quietly in the southern provinces. At the academies of Marfelles and Lyons he founded several prizes for essays upon given subjects, of which the most remarkable was whether the discovery of America had been more useful or prejudicial to Europe.

America has now, owing to the quarrel and war subsisting between Great Britain and its colonies, become an object of peculiar interest; and the abbe Raynal, in 1781, published "Tableau et Revolutions des Colonies Angloise dans l'Amerique Septentrionale," which was commented upon and exposed by Thomas Paine, who was a zealous and able defender of the American cause, against the mother country.

The abbe came to Paris in the important year 1788, when the revolution was just ready to burst forth. He had not been long in the city, before the National Assembly was convoked, and one of its early acts annulled the decree passed against him; for this favour, he addressed a letter of thanks to the president, containing a retraction of certain principles contained in his work. Observing, afterwards, that the constituent assembly were occupied in decrees which he thought were violent infringements on the rights of property, and in others calculated to augment the popular effervescence, he wrote, in May 1791, a long letter of advice and remonstrance. It was soon seen that the sentiments in this letter were very different from those which were generally expected from the author of the "Histoire Philopolique," their tendency being to reprefs popular licence, and to strengthen the hands of civil authority. Raynal, like many other philosophers of that day, had aid in his power to produce the change, at which, when put into practice, he and they were greatly alarmed. But it was now too late to return: they had flown the people their power, had taught them their rights, which it was in vain to expect they would be induced to abandon for any arguments he could produce. In the letter referred to, he says, "I have long dared to speak to kings of their duty, suffer me now to speak to the people of their errors, and to their representatives of the dangers which threaten us. I am, I own to you, deeply afflicted at the crimes which plunge this empire into mourning. It is true that I am to look back with horror at myself for being one of those who, by feeling a noble indignation against arbitrary power, may perhaps have furnished arms to licentiousness. Do, then, religion, the laws, the royal authority, and public order, demand back from philosophy and reason the ties which united them to the grand society of the French nation, as if, by exposing abuses, and teaching the rights of the people and the duties of princes, our criminal efforts had broken these ties? But no! — never have the bold conceptions of philosophy been represented by us as the strict rule for acts of legislation." He next proves, that it was not the business of the assembly to abolish every ancient institution; that the genius of the French people is such, that they can never be happy or prosperous but under a well regulated monarchical government; and that if they wished not the nation to fall under the worst kind of despotism, they must increase the power of the king. Raynal was considered to be in his dotage, and himself and his writings were now disregarded. He retired in the midst of florms to Passy, where, being reduced to a state of indigence, he died in March 1794, at the age of 85. Besides the works already mentioned, the abbe Raynal published "The History of the Divorce of Catharine of Arragon, by Henry VIII.;" and "A History of the Revolution of the Edict of Nantes," in four volumes; but he committed many of his papers to the flames during the bloody reign of the monster Robespierre.

Raynerius, a learned Italian monk, who flourished most probably in the 13th century, was a native of Pisa. He
RAY

He acquired the character of a consummate divine and civilian, and was appointed professor of divinity, as well as raised to the most considerable offices of trust and honour belonging to his order. It is uncertain at what period he died. He left behind him many works, of which the chief is entitled "Pantheologia, seu, Summa universæ Theologiae." This is a dictionary of theology, with the subjects disposed of in alphabetical order; it has been held in high estimation among the members of the Catholic communion. It has gone through several editions in folio and quarto. The last edition was printed at Paris in 1655, in 3 vols. folio, with additions of father Nicolai.

RAYNHAM, in Geography, a township of Massachusetts, in Bristol county, taken from Taunton, and incorporated in 1731. It contains 1154 inhabitants. Besides the great river Taunton, this township is watered by several streams, upon which are six saw-mills, three grist-mills, a furnace, a forge, and fulling-mill. Here are also numerous ponds, of which Nippanniquit, or Nippahoniit, is two miles long and one broad. In this pond millions of alewives annually resort and leave their spawn in it. An excellent kind of oar, and various kinds of fish, are found in this township. Besides the usual occupations of husbandry and mechanics, many of the inhabitants are employed in the manufactories of bar-iron, hollow ware, nails, iron for vesseis, iron-hovels, pottash, thingles, &c. The first forge set up in America was introduced into this town by James and Henry Leonard, natives of England, in 1652. The family, in the 6th generation, now ploughs it. King Philip's hunting hounds flushed on the northern side of Fulling pond, about one mile and a quarter from the pond. When the war broke out in 1675, which terminated in the death of the king and the ruin of his tribe, he left strict orders to all his Indians not to hurt the Leonards. Before Philip's time, Fulling pond was two miles long, and three miles and a quarter wide. But the water is now almost gone, and the large tract it once covered is grown up to a thick-fet swamp of cedar and pine. The vicinity has abounded with excellent oar, which has supplied the forge for 80 years; it is, however, incapable of being wrought into iron of the best quality.

RAYNOLES, or RAYNOLDS, John, in Biography, a learned English divine, was born at Pinhoe, near Exeter, in the year 1549. In 1562 he was admitted a student at Merton college, Oxford, whence he was removed, in 1563, to a fellowship of Corpus Christi college. In 1572, having taken his degrees in the arts, he was appointed Greek lecturer in his college, in which department he acquitted himself with great applause. Fuller speaks of him in the highest terms as a commentator of Aristotle's Rhetoric. He had hitherto been zealously attached to the Popish religion, while his brother William was equally zealous for the Reformation. The difference in their sentiments leading them to frequent conferences and disputations, they made converts of each other, William becoming a determined Papist, and John a steady Protestant. He frequently appeared in the pulpit, and was greatly admired as a preacher. In the year 1588 he was admitted to the degree of doctor of divinity, and soon afterwards the fame of his great learning induced queen Elizabeth to appoint him professor extraordinary in that faculty at Oxford; after which she gave him the deanery of Lincoln, which he held only a short time, when he exchanged it for the presidency of Corpus Christi college, of which he was a fellow. He made this exchange from his attachment to an academical life, and his love of retirement and study. Similar motives led him afterwards to refuse a bishopric which queen Elizabeth offered him. He retrieved the finances of his colleges, which had been suffered to fall into dilapidation, and he reformed his decayed discipline, strictly obeying the statutes himself, and compelling all the other members to observe them. After the accession of James, he was appointed, with Dr. Sparks, Mr. Chaderton, and Mr. Knewthubs, to appear on behalf of the Puritans in the pretended conferences at Hampton Court; of which we have a full account in the second volume of Neal's "History of the Puritans," by Dr. Toulmin, p. 10–20. Dr. Raynolds did not on this occasion act according to his usual spirit, and, suffering himself to be browbeaten by the royal tyrant, lost much of the respect which his character usually laid claim to. It was at the conclusion of this conference, that the king said to Dr. Raynolds and his friends, in answer to their arguments; "If this be all your party hath to say, I will make them conform themselves, or else I will harry them out of the land, or else do worse, only hang them, that's all." When James gave directions for undertaking a new and more correct translation of the bible, Dr. Raynolds was one of the Oxford divines who were commissioned to give a new version of the four greater prophets, the book of Lamentations, and the twelve minor prophets. While employed in this great work he was feized with the gout, under which he had been a sufferer many years, and which at length proved fatal to him. In the midst of the severest pains, he persevered in the task assigned to him, and once a-week his fellow-labourers at Oxford regularly assembled in his apartments, where they compared the fruits of their respective studies, determining what appeared to them to be the most faithful translation, till they had accomplished their task. Dr. Raynolds died in the year 1677, highly respected for his erudition, his piety, his modesty, and humility. Several of his biographers speak of him in the highest terms. Wood says he was a prodigiously seen in all kind of learning, and had turned over all writers, profane, ecclesiastical, and divine, all the councils, fathers, and histories of the church. He was author of many theological works, of which we may mention "De Romanæ Ecclesiæ Idolatria, in Cultu Sanctorum, Reliquiarum, Imaginum," &c. 1596; and "Centuria Librorum Apocryphorum Veteris Testamenti, adversus Pontificios," which was a polemical work, and printed at Oppenheim, in Germany, 1611, in 2 vols. 4to.

RAYPOUR, in Geography, a town of Hindooftan, in Bahar; 40 miles N.W. of Chuprah.

RAYPOUR, a town of Hindooftan, in Bahar; 32 miles E. of Bahar.

RAYPOUR, a town of Bengal; 55 miles W.S.W. of Burdwan. N. lat. 22° 48'. E. long. 87° 5'.—Also, a large and commercial town of Hindooftan, in the country of Ruttunpour; 55 miles S. of Ruttunpour. N. lat. 21° 24'. E. long. 82° 28'.

RAYPOUR, or Ray-Gaut, a remarkable pass on the Beyah river, about 17 or 18 miles from Noorpour; situated a considerable way within the level country of the Panjab.

RAYTE, or Ryche, in Ichthyology, a name given by Joannes Cuba, Albertus, and others, to the common skate, or flaire. See Rayta Bait.

RAZANT. See Razant.

RAZANT Flank. See Flank.

RAZANT Line of Defence. See Defence.

RAZBOINIKOVA, in Geography, a town of Russia, in the government of Irkutsk, on the Angara; 56 miles N.W. of Balaganusk.

RAZBOINOK, a fort of Russia, on the Ural; 92 miles E. of Orenburg.

RAZE,
RAZE. See Tomb.
Raze, in the Manuge. A horse is said to have razed, whose corner teeth cease to be hollow; so that the cavity, where the black mark was, is filled up; that is, wholly disappears, and the age of the animal cannot be known with any degree of certainty. See Mark.

RAZI, in Biography, one of the surnames of the famous Mul Unified the famous

Muhammad and Ben Omar Ben Khatid Riz, Al Tom in Al-Biruni, a native of the city of Rez, in the Persian Iran, of which the word Razi is the appellative. He was born in the year of the Hegira 543, corresponding with 1148 of the Christian era, and became one of the most celebrated doctors. His knowledge was not confined to the learning usually taught in the Mohammedan schools, but it comprehended likewise the sciences imported into the East with the writings of the Grecian fages. He was, moreover, a very eloquent preacher both in the Arabic and Persian languages. By these qualifications he acquired the favour of several princes, particularly of a sultan of the Gaurid dynasty, who erected a college for him in the city of Herat in Chorasan. He was driven from this situation by the intrigues of Cadi Abdalmegid, of the sect of Karamians, who contended that the deity was corporeal, and of human shape. Having challenged Razi one day to a public disputation on the attributes of God, he was so confounded by the superior reasoning of the latter in defence of the divine spirituality, that he became his bitter enemy, and feigned every opportunity of calumniating him to the sultan, as a man who, under the cloak of philosophy, concealed irreligious and impious notions. By his perjuries, the prince banished Razi from the city, but he soon repented of his rash decree, and recalled him. This happened in the year 606 of the Hegira. He was author of an "Introduction to the most subtle Mysteries for the Use of Men of Genius," in which he expresses the principles of the Mohammedan philosophy; and several other pieces. "Select Astronomical Researches" have been attributed to him, but perhaps on insufficient authority.

Razi is also the surname of a celebrated philosopher, chemist, and astronomer, called Mohamed Ben Zakaria, a native of the same city of the preceding, who flourished under the caliphate of Mothader of the dynasty of the Abbasides. He died about the year 922 of the Christian era.

RAZIMIERZ, in Geography, a town of the duchy of Warsaw, situated between Sieprzka and Poben, where the unfortunate count Parkul was broken alive on the wheel, and impaled by order of Charles XII. of Sweden in 1708.

RAZINPAINIA, a fort of Ufalla, in the government of Upaha, on the Ural; 56 miles S.W. of Orenburg.

RAZIOIS, Port, a port at the S.W. extremity of the coast of Nova Scotia, and N.E. of cape Negro.

RAZOR, a well-known edged instrument used in shaving. Heat appears to give a partial increase of tenacity to a razor's edge, probably because the edge cools faster, contracts, and is stretched.

RAZOR-BILL, in Ornithology, the common English name of the alca, a web-footed bird with no hinder toes, common on our sea-shores. See Alca Torda.

RAZOR-FISH, in Ichthyology, the Coryphaena novaculorum of Linnaeus, having the head and fins barred with bluish lines. See Novacula.

RAZOR-ILAND, in Geography, a small island on the coast of Brazil; 12 miles S. of Rio Janeiro.

RAZUDA, a town of Hindooostan, in Guzerat; 40 miles E.S.E. of Chip Burr.

RE, an island in the Atlantic, near the west coast of France, about 16 miles long, and 3 broad; separated from the coast of Vendee by the islands of Breton, which are about 7 miles wide. The principal town is St. Martin de R. N. lat. 46° 13'. W. long. 1° 20'.

RE, in Commerce. See Ree.

Re, in Grammar, &c. an invariable particle, or preposition, prefixed to the beginning of words, to vary, double, or otherwise modify their meaning.

The Peripatetics define re-action to be that which a passive body returns upon the agent, by means of some quality contrary to that received from it, in the same part with which the agent acted, and at the same time; as if water, while it is heated by the fire, does at the same time cool the fire.

It was known, even in the schools, that there is no action in nature without re-action; and it was a maxim among them, ommis agent, agens repatis.

But the equality of the actions was not known. Sir Isaac Newton established it as one of the laws of nature, that

**REA**

**REA**
action and re-action are equal and contrary; or that the mutual actions of two bodies, striking one against another, are exactly equal, but in contrary directions; or, in other words, that by the action and re-action of bodies one on another, there are produced equal changes in each: and those changes are impervious towards directly contrary parts or ways of NATURE.

Some of the school-philosophers deny any such thing as re-action, properly so called, at all; urging, that action arises only from the ratio of the greater inequality; that is, we are only to account for action the excess of action, or what the agent does more than is returned by the patient. But the equality between action and re-action sets aside this exception.

READ, in Geography, a river of England, in the county of Northumberland, which runs into the Tyne, 10 miles N. of Hexham.

Read Head, a cape on the E. coast of Scotland. N. lat. 56° 35'. W. long. 2° 28'.

READFIELD, a post-town of America, in Kennebec county, and district of Maine, bounded on the E. by Hallowell, and separated from Sterling on the W. by the eastern branch of the Androscoggin river; 8 miles W. of Hallowell, and 190 N.E. of Boston. It contains 1396 inhabitants.

READING, John, in Biography, organist, first at Lincoln, then at Hackney, and finally at St. Dunstan's church in Fleet-street, London. He was a scholar of Dr. Blow, and Stanley's first maker. He published Hymns early in life, for psalmists in parochial congregations; and, lastly, a work engraved on copper, which he called "A Book of my Anthems, with a Thorough-bafe, for the Organ or Harpsichord." He died in 1766, far advanced in years.

Reading, in Geography, a borough and market-town in the hundred of Reading, and county of Berks, England, is 38 miles W. by S. from the metropolis. It is a town of considerable extent and importance, and contains, according to the parliamentary returns of 1811, 2032 houses, and 10,788 inhabitants.

Historical Events.—Reading is unquestionably of very great antiquity; but whether it is indebted for its origin to the Britons, the Romans, or the Saxons, is unknown. Conjectures, however, have been hazarded on the subject by various writers. Camden thinks its foundation ought to be referred to the Britons; Leland calls it the Pontes Antoninius; and Dr. Beeke, the learned professor of modern history at Oxford, considers it the Calleva of Richard of Cirencester. But the circumstances which are alleged in favour of these opinions, by their respective authors, are far from being satisfactory. This place is first mentioned in history, under its present appellation, in the year 871; at which time it is described by Asser as being a fortified town, belonging to the Saxon kings, but then occupied by the Danes invaders, who had retrenched likewise after their defeat at Englefield. The victorious Saxons immediately invaded the town; but their enemies, having received reinforcements, attacked the besiegers with much impetuosity; that, after an obstinate contest, they deemed it prudent to retire to Ald. Hither they were followed by the Danish forces, which were again overthrown, and driven back to Reading. Here the latter remained unmolested till the following year, when they marched to London. In the reign of Alfred, who crowned the throne of Wessex soon after this event, the Danes once more feizcd upon Reading, and they doubtless poifoned it occasionally during their incursions in the tenth century. Throughout that long period of incessant hostility and depredation, however, this town seems to have escaped any very serious disaster; but in 1006 it was reduced to ashes by Sweyn, king of Denmark, along with its famous nunnery, said to have been founded by Elfride, widow of king Edgar, as an atonement for the murder of Edward the Martyr. Reading soon recovered from this disaster, and in the course of a century afterwards became a place of considerable importance. In 1121 king Henry I. laid the foundation of its magnificent abbey, in which his remains were subsequtently interred, according to his own desire. Stephen, who usurped the throne after Henry's death, built a castle here, which was further adorned by his antagonist Henry Fitz-Empress, who no sooner obtained the crown, than he ordered it to be demolished; so that even the site of it is now uncertain. That monarch, however, otherwise evinced much partiality for Reading. Here he passed much of his time, and convened a parliament, as also an ecclesiastical convocation, in which Baldwin was elected archbishop of Canterbury. The abbey church was finished in this reign, and dedicated in presence of the king. In 1185 he came hither from London, to receive Heraclius, patriarch of Jerusalem, who presented him with the keys of the holy sepulchre, and the royal banners of Jerusalem, which Henry returned. In the reign of his successor, Richard I., a convention for the trial of Longchamp, chancellor and bishop of Ely, who had been appointed regent of the kingdom during the king's absence, was held here. King John also held a convention in this town, in 1206; and in 1212 a council was convened here by the pope'slegate, for the purpose of effecting a reconciliation between that infatuated prince and the exiled bishops. In 1213 the king met the legate and barons at the abbey, and held a parliament. King Henry III. spent his Christmas at Reading in 1226; and twice during his reign summoned the estates of the realm hither, for the transactio of national business. He was the first monarch who granted a charter of incorporation to the town. In 1346, Edward III. held a great tournament here; and in 1359, the marriage of his son, John of Gaunt, with Blanche, daughter of Henry, duke of Lancaster, was solemnized in the abbey church. In 1384, Richard II. and his court, together with the mayor and aldermen of London, being assembled at Reading, John Northampton, the preceding mayor of that city, was convicted before them of fœtidus practices, and sentenced to perpetual imprisonment. In 1389 a great council was held at Reading, at which the king and his barons were reconciled by John of Gaunt. Parliaments were held here also in 1440 and 1451; in the former of which the order of nobles called vilcounts was first established; and in the year following, the parliament adjourned hither from Westminster, on account of the plague. King Edward IV.'s marriage with Elizabeth, lady Grey, was first acknowledged at Reading, in 1464; on which occasion she made her public appearance at the abbey, conducted by the duke of Gloucester and the earl of Warwick. In 1466 parliament was a second time adjourned to Reading, to avoid the plague. King Henry VIII. frequently resided here, having converted the dilapidated abbey into a palace. His son, king Edward VI., visited this town in 1552, when he was met by the mayor and aldermen at Coley-Crofts, and presented with two yokes of oxen; the mayor riding before him, uncovered, to the palace. The same ceremony was repeated, when Reading was visited by the bigotted Mary, and her husband, king Philip of Spain. Queen Elizabeth was a frequent visitant here, and had a seat in the church of St. Lawrence.

Early in the reign of Charles I., when the plague raged with
with great violence at London, the courts of chancery, king's bench, and common pleas, were held here, as were likewise the court of exchequer, the court of wards and liversies, and the court of requelts. In 1642, Reading was a parliamentary poll, but the garrison, being defective as to ordnance and ammunition, quitted the town, without refilience, on the approach of a party of the king's horse. In consequence of this event it became a royal garrison, and continued to be so till taken by the earl of Essex in April 1645, after a siege of eight days. The king, however, again recovered it in September the same year, and held it till May following, when he ordered the works to be demolished, and evacuated the town. After this event Reading was frequently occupied as the head-quarters of the parliamentary army, and was consequently much impoverished by the contributions levied upon its inhabitants for the support of the military. In 1688 the army of king James II. was quartered in this town, but quitted it on the approach of the prince of Orange. On this occasion a skirmish took place in the market-place between two detachments of horse, which terminated in favour of the Protestant interest, and is still commemorated, by bell-ringing, on the anniversary of its occurrence. Queen Anne visited Reading in 1700, when she was received by the corporation in state, and presented with forty broad pieces of gold in an elegant purse made for the occasion.

Municipal Government.—Reading claims the honour of having been originally constituted a guild, by charter from Edward the Confessor. This claim, however, is extremely questionable; and at all events we feel convinced that the ancient guild was nothing more than an association of mechanics and tradesmen for their individual benefit. The first monarch who conferred upon Reading the privilege of separate jurisdiction was Henry III., in the 37th year of his reign. His charter was subsequently confirmed by all his successors, but without any material alterations, till the reign of Henry VI., when the corporation is first mentioned by the title of the mayor and burgesses. Thus it continued to be designated till queen Elizabeth divided the burgesses into capital and secondey, and declared the mayor and them to be a common council for the borough. That prince further conferred upon the corporation considerable effates. Charles I. authorized aldermen to be elected, and invested the mayor and them with ample powers for the government of the town. This charter was confirmed, after the restoration, by his son Charles II., and is the one under which the corporation now acts. By it the officers are declared to be a mayor, twelve aldermen, and the same number of capital burgesses; the mayor, and his deputy, (the preceding mayor,) the senor alderman, the bishop of Salisbury, and his chancellor, being justices of the peace for the borough, and empowered to hold feessions, and a court of record. The recorder is an officer added by Charles II., who likewise first acknowledged the town clerk. Reading sent members to parliament from the time of the earliest records. Before 1716 the right of election was vested in the freemen not receiving alms, and in the inhabitants paying poor and lot; but in that year it was limited, by a decision of the house of commons, to the inhabitants paying poor and lot only. The number of voters is estimated at 560, and the mayor is the returning officer. The spring afizes for the county are held at this town, as are likewise the Epiphany feessions, but the summer afizes are held at Abingdon, and the Michaelmas, either there or at Reading, as the magistrates may judge most convenient.

Reading is a town of considerable extent, situated on both banks of the river Kennet, which separates itself into several branches in passing through the town. It contains three parishes, St. Giles, St. Mary, and St. Lawrence, and is divided into five wards, called the High-ward, New-ward, Minster-ward, Old-ward, and London-ward, for each of which a constable is appointed. Formerly it was a place of great trade in woollens, but that manufacture fell to decay during the seventeenth century, and has never since revived. At present the chief manufactured products are, coarse linens, (such as sheeting, fail-cloth, floor-cloth, and facking goods,) gautes, crapes, muffates, ribbons, hat-bands, shoe-liner, and other similar articles. These afford employment to a great portion of the inhabitants among the lower orders; but the principal support of the town arises from its water communications with London, Bath, and Bristol. The articles exported are, flour, of which 20,000 facks are sent annually to the metropolis, timber, bark, straight hoops, linen, wool, cheeff, beer, and a variety of minor articles; in exchange are received groceries of every kind, iron, spirits, fir timber, deals, flaves, Portland stone, bricks, hemp, flax, hides, leather, coals, Bath free-flone, Birmingham goods, &c. For the convenience of trade, several wharfs are formed at Reading, and many improvements have been lately made in the internal navigation of the districts at large.

This town, from time immemorial, has been noted for its markets, which are held weekly, on Wednesday and Saturday. The Wednesday's market is chiefly for fruit; but that of Saturday embraces corn and every article of provision. The spot on which the corn market is held, is a spacious piece of ground, of a triangular form, environed by commodious shops for the accommodation of people attending the market, who may be supplied here with colonial or manufactured goods cheaper than in any other town in the county. This market-place is kept in repair by the corporation, for which they are entitled to take one pint out of each fack of corn sold in the market, amounting to about 54,000 quarters annually. The provision market buildings adjoin to the corn market-place, and form a large square, containing, one-half of two ranges of butcher's shops, and the other half of apartments for the market-women, who bring butter, eggs, poultry, &c. for sale. At the southern end of this building is a square open area for fishmongers' and hawkers' stalls, and next to this, and fronting a street called Fish-street, is a large square gate-way, over which is the house occupied by the clerk of the market. Besides these market-places, there is another for the sale ofscore pigs, conveniently situated between Friar-street and Broad-street. This is private property, but the corporation receive the toll. At Reading are four annual fairs, one on the 2d of February, another on the 1st of May, a third on the 25th of July, and a fourth on the 21st of September. The three frst are chiefly for the sale of horses and cows; but the last is also a fair for the hiring of servants, and is further remarkable for the quantity of cheese brought hither from the counties of Gloucester and Wilts. Hops are also plentiful at this fair.

The houes of Reading are mostly confructed of brick, and are generally disposed in regular streets, some of them very narrow, which have been paved under the authority of an act of parliament, passed in the year 1785.

The principal public buildings and institutions in the town are the three churches of St. Lawrence, St. Mary, and St. Giles, and several dissenting meeting-houses, the town-hall and free-school, the blue-coat school, the grammar school, the foundation school, the school of induftry, the Lanealterian school, the school for national education, the theatre, and the county gaol.
The church of St. Lawrence was chiefly erected towards the close of the 16th century, and is partly constructed of materials taken from the buildings of the abbey. Among the parts of it, so pillared from the monastery, is a large doorway, which is composed of a circular arch, ornamented with rich mouldings, from which were fupplied on each side the arms of the abbey; but these are now nearly obliterated. This doorway is likewise ornamented with niches, in which statues formerly stood. The advowson of the church belongs to St. John's college, Oxford. St. Mary's church is somewhat more ancient than that of St. Lawrence, having been constructed about the year 1547, in the stead of a previous one, which had gone to decay. Some portions of this building have evidently belonged to an older edifice, particularly a window over the west door, which is in the early pointed style of architecture. St. Giles's church was probably constructed at the commencement of the 12th century. The tower only is modern, the ancient one having been demolished during the civil war. The livings of both the churches last mentioned are in the gift of the lord chancellor. The principal meeting-houses for dissenters are the Calvinistic or Independent meeting-house in Broad-street, a Baptist meeting-house and a Quaker's meeting-house in Church-street, a Methodist chapel in Castle-street, and another in Minster-street, a Cudworthian and an Unitarian meeting-house in London-street, and a Catholic chapel in Vatier-lane. Another meeting-house for Baptists has also been lately erected in Sievier-street.

The town-hall and free-school form one building; the free-school occupying the ground floor, and the hall, court-room, and offices, the floor above. The free-school was established in the reign of Henry VII., by John Thorne, abbot of Reading, with the funds of a suppressed almshouse. This school has two scholarships in St. John's college, Oxford, the gift of Sir Thomas White, in 1557. Julius Palmer, one of the masters of this school, fell a martyr to his Protestant tenets in 1556. The blue-coat school, which is so named from the dress of the scholars, was founded in 1676, by Mr. Richard Aldworth, who bequeathed 4000l. for the support of a master, lecturer, and twenty boys. The present school-house is of late erection, and consists of a centre and two wings. Several donations and bequests having been made to this establishment by various persons, it now usually supports about 48 boys. The green school is situated in Broad-street, and is appropriated for the education of the daughters of decayed tradesmen, residents in the town, and of orphans, who have been left unprovided for by their parents. The inhabitants of Reading are indebted for the institution of this school to the Rev. Charles Sturges, the Rev. Dr. Nicholls, and the Hon. and Rev. W. B. Cadogan, former vicars of the three parish churches belonging to the town. It is supported by annual subscriptions, and the proceeds of different donations and bequests. In the foundation school, founded in 1765, eight male and eighteen female children are taught to read. It was instituted with a legacy left for that purpose by Mr. Joseph Neale. The school of industry originated under the patronage of Mrs. Cadogan, for female children, and is supported by the voluntary contributions of ladies in the town. The Lancasterian school, established in 1816, is situated in Southampton-street, and is attended by about 350 boys, who are nominated by the subscribers individually. The school for national education was opened in September, 1813. It is founded on the plan of instruction recommended by Dr. Bell, and is chiefly supported by the clergy of the town and county. Both these institutions are calculated to be highly beneficial to the rising generation. Besides these seminaries of education, there are in Reading several Sunday schools, all the children attending which receive a suit of clothes annually, from a fund provided by the bequest of Mr. Edward Simeon, who clothed them in the same manner during his life-time. The theatre of Reading is a neat and convenient building, lately erected, under the act for regulating provincial theatres. The gaol was built in 1793, on the site of some of the abbey ruins. It is a large edifice, and contains commodious apartments for the keeper, a neat chapel, an infirmary, and a room for the reception of the magistrates, in the centre; and two wings, one for male, and the other for female prisoners, with yards, cells for refractory individuals, &c.

Besides the above public buildings and establishments, there is a public library lately established at Reading, under the name of the "Reading Institution," also a dispensary, which is attended by one of the medical gentlemen of the town. The house is the property of the corporation, and the general expences are defrayed by subscription. The Oracle may likewise be reckoned among the public buildings of Reading. This structure was erected by the mayor and burgesses, in conformity to the will of John Kendrick, who left 7500l. "to build a strong house of brick, fit and commodious to let the poor to work therein." The funds of this charity having been at different periods greatly abused and misapplied, the subject has been several times before the supreme courts of justice. The tefator's object, in bequeathing his large legacy, was the improvement of the woollen trade; but instead of this, it was perhaps the first occasion of the decay of that manufacture, by enabling such as could obtain its advantages to underfly those who were not so fortunate. The fame complaints are made against it, with respect to the manufacture now carried on in it, and, as we suspect, not without some show of reason.

Monastic Establishments.—As already mentioned, the earliest religious institution at Reading was a monastery for nuns, founded by Elfrida, the mother-in-law of Edward the Martyr. This nunnery was founded in 979, and was destroyed, in 1009, by the Danes. The precise site on which it stood is uncertain, but there can be no doubt of its existence. It appears from the Domesday-book, and also from Tanner's Notitia, that another nunnery was established here at a later period, but nothing of its history is known. The abbey, the ruins of which are still sufficient to attest its extent and importance, was founded by Henry I. in 1121. It occupied a spot of ground, equal, if not superior, to any in Berkshire for fertility of soil and beauty of situation. This spot comprehended about thirty acres, and was environed on three sides by a massive and lofty wall, and on the fourth by the river Kennet. Exterior to this wall was a piece of ground, about fifty yards wide, (like the pomarium that surrounded the Roman cities,) which it was not allowable either to cultivate or build upon. It had four entrances to it, defended by arched gateways, and having battlements on their tops similar to those on the walls. Within these was the outer court, whence another gate-way led into the inner court. Part of this building remains, and is composed of bricks, chalk, and stone; and, from the diffimilarity of styles which it exhibits, has evidently undergone many alterations and repairs. Some of it is probably as late as the reign of Henry VII. 1 though other portions of it are, undoubtedly, of much higher antiquity. The inner court conducted to the principal entrance to the abbey; the situation of which, owing to the ground having been since built upon, and the confusion occasioned by throwing up the ramparts in the civil war, cannot now be accurately determined. The only entrance on this side at present is through an arched passage, opening into the south-east corner of the cloisters, which is certainly
READING.

Certainly too mean to be supposed to have been the grand entrance to this superb monastery. On the right-hand of the paling is a door-way, leading to a range of apartments, and within is a circular stair-case, which conducts to the upper part of the building. This division of the abbey is conjectured to have been appropriated as offices for servants and others, as, underneath it, is a series of arched cellars, and at its southern extremity was the kitchen. The great hall, or cloister, was entered from the cloisters by three large entrance doors. It measured 80 feet in length, 46 in width, and the nave was 40 feet wide, and was divided from the side-aisles by alternate piers and arches. From the massive character of this structure, in general, and from the circular form of the windows in the dormitory, it is conjectured that its windows also had circular arches. In the ground to the east of the church, many skeletons have been discovered, a circumstance which points it out as the probable burial-place of the monks. The above-mentioned buildings constituted the body of the abbey, but there were likewise many others, both connected with and detached from them. Among those were the infirmary, the stables, and the mill. This hall is yet standing, and appropriated to its original purpose. It is a substantial edifice, built of flint and stone, and is probably coeval with the abbey-church.

Reading monastery was indubitably among the most distinguished in England. The monks were of the Benedictine order, and were endowed with many privileges and immunities, not only by the founder, but by several of his successors, and by some of the popes. They had the right of coining granted to them by king Edward III., also the right of holding three annual fairs, and a market every Sunday at Thatcham. The abbots were among those entitled mitred, and took precedence in the house of peers, next after the abbots of Glastonbury and St. Alban's. He was lord of the manor of Reading, and possessed otherwise much influence in the government of the borough. Many of the monks were distinguished for their talents and their acquirements in the learning of their respective ages. Robert of Reading, one of the first monks, was particularly famous, as being, with Adelard of Bath, the only Englishmen of their time who were masters of the Arabic language. The abbey-church was the place of sepulture of many royal and noble personages, among whom were Henry I., and his second queen, Adeliza, and probably also his first queen, Matilda; the empress Matilda, and William, eldest son of Henry II.; Constance, grand-daughter to Edward III.; Ann, countess of Warwick; Richard, earl of Cornwall, and king of the Romans; and Richard de Curtenese, natural son of Henry II. At the dissolution, the revenues of this monastery were estimated at £116l. 4s. 9d. annually, above £2,000l. according to the present value of money. The lands, of course, were seized upon by king Henry, who parcelled them off, either in gifts or in lease, to different individuals; but the monastery itself was converted into a royal palace, and continued to be occasionally occupied by our kings till its destruction during the grand rebellion, in the reigns of Charles I. and II.

The other monastic institutions in Reading, besides those already noticed, were two convents for Franciscan or Grey friars, St. Edmond's chapel, and Colney chantry. One of the convents was founded about the middle of the thirteenth century, soon after the first appearance of the Franciscan order in this country. Its original situation was on a marshy ground adjoining the Caverham road, and still called the Friary Meadow; but in 1284 the friars removed to their inefquential residence, at the western extremity of Friar-street. After the dissolution this house was appropriated as a work-house for the poor; and part of the church now forms the borough prison. This building is in the early pointed style, and has at its western end a very beautiful lancet window. The other convent stood in Castle-Airect, probably on the spot now occupied by the Methodist chapel. This institution seems to have been on a very small scale, though it is mentioned by Leland as "a fare house of Grey freres." St. Edmond's chapel stood on the rising ground, called Chapel Hill, near the borough prison. It was founded, in 1264, by Lawrence Burget, then bailiff of the town. In the civil war it was converted into a fort; and afterwards, about the year 1750, was demolished, and another chapel erected in its stead on Battle-Farm. Colney chantry was instituted by one of that family in the reign of Richard II., for the souls of king Edward III., of Thomas Colney, John Colney, and William Catour. It had distinct incumbents of its own, and was under the patronage of the corporation.

Reading has given birth to several persons of eminence. Sir Thomas White, founder of St. John's college, Oxford, is said to have been born here; but Fuller affirms that he was a native of Rickmanworth. Archibishop Laud was born in this town in 1573, having been the son of William Laud, then a clothier in Broad-Airect, who, as the archbishop himself told lord Say, had borne all offices in the corporation, save the mayoralty. John Blagrave, the mathematician, is also commonly reputed to have been a native of Reading; as was Joseph Blagrave, a celebrated astrological writer, who does not seem to have been related to the mathematician. The other distinguished natives of Reading were, Sir Thomas Hanmer, Sir John Barnard, a noted alderman of London; James Merrick, the translator of the Psalms; William Baker, a learned printer; Sir Constandine Phipps, lord chancellor of Ireland; and Dr. Phanuel Bacon, author of several dramas, &c.

The vicinity of Reading presents several objects worthy of notice. At a short distance to the southward, close to a place called Catgrove-lane, may be seen a remarkable stratum of oyster-shells, imbedded in a vein of sea-clay, at least twenty fathoms beneath the surface of a hill. This stratum is from one to two feet in thickness, and extends through a circumference of five or six acres of ground. Mixed with the shells is a considerable quantity of small teeth, apparently of fish. Caverham, formerly a seat of the Craven family, and afterwards of the Cadogans, is situated nearly opposite the town, on the north bank of the river Thames. The house was built by the earl of Cadogan, in the reign of George I., but has since undergone material alterations. In the old manor, Anne of Denmark, queen to James I., was splendidly entertained by lord Knowles, when on her journey to Bath, in 1613. At the time Charles I. was a prisoner at Windsor, the parliament, through the mediation of general Fairfax, permitted him to visit Caverham Lodge, where all his children who were in England then resided, in the custody of the earl of Northumberland. In the hamlet of Woodley is a very pleasing seat, belonging to lord Sidmouth; and two miles to the westward
wellward is another, the property of the Blgrave family.

The park is very extensive, and is noted for fine venison. South-ea., about the same distance, is White-Knites, the seat of the marquis of Blandford. Sunning, celebrated in history as having been for some time the seat of the see of Wilshire, and subsequently the site of one of the palaces of the bishops of Salisbury, is a village three miles to the eastward, on the road to Maidenhead. Leland mentions the bishop’s palace as standing in his time. It was given by bishop Gheaf, along with the manor, to queen Elizabeth, in exchange for all estates in Dorsetshire. The antiquity of this place is strongly marked by the fculptrul monuments in the church. Close to Sunning is an elegant mansion, the seat of Charles Fyl Palmer, esq. the Lyons's Magna Britannia, 4to. Berkshire, H. of England and Wales, vol. ii. by John-Britton and E. W. Brayley, 1801. The History and Antiquities of Reading, by John Mano, 4to. 1814.

From the latter work, the chief and most essential parts of this account have been obtained: and those who wish to poffess the most copious and authentic history of Reading will procure this volume.

Reading, a township of America, in Fairfield county, Connecticut, S. of Danbury adjoining. It contains 1717 inhabitants.—Also, a large township of Middlesex county, in the state of Massachusetts, incorporated in 1644, and containing 2278 inhabitants, many of whom are employed in the manufacture of shoes, from 2 to 300,000 pair being annually exported; 12 miles N. of Boston.—Also, a township of Vermont, in Windsor county, W. of Windsor, adjoining. It contains 1565 inhabitants.—Also, a beautiful poff-town, and the capital of Berkys county, Pennsylvania, situated on the N.E. tide of Schuykill river; 54 miles N.W. of Philadelphia. This town is regularly laid out, and flourishes: its inhabitants are chiefly German: the borough and township contain 3452. The public buildings are, a stone gaol, a court-houfe, an elegant church for German Lutherans, erected in 1793, a church for Calvinits, one for Roman Catholics, a meeting-houfe for Friends, and a large edifice for the public offices. In the neighbourhood are 10 fulling mills, and several iron-works: and at the distance of 10 miles, on the road to Harrisburgh, is a spring, about 15 feet deep and 30 feet wide, from which flows a copious stream, containing some fine trout. In 1795 the sum of 12,000 was voted by the county for building a stone arch bridge over the Schuykill, at this town, on the high road to Harrisburgh. N. lat. 40° 21'. W. long. 75° 55'.—Also, a township of Adams' county, in Pennsylvania, containing 752 inhabitants.

Reading. See Lectio.

Reading of a Deed. See Deed.

READINGS, in Criticism. Various readings, variæ lectiones, are the different manners of reading the text of authors in ancient manuscripts; where a diversity has arisen from the corruption of time, or the ignorance of copyists.

A great part of the business of the critics lies in settling the readings, by confronting the various readings of the several manuscripts, and considering the agreement of the words and sentences. The various readings in the bible, (see Hebrew Bibles,) and in the classic authors, are almost innumerable.

Readings are also used for a fort of commentary or gloss on a law, text, passage, or the like; to shew the sense an author takes it in, and the application he conceives to be made of it.

READINGTON, or RIDDENTON, in Geography, a town of New Jersey, in Hunterdon county; 17 miles N.W. by W. of New Brunswick. It contains 1797 inhabitants.

READ'S BAY, a road for ships on the W. coast of the island of Barbadoes, between Holetown and Speight's-town; half a mile broad. Ships may anchor here in safety, in fix to twelve fathoms water, the ground being soft oze, defended from all winds, except the west, which blows right into the bay. N. lat. 13° 7'. W. long. 59° 47'.

READSBOROUGH, or REEDSBOROUGH, a poff-town of America, in Bennington county and state of Vermont; 435 miles from Washington. It contains 410 inhabitants.

READ-AFFOREST, is where a forest, having been defulted, is again made a forest. As the foreif of Dean was, by an act of parliament in the 20th of king Charles II. See Forest.

READ-AGGRAVATION, in the Romish Ecclesiastical Law, the last monitory, published after three admonitions, and before the last excommunication.

Before they proceed to fulminate the laft excommunication, they publish an aggravation, and a re-aggravation. Frevet observes, that in France the minister is not allowed to come to re-aggravation, without the permission of the bishop or official, as well as that of the lay judge. See Excommunication.

READAH, in Geography, a town of Syria, in the pachalic of Aleppo, situated in a country that abounds with olives, of which considerable quantities are prepared, and sent to Perfa and other parts. This is the residence of an Aga; 36 miles S.S. W. of Aleppo.

REAL, RÃ£LE, is applied to a being that actually exists; in which sense it coincides with actual.

REAL, in Law, is opposed to personal.

REAL ACTION, that by which the plaintiff lays title to land, &c. See Action.

Customs are said to be real; that is, they determine all inheritances within their extent; and none may dispose of them, but according to the conditions allowed by the customs where they are situate.

REAL ALTITUDE, afefts, character, chattals, covenant, distinction, dieresis, elate, horizon, optical plane, patronage, privileges, qualities, root, services, suit, and seale. See the several substantives.

REAL, in Commerce, a Spanish money of account, of which there are four different forts. The real vellon is that which is most general; it consists of 5½ quarts, 17 ochovas, or 34 Maravedis vellon. Madrid, and the whole of Calife, with most of the adjacent provinces, and to Bilboa, Malaga, and Galicia, keep accounts in reals and Maravedis vellon. The real of new plate (real de plata nueva, or provincial) is double the real vellon; it is worth 17 quarts, or 34 ochovas; and it is also reckoned at 34 Maravedis of new plate. This real is represented by an effective coin of baffe silver, but books are not kept in any part of Spain in this money.

The real of old plate (real de plata antigua), mostly called the real of plate, is chiefly used in foreign commerce and exchanges; it is worth 10 quarts, or 32 ochovas; and it is also reckoned at 34 Maravedis of old plate. Cadiz and Seville keep accounts in reals and Maravedis of old plate.

The real of Mexican plate (real de plata Mexico) is used in transactions with Spanish America, where accounts are mostly kept in hard dollars, reals, and quarters, and sometimes in sixteenths; 8 Mexican reals make 1 hard dollar (peño duro); this coin is worth 10 reals of new plate, 10½ reals of old plate, or 20 reals vellon. Thus, 1 realse of new plate = 2 reals vellon; and 4 reals Mexican
can = 5 reals of new plate: 64 Mexican reals = 85 reals of old plate: 2 Mexican reals = 5 reals vellon: 16 reals of new plate = 17 reals of old plate: 17 reals of old plate = 32 vellon. The pilote of exchange (dobloun de plata) is worth 32 reals of old plate, or 60 reals 8 Maravedis vellon. The dollar of exchange (pecho de plata) is worth 8 reals of old plate, or 15 reals 2 Maravedis vellon. The duet of exchange (ducado de plata) is worth 11 reals 1 Maravedi of old plate, or 20 reals 2 1/2 Maravedis vellon. But, in commercial transactions within the country, the dobloun is reckoned only at 60, the pecho at 15, and the duet at 11 reals vellon.

The coins now current in Spain are as follow:

From 1730 to 1772, the gold was 22 carats, and the silver 11 dineros fine. In 1786 the standard of the gold was again reduced to 21 carats for the different doblouns and their divisions; and to 20½ carats for the coronilla or vein-

For the assay, weight, value, &c. of gold coins, see Pistoie.

Real, or Reali, is also a money of account at Leghorn. At Zante, and also Cefalonía and Corfu, accounts are kept in reali, of 10 lire, or 100 soldi, also called aspri.

Real is the name of a kind of boat in some places.

Real or Novita, in Geography. See Novita.

Real Nuevo, a town of Mexico, in the province of New Biscay; 120 miles N.W. of Parral. N. lat. 29° 10', W. long. 107° 20'.
Upon an examination, which had like to have cost M. Homberg dear, he found it to be a kind of realgar, or red arsenic, much more caustic than our's.

Its use among the Siamese, he takes to have been the same with that of regular of antimony; viz. to give an emetic quality to the wine drunk out of it.

As the dose of medicines is much stronger in the torrid zone than among us (the quantity of ipecacuana, e. gr. ordinarily taken by the Indians, being twenty times as great as that among us), it is very possible a cup of realgar, though not so potent an European, may prove a gentle medicine to a Siamese.

REALJO, in Geography, a small island in the Pacific ocean, near the coast of Popayan. N. lat. 4° 16'.

REALIZE, in Commerce, a term little known in trade before the year 1719, when those immense fortunes began to be made in France and England, by the buiness of actions or flocks.

By realizing is meant the precaution many of those who had gained most, took, to convert their paper into real effects; as lands, houses, rich moveables, jewels, plate; but, above all, into current species. A precaution capable of ruining the state; but the French regency had the wisdom to frustrate it, by taking proper measures to have the money, thus ready to be hoarded up, returned to the public.

REALISTS, REALISTAE, a sect of school-philosophers who followed the doctrine of Aristotle with respect to universal ideas, formed in opposition to the Nominalists, (see that article,) who embraced the hypothesis of Zeno and the Stoics upon that perplexed and intricate subjed.

Aristotle held, against Plato, that, previous to, and independent of, matter, there were no universal ideas or effences; and that the ideas or exemplars which the latter supposed to have existed in the divine Mind, and to have been the models of all created things, had been eternally impressed upon matter, and were coeval with, and inherent in, their objects. Zeno and his followers, departing both from the Platonic and Aristotelian systems, maintained, that these pretended universals had neither form nor effence, and were no more than mere terms and nominal representations of their particular objects.

Under the Realists are included the Scotists, Thomists, and all excepting the followers of Occam.

Their distinguishing tenet is, that universals are realities, and have an actual existence, out of an idea and an imagination; or, as they express it in the school-language, a parte rei; whereas the Nominalists contend, that they exist only in the mind, and are only ideas, or manners of conceiving things.

Doctor Odo, or Oudard, a native of Orleans, afterwards abbot of St. Martin de Tournay, was the chief of the sect of the Realists. He wrote three books of dialectics, where, on the principles of Boethius and the ancients, he maintained that the object of that art is things, not words; whence the sect took its rile and name.

REALITY, REALITAS, in the Schools, a diminutive of res, thing, first used by the Scotists to denote a thing which may exist of itself, or which has a full and absolute being of itself, and is not considered as a part of any other.

Yet a reality is conceived as something less than res; and accordingly every rei is supposed to contain a number of realities, which they otherwise call formalities.

Thus, e. gr. in a man, according to the doctrine of the Scotists, are a number of realities; viz. a substance, life, animal, and reason.
REA

Some distinguishing reality into subjective and objective.

REALM, REGNUM, Kingdom, a country which gives its head or governor the denomination of king.

The word is formed of the French royaume, which denotes the same.

REALMONT, in Geography, a town of France, in the department of the Tarn, and chief place of a canton, in the district of Albay; 9 miles S. of Albay. The place contains 2247, and the canton 8940 inhabitants, on a territory of 2275 square miles, in 19 parishes.

REALVILLE, a town of France, in the department of the Lot; 8 miles N. E. of Montauban. N. lat. 44° 6'.

E. long. 1° 34'.

REALMIA, a town of the Arabian Irak; 10 miles W. of Ballora.

REAMO, a town of Naples, in Abruzzo Ultra; 6 miles W. N. W. of Teramo.

REAMUR, a town of France, in the department of the Vendée; 18 miles N. of Fontenay le Comte.

REANG, a town of Bengal; 45 miles S. of Silhet.

REAPER, a person whole business it is to reap or cut grain.

REAPING, the operation of cutting crops by means of the fickle. It is a very laborious sort of field-work, and one which requires considerable attention and care to perform it in a neat and exact manner. Reaping is performed with some other sorts of crops, besides those of the grain kinds; as occasionally for peas, beans, flax, and others of a similar nature. Work of this nature is executed in many different ways, according to the differences in the customs of different districts; as by sets of men hired by the month, for this particular purpose, called reaper-men; by persons taking it by the piece, or by the acre, and by the sheaf or fshoek of eight sheaves.

In some methods, the piece or the quantity is unquestionably the best, in most cases, on account of the very high prices which are exacted at this very busy season, and the very small extent of labour which is performed in working by the day, which cannot be controlled by the farmer at such hurrying times. Besides, the work is, for the most part, the belt and most expensively performed in these ways; which are objects of very great importance, and deserving of much consideration in this sort of business. The eye of the farmer is, however, constantly necessary to see that all goes on in a right manner.

In the northern parts of Lancashire, this sort of labour is mostly performed by the day, or the hattack of ten sheaves, or the flshoek of twelve sheaves; three-pence being often paid for the former, and four-pence or five-pence for the latter, in these places.

In some districts, the reaping of the crops commences before they are quite ripe; but in others, not until this has fully taken place.

REAPING of Corn, the practice of cutting it with the fickle, or otherwise, by persons employed for the purpose. It may be observed, that the business of reaping or cutting grain crops differs much in the manner of performing the work, in different districts of the kingdom, and kinds of crops. In the more southern parts of the island, the crops of this sort are mostly cut by means of short flshy scythes, made for the purpose, having bows formed of bent sticks, or what in some places are termed caddles, fixed upon the lower parts of the handles, for the more readily depositing the ears or heads of the corn in one uniform direction, as much as possible, in order that it may be afterwards bound up into sheaves. But in other cases, the naked scythe is made use of; the corn being seldom bound up, being simply raked together into small heaps, in a similar manner to hay.

In the more northern parts of England, and in Scotland, the reaping of grain crops is, however, in general performed by the fickle, or reaping hook; the different handtools, as soon as cut, being deposited upon hands, formed by twirling together a few flshes of the corn at the ends next the ears, and afterwards bound up into sheaves, in order to their being let up into flocks or batches. This method is, in most instances, adopted with the wheat and rye crops, in every part of the island; as in cutting them with the scythe, it is difficult to be performed without much loss being fullfilled by the shedding of the grain. And, in addition, it is of great advantage to have these sorts of crops bound up regularly into sheaves, the straw being much better.

Besides these, there is another mode sometimes practised, which is by means of a hook with a sharp edge, without any teeth; the labourer, in executing the work, hooking up the corn towards his. It is mostly made use of in the southern districts, where it is known by the name of bagging, the grain in this way being cut very low.

In this way the reaper collects enough for one sheaf at a time, binds it, and puts it up in tons, called a flock in Middlesex. This bagging (or bagging) practice is to all intents and purposes, mowing with one hand against the standing corn. The toothless hook, employed in doing it, is of nearly twice the weight of the common scythe. It is sharpened occasionally, when necessary, in the manner of the scythe; and the operation of cutting the crop down is by a succession of blows made upon the flax of the standing grain, very nearly in the direction down towards the surface of the ground. Reaping in Middlesex is mostly all done in this way, as the proper use of the scythe is but little known.

This method has the advantage of being done closer, and with equal or more expedition than the hand-reaping mode, besides the saving in flax, which is here supposed worth 2s. the acre.

In Essex wheat crops are generally reaped or cut with the fickle, though in the vicinity of the metropolis it is not uncommon to have it mown with the scythe, as close to the ground as other sorts of grain crops, in the view of increasing the quantity of flax, which is there very valuable. It is thrown, in these cases, with great skill and dexterity into swathes. When perfectly ripe, it is soon bound up into sheaves of six or eight inches diameter, with bands of wheat-flax of single or double lengths; but when not in this ripe or dry flax, it is allowed to remain in the swaths two or three days, as necessary. However, in more than three quarters of the county, it is reaped or cut with the fickle; and indeed in almost all places, when beaten down by the wind and rain.

In regard to the time of reaping the grain, there is considerable difference in different districts; some not reaping it until it is quite ripe, while others cut it when something short of this late. This, however, should probably be regulated by the nature of the season, and the kind flax or quality of the crop, as well as the use to which the grain is to be put.

In respect to the manner of reaping grain crops, whether the fickle or scythe be employed for the purpose, there is much difference in the height at which the crops are cut in different places. In some it is the practice to have the business performed in as close a manner as possible; while in others a flub of eight, ten, and fifteen inches; or more,
is left. These different practices have their advocates; one party supposing that the work proceeds more slowly, where it is executed in so close a manner; while the other contend that the contrary is the case. But as the flubbe which is left is not only useless to the land, but in many cases very troublesome in its succeeding culture, being frequently under the necessity of being removed, it would seem to be the best as well as cheapest practice, to have the busi-
nesses constantly executed in a close manner. It has been ob-
 served by a late practical writer, that by this means the agricul-
tor will not only have more litter at command, for the
bedding of his yards, flalls, and other places, and conse-
sequently an increase of manure, but have the businees more
expeditiously performed, with much less waste of grain, and at the same time be freed from the trouble and expence of removing the flubbe. It has indeed been fully flown,
by a careful trial, made with the view of ascertaining the
difference between high and low reaping, that the advantage
is considerably in favour of the close method.

And the result of the trial is thus stated by the writer of
the Agricultural Survey of the West Riding of Yorkshire,
who observes that the experiment was made upon part of a
field of wheat, two ridges of which were cut close by the
ground, and the other two considerabily higher, though not
to high as the general run of the Yorkshire flubbes. Each
of the divisions was apparently of equal quality, and mea-
sured a trifle more than a quarter of a Scotch acre, which is
about one-fifth larger than the English statute acre. The
crop was flacked separately, and the time taken to cut
was one hour and twenty-four minutes, of eight
heares; while the high cutting was performed by the same
number of hands in forty-eight minutes. The wages paid
that week were 15d. per day, and the supposed expe-
cence of maintenance 6d. or 2s. per day altogether. When threified,
the grain and straw were carefully measured and weighed,
and the result of the experiment was as follows:

<table>
<thead>
<tr>
<th></th>
<th>£</th>
<th>s</th>

</tr>
</tbody>
</table>
| Difference of expe-
cnce |                                            |

In favour of high cutting one shilling, or four shillings

per acre.

£ 1 6
1½ peck of wheat more upon the low cut
ridges than those cut high, at 1s. 4d. per
peck

£ 0 1 8
14 flones (22 avoirdupois pounds) of more
straw, 3 d. per Rone

£ 0 1 0
Or sixteen shillings per Scotch acre.

From which deduced the increased expe-
cnce of cutting, there remains a benefit of twelve shillings per acre in favour
of low cutting.

It is noticed farther, that the above trial, according
to the belt of the reporter's judgment, was fairly made; and the
reason which urged him to make it, was to silence the
objections of some neighbours, who alleged low hearers
was not profitable. It is also proper to observe, that the
field of wheat, on which the trial was made, was not broke
down nor irraggled, so was in a favourable condition for
high cutting. We have seen wheat-fields, where three times
the quantity might have been left, unless great pains were
used.

But the methods of reaping grain crops, both with the
tickle and the scythe, have each their advantages and disad-
vantages. In the first manner, the crops are deposited with
more regularity and exactness, and consequently bound into
sheaves with greater facility and dispatch. Beside, in many
cases less loss is incurred by shedding, in the time the work is
in performing; but the labour is executed with greater diffi-
culty and trouble. The latter posseis the superiority of
being more expeditious, and of being performed to any de-
gree of closeinets that may be required; while it has the evi-
dent disadvantage of leaving the cut grain in a more irregular
and uneven situation, by which it is rendered less fit for
being bound up into sheaves, which in many cases is an in-
convenience of great consequence. When the grain has
attained a high degree of ripeness, there may likewise be great
loss sustained, by its being laid during the operation, in
this way of reaping and cutting the crop. Where this
method is practiced, it is, however, not unfrequently the case
to have it bound into sheaves; though the most common
custom is to let it remain in the rows or swathes, till fit for
being put into the flack. When bound, it is generally the
practice to cut it downwards against the crop on which it rests:
in the other case, it is cut in the manner of grafs for hay.
It is obvious, therefore, that when labourers are procured
with difficulty, this mode of reaping is the most advisable;
while, under the contrary circumstances, the former may be
had recourse to with more advantages, as the work may be ex-
ecuted in a nearer and more exact way. See Har-
vesting and Sickle.

It may be remarked, that this is a sort of work that is
often let by the acre to persons that go about for harvest
work; and it may, in many cases, be the belt performed in
this manner. But great attention should be paid by the
farmer, to see that the grain is cut and bound up in a pro-
per method, and that the work be not performed in improper
weather. The prices vary according to the nature of the
crops, the season, and other circumstances, sometimes rising
as high as eleven or twelve shillings the acre, and sometimes
much higher.

Reaping Fork, a tool of the fork kind, invented for the
purpose of raising and collecting the mown grain into
sheaves, so that it may be bound up. It is constructed
with two, rather long, prongs below, lightly curving up-
ward, somewhat in the manner of the common large hay
fork, to which are attached, at the upper part, near the in-
sertion into the handle, two other upright prongs, which
bend a little forward towards their tops or ends; by means of
which, with the under prongs running along the ground,
the tool being pushed forward by the labourer, the grain is
the flack is raised up, brought together, held in a firm
manner, and removed from the swathe so as to be bound
into sheaves. In this way, the lower prongs perform the
work of picking the flakewv material from the land, while
the higher upright ones prevent it from falling backwards,
and determine the quantity which is necessary for a sheaf.
In this manner, by this simple contrivance, the mown grain
can be brought together and bound up with much greater
regularity, and in a much more expeditious method than is
possible to be done by mere hand labour.

Reaping Hook, an implement of the tickle kind, with
which the busines of reaping is performed in some districts.
These hooks are sometimes formed with teeth, or in a
toothed manner, and sometimes with a cutting edge. In
Devonshire, and some other counties, those with smooth
edges are generally preferred to sickles with sawed ones:
thee sorts of hooks are used occasionally with either hand, the operator shifting hands, chopping the straw low down, and gathering about half a sheaf at a time, which, when put together, is bound with reed, combed from former wheat-straw, or with a double length of the wheat which is reaping. See Sickle.

Reaping Machine, a contrivance for the purpose of reaping grain by means of animal labour. With this view, and to facilitate an operation of such importance to the farmer, different attempts have been made to construct machines, so as to dispatch the work in a rapid manner by the assistance of horse labour, but the successes which with which they have been attended, has hitherto been far from complete. An implement of this sort has lately been made by Mr. Plunkett; it is upon a somewhat new principle, the horse drawing the machine instead of pulling it forward, as was the old mode of applying the power.

In this machine, the horse tracks from the front side of it, which is seen at once by the appearance of the implement, so as to be clear of the crop, and the two large wheels, by means of the axle, drive another wheel, which communicates with the two other wheels, the latter of which is found in the axis of the cutter: a man at the handles regulates the direction, &c. This machine may be seen fully represented in the second volume of the Farmer's Dictionary; and a reaping machine for clover may be seen in the same work in the same plate.

Other machines of this kind have still more lately been invented by other persons, but without answering the purpose in that full and complete manner which is necessary in this sort of work.

What appears to be chiefly wanting in these sorts of machines, to render them complete and effectual, as tools for the purpose of reaping, is that of their having more power or velocity in the cutting parts, so that the work may be performed in a perfectly clean neat manner, without the straw being drove or forced down in an improper manner before the instruments which are to cut it; their cutting it out fully in the whole of its breadth; their being capable of being regulated to cut at different heights, and to different breadths; their being made capable of directing the cut strawy grain all in one even regular direction, so that it may be bound up with facility; the horses, or other animals, being so attached to them as to permit of their walking along on the side of the standing grain, where the former cut was made, or where they pull the implements before them, the leaving them so conveniently fixed in them as to admit of no fear of interruption to the labour in any way; their being made light and of ready application, as well as at a cheap rate; and their keeping the feythes or cutting parts in a perfectly sharp state, without their being taken out, and undergoing the operation of whetting. There are, besides these, some other points, which should be attended to, but these are, probably, the most material.

REAPS, small parcels of corn, laid along on the flabb of, in reaping, to be afterwards gathered into sheaves by the binder. This is most commonly the cafe, when the weather is moist, as in dry times the reaps of corn are usually laid in the bands, and tied up, as soon as they are in sufficient quantity, into sheaves.

REAR, a term frequently used in composition, to denote something behind or backward in respect of another; in opposition to van, or avant, before.

It is formed by corruption of the French arriere, signifying the same.

REAR, in a Military Sense, is used for the hind-part of an army, &c. in opposition to the front, or face of it.

REAR, in Naval Language, is a name given to the last division of a squadron, or the last squadron of a fleet, and which is accordingly commanded by a rear-admiral, or the third officer of the said fleet or squadron.

REAR-admiral. See Admiral.

REAR-guard. See Guard.

REAR-half-sheets, are the three hindmost ranks of a battalion, when it is drawn up in deep. See File-leaders.

REAR-line of an army encamped, is always twelve hundred feet at least from the centre line, both of which run parallel to the front line, and also to the referve.

REAR-rank, is the last rank of a battalion, or squadron, when drawn up, and generally sixteen or eighteen feet from the centre line, when drawn up in open order.

REAR-va, in the Manege, chelled in French, is the action of a horse, when he raises himself upon his houghs or binder legs, as if he would fall quite over in a backward direction, to the great danger of his rider. This is often caused by his having too much of the curb.

REAR, in Rural Economy, to raise the roof part of any sort of shed or other building for containing some kind of live-stock.

REARED, or Well-REARED. See Wale-reared.

REARING ANIMALS, in Agriculture and Rural Economy, the busines of breeding and bringing them up to the most suitable states for the purposes of the farmer. The principles of this art depend upon a variety of different circumstancies and kinds of knowledge, as has been already explained. See Breeding, and Live-Stock.

Animals of the horse kind should invariably be brought up in the best manner, without any sort of flitting in their food, according to the ufed they are designed to serve, in order that they may have their full growth and power. In the labouring cattle kinds of animals, attention should, in some degree, be paid to hardines, both in their food and their exposure, by having recourse to the more coarsé forts of feeding in the less sheltered situations, but nothing of flitting should ever be allowed, as by these means they become large, and capable of sustaining a greater degree of exertion. There is, likewise, much utility in good training, in rearing all forts of animals in this intention; and it requires careful, ready, mild persons to be employed in it, as they, for the most part, acquire the habits and dispositions of those about them, in some measure; and the more early they are obtained the better. This point deserves much more attention from farmers and others than it has hitherto met with, as one of the chief habits of working animals arise from the neglect of it. Besides, good training and mild dispositions are highly favourable to fattening animals. See Horse.

In rearing poultry, pigeons, rabbits, and fish, much care, management, and circumspection, are constantly necessary, in order to their perfect success. Too little attention is for the most part bestowed on the nature of the birds, in some forts of the more wild poultry kinds, as those which are of the game description, for instance, the galena, the pheasant, the swan, and some others. These cannot be so readily reared, or with so much facility, under hands of the domestic kind, as other sorts are, such as the turkey, peacock, &c. This circumstance should therefore be always kept in mind in rearing such birds. See Poultry, Pigeons, Rabbit, &c.

A very nice attention and management is also requisite in the rearing and perfecting of fish. See Fish, Pond-Fisheries, and Salmon Fishery.

In rearing birds of the game kind, such as the above, in the way of ornament about a residence, Mr. Loudon has remarked, much depends upon encouraging them, when al-
lowed to go wild, by giving them proper and abundant cover, and flowing among fig herbs and plants as they are particularly fond of, as those of the cress, chervil, parsley, thyme, and some other kinds. They have likewise a tendency to encourage and domesticate hares. Abundance of fear lends game about a residence, he thinks, give peculiare nobleness, and appearance of freedom, which few things else can communicate or afford.

REASON, Ratio, a faculty or power of the soul, by which it distinguishes good from evil, and truth from fallacy. Or, reason is that principle, by which, comparing several ideas together, we draw consequences from the relations they are found to have.

Some of the later school-philosophers define reason to be the comprehension of many principles which the mind successively can conceive and from which conclusions may be drawn.

Others conceive reason as no other than the understanding itself, considered as it discourses.

Reason, Mr. Locke observes, comprehends two distinct faculties of the mind; viz. sagacity, by which it finds intermediate ideas; and illusion, by which it so orders and disposes of them, as to discover what connection there is in each link of the chain, by which the extremes are held together; and by them, as it were, draws into view the truth sought for.

Illusion, or inference, consists in nothing but the perception of the connection there is between the ideas in each step of the deduction, by which the mind comes to see either the certain agreement or disagreement of any two ideas; as in demonstration, in which it arrives at knowledge; or their probable connection, on which it gives or withholds its assent; as in opinion.

Sense and intuition reach but a little way; the greatest part of our knowledge depends upon deductions, and intermediate ideas. In those cases, where we must take propositions for true, without being certain of their being so, we have need to find out, examine, and compare, the grounds of their probability; in both cases, the faculty which finds out the means, and rightly applies them to discover certainty in the one, and probability in the other, is that which we call reason.

In reason, therefore, we may consider four degrees; first, the discovering and finding out of proofs. See Invention.

Secondly, the regular and methodical disposition of them, and laying them in such order, as that their connection may be plainly perceived. See Method.

Thirdly, the perceiving of their connection (see Judgment.) And,

Fourthly, the making a right conclusion.

Reason fails us in several instances; as, first, where our ideas fail.

Secondly, it is often at a loss, because of the obscurity, confusion, or imperfectness, of the ideas it is employed about. Thus, having no perfect idea of the least extension of matter, nor of infinity, we are at a loss about the divisibility of matter.

Thirdly, our reason is often at a stand, because it perceives not those ideas which would serve to shew the certain or probable agreement or disagreement of any two other ideas.

Fourthly, our reason is often engaged in absurdities and difficulties, by proceeding upon false principles, which, being followed, lead men into contradictions to themselves, and inconsistency in their own thoughts.

Fifthly, dubious words, and uncertain signs, often puzzle men's reason, and bring them to a nonplus.

Though the deducting one proposition from another be a great part of the office of reason, and that about which it is usually employed; yet the principal act of reasoning is the finding the agreement or disagreement of the ideas one with another, by the intervention of a third. As a man, by a yard, finds two houses to be of the same length, which could not be brought together to measure their equality by juxta-position. Words have their consequences as the signs of such ideas and things agree or disagree with what they really are; but we observe it only by our ideas.

Hence we may be able to form an idea of that ordinary diffinition of things, into such as are according to, those that are above, and those contrary to reason.

Those according to reason are such propositions, whose truth we can discover by examining and tracing those ideas we have from sensation and reflection, and by natural deduction find to be true or probable.

Those above reason are such propositions, whose truth or probability we cannot by reason derive from those principles.

Those contrary to reason are such propositions as are inconsistent with, or irreconcilable to, our clear and distinct ideas.

Thus the existence of God, is according to reason; the existence of more than one God, is contrary to reason; and the resurrection of the body after death, above reason.

Above reason may be also taken in a double sense; viz. above probability or above certainty.

They who dispute most about the power and privileges of human reason, do it because their own reason persuades them to that belief; and so, whether the victory be on their or our side, they are equally defeated.

They seek to terrify us with the example of many great wits, who, by following this ignis fatua (so they call the only pole-star God has given us to direct our course by), have fallen into wild and ridiculous opinions, and increased the catalogue of heresies to a great number; but these men either followed not their reason, but made it follow their will; or else they first hoodwinked it by interest and prejudice, and then bade it shew them the way; or were wanting in those necessary diligences required for so doubtful a passage; or if, without any of these, the weakens of their understanding had deceived them, the error is neither hurtful to themselves, nor would be to others, if this doctrine of governing ourselves by our own reason, and not by authority and example, were generally establised. Dis. Concern. Hum. Real.

It is not the use of such liberty, but the appropriating it to ourselves, that is the cause of all the disorders charged upon it; for those who lay a restraint on other men's reason, have first made use of their own to settle them, and to make use of it in this very restraining of others. Ibid.

Reason, in Matters of Religion, is used in opposition to faith.

This use of the word, Mr. Locke takes to be in itself very improper; for faith is nothing but a firm assent of the mind; which, if it be regulated, as it is our duty, cannot be afforded to any thing but upon good reason, and so cannot be opposite to it.

He that believes without having any reason for believing, may be in love with his own fancies; but he neither sees truth as he ought, nor pays the proper obedience due to his Maker, who would have him use those differing faculties he has given him, to keep him out of mistake and error.
But since reason and faith are by some men opposed to one another, it may be necessary to consider them together.

Reason, as contradistinguished to faith, is the discovery of the certainty or probability of such propositions, or truths, which has not by the use of its natural faculties; viz. by sensation, or reflection.

Faith, on the other hand, is the assent to any proposition upon the credit of the proponer, as coming immediately from God; which we call revelation, which fee.

Reason, in Logic and Rhetoric, denotes a necessary or probable argument; or an answer to the question, *why is it?*

As if it be inquired, why do the subject and predicate agree? and it is answered, because they are spoken of the same thing: this latter enunciation is a reason. Hence, say the schoolmen, because *qua* is the sign or character of a reason, as *non*, *no*, of a negation, and *est*, *is*, of an affirmation.

They make three kinds of reasons, *rationes; viz. ratio ut, that is, left; and quia, because.* For, answering to a question, *cur aed *, we begin with because, *qua* is: why do you fludy? that I may become learned; which is the *ratio ut.* Again, why do you fludy? left I shoul be ignorant; which is the *ratio ne.* Lastly, why is a body tangible? because matter is impenetrable; which is the *ratio quia*.

The *reason ut* properly denotes the end, or final cause; and the *reason ne* the beginning; accordingly the one is called the beginning, the other end: so that the *reason quia* is left the only reason, properly so called.

Reason, among *Metaphysicians*, is used in the same sense with offence; or that by which any thing is it.

This is sometimes also called formal reason, as representing the thing under that form or nature under which it is conceived.

Reason of State, *Ratio Status*, in Matters of Policy, denotes a rule or maxim, whether it be good or evil, which may be of service to the state.

The phrase is borrowed from the Italians, who first used *ragione di stato* in this sense.

Reason of state is properly understood of something that is necessary and expedient for the interest of the government, but contrary to moral honesty, or justice.

Politicians have a long time disputed about the *ratio statut*; whether states and governments are tied down to the same laws of morality with individual persons; or whether things, otherwise immoral and unlawful, may be practiced on urgent occasions, by way of reason of state?

The question is, whether any thing be unlawful, or prohibited a state, that is necessary to the preservation of that state, or whether it be allowed to preserve itself on any terms?

Reason, Challenge upon. See CHALLENGE.

Reason sufficient of Leibnitz. See LEIBNITZIAN Philosophy.

Reasonable Aid, a duty which the lord of the manor, or of his tenants, holding in knight's service, or on socage, towards the marrying his daughter, or the making his eldest son knight.

This is taken away by *flat. 2 Car. II.* See Aid.

Reasoning, Ratiocination, the exercise of that faculty of the mind called reason: or, it is reason deduced into discourse; which fee.

The agreement or disagreement of two ideas does not appear from the bare consideration of the ideas themselves, unless some third be called in, and compared, either sepa-rately, or conjointly with it; the act, then, by which, from ideas thus disposed and compared, we judge this or that to be so, or not so, is called reasoning. Or, it is that operation of the mind, by which we infer one thing, i. e. one proposition from two or more propositions premised. Or, again, it is the drawing of a conclusion, which before was either unknown, or dark, or doubtful, from some propositions which are more known and evident. It is the narrowness of the human mind which introduces the necessity of reasoning; for if the mere perception and comparison of two ideas would always teach us whether they agree or diverge, then all rational propositions would be matters of intelligence, or first principles, and there would be no use of reasoning, or drawing any conclusions. But when we are unable to judge of the truth or falsehood of a proposition in an immediate manner, by the mere contemplation of its subject and predicate, we are then constrained to use a medium, and to compare each of them with some third idea, that by seeing how far they agree or disagree with it, we may be able to judge how far they agree or disagree among themselves. Watt's Logic, part iii. chap. 1.

Rohault defines reasoning to be a judgment depending on some antecedent judgment: thus, having judged that no even number can be composed of five uneven numbers, and that ten is an even number; to conclude, that ten cannot be divided into five uneven parts, is a ratiocination, or reasoning.

This agrees with father Malebranche's doctrine, one of the great points of which is, that reasoning, on the part of the underlinding, is only a mere perceiving.

That ingenious author endeavours to shew, that, as to the understanding, there is no difference between a simple perception, a judgment, and a reasoning, except in this, that the understanding perceives a simple thing without any relation to any thing else, by a simple perception; that it perceives the relations between two or more things in a judgment; and, lastly, that it perceives the relations that are between the relations of things, in a reasoning. So that all the operations of the understanding are no more than mere perceptions.

Thus, *a. gr.* when we conclude, that 4 being less than 6, twice 2 being equal to 4, are of consequence less than 6, we do no more than perceive the relation of the inequality between the relation of twice 2 and 4, and the relation of 4 and 6.

The manner of proceeding judiciously in reasoning; so as to arrive with the greater safety at the knowledge of truth, makes what we call method.

For the real benefit of logic to reasoning, see Logic and SYLLOGISM.

RE-ATTACHMENT, in Law, a second attachment of him who was formerly attached, and dismissed the court without day, by not coming of the justices, or the like casually.

Brook makes re-attachment either *general* or *special*. General is where a man is re-attached for his appearance on all writs of affize lying against him: *special*, for one or more certain writs.

REAU, in Geography, a town of Germany, in the principality of Culmbach; 9 miles s.e. of Hof.

REAVE, in Rural Economy, a provincial term, used to signify the unroofing or disturbing the thatch or other covering of a building by winds, &c.

REAUOR, RENÉ-ANTOINE FERCHAULT, SIEUR DE, in Biography, was born in 1683 at Rochelle. He was brought up to the study of the law, which he quitted for that
that of the mathematicians, natural history, and natural philosophy. In 1703 he went to Paris, and so distinguished himself in a few years, that in 1708 he was admitted into the Academy of Sciences. From that time he entirely gave himself up to the pursuits of natural history in all its branches, and few men have paved a life more actively and usefully employed. Utility was the dominant aim in all his enquiries, even into the most minute parts of nature; and experiment and observation were his perpetual guides. No one surpassed him in the patient industry with which he observed natural phenomena, or followed the progress of art.

The memoirs of the Academy of Sciences, from 1709 to 1756, are enriched with his communications. The improvement of manufactures was also an object of his attention. In 1722 he published a work, entitled "L'Art de convertir le Fer forgé en Acier, et l'Art d'adoucir le Fer fondu," which contained a minute and scientific account of the processes employed in that branch of manufacture, with hints for their improvement. He introduced into France the manufacture of iron, which article had before been imported from abroad; and he made a great many experiments in the manufacture of porcelain, which contributed to its perfection in France. He also performed numerous experiments relative to the art of hatchling chickens by artificial heat, as practiced in Egypt, an account of which he published in two vols. 1752. M. Réaumur rendered his name celebrated by his peculiar method of graduation on the thermometer, which is still the only one used in France and many parts of the continent. In this thermometer the freezing point is marked zero, and the boiling point at 80°.

(See Thermometer.) Some of the most valuable of Réaumur's physiological experiments were those relating to the concave powers of the stomach in granivorous and carnivorous birds, in which he clearly established the different modes of action in these two classes, viz. by trituration, and by solution. In natural history, he acquired the greatest fame as an entomologist. Besides a number of curious papers on this subject in the memoirs of the Academy, he published a very elaborate work, entitled "Mémoires pour servir à Histoire Naturelle des Insectes," in six vols. 4to. 1734-1742. This work was the labour of many years, and the result of innumerable observations made in his garden, in which he kept insects of all kinds, that he might examine their generation, changes, and mode of life. Réaumur was a man of much private worth, of mild and amiable manners, and correct morals. He died in 1757, at the age of 75. He bequeathed his manuscripts, and cabinet of natural philosophy, to the Academy of Sciences.

REAUAMUR, in Botany, so called in honour of the great French naturalist, René Antoine Ferchault de Réaumur, principally known, as a botanist, by his examination of the fructification of Fuci, but chiefly celebrated as a philosophical inquirer into the history of insects, and their transformations, to which the specific name of the original species, vermiculata, evidently alludes. Linnaeus mentions Haflequint as the author of the name Reaumur; of which we can find no traces in his book, though the specimen of the plant in the Linnaean herbarium, has some appearance of having been gathered by this distinguished Oriental traveller. Is it possible, that the Anonima dubia, n. 15, of his Iter Palatinum, 405, which his editor Linnaeus could not make out, can be the Réaumur? The description is not inapplicable, except what concerns the flaminus and style. Yet this does not make him the author of the name, though it may possibly account for Linnaeus's mention of him in conjunction therewith. The latter appears, by his manuscripts, to have once defined Vermiculata for the generic appellation.—Linn. Gen. 276. Schrebb. 371. Willd. Sp. Pl. v. 2. 1249. Mart. Mill. Dict. v. 4. Witt. Hort. Kew. v. 3. 537. Jaff. 316. Lamarck Illus. t. 489. Dict. v. 6. 84. —Clais and order, Polyandra Pentagyna. Nat. Ord. succenture. Linn. Ficoides, Jaff.

Gen. Ch. Cal. Perianth inferior, of five prominent, ovate, pointed, permanent leaves. Cor. Petals five, oblong, equal, fertile, rather longer than the calyx, oblique, or lobed, at the extremity. Nectary of five double, fringed scales, at the meeting of the petals, attached to their lower part. Stam. Filaments numerous, capillary, the length of the calyx, inserted into the receptacle; Desfont.; anthers roundish, incumbent. Petl. German superior, roundish; styles five, thread-haired, erect, approaching each other, on a level with the flaminus, stigmata simple. Peric. Capsule ovate, of five cells, with five flat, at length reflexed, valves; the partitions membranous, unconnected, deciduous. Seeds several, erect, oblong, entirely clothed with numerous, filiky, simple hairs, twice their own length.

Eff. Ch. Calyx of five leaves. Petals five, with ten fringed scales at their base. Capsule of five cells, with five valves, and five deciduous partitions. Seeds several, oblong, hairy.

Obl. Specimens in seed, from professor Desfontaines, have enabled us to reconcile his account, and that of Linnaeus, with the observation of Forksall, that "the capsule has only one cell," the partitions being deciduous, and concealed among the hairy seeds. Not having examined the nectariferous scales, we have, in deviding to Labillardiére's and Hooker's plates of the second species, made the description so general as to accord with both.

1. R. vermiculata. Saltwort-leaved Reaumuria. Linn. Sp. Pl. 754. Willd. n. 1. Forsk. Egypt. Arab. 101. Desfont. Atlant. v. 1. 431. Lamarck Illus. t. 489. f. 1. (Sedum fiscum maritimum vermiculatum, flore Saxifragae albo, femine villoso; Bocc. Sic. 6. t. 4. f. C. G. S. minimum arborecens vermiculatum; Lob. 1c. 386. Kali vermiculatum albo et amplo sedis rofis flore; Barcel. 1c. t. 888. Vermiculata frutex minor; Ger. Em. 523; at least the figure, which is that of Lobel. The description accords rather with Salsola fruticosa, as cited by Hudson.)—Leaves linear-awl-shaped, convex beneath. Calyx entire.—Native of barren sandy ground towards the sea, in Sicily, Barbary, Egypt, and Syria, flowering in summer. The habit of the plant is like a Tamarius, or Salsola. Stem shrubby, bushy, much branched, round, smooth, whitish, leafy. Leaves numerous, scattered, soft, from a quarter to three quarters of an inch long, spreading, linear-awl-shaped, acute, feathery, smooth, glaucous; convex beneath; flat above; dotted on both sides with minute depressions. Desfontaines compares the leaves to those of Sedum reflexum. Flowers terminal, solitary, white, not unlike those of Saxifraga Cotyledon, each encompassed with a number of imitated floral leaves, like those of the same order or branch, but longer. Calyx leaves ovate, with a narrow, entire, membranous edge; and awl-shaped leaf-like point. Petals terminating in three or four lobes, well represented by Barcelier. Gatufae brown, very smooth, and somewhat shining; its valves rigid, reflexed after the seeds are discharged, and permanent. Seeds clothed with long, tawny, shining hairs. Forksall says this plant is used at Alexandria as a cure for the itch, being applied bruised externally, and taken internally in the form of a decoction. It is an elegant little shrub, well worthy of a place in our gardens, or green-houses, to which it is as yet a stranger.

2. R. hypericoides. Elliptic-leaved Reaumuria. Wild. a. 2. Ait. n. 1. Lamarck f. 2. (R. linifolia; Salix Parad.}
Parad. t. 18. Hypericum alternifolium; Labillard. Syr. facs. 2. 17. t. 10. —Leaves elliptic-lanceolate, flat. Calyx minutely crenate.—Gathered in barren dry ground, near the defert of Syria, by M. Labillardiere, to whom we are obliged for a wild specimen. The plant is said to have been introduced into England, by the late Mr. John Bell, about 1800, and is marked by Mr. Aiton as a hardy perennial. Its true genus is well ascertained by Lamark, Poiret, and Salisbury. The stem is herbaceous, about a foot high, simple, or branched, smooth, pale or reddish. Leaves alternate, glaucous, from half an inch to an inch in length, elliptic-oblong, or somewhat lanceolate, varying greatly in breadth, dotted all over. Flowers terminal, solitary, pale rose-coloured, with ebiqule petals. Calyx-leaves broader than in the former, their membranous edges finely crenate, their points very small. We know nothing of the capsula or seeds.

REAY, in Geography, a town of Scotland, in the county of Caithness; 6 miles W. of Thurso.

REBACH, a river of France, which runs into the Rhine, nearly opposite to Manheim.

REBAIS, a town of France, in the department of the Seine and Marne, and chief place of a canton, in the district of Coulommiers; six miles N.E. of it. The place contains 1376, and the canton 11,284 inhabitants, on a territory of 196 kilometres, in 18 communes.

RE-BAPTISANTS, a religious sect, who maintain, that persons irregularly baptiz'd are to be baptiz'd afresh.

The Anabaptists are re-baptiz'd, inasmuch as they baptiz'd those at maturity, who had been before baptiz'd in childhood.

St. Cyprian and pope Stephen had mighty differences about the re-baptiz'd of converted heretics.

Donatus was condemned at Rome in a council, for having re-baptiz'd some persons, who had fallen into idolatry after their first baptism.

REBAT, in Geography. See Rabat.

REBATE, in Architecture. See Joinery and Plane.

Rebate, or Rabat, Rebatement, in Commerce, a term much used at Amsterdam for a discount or abatement in the price of certain commodities, when the buyer advances the sum in hand, for which he might have taken time. See Discount.

Rebate (among us usually called prompt payment) is estimated by months, and is only allowed for certain kinds of merchandize, which, according to the custom of Amsterdam, are

15 months, or 10 per cent. on German, Prussian, and Polish wools.

18 months, or 12 per cent. on brown Muscovado sugar, pot-athes, soda, Italian Armoines, fatin, damalk, and flax fluffs.

21 months, or 14 per cent. on Spanish wool and lamb's wool.

23 months, or 22 per cent. on Italian silk and raw silk from the Levant, which silks are sold by the Antwerp weight, about 5 per 100 lighter than that of Amsterdam.

Dutch cloths, camlets, &c. are sold with 4 per cent. rabat, for ready money, or without any rabat at 9 months' credit.

Dutch flax fluffs are sold with 2 per cent. rabat at 6 months' credit: with 4 per cent. at 3 months; or with 6 per cent. for ready money.

In all sales of goods, except those last mentioned, a further abatement is made of 1 or 2 per cent. for prompt payment.

At Hamburgh, some sorts of merchandize, when sold in large quantities, have an allowance made of 7, 13, or 19 months rabat, reckoned at 8 per cent. per annum; which the buyer, when he pays ready money, or pays within four weeks of the day of sale, deducts from the nominal price.

Refined sugars, Englifh and Dutch cloths, Englifh baize, hallabons, flammes, kerfeymeres, ratteens, and ferges, are sold with 7 months' rabat, or 41 per cent.; that is, 41 are deducted from 1045, or 7 from 157.

Cotton, cinnamon, cochineal, indigo, ginger, nutmegs, cloves, mace, rice, raw sugars, capers, currants, cumine, gall-nuts, Ruffian leather, linen, crape, Italian silks, table-linen, Silefia cloth, Marfellis foap, almonds, furnac, mollofies, Turkish yarn, Italian tartar, are sold with 13 months' rabat, or 8 per cent. per annum; or 8 are deducted from 1032.

Silks from the Levant, as Ardaffette, Barutine, and Cerbbalf, are sold with 16 months' rabat, or 102 per cent.; that is, 8 is deducted from 87.

Kelly's Un. Camb. vol. i.

This interell called rebates, or rabat, is usually regulated on the footing of 8 per cent. per annum.

The reason of this expedient is, that the merchants having not always wherewithal to pay for their goods in hand, by means of the rebate, such as have, will find their acon in it; and such as have not will be engaged to discharge themselves as soon as possible, for the sake of the discount.

Rebatement, in Heraldry, a diminution or abatement of the dignity of the figures or bearing in a coat of arms. See Abatement.

REBECC, in Commerce, a measure of corn in Egypt, particularly at Alexandria, equal to about 4¼ bushels; as kiflos, another measure, is equal to 4 bushels, English measure: 17.94 rebbes are equal to 10 English quarters, and each of them contains 9587 cubic inches; and 16.51 kiflos are equal to 10 English quarters, and each contains 10418 cubic inches.

Rebec, a musical instrument resembling a fiddle, with a neck, finger-board, three lines tuned 5ths, and played with a bow.

Etymologists have tortured themselves to find a derivation for the name of a vulgar instrument, no longer in use. Some trace it from the Arabic, some from the Celtic, the Welsh, the Spanish, Italian, and old French. Indeed, so numerous, discorant, and unsatisfactory are their opinions, as neither to be worth writing, nor perusal, if we could give them a place.

Rebec and ribble feem to be the fame instrument, and are often indiscriminately used by Gower, Chaucer, and the still more ancient bards of Normandy, and our own country.

As the head, or scroll-work, of old viol and violins used to be curiously carved, so seems to have been that of the rebec. Chaucer compares the face of an old woman, an old trott, to the head of a rebec. Rabelais does the fame.

"A tel mineftrier tel rebec
Tenant toujours le verre au bec
Car elle avoit vilage de rebec."

REBECCHI, in Geography, a town of Italy, in the department of the Padua; 29 miles S.W. of Modena.

REBEL, Jean-Ferrv, ten. in Biography, one of the 24 violins of the king of France's band, and chamber compos-er to his majesty. He beat time for many years at the opera, and, in his day, praised for a great composer. His music for dances is still heard with pleasure. His capriccios, freaks, and dancing characters, have enjoyed great reputation. In 1703 he fet the opera of Ulysses, written by Guichard.
Rebel left two children: Francis, who died in 1775, and Anne, the wife of the celebrated Lalande, master of the king's band.

Rebel, François, knight of St. Michael, master, like his father, of the king's band, and director of the opera, born 1702, and died in 1775. He was the son of Jean-Ferry Rebel, director of the orchestra at the opera, and one of the twenty-four violins of the king's band. His son had obtained the revervation, in 1717, of chamber musician to the king, and in 1703, that of composer; having given proofs of his abilities by many different works, but, above all, by his "Pyramus and Thisbe," composed in partnership with Franoeur.

He was successively appointed to all the musical posts of honour and profit under the royal patronage and that of the public. The close and uninterrupted friendship between this musician and Franoeur, does honour to the memory of both; having composed jointly, for 50 years, successful pieces, without discovering to which of them the greater honour was due. Labordé. See Franoeur.

REBELLION originally signified a second resistance or rising of such as had been formerly overcome in battle by the Romans, and had yielded themselves to their subjection.

It is now generally used for a traitorous taking up of arms against the king, either by his own natural subjects, or by thefe formerly subdued; whether their view be to deprive him of the supreme authority, or whether they intend to retrench his commands in some particular affairs, in order to impose conditions on him. Popular commotion is a concourse of people, tumultuously assembled, and refting the voice of their superiors, whether their designs be against those superiors themselves, or only some private persons. Such violent commotions are common when the people think themselves aggrieved, and are occasioned by no order of men fo frequently as the tax-gatherers. (See the next article.) If the rage of the malcontents be particularly levelled at the magistrates, or others vested with the public authority, and they proceed to a formal disobedience or violent proceedings, it is called a "sedition." When the evil spreads, infecting great numbers in the city or provinces, and furnish in such a manner, that the sovereign is no longer obeyed, such a disorder custom has more especially distinguished by the name of "insurrection." All these disorders disturb the public order, and are crimes of state, even when arising from just caufes of complaint. For violent measures are interdicted in civil society; the injured party should have recourse to the magistrates, to whom they may apply for redress; and if justice be not obtained from them, their complaints may then be laid at the foot of the throne. Every citizen should even patiently suffer supportable evils, rather than disturb the public peace. Nothing less than a denial of justice from the sovereign, or affected delays, can excite the furious commotions of a provoked people; they in some measure justify themselves, if the evils be intolerable, and the oppressors great and manifest. But, it may be asked, what conduct shall the sovereign observe towards the insurgents? The reply in general is, that which shall at the same time be most consonant to justice, and most salutary to the state. If he is to reproach those who unnecessarily disturb the public peace; he is, by the same reason, to shew clemency towards unfortunate persons, to whom just cause of complaint has been given, and who are guilty only in having undertaken to do themselves justice; so that they have been wanting in patience rather than fidelity. The sovereign should consider that his rights are derived from those of civil society, from the truth reposed in him, from the obligation devolved upon him of watching over the welfare of the nation, of procuring its greatest happiness, and of maintaining in it order, justice, and peace. He will also duly distinguish the nature and degree of the different disorders which may disturb the state, oblige him to take arms, or substitute the means of force instead of those of authority. By confidcrations of this kind he will regulate his behaviour towards revolted subjects. It cannot be questioned, that subjects rising against their prince without cause deserve severer punishments; yet in this case the number of delinquents calls for the sovereign's clemency; shall he deplete a city, or defolate a province, in punishing their rebellion? Such a chaitlen, however just in itself, becomes a cruelty when extended to so great a number of persons. Had the insurrection of the Netherlands against Spain been totally unwarantable, every man of virtue would still execrate the memory of the duke of Alva, who made it his boast that he had cauused above 20,000 heads to be struck off by the hands of the common executioner. Let not his flagitious imitators (says the excellent Vattel) expect to justify their enormities by necessitj. Who was ever more unaccountably insulted by his subjects than Henry the Great of France? His conquests were ever accompanied by an uniform clemency, and at length that excellent prince obtained the succor he desired; he thereby gained over loyal subjects; whereas the duke of Alva lost his master the United Provinces. Tyrants alone will treat, as feditious, those brave and resolute citizens, who exhort the people to preserve themselves from oppression in the vindication of their rights and privileges; a good prince will commend such virtuous patriots, provided their zeal be tempered with moderation and prudence. If he has justice and his duty at heart; if he aspires to that immortal and unfailing glory of being the father of his people; let him influence the faltifh suggestions of a minister, who represents to him as rebels all those citizens who do not hold out their hands to chains, who refuse tamely to suffer the strokes of arbitrary power.

The safest, and the most just way thoroughly to appease sedition, is to give the people satisfaction; and if the insurrection has been without cause, which perhaps has never been the case, fill an amnesty is to be granted where the offenders are numerous. When this amnesty is once published and accepted, whatever has past must be buried in oblivion. A prince who makes any confidence of his word, is faithfully to keep what he has promised to rebels themselves; i.e. to those subjects who have revolted without reason or necessity. If his promises are not inviolable, what security have the rebels in treating with him? When they have once drawn the sword, they have nothing to do but, as one of the ancients expresses it, to throw away the scabbard. The prince will then want the mild and salutary means of appeasing a revolt; to exterminate the rebels will be the only expedient remaining. These will become formidable through despair; compassion will bellow succours on them; their party will increasell, and the state will be in danger. Vattel's Law of Nations, b. iii. See Civil War.

Rebel is sometimes also used, in our ancient statutes, for a person who willfully breaks a law; and sometimes for a villain disobeying his lord.

REBELLION, Commission of. See Commission.

REBELLIOUS Assembly, a gathering of twelve persons, or more, intending, going about, or practising, unlawfully, and of their own authority, to change any laws of the realm, or to destroy the indolence of any park or ground inclosed, banks of fish-ponds, pools, conduits, &c. to the intent the same shall remain void, or that they shall have way in any of the said grounds; or to destroy the deer in any park, fish in ponds, conyes in any warren, dovecotes,
Rebut is also used by the chemical writers, sometimes to signify four milks, and sometimes for what they call the ultimate matter of which all bodies are composed.

REBUTTER, from re, and the French bouter, to repel, or bar, in Law, the answer of the defendant in a cause to the plaintiff's sur-rejoinder.

The plaintiff's answer to the defendant's rebuttal, is called a sur-rebuttal.

REBUTTER is also when a man warrants any land or hereditament to another, and the perfon making the warranty, or his heir, sues him to whom the warranty is made, or his heir or assignee, for the same thing: if he, who is so sued, pleads the deed or fine with warranty, and prays judgment, if the plaintiff shall be received to demand the thing which he ought to warrant to the party, against the warranty in the deed, &c. this is called a rebuttal.

Again, if I grant to the tenant to hold fines impetitions vagi, and afterwards impede him for waste, he may debar me of the action, by shewing my grant; which is likewise a rebuttal.

REC, in Geography, a river of France, which runs into the Sarre, at Sarre Alb.

RECANATI, a town of the marquisate of Ancona; near which towards Macerata are seen the ruins of Helvira Ricina; a town built by the emperor Sept. Severus, and destroyed by the Goths; 8 miles N.E. of Macerata. N. lat. 43° 25'. E. long. 13° 39'.

RECIPIBAL, in Rural Economy, a term provincially used to signify filed or discoloured in stripes.

RECAPITULATION. See PALINODY, or RETRACTATION.

Recapitulation is a summary of the preceding discourse; or a concise, transient enumeration of the principal things insinuated on at large in it; by which the memory of the hearer is refreshed, and the force of the whole collected into one view.

An instance of this may be given in the peroration of Cicero's Manilian: "Quare, cum bellum ita necessarium fuit, ut negligi non posset: its magnum, ut accurate limine fit admissiitandum; & cum ei imperatorem praecipere politiss. in quo sit eximia bellis scientia, singularis virtus, clarifica auctoritas, egregia fortuna; dubitatis, Qurites, quin, &c."

In order to constitute a good repetition or recapitulation, it must be short and concise: it is also convenient to recite things in the same order in which they were at first laid down; but sometimes a repetition is made, by running a comparison between the speaker's own argument, and those of the adverse party, and placing them in opposition to each other; and this method Cicero takes in the conclusion of his third oration upon the Agrarian law. In some cafes, when the discourse is very long, and the arguments insinuated on have been many, the orator only mentions such things which he thinks of least consequence, by saying that he omits or passes over them, till he comes to what is of greater moment, which he represents more fully. Ward's Orat. vol. i. sect. 18. See PRETERITION.

RECAPTION, Recapitio, or Retractio, in Law, is a remedy given to the party himself for an injury to his personal property. This happens, when any one hath deprived another of his property in goods or chattels personal, or wrongfully detains one's wife, child, or servant; in which case the owner of the goods, and the husband, parent, or master, may lawfully claim and retake them, wherever he happens to find them, so be it not in a riotous manner, or...
or attended with a breach of the peace. Thus, e. g., if my horse is taken away, and I find him in a common, a fair, or a public inn, I may lawfully seize him to my own use; but I cannot justify breaking open a private stable, or entering on the grounds of a third person to take him, except he be feloniously stolen, but must have recourse to action at law. Recapture is unlawful, if it be done with intention to smother or compound a larceny. See Restitution of Stolen Goods.

Recaptur is also the taking a second dills of a formerly dills for the same cause, and also during the plea grounded on the former dills. Recapture is also the name of a writ lying for the party thus dills to recover damages. See REPLEVIN.

RECAPTURE, in Naval Injurious, denotes the recovery of a ship, or its cargo wholly or in part, after having been taken by an enemy. For every los occasioned by capture, whether lawful, i.e. when made by a declared enemy, according to the laws of war, or unlawful, i.e. when it is against the rules established by the law of nations, whether by friends or enemies, the insurer is liable, agreeably to the comprehensive and express words of the policy: and in every case of capture the insurer is answerable, to the extent of the sum insured, for the los actually sustained. This may be either total, as where the ship and goods insured are not recovered; or partial, as where the ship is recaptured or restored before abandonment; in which case the insurer is bound to pay the salvage, and any other necessary expenses the insured may have incurred by the recovery of his property. The insurer is liable for a los by capture, whether the property in the thing insured be changed by the capture or not.

As to the length of possession by an enemy, which is deemed sufficient to divest the property out of the original owner, or the effect of a recapture in revesting it; these are matters which can never now come directly in question between the insurer and insured, in any case of insurance upon real interest. In gaming injurious, or injurious without interest, indeed, when there was a recapture, the claim, as for a total los, seems formerly to have involved the question, whether the property in the thing insured had, by the capture, or any proceeding founded on it, been divested out of the original owner, or not, before the recapture. Nevertheless, when a ship is insured "intereet or no intereet," it has been repeatedly determined, that if the ship be taken, it is a total los, however illegal the capture may be, and though the ship may be retaken and restored to the owner. But though no question can now arise between the insured and the insurer, as to the effect of a capture or recapture, in divesting or revesting the property; it may not be deemed unimportant to inquire when a capture shall be deemed to transfer the property to an enemy, and what shall be the effect of a recapture in revesting it in the original owner. The general opinion seems to be that by the law of nations, the property of things captured in war is changed when all reasonable hope of recovering them is gone; and, with respect to things moveable, all reasonable hope of recovering them is presumed to be gone when they are brought within the protection of the enemy's forts. Grotius says, that ships or goods, taken at sea, become the property of the captors, when they are brought into the enemy's harbours, or to the place where his whole fleet is stationere: for then all hopes of recovering them may be said to vanish. But, he adds, that by the law of nations, as introduced among European states in more modern times, things are considered as captured, when they have been 24 hours in the power of the enemy. Others deny this rule of the law of nations, and infitl on the rule of the Roman law, that the prize must be carried "infra praefidium" before it can become the property of the captors; and by "praefidium" Grynberg underlands the camps, the ports, the towns, and the fleets, of the enemy. In our courts of admiralty, however, it has always been held, by the marine law of England, independent of the statute which commands restitution, and fixes the rate of salvare, the property is not changed in favour of a vendee or recaptor, fo as to bar the original owner, till there has been some regular letter of condemnation: and in the reign of King Charles II, a solemn judgment was given upon this point; and restitution of a ship taken by a privateer was decreed, after it had been fourteen weeks in the enemy's possession, because he had not been condemned. The same doctrine has, in several instances, prevailed in our courts of common law. In one case, it was held that nine days' possession by the captor, and in another, that four years' possession, and several voyages performed, will not change the property, without a sentence of condemnation.

In general, whenever a ship is taken by the enemy, the injured may abandon, and demand as for a total los; and he is not bound to make any claim or appeal in the enemy's courts of admiralty, or to litigate there the validity of the capture.

But the injured is in no case bound to abandon; and, as the law now stands, no capture by the enemy can be so total a los as to leave no possibility of recovery, for the jus poli- minimii continues for ever, except in the case of a captured ship converted into a ship of war. (Stat. 33 G. III. c. 66. § 42.) If the owner himself should retake his ship or goods, he will be fully intitled to them; and if they be retaken at any time, whether before or after condemnation, he will be intitled to restitution, upon payment of a settled salvare. Stat. 29 G. II. c. 34. § 24; and 33 G. III. c. 66. § 42.

The chance of the owner's recovering his property, does not, however, fulfill the demand of the injured, as for a total los: but in the case of a recapture, justice is done to the injured by putting him in the place of the injured. In questions upon policies of insurance, the nature of the contract as an indemnity, and nothing else, is always liberally considered.

When there has been a capture, whether legal or not, and the ship has been recaptured or restored, the insurer is bound to defray all necessary expenses which the injured has been put to for the recovery of his property. He is therefore liable for a sum of money paid by the injured to the captors, as a compromis made bonâ fide, to prevent the ship being condemned as prize. See RANSOM.

It often happens that a recaptured ship is in a state to prosecute her original voyage; and, in that case, it is the interest of the recaptors, as well as of the other parties concerned, that she should be permitted to do so. The last prize act (Stat. 33 Geo. III. c. 66. § 44.) has therefore very properly provided, "That if a ship be retaken before she has been carried into an enemy's port, it shall be lawful for her, if the recaptors consent thereto, to prosecute her voyage; and it shall not be necessary for the recaptors to proceed to adjudication till six months after the recapture, or till the return of the ship to the port from whence she failed; and the master, owners, or agents, with the consent of the recaptor, may dispose of their cargoes before adjudication; and in case the vessel shall not return to the port from whence she failed, or the recaptors shall have had no opportunity of proceeding regularly to adjudication within the six months, on account of the absence of the said vessel, the court of admiralty shall, at the instance of the recaptors, decree restitution to the former owners, they paying salvare, upon such evidence as to the court shall, under all the cir-

Vol. XXIX.
RECAPTURE.

circumstances of the cafe, appear reasonable; the expense of
such proceeding not to exceed fourteenth pounds."

We shall here observe, that there is an obvious difference
between capture and arrest of princes; the object of the one
is prize, that of the other detention, with a design to restore
the ship or goods detained, or to pay the value to the owner.

When a ship is detained in a port after a declaration of war,
or the issuing of letters of reprisal, this more resembles a
capture than a detention, and gives the injured an immediate
right to abandon, as for a loss by capture, even though no
condemnation be pronounced, and though the ship be after-
twards recovered. The most frequent cause of detention is
an embargo, which is a proclamation or order of state, usu-
ally issued in time of war or threatened hostilities, prohib-
iting the departure of ships or goods from some or all of the
ports of such state until further order. An embargo
laid on ships and merchandise in the ports of this kingdom
by virtue of the king's proclamation, is illicitly legal, when
the proclamation does not contravene the ancient laws, or
tend to establish new ones; but only to enforce the execution
of such laws as are already in being, in such manner as the
king shall judge necessary. But whether an embargo be
legally or illegally laid, the injury to the owner, by the de-
tention of his ship or goods, is the same; and the insurer is
equally liable for the loss occasioned by it. If a ship be
seized after a cessation of arms and preliminary articles of
peace are signed, this shall not be deemed a capture, but only
an arrest of princes. For the regulation of salvage upon a
recapture, we refer to the article SAVAGE.

Capture by an enemy or a pirate, or an arrest of princes,
or even an embargo, is prima facie a total loss; and imme-
diately upon the capture, or upon a mere arrest, or at any
time while the ship continues under detention, the injured
may elect to abandon, and give notice to the insurer of his
intention so to do; and thus entitle himself to claim as for
a total loss from the insurer. For, from the moment of the
capture, the owners lose their power over the ship and cargo,
and are deprived of the free disposal of them; and, in the
opinion of the merchant, his right of disposal being su-
pended or rendered uncertain, is equivalent to a total de-
privation. It would therefore be unreasonable to oblige
the insured to wait the event of capture, detention, or
embargo.

There is this difference between a policy upon interest, and
a wager policy, that in the one case the injured may, if he
thinks proper, abandon the moment he has notice of a cap-
ture or detention, and this will bind the underwriters, what-
ever may be the ultimate fate of the ship; but in the case of
a wager policy there can be no abandonmemt, because the
insured has nothing to abandon.

But a capture or arrest does not necessarily, and at all
events, terminate in a total loss, so as to entitle the injured to
abandon; for as he cannot abandon till he has received ad-
dvice of the loss; if, at the time he receives such advice, or
before he has elected to abandon, he receive advice that the
ship or goods injured are recovered, or are in safety; he can-
not then abandon; because he can only abandon while it is a
total loss, and he knows it to be so; nor after he knows of the
recapture. Therefore, if a captured ship be retaken and
permitted to proceed on her voyage, so that the sufferers but
a small temporary inconvenience; this would only be a par-
tial, and not a total, loss.

On the other hand, a title to restitution upon a recapture
does not necessarily, and at all events, deprive the injured of
the right to abandon; for if, in conformance of the cap-
ture, the voyage be lost, or not worth pursuing; if the
salvage be very high; if farther expense be necessary, and
the insurer will not undertake at all events to pay it, he may
abandon. The rule is, that, if the thing injured be recovered
before any loss is paid, the insured is entitled to claim as for
a total, or a partial loss, according to the final event; that
is, according to the state of the case at the time he makes
his claim. There is no vested right to a total loss, till the in-
jured, having a right to abandon, elects to do so; for he is
only entitled to an indemnity for his loss as it stands at the
time of the action brought, or offer to abandon.

But if, after a total loss has been actually paid, the
thing injured be recovered, the insurer cannot oblige the
insured to refund the money he has received; but he
shall stand in the place of the injured, and so no injustice is
done.

Cafes are mentioned by Mr. Serjeant Marshall, which serve
as examples to shew that though a captured ship be recap-
tured, yet if the voyage be lost, the loss will be total, and
the insured will have a right to abandon.

By the marine law, the property was not changed by the
capture, till after condemnation; and since the 29 Geo. II.
c. 34, the "jus po!fllimiini" continues for ever. A recapture
does not in all cases prevent the loss being total. If the
voyage be absolutely lost, or be not worth pursuing; if the
salvage be very high; if further expense be necessary; if the
insurer will not engage, at all events, to bear that expense,
though it should exceed the value, or fail of success: under
these, and many other familiar circumstances, the injured may
difentangle himself and abandon, notwithstanding there was
a recapture. Upon a recapture the property returns to the
original owner, pledged to the recaptors for the amount of
the salvage: upon the payment of which he is intitled to
restitution. If upon a recapture the captain, finding that
the voyage cannot be pursued, and, acting fairly for the
benefit of all concerned, sells the ship and cargo to pay the
salvage, and thereby put an end to the voyage, the in-
jured may abandon and recover as for a total loss. How-
ever, a capture does not necessarily amount to a total loss, nor
does a recapture prevent its being total. If the captain
purchase the ship from the captors for account of his
owners, the money paid, being in the nature of salvage, is
only partial loss.

To this article we shall subjoin two or three remarks
upon the subject of abandonment, which do not elsewhere
occur. A time should be fixed when the degree of the in-
urer's responsibility should be ascertained. In several me-
ritime states on the continent, positive regulations have
been established, limiting the time, after a loss has happened,
within which the injured may abandon. In England we have
no such positive regulation, nor any time limited by law for
abandoning. But the courts have laid down a rule, better
adapted to the purpose; and the rule is, that as soon as the
insured receives advice of a total loss, he must make his
election whether he will abandon or not. If he determines
to abandon, he must give the underwriters notice of this
within a reasonable time after the intelligence arrives; and
any unnecessary delay in giving this notice will amount to a
waver of his right to abandon; for unless the owner does
some act, signifying his intention to abandon, it will be
only a partial loss, whatever may be the nature of the loss,
or the extent of the damage. If the insurers in any manner
prevent the abandonment, they shall pay the whole loss, to
the amount of the sum injured. If no intelligence be re-
ceived of a ship within a reasonable time, it shall be pre-
sumed that she foundered at sea: when the time has elapsed
which affords that presumption, the injured may abandon,
and claim as for a total loss. Marshall on Insurance,
vol. ii.
RECARDAINS, in Geography, a town of Portugal, in the province of Beira; 6 miles E. of Bragança Nova.

RECCAN. See Arracan.

RECCO, a town of the Ligurian republic, near the seacoast; 11 miles S.E. of Genoa.

RECEIT, a fort and harbour on the coast of Brazil. S. lat. 8° 10'.

RECEIT, or RECEIT, in Commerce, an acquittance or discharge; or a written acknowledgment of having received a sum of money.

Where the receipt is on the back of a bill, &c., it is usually called an endorsement.

Among trademen the receipt usually makes the second of the three articles of an account; the former contains the monies received; the two others the expense, and the return or balance.

By the 44 Geo. III. c. 98, the former flamp duties were repealed, and others imposed; by the 48 Geo. III. c. 149, these last were repealed, and the following were imposed; viz.

receipt or discharge given for or upon the payment of money

And where any sum of money whatever shall be therein expressed, or acknowledged to be receiv'd, 5.

And any note, memorandum, or writing whatsoever, given to any person for or upon the payment of money whereby any sum of money, debt, or demand, or any part of any debt or demand therein specified, and amounting to 2l. or upwards, shall be expressed or acknowledged to have been paid, settled, balanced, or otherwise discharged or satisfied, or which shall import or signify any such acknowledgment, and whether the same shall or shall not be signed with the name of any person, shall be deemed and taken to be a receipt for a sum of money of equal amount with the sum, debt, or demand so expressed or acknowledged to have been paid, settled, balanced, or otherwise discharged, or satisfied, within the intent and meaning of this schedule, and of the foregoing act, and shall be charged with a duty accordingly.

And any receipt or discharge, note, memorandum, or writing whatever, given to any person for or upon the payment of money, which shall contain, import, or signify any general acknowledgment of any debt, account, claim, or demand, debts, accounts, claims, or demands, whereby the amount shall not be therein specified, having been paid, settled, balanced, or otherwise discharged or satisfied, or whereby any sum of money therein mentioned shall be acknowledged to be received in full, or in discharge or satisfaction of such debt, account, claim, or demand, debts, accounts, claims, or demands, and whether the same shall or shall not be signed with the name of any person, shall be deemed and taken to be a receipt for the sum of 50l. or upwards, within the intent and meaning of this schedule, and of the foregoing act, and shall be charged with the duty of 5e. accordingly.

By 43 Geo. III. c. 126, such receipt shall not be available in law or equity as such acknowledgment, or be given in evidence, unless duly stamped as aforesaid.

And all receipts, discharges, and acknowledgments of the description aforesaid, which shall be given for or upon payments made by or with any bills of exchange, drafts, promissory notes, or other securities for money, shall be deemed and taken to be receipts given upon the payment of money within the intent and meaning of this schedule and of the foregoing act.

Exemptions from the preceding Duties on Receipts.

Receipts exempted from stamp duty by any act or acts of the present parliament, relating to the aforesaid taxes.

Receipts or discharges given by the treasurer of the navy for any money imprested to or received by him for the service of the navy.

Receipts or discharges given by any agent for money imprested to him on account of the pay of the army or ordnance.

Receipts or discharges given by any officer, seaman, marine or felder, or their representatives respectively, for or on account of any wages, pay, or pension due from the navy-office, army pay-office, or ordnance-office.

Receipts or discharges given for the consideration money, for the purchase of any share in any of the government or parliamentary fleets or funds, or in the fleets and funds of the government and company of the bank of England, or of the East India company, or South Sea company, and for any dividend paid on any share of the said fleets or funds respectively.

Receipts given for money deposited in the bank of England, or in the bank of Scotland, or royal bank of Scotland, or in the bank of the British linen company in Scotland, or in the hands of any banker or bankers, to be accounted for on demand, provided the same be not expressed to be received of or by the hands of any other than the person or persons to whom the same is to be accounted for; but if with interest, see Promissory Notes.

Receipts or discharges written upon promissory notes, bills of exchange, drafts or orders for the payment of money duly stamped according to the laws in force at the date thereof, or upon bills of exchange drawn out of, but payable in Great Britain.

Receipts or discharges given upon bills or notes of the governor and company of the bank of England; letters by the general post acknowledging the safe arrival of any bills of exchange, promissory notes, or other securities for money.

Receipts or discharges indorsed or otherwise written upon, or contained in any bond, mortgage, or other security, in any conveyance, deed, or instrument whatever, duly stamped according to the laws in force at the date thereof, acknowledging the receipt of the consideration money therein expressed, or the receipt of any principal money, intereß, or annuity thereby secured.

Release of discharges for money by deeds duly stamped according to the laws in force at the date thereof.

Receipts or discharges given for drawbacks or bounties upon the exportation of any goods or merchandise from Great Britain.

Receipts or discharges for the return of any duties of customs upon certificates of over entry.

Receipts or acknowledgments of payments indorsed upon any bills, orders, remittance bills, or remittance certificates, drawn by commissioned officers, masters, and surgeons in the navy, or by any commissioner or commissioners of the navy, under the authority of the act passed in the 35th year of his majesty's reign, for the more expeditious payment of the wages and pay of certain officers belonging to the navy.

3 T 2

Receipts
Receipts or acknowledgments of payments indorsed upon any bills drawn pursuant to any former act or acts of parliament, by the commissioners of the navy, or by the commissioners for managing the transport service, and taking care of sick and wounded seamen, upon and payable to the treasurer of the navy.

If any person shall write or sign any receipt liable to any stamp duty, without being first duly stamped as aforesaid; or with a stamp of a lower value than is herein directed; he shall forfeit 10l. if the sum paid or expressed therein shall not amount to 10l.; and 20l. if the sum amount to 10l. or upwards. 31 Geo. III. c. 27. s. 17. 35 Geo. III. c. 55. s. 8.

Every person who shall give any receipt or writing acknowledging the payment of money, in which a less sum shall be expressed than the sum actually paid or received, or who shall separate or divide the sum actually paid or received into divers sums, or shall write off any part of any debt, or demand, or be guilty of or concerned in any contrivance with intent to defraud his majesty, shall forfeit 50l. 35 Geo. III. c. 55. s. 9.

And the persons, or their agent, from whom any sum shall be due or payable, and who shall have paid such sum, may provide a stamp with the proper duty, or of some higher rate of duty than required, and demand of the person entitled to such sum, or any agent to whom the same shall have been paid, a receipt for such sum, and also the amount of the duty thereon as aforesaid; and if such person refuse to give such receipt upon demand thereof, or to pay the amount thereof, every such person shall forfeit for each offence 10l. 43 Geo. III. c. 126. s. 5.

Stamps denoting the duties under former acts may be used, provided they be applied to receipts of the like amount as required by this act. s. 8.

And all vellum, parchment, and paper liable to any stamp duty as aforesaid, shall be stamped before the same be written or printed upon; or may be brought to the said commissioners or their officers to be stamped within 14 days after such receipts shall be given or bear date, and shall be stamped on payment of 5l. over and above the duty; and if brought after 14 days within one calendar month, on payment of 10l. over and above the duty. 31 Geo. III. c. 25. s. 19. 20. 35 Geo. III. c. 55. s. 10. 11.

All penalties by this act incurred may be fixed for in the courts of Westminster; or any neighbouring justice may hear and determine any offence which subjects the offender to any pecuniary penalty; who may, on complaint made within three calendar months, summon the party accused, and the witnesses, and examine into the matter of fact; and on confession, or the oath of one witness, may give judgment therein, and levy such penalty by direct, on the goods of the offender, which, if not redeemed within six days, may be sold; and such penalty shall be divided half to the king, and half to the informer; and for want of sufficient direct, the offender shall be committed to prison for three calendar months, unless such penalty shall be sooner paid. 31 Geo. III. c. 25. s. 24. 25. 35 Geo. III. c. 55. s. 12. 13.

If any person shall find himself aggrieved by the judgment of such justice, he may, upon giving security to the amount of such penalty and costs, appeal to the next sessions, which shall happen 14 days next after such conviction, on giving reasonable notice; and in case such judgment be affirmed, they may award the person appealing such costs 2s. to them shall seem meet. Id.

Provided, nevertheless, that such justice may, where he shall see cause, mitigate any such penalty, so as not to reduce the same to less than one moiety thereof and above the costs. 31 Geo. III. c. 25. s. 26. 35 Geo. III. c. 55. s. 14.

Witnesses not appearing, having been duly summoned, without reasonable cause to be allowed by such justice, or refusing to give evidence, shall forfeit 40s. to be recovered in like manner. 31 Geo. III. c. 25. s. 27. 35 Geo. III. c. 55. s. 15.

Perfons counterfeiting or forging any stamp hereby directed to be made use of shall be guilty of felony without benefit of clergy. 31 Geo. III. c. 25. s. 29. 35 Geo. III. c. 55. s. 17. 43 Geo. III. c. 126. s. 11.

All powers given by any former act relating to the stamp duties shall extend to this act. 31 Geo. III. c. 25. s. 30. 35 Geo. III. c. 55. s. 18. 43 Geo. III. c. 126. s. 12.

Perfons sued or prosecuted on account of any thing done in pursuance of this act may plead the general issue and give the special matter in evidence; and if a verdict be for the defendant, or the plaintiff be non-suited, treble damages shall be awarded against such plaintiff. s. 15.

By the 44 Geo. III. c. 98, the former duties on legacies under the care of the commissioners for stamp duties were repealed, and new duties were imposed. By the 45 Geo. III. c. 28, additional duties were imposed, and by the 43 Geo. III. c. 149, the following were imposed (being by f. 3. of this last act placed under the provisions of former acts relating to such duties,) and those imposed by former acts were repealed.

Schedule, Part III. Legacies and successions to personal or moveable estate upon intestacy.

I. Where the testator, testatrix, or intestate, died before or upon the 5th of April 1805.

For every legacy, specific or pecuniary, or of any other description, of the amount or value of 20l. or upwards, given by any will or testamentary instrument of any person who died before or upon the 5th day of April 1805, out of his or her personal or moveable estate, and which shall be paid, delivered, retained, satisfied, or discharged, after the 10th of October 1808.

Also for the clear residue (when devolving to one person), and for every share of the clear residue (when devolving to two or more persons), of the personal or moveable estate of any person who died before or upon the 5th day of April 1805 (after deducting debts, funeral expenses, legacies, and other charges first payable thereout), whether the title to such residue, or any share thereof, shall accrue by virtue of any testamentary disposition, or upon a partial or total intestacy; where such residue, or share of such residue, shall be of the amount or value of 20l. or upwards, and where the same shall be paid, delivered, retained, satisfied, or discharged, after the 10th of October 1808.

Where any such legacy, or residue, or share of such residue, shall have been given, or devolved, to or for the benefit of a brother or sister of the decease, or any descendant of a brother or sister of the decease; a duty at and after the rate of 2l. 10s. per cent. on the amount of the value thereof.

Where to or for the benefit of a brother or sister of the father or mother of the deceased, or any descendant of a brother or sister of the father or mother of the deceased; a duty at and after the rate of 4l. per cent. on the amount or value thereof.
Where to or for the benefit of a brother or sister of a grandparent or grandmother of the deceased, or any descendant of a brother or sister of a grandparent or grandmother of the deceased; a duty at and after the rate of 5l. per cent. on the amount or value thereof. 

Where to or for the benefit of any person in any other degree of collateral consanguinity to the deceased, than as above described, or to or for the benefit of any stranger in blood to the deceased; a duty at and after the rate of 8l. per cent. on the amount or value thereof.

Where to or for the benefit of a brother or sister of a grandparent or grandmother of the deceased, or any descendant of a brother or sister of a grandparent or grandmother of the deceased; a duty at and after the rate of 5l. per cent. on the amount or value thereof. 

Where to or for the benefit of any person in any other degree of collateral consanguinity to the deceased, than as above described, or to or for the benefit of any stranger in blood to the deceased; a duty at and after the rate of 8l. per cent. on the amount or value thereof.

And all gifts of annuities, or by way of annuity, or of any other partial benefit, or intereft, out of any such estate or effects as aforesaid, shall be deemed legacies within the intent and meaning of this schedule.

11. Where the testator, testatrix, or intestate, shall have died after the 5th of April 1805.

For every legacy, specific or pecuniary, or of any other description, of the amount or value of 20l. or upwards, given by any will or testamentary instrument, of any person who shall have died after the 5th of April 1805; either out of his or her personal or moveable estate, or out of or charged upon his or her real or heritable estate, or out of any monies to arise by the sale, mortgage, or other disposition of his or her real or heritable estate, or any part thereof, and which shall be paid, delivered, retained, satisfied, or discharged after the 10th of October 1808.

Also, for the clear residue, (when devolving to one person), and for every share of the clear residue (when devolving to two or more persons), of the personal or moveable estate of any person who shall have died after the 5th of April 1805, (after deducting debts, funeral expenses, legacies, and other charges first payable thereout), whether the title to such residue, or any share thereof, shall accrue by virtue of any testamentary disposition thereof, or upon a partial or total intestacy, where such residue, or share of residue, shall be of the amount or value of 20l. or upwards, and where the same shall be paid, delivered, retained, satisfied, or discharged after the 10th of October 1808.

And also for the clear residue (when given to one person), and for every share of the clear residue (when given to two or more persons), of the monies to arise from the sale, mortgage, or other disposition of any real or hereitable estate, directed to be sold, mortgaged, or otherwise disposed of, by any will or testamentary instrument of any person who shall have died after the 5th of April 1805, (after deducting debts, funeral expenses, legacies, and other charges, first made payable thereout, if any), where such residue, or share of residue, shall amount to 20l. or upwards, and where the same shall be paid, delivered, retained, and discharged, after the 10th of October 1808.

Where any such legacy or residue, or any share of such legacy or residue, shall have been given, or have devolved, to or for the benefit of a child of the deceased, or any descendant of a child of the deceased; a duty at and after the rate of 1/4 per cent. on the amount or value thereof. 

Where to or for the benefit of a brother or sister of the deceased, or any descendant of a brother or sister of the deceased; a duty at and after the rate of 1/4 per cent. on the amount or value thereof.

Where to or for the benefit of a brother or sister of the father or mother of the deceased, or any descendant of a brother or sister of the father or mother of the deceased; a duty at and after the rate of 1/4 per cent. on the amount or value thereof.
appeal, the duty shall be paid according to such variation; and if the duty affixed in manner aforesaid shall exceed the duty offered to and refused by such flamp officers, the expenses shall be borne by the person liable to pay such duty. If any dispute shall arise between persons entitled to any such legacy, or residue, or taking administration as aforesaid, respecting the value thereof, or duty to be paid thereon, the duty shall be affixed by such flamp commissioners on reference to them by either party; and if the value of such property shall be in dispute, such flamp commissioners shall cause an appraisement to be made thereof, at the expense of the person liable to pay the duty, in manner aforesaid; and if such person shall be dissatisfied with such valuation, the same shall be reviewed and finally determined by the said commissioners of the land-tax, upon appeal to them within the time and in the manner aforesaid. And if the effects whereon such duty is payable shall be ten miles from London, such persons as shall be deputed by the said flamp commissioners shall act in their stead. f. 22. Geo. III, c, 52.

And if it shall appear to the said flamp commissioners, upon oath, to be administered by a justice, or master extraordinary in chancery, that such duty has been paid than ought to have been, by mistake, without intention of fraud, such mistake may be rectified by such commissioners, who may accept the duty really due within three calendar months, if no suit hath been instituted, and on payment of 10l. per cent. thereof by way of penalty. f. 30.

Every person paying or receiving money contrary to this act, who shall within twelve calendar months discover the other party offending, so as be convicted thereof, shall be indemnified and discharged from all penalties against this act. f. 31.

And all powers of forming acts relating to the flamp duties, not hereby altered, shall be in force, in the execution of this act. f. 42.

Wherever any executor or administrator shall not have paid the said duties within time, the court of exchequer may, on application from the flamp office on satisfactory affidavit, grant a rule for such executor to shew cause why he should not deliver to the commissioners an account on oath of all legacies, or of the personal property paid or payable by him, and why the duties thereon have not been, or should not be forthwith paid, and may make such rule absolute where it appears proper. And regisrars of ecclesiastical courts shall, within a month of requisition, deliver to the flamp office an account of wills and letters of administration in their custody, with particulars relating thereto, and extracts from any wills deemed necessary by the commissioners, on payment of fees agreed on or allowed by the ecclesiastical court, on pain of 50l. recoverable by information by the attorney-general. 42 Geo. III, c. 99. f. 2, 3.

And by the 5 W. c. 21, the probate of any will or letters of administration of any common folder or scaman, slain or dying in the service, shall be exempt from the flamp duties. f. 6.

RECEIPT, of Rescrt, in Law, See Rescrt.
RECEIPT of Homage. See rescr.
RECEIPT of the Exchequer. See COURT of Exchequer.
RECEIPT, in Medicine. See RECIPE.
RECEIPT, Auditor of. See AUDITOR.
RECEIVER, or RESCRIPT, in Chemistry. A globe-shaped vessel, which is adapted to the neck or beak of an alembic, retort, or other distillatory vessel, in order to collect, receive, and contain the products of distillations.

Receivers should be made of glass, not only because this matter refits the action of the strongest and most corrosive substances, but also because being transparent, it allows the operator to see through it, and to judge by the frequency of the drops, if the distillation be too quick or too slow, and also if the quantity and nature of the substances that come over be such as are required.

Almost all receivers are kinds of bottles of different sizes, of a spherical form, the necks of which are cut short, and each of which is pierced with a small hole in its lateral or upper part, to give vent to the air or vapours, which are too expansive. Receivers of this form are called balloons; which see. Some receivers are made of long necks. These are generally adapted to the beaks of glafs alembics. The long neck serves to keep the belly of the receiver, where the liquor is collected, at a proper distance from the fire.

Receivers have different forms for particular operations. Such are those which have two or three beaks, either to be adapted to other receivers, or to admit at the same time the necks of several distillatory vessels, when the intention of the operator is, that the vapours of different substances should meet in the same receiver. Such also are receivers for essential oils, obtained from aromatic plants distilled with water, which are so made, that they are never full, but that the water runs out, and leaves the oil behind. These are a kind of glafs cucurbits, which contract as they rise higher; so that their neck or upper opening is but nearly of a convenient size to receive the beak of the worm. These receivers have another opening about the middle of the swelling or belly; and to this opening is joined a glafs tube, which bends and rises vertically along the outer part of the receiver, so as to be within two inches and a half as high as the upper opening. At this height the tube bends again towards the side opposite to the body of the receiver, to pour into another vessel the liquor which arises there. It forms the figure of an S.

When this receiver is to be used, it is to be placed vertically under the beak of the worm. During the distillation, the liquor rises to an equal height in the body of the receiver, and in the crooked tube: when, therefore, the height of the liquor in the receiver becomes greater than the height of the tube, it must begin to flow from the mouth of this tube into another vessel placed on purpose to receive it; but as essential oils are either lighter or heavier than water, and as they are, therefore, always collected either above or under the water, and as the liquor which discharges itself through the tube is taken from the middle part of the receiver, nothing but water can be evacuated at the mouth of the pipe, while the oil always remains in the receiver. With such a receiver distillation may be performed without the trouble of changing the vessels. Macquer's Chem. Dict.

See DISTILLATION and LABORATORY.

RECEIVER of an Air-Pump, is part of its apparatus; being a glass vessel placed on the top of the plate, out of which the air is to be exhausted. To an air-pump belong various receivers, of various forms and sizes, and serving for various purposes. See AIR-PUMP.

RECEIVER, Exhausted, in Pneumatics. See EXHAUSTED. And for the method of repairing those that are cracked, see CEMENT.

RECEIVER, Receptor, or Receptacle, in Law, is used commonly in the bad sense, for such as knowingly receive stolen goods from thieves, and conceal them.

This offence is only a misdemeanor at common law: however, by the statutes 3 & 4 W. & M. c. 9. and 5 Ann. c. 31, the offender is made accessory to the theft and felony. But because the accessory cannot in general be tried, unless with the principal, or after the principal is convicted, the receivers
receivers by that means frequently eluded justice; to remedy which it is enacted by statute 1 Ann. c. 9. and 5 Ann. c. 31. that such receivers may be still prosecuted for a misdemeanor, and punished by fine and imprisonment, though the principal felon be not before taken, so as to be prosecuted and convicted. And in case of receiving stolen lead, iron, and certain other metals, such offence is, by statute 29 Geo. II. c. 30. punishable by transportation for fourteen years. So that now the protector has two methods in his choice: either to punish the receivers for the misdemeanor immediately, before the thief is taken (Folter. 373.); or to wait till the felon is convicted, and then punish them as accessory to the felony. But it is provided by the same statute, that he shall only make use of one, and not of both these methods of punishment.

By the same statute also (29 Geo. II. c. 30.) persons having lead, iron, or other metals in their custody, and not giving a satisfactory account how they came by the same, are guilty of a misdemeanor, and punishable by fine and imprisonment. And by statute 10 Geo. III. c. 48. all knowing receivers of stolen plate or jewels, taken by robbery on the highway, or when a burglarly accompanies the stealing, may be tried as well before as after the conviction of the principal, and whether he be in or out of custody; and, if convicted, shall be adjudged guilty of felony, and transported for fourteen years. By stat. 21 Geo. III. c. 68. the receiving of any stolen copper, brass, bell-metal, or utensil fixed to any building, or any iron rails or fencing set up in any court or other place, is made transportation for seven years, or three years imprisonment to be kept to hard labour. By stat. 21 Geo. III. c. 69. the receiving of stolen pewter of any kind is subjected to the like penalty, although the principal has not been convicted. By stat. 22 Geo. III. c. 58. the receiving of any stolen goods, (except lead, iron, copper, brass, bell-metal, and folder,) is made a misdemeanor, punishable by fine and imprisonment, or whipping, as the court shall appoint; which shall exempt the offender from being punished as accessory, although the principal be afterwards convicted, and the offence shall appear to be grand larceny, or some greater offence. (See Larceny.) For the punishment of receivers of goods stolen by bum-boats, &c. on the river Thames, see stat. 2 Geo. III. c. 28. § 12. Receivers of stolen goods stolen from the bleaching-grounds are, by stat. 18 Geo. II. c. 27. declared felons without benefit of clergy.

In France, receivers are punished with death; and the Gothic constitutions diluguihino also three sorts of thieves: “Unum qui confilium dare, alterum qui contraret, tertium qui receptaret et occula: part viae sanguis obnoxios.”

Receiver also denotes an officer, of which there are various kinds, denominated from the particular matters they receive, the places where, or the persons for whom, &c.

As receiver of rents; receiver-general of the customs; receiver of the fines, upon original writs in chancery, &c.

Receiver-General of the Duchy of Lancaster, is he who gathers all the revenues and fines of the lands of the said duchy, all forfeitures, nullities, &c.

Receiver-General of the public revenue is an officer appointed in every county, to receive the taxes granted by parliament, and remit the money to the treasury.

Receiver’s Office. See Greenwich Hospital.

RECENT FRUITS. See Fruit.

RECEPtACLE of Stall Manure, in Agriculture, the place where the various matters from the stalls, and other places where animals are kept, are deposited and laid up.

Some suppose that these places should be a little hollow or excavated; while others are of quite a different opinion, and think that they should be even, or a little raised. A very slight hollowing is, however, probably the best. An experienced writer on this subject suggests, that it is not to be inferred that, because they should be hollow, they should also be deep; as one principal use of them is to bring the rain waters, which fall within the yards or inclosed parts, into a flagrant slate, and to let them off superficially, so as to prevent any thing of the ground current kind from carrying away the dung, either in a bodily manner, or in a thick fluid slate: they may, in this way, suffer the more watery particles only to pass away into reservoirs, prepared to preserve and keep them for future use. It is believed that two feet on the lower side, or deeper parts, may be taken as a mean depth; but less may often be quite sufficient: and the bottoms of the waste-water channels being laid six or eight inches lower than the rim of the basons, the depth of water which they can contain is, it is concluded, not more than sixteen or eighteen inches, when empty of manure. But it is suggested, as necessary to good farm management, that, soon after the winter’s manure has been removed and cleared away, floorings of marble, or some other earthy fertilizing material, mixed with lime, to the thickness of ten or twelve inches, should be spread out over the bottoms of the basons or hollowed parts; by which means a rich compost for grass lands may be formed at small expense, on which all the offal materials of manure which can be collected, free from seeds of weeds, during the summer and autumn, should be deposited. In this manner the receptacles should be filled to the brims, even though no soluble manure were put into them during the above two seasons; so that the winter’s stall manures may have firm platforms to rest upon, out of the way of water, the great evil which antiquated prejudice so much fears in these manure receptacles, as the prevention of the due maturation of their different contents.

With these receptacles of manure there should be connected drains from the cattle-houses, stalls, and farm-offices, for receiving and conveying the urine, and other liquid matters, from them to these basons or receptacles; and the mouths of their outlet channels should be well guarded, in order to prevent their being choked up by the manure, when piled up to considerable height above them. The receptacles, pits, or wells, which are made before them, are always to be kept free, for the superfusions of water, or other liquid matters of the receptacles, to drain or filtrate into; and thence to pass away in moist weather; or to be pent up in them, in dry warm seasons, for the purpose of being thrown over the piled-up manures, for the promotion of their decay and maturation.

Where there are grass lands lying conveniently below these receptacles and reservoirs for receiving their overflows, all the different parts of the places, where they are situated, may be made to beleve gently towards them; but where land cannot be commanded for favouring this intention, the receptacles or basons should receive no other waters than what are supplied to them by the atmosphere. This regulation may easily be accomplished, simply by raising their rims a few inches higher than the surrounding surfaces, which should be frequently cleared from the manure and litter dropped upon them, deposing all such substances within their rims. The rain-water which falls in these cases, is to be conveyed to the catch-pools, or the most contiguous common drains. In all cases, that which falls upon the buildings should be conveyed away, without being suffered to pass through the receptacles or basons, unless
unles where liquid manure is more in demand than that of the bulky kind.

From the flow progresses made by manures of this sort to maturation, in the winter season, in the open air, even when piled up in the worst situations, on account of its being constant, moist, or faturated with moisture, and exposed to the effects of the cold atmosphere, the plan of giving receptacles of this sort a long oval square form, and covering them with roofs, to free them wholly from rain, as well as to defend them from cold, has been hit upon, and recommended from authority. As by thus affording the articles of manure the means of passing into the state of fermentation, in the winter months, their putrefaction and decay would be beneficially promoted, for the use of the more early crops of the spring. But how far the advantage, gained in this way, may equal or be superior to the expense of building, and extra labour in the removals of the manure, is a point which is by no means yet fully decided. And the superior benefits, which have lately been derived from the use of manure in its more raw or fresh state, render all such schemes perhaps of less importance than would otherwise be the case.

As it is a matter of great consequence to prevent the evil waste of this sort of manure, which at present frequently takes place in most parts of the country, it has been suggested by an experienced writer, who has attended much to the subject, and thought a great deal upon it, that piling it in shallow receptacles or basins, and conducting the liquor, when not wanted for moistening the piles of manure, which overflows from them, to reservoirs or catch-pools, in order to stop, deposit, and arrest the heavier and more gross particles that may be conveyed in it, and to provide a valuable collection of liquid manure in particular situations, and of rich muddy matters in others, are the most appropriate practical means of accomplishing the matter, in an easy and cheap way, that can be adopted or had recourse to. See Dung, Farm-Yard, Homestead, Manure, Reservoir, and Yard Manure.

RECEPTACULUM, Receptacle, in Botany and Vegetable Physiology, is the seventh, or last, part of fructification distinguished by Linnæus, being the common bases, or point of connection, of the others. (See Fructification.) It is evident that such a part must exist, under some shape or other; yet the receptacle is not always distinguished by any particular figure. In simple flowers it is often little more than a mere point; in compound ones it is very remarkable and important, serving, by its differences of structure, to afford very good generic distinctions. The receptacle of the Daily, Bellis, is conical; that of Chrysanthemum convex. In Spharanthus this part is very nearly globular, while in some species of Centarea and Carline it is either flat, or slightly concave. In Secus it is naked, destitute of hairs or scales between the florets or seeds; while in Cardus it is hairy, and in Anthemis variously scaly. This last genus differs, by the character in question alone, from Chrysanthemum, whose receptacle is naked; but the character is not quite so natural, in this case, as could be wished. Mr. Brown has observed to us, that it affords not even a certain artificial distinction, in the Chrysanthemum indicum of the gardens, Curt. Mag. t. 327; which Wilde-now, like M. de Ranuatre and professor Desfontaines, has referred to Anthemis, because they found the receptacle to be scaly. We are convinced they are in the right, and yet this appears to be the very same plant with Chrysanthemum indicum, the scales of the receptacle being variable, and sometimes almost, if not altogether, evanescence. Some genera of these clods have a cellular, or honeycomb-like receptacle, as Onapodium, and Tolpis (Crepis barbata of Linnæus). In that case the edges of the cells are variously jagged, toothed, or fringed, and they now and then are fearfully distinguishable from the reticulations or rugosities of some naked receptacles.

The receptacle of the flowers, in Linnæan language, means the area or space between the flauens and styles, in certain genera whose semen is inferior; as the whole umbelliferous order, in which the part in question is more or less tumid, often coloured, and assumes a glandular aspect. The receptacle of the seeds is not unfrequently a distinct part from the capsule or its valves, serving to connect the seeds therewith. (See an example of it in Redtea.) The rachiis, or common stalk of a spike, or spikelet, in Grapis, is also termed a receptacle.

In some plants the receptacle undergoes great changes, acquiring a different texture in the fruit, from what it had in the flower. Thus, the whole fruit, as we call it, of the Fig, (see Ficus,) is a common receptacle, at first coriaceous, and, like the rest of the plant, containing a milky, somewhat acid, juice. It forms a bag, lined with flowers or florets, and having a small aperture at the top. After the flowers are past, this bag becomes pulpy, coloured, and full of sweet aromatic juice. So the fruit of the Strawberry, (see Fragaria,) is but an originally small dry receptacle, subsequently enlarged, and become pulpy, whose outside is fluid with naked seeds. In Broadenetta, described under our article Papryus, the separate flake of each-germen becomes the enlarged and pulpy supporter of a naked feed. In Pollichia, (see that article,) the common receptacle of the flowers, minutely scaly, and hardly discernible, in its earlier state, changes to a congeries of white, juicy, sweet, tooth-like scales, elevating the seeds in their appropriate withered perianths, and altogether constituting one of the most extraordinary pulpy fruits that we have ever met with. A familiar change of substance is observable in the calyx of the Mulberry, as well as in Camellina Zanonia; a change common and natural in the germs of pulpy fruits, though rare in the particular parts of which we have been speaking.

RECEPTACULUM Gyni, in Anatomy, that portion of the trunk of the absorbing vessels, into which the lacteal absorbents pour the fluids which they have taken up in the alimentary canal; it is usually rather larger than the neighbouring portions of the vessel, and sometimes very considerably so. See Absorbents.

RECEPTARI, a term of reproach used for such physicians as wrote pompous receipts for loads of medicines, more confuting the good of the apothecary than the patient; as also for such as gave receipts for general medicines, to be used at the discretion of people wholly unacquainted with the nature of diseases.

RECEPTION, Receipt, in Philosophy, denotes the fame with passion, considered as opposed to action.

RECEPTION is also properly used for the manner of treating or entertaining a person; and the solemnities and ceremonies practised on that occasion. See Entry.

The reception of ambassadors is usually performed with a great deal of pomp.

RECEPTION is sometimes also used for the act of approving, accepting, and admitting a thing. See Acceptance.

The canon law only binds where it is received: the civil law is received in some countries, and not in others.

The French would never receive the council of Trent, the Spanish inquisition, nor the dogmata of the ultramontane canonists.

Reception,
The Rechabites, a kind of religious order among the ancient Jews, instituted by Jonadab the son of Rechab; and comprehending his family and posterity. Their founder preferred them three things: first, Not to drink any wine. Secondly, Not to build any houses, but to dwell under tents. Thirdly, Not to sow any corn, or plant any vines.

The Rechabites observed these rules with great strictness, as appears from Jerem. xxxv. 6, &c. Whence St. Jerom, in his thirteenth epistle to Paulinus, calls them "naebei, monks." Jonadab, their founder, lived under Jehoshaf, king of Judah, contemporary with Jethro, king of Israel; his father Rechab, from whom his posterity were denominated, descended from Raguel or Jethro, father-in-law to Moses, who was a Kenite, or of the race of Ken; whence Kenite and Rechabite are used as synonymous in scripture.

The Kenites entered the promised land with the Hebrews, and dwelt in the tribe of Judah, about the Dead sea. They were distinguished from the Israelites by their retired sort of life, and by their contempt of cities and houses. Serrarius distinguishes the ancient Rechabites from the new Rechabites of Jonadab. The injunction of Jonadab laid no obligation on the other Kenites, nor on the other descendants of Jethro. This they continued to observe above 300 years. Jethro began to reign A.M. 3120, and Jethro, king of Judah, was put to death A.M. 3455, B.C. 599; but in the last year of Jethro, king of Judah, Nebuchadnezzar coming to besiege Jerusalem, the Rechabites were forced to take refuge in the city, still, however, lodging in tents. During this siege, Jeremiah received orders from the Lord to converse with the disciples of Rechab, to invite them into the temple, and to offer them wine to drink. But the Rechabites would not accept the offer.

The Rechabites were, probably, led captive, after the taking of Jerusalem by the Chaldæans. (See Psalms lxv.) They returned from their captivity, and settled in the city of Jabez, beyond Jordan. (2 Chron. iv. 25.) Some have suggested, that the Alzidans of the Maccabees, (1 Macc. ii. 42. viii. 13. and 2 Macc. xiv. 6.) were successors and followers of the Rechabites. Others have connected their origin with the city of Rechab, now called Reching, about 100 miles to the north of Jerusalem. They were said to be of the royal family of David, and to be a branch of the Kenites. (See 2 Chron. xiv. 12.) Their language is not known, but they are said to have been a race of shepherds, who dwelt in the wilderness, and were not subject to the government of the Jews. (See 2 Chron. xiv. 12.) They are said to have had their own laws, and to have been governed by a council of elders. (See 2 Chron. xiv. 12.) They are said to have been a race of shepherds, who dwelt in the wilderness, and were not subject to the government of the Jews. (See 2 Chron. xiv. 12.) They are said to have had their own laws, and to have been governed by a council of elders. (See 2 Chron. xiv. 12.)
RECIPIENT, in Algebra, is the quotient arising from the division of unity by any number or quantity. Thus, the reciprocal of \(a = \frac{1}{a}\), the reciprocal of \(\frac{b}{a}\) is \(\frac{1}{b}\), and so on.

**Reciprocal Equations**, in Algebra, are those equations which contain several pairs of roots which are the reciprocals of each other. Thus, an equation whose roots are \(a, \frac{1}{a}\), \(b, \frac{1}{b}\), &c., is called a reciprocal equation. Some authors define reciprocal equations, to be those equations whose coefficients proceed in the same order from both extremes, and respectively equal to each other; thus, \(x^n + a x^{n-1} + b x^{n-2} + \ldots + b x^2 + a x + 1 = 0\), is a reciprocal equation; but this form ought rather to be considered as a necessary property of these equations, by which they may be readily distinguished, than to be employed in the definition of them; it being doubtless the reciprocity of the roots from which they have received their peculiar appellation.

The solution of these equations may always be made to depend upon others of half the original degree, when the equation is of even dimensions; or upon half the dimension minus 1, when it is odd.

Thus far, in fact, this property is not exclusively due to reciprocal equations, as the same may be done in all cases where any familiar relation is known to have place between the roots of an equation, whether by multiplication, division, addition, or subtraction; but in these cases there is nothing in the form of the equation by which such relations may be known to have place, whereas in reciprocal equations their reciprocity becomes immediately obvious by the peculiar order of their co-efficient, these being the same from both extremes, both with regard to sign and magnitude. Hence any equation of the form

\[x^n + a x^{n-1} + b x^{n-2} + \ldots + b x^2 + a x + 1 = 0\]

is immediately known to be reciprocal, and we may proceed in its solution as follows.

First, if the equation be of odd dimensions, as

\[x^{n+1} + a x^n + b x^{n-1} + \ldots + b x^2 + a x + 1 = 0\]

then it is obvious that either \(x + 1\), or \(-1\), is one of its roots, for either \(x + 1\), or \(-1\), substituted for \(x\) according as the signs of the co-efficients may require, will obviously render the whole expression equal to zero, and is therefore a root of the equation. The equation may, therefore, be immediately reduced to another of lower dimensions, by division, according to the known theory of equations; thus, let the proposed equation be

\[x^n - 5 x^{n-1} + 7 x^{n-2} + 7 x^{n-3} - 5 x + 1 = 0\]

Here \(x = -1\) is obviously one of the roots, as this substituted for \(x\) renders the whole equal to zero; and consequently the whole equation is divisible by \(x + 1\), according to the known theory of equation, which division being made, we have, for our reduced equation,

\[x^4 - 6 x^3 + 13 x^2 - 6 x + 1 = 0\]

which is now of even dimension one degree less than the original equation, and still reciprocal. We need, therefore, only consider equations of the latter form; viz. those of which the index of the highest power is an even number.

Let \(x^n + p x^{n-1} + q x^{n-2} + \ldots + &c. q x^2 + p x + 1 = 0\) be any reciprocal equation, whose roots are \(a, \frac{1}{a}; b, \frac{1}{b}; \ldots\), etc.
RECIPECAL EQUATIONS.

Find the two values of \( z \) in the equation \( z^2 + (p - 1) \)
\[ z + q - p - 1 = 0, \]
and call them \( r, r' \); then \( x = -1 \)
\[ x = \frac{r}{2} \pm \sqrt{\left(\frac{r}{2} \right)^2 - 1}, \]
6th deg. \( x^4 + p x^3 + q x^2 + r x + s = 0 \); then
\[ x = \frac{r}{2} \pm \sqrt{\left(\frac{r}{2}\right)^2 - 1}. \]

Find the three values of \( z \) in the cubic equation \( z^3 + \)
\[ (q - 3) z + r - 2 p = 0, \]
and call them \( r, r', r'' \); then
\[ x = \frac{r}{2} \pm \sqrt{\left(\frac{r}{2}\right)^2 - 1}. \]

Find the three values of \( z \) in the cubic equation \( z^3 + \)
\[ (q - 3) z + r - 2 p = 0, \]
and call them \( r, r', r'' \); then
\[ x = \frac{r}{2} \pm \sqrt{\left(\frac{r}{2}\right)^2 - 1}. \]

7th deg. \( x^3 + p x^2 + q x^2 + r x + s = 0 \); then
\[ x = \frac{r}{2} \pm \sqrt{\left(\frac{r}{2}\right)^2 - 1}. \]

Find the three values of \( z \) in the cubic equation \( z^3 + \)
\[ (q - 3) z + r - 2 p = 0, \]
and call them \( r, r', r'' \); then
\[ x = \frac{r}{2} \pm \sqrt{\left(\frac{r}{2}\right)^2 - 1}. \]

8th deg. \( x^3 + p x^2 + q x + s + \ldots + q x^2 + p x + 1 = 0. \)

Find the four values of \( z \) in the equation \( z^4 + p z^2 + \)
\[ (q - 4) z^2 + (r - 3 p) z + s - 2 q - 1 = 0, \]
and call them \( r, r', r'', r''' \); then
\[ x = \frac{r}{2} \pm \sqrt{\left(\frac{r}{2}\right)^2 - 1}. \]

Find the four values of \( z \) in the equation \( z^4 + (q - 3) z^2 + \)
\[ (r - 3 p) z + s - 2 q + 1 = 0, \]
and call them \( r, r', r'', r''' \); then \( x = -1 \)
\[ x = \frac{r}{2} \pm \sqrt{\left(\frac{r}{2}\right)^2 - 1}. \]

Find the four values of \( z \) in the equation \( z^4 + (q - 3) z^2 + \)
\[ (r - 3 p) z + s - 2 q + 1 = 0, \]
and call them \( r, r', r'', r''' \); then \( x = -1 \)
\[ x = \frac{r}{2} \pm \sqrt{\left(\frac{r}{2}\right)^2 - 1}. \]

A reciprocal equation of the 10th and higher powers,
requires the general solution of equations of the 5th and
higher powers, and therefore cannot be exhibited analyti-
cally. Bonnycastle’s Algebra, vol. i.

Binomial equations are all reciprocal equations of a pecu-
nular kind, which renders them all solvable by means of
certain trigonometrical formulæ.

Binomial equations are all reducible to the form \( x^n \pm 1 \)
\[ = 0; \] or \( x^n = 1; \) or \( x^n = -1. \) Where it is obvious,
that if \( m \) is even, or \( m = 2 n, \) then \( x^n = 1 \) will have two
real roots, viz., + 1, and - 1; and \( x^n = -1 \) will have
two of its imaginary roots + \( \sqrt{-1} \), and - \( \sqrt{-1} \), so
that, in both cases, such an equation may be reduced two
degrees lower, by dividing it by \( x^2 - 1 \), or \( x^2 + 1 \), and
the resulting equation will be a reciprocal one, having
each of its co-efficients equal to unity. If \( m \) be odd, then
the equation will necessarily have one real root, and no
more, which will be + 1 in the first case, and - 1 in the
second; consequently, such an equation can be reduced but
one degree, the fame as those above stated. We may, there-
fore, find a direct solution for all binomial equations of odd
dimensions as far as the 9th power, and of even dimensions
as far as the 10th power, by the principles and formulae al-
ready given, by merely making \( p = 1, q = 1, r = 1, \) &c.
and it would, therefore, be useless to repeat them again in
this place; we shall proceed immediately to the general
solution of binomial equations, on the principles of analyti-
cal trigonometry.

All the imaginary roots of the equation
\[ x^n - 1 = 0 \]
are
Reciprocal Equations.

are contained in the general formula

\[ x^n - 2 \text{ cof.} \frac{2 \pi}{n} x + 1 = 0; \]

\( k \) being any integer not divisible by \( n \), and \( \pi \) representing the semi-circumference. For it is a known trigonometrical property, that if

\[ 2 \text{ cof.} y = x + \frac{1}{x}; \]

then \( 2 \text{ cof.} n y = x^n + \frac{1}{x^n}; \)

from which two equations we readily draw the following; \( \text{viz.} \)

\[ x' = 2 \text{ cof.} \ y \cdot x + 1 = 0 \]

\[ x'^n = 2 \text{ cof.} n y \cdot x^n + 1 = 0 \]

which have necessarily one common root, being both derived from the same value of \( x \); and since these are both reciprocal equations, if \( x \) be one root, \( \frac{1}{x} \) will be another; they have therefore two roots common, and consequently, from the known theory of equations, the former is a divisor of the latter. If, now, we make \( y = \frac{2 \pi}{n} \), or \( n y = 2 \pi \), these equations become

\[ x^n - 2 \text{ cof.} \frac{2 \pi}{n} x + 1 = 0; \]

\[ x^n - 2 \text{ cof.} 2 \pi x^n + 1 = 0; \]

But the \( \text{cof.} \frac{2 \pi}{n} = 1, 2 \pi \) representing the whole circumference; therefore the latter equation is the same as

\[ x^n - 2 x^n + 1 = 0, \]

or \( (x^n - 1)^2 = 0, \)

having still for its divisor

\[ x' = 2 \text{ cof.} \frac{2 \pi}{n} x + 1 = 0; \]

that is, the roots of the equation

\( (x - 1)^2 = 0, \) or \( x^n - 1 = 0, \)

are all contained in the general formula

\[ x^n - 2 \text{ cof.} \frac{2 \pi}{n} x + 1 = 0; \]

and, therefore, by giving to \( k \) the successive values 1, 2, 3, \ldots \( \frac{1}{2} (n - 1), \) the following formulae will be obtained; \( \text{viz.} \)

\[ x^n - 2 \text{ cof.} \frac{2 \pi}{n} x + 1 = 0; \]

\[ x^n - 2 \text{ cof.} \frac{4 \pi}{n} x + 1 = 0; \]

\[ x^n - 2 \text{ cof.} \frac{6 \pi}{n} x + 1 = 0; \]

\[ x^n - 2 \text{ cof.} \frac{(n - 1) \pi}{n} x + 1 = 0; \]

which contain among them all the imaginary roots of the equation \( x^n - 1 = 0. \)

And if, instead of making \( y = \frac{2 \pi}{n}, \) as above, we make \( y = \frac{(2k + 1) \pi}{n}, \) our second formula becomes

\[ x^n + 2 x^n + 1 = 0, \] or \( (x^n + 1)^2 = 0; \)

because \( \text{cof.} \frac{(2k + 1) \pi}{n} = -1. \) Consequently, the equation \( x^n + 1 = 0, \) or \( x^n = -1, \) will have for its general factor

\[ x^n - 2 \text{ cof.} \frac{(2k + 1) \pi}{n} x + 1 = 0; \]

which, by substituting for \( k \) as above, becomes

\[ x^n - 2 \text{ cof.} \frac{1 \pi}{n} x + 1 = 0; \]

\[ x^n - 2 \text{ cof.} \frac{3 \pi}{n} x + 1 = 0; \]

\[ x^n - 2 \text{ cof.} \frac{5 \pi}{n} x + 1 = 0; \]

&c. &c.

which formulae contain all the imaginary roots of the binomial equation \( x^n + 1 = 0. \)

Suppose, for example, all the imaginary roots of the binomial equation \( x^3 - 1 = 0 \) were required.

Here we should have

\[ x^3 - 2 \text{ cof.} \frac{360^\circ}{11} x + 1 = 0; \]

\[ x^3 - 2 \text{ cof.} \frac{3 \cdot 360^\circ}{11} x + 1 = 0; \]

\[ x^3 - 2 \text{ cof.} \frac{4 \cdot 360^\circ}{11} x + 1 = 0; \]

\[ x^3 - 2 \text{ cof.} \frac{5 \cdot 360^\circ}{11} x + 1 = 0; \]

whence,

\[ x = \text{cof.} \frac{360^\circ}{11} \pm \sqrt{\left(\text{cof.}^2 \frac{360^\circ}{11} - 1\right)} \]

\[ x = \text{cof.} \frac{720^\circ}{11} \pm \sqrt{\left(\text{cof.}^2 \frac{720^\circ}{11} - 1\right)} \]

\[ x = \text{cof.} \frac{180^\circ}{11} \text{ &c.} \]

And if the roots of \( x^3 + 1 = 0 \) were required, we should have from the second general formula

\[ x^3 - 2 \text{ cof.} \frac{180^\circ}{11} x + 1 = 0; \]

\[ x^3 - 2 \text{ cof.} \frac{3 \cdot 180^\circ}{11} x + 1 = 0; \]

\[ x^3 - 2 \text{ cof.} \frac{5 \cdot 180^\circ}{11} x + 1 = 0; \]

&c. &c.

Whence,

\[ x = \text{cof.} \frac{180^\circ}{11} \pm \sqrt{\left(\text{cof.}^2 \frac{180^\circ}{11} - 1\right)} \]

\[ x = \text{cof.} \frac{540^\circ}{11} \pm \sqrt{\left(\text{cof.}^2 \frac{540^\circ}{11} - 1\right)} \]

\[ x = \text{cof.} \text{ &c.} \]

For more on this subject, see Barlow's Theory of Numbers, Bonnycastle's Algebra, and our article Polygon.

Reciprocal Figures, in Geometry, are such as have the antecedents and consequents of the fame ratio in both figures. See Plate XII. Geom. fig. 2. Here

\[ A : B :: C : D, \]

or, \[ 12 : 4 :: 9 : 3 \]

That
That is, as much longer as the side A, in the first rectangle, is than the side B of the second rectangle; so much deeper is the side C in the second rectangle, than the side D in the first; and, consequently, the length of one is compensated by the depth of the other.

Also, as the side A is \( \frac{1}{4} \) longer than the side C, so the side B is \( \frac{1}{4} \) longer than D: wherefore the rectangles must be equal.

This is the foundation of that Catholic theorem; that the rectangle of the extremes must always be equal to that of the means; and, consequently, the reason of the rule of three, or golden rule.

For, suppose there were given any three numbers, or quantities, geometrically proportional, as A, B, and C; and, that it was required to find a fourth, D, proportional to them: since A : B :: C : D, therefore A D = B C, and, consequently, \( D = \frac{A B}{C} \); that is, the fourth term is equal to the quotient of the second, multiplied by the third term, divided by the first.

Or, thus in numbers; suppose given \( 12, 4, \) and 9, required a fourth proportional. Now as \( 12 : 4 :: 9 : Q \).

But \( 12 = 4 \cdot 9 = 36 \). Therefore \( Q = \frac{4 \cdot 9}{12} = 3 \),

by dividing both sides by 12.

And hence it follows, that if any two triangles, parallelograms, prisms, parallelepipeds, pyramids, cones, or cylinders, have their bases and altitudes reciprocally proportional, those two figures or solids are equal to one another; and, vice versa, if they are equal, their bases and altitudes are reciprocally proportional.

*Reciprocal Proportion*, is when in four numbers the fourth is less than the second by so much as the third is greater than the first; and vice versa. See *Proportion*.

This is the foundation of the inverse, or indirect rule of three. Thus, \( 4 : 10 :: 8 : 6 \).

Great use is made of this reciprocal proportion, by sir Isaac Newton, and others, in demonstrating the laws of motion.

*Reciprocal Theorem*. See *Theorem*.

Reciprocally, the property of being reciprocal; thus we say, that in bodies of the same weight, the density is reciprocally as the magnitude; *viz.* the greater the magnitude the less the density; and the less the magnitude the greater the density; so again, the space being the same, the velocity is reciprocally as the time, and the contrary.

*Reciprocity*. The law of reciprocity is a term used by Legendre, in his "Theory of the Names," to denote a reciprocal law, which has place between prime numbers of different forms; which is this; that \( m \) and \( n \) being prime odd numbers,

\[
\text{the remainder of } m^2 \div n = \text{the remainder of } n^2 \div m
\]

provided \( m \) and \( n \) are not both of the form \( 4x - 1 \), and if they are both of this form, then

\[
\text{the remainder of } m^2 \div n = -\text{the remainder of } n^2 \div m,
\]

or they will have only contrary signs.

*Recess*, in *Law*. See *Ademption*.

*Recit*, Fr., a generical term in music, for what is sung by a single voice. It is likewise applicable to instruments; as, recit de baffe, recit de hautbois, a solo part for the violoncello or hautbois. Indeed *recit*, in French, seems synonymous with the word *sol* in Italian, to whatever vocal or instrumental part it is applied, in opposition to *tutti*, or chorus, in which the whole band is employed.

*Recit* in France is not only a technical term in music, but in the drama, where, at the opening of a tragedy, or subsequent to an event, it implies an account, a narration, the recital of an event. In the French and Italian tragedies, in imitation of the Greeks, battles and murders are always recited, but never translated on the stage.

*Recitativo*, in *Laus*, the rehearsal, or making mention, in a deed or writing, of something which has been done before.

*Recitativo* is not conclusive, because it is no direct affirmation; and by feigned recitals in a true deed, men might make what titles they pleased, since false recitals are not punishable. If a perfon, by deed of allignment, recite that he is possesfed of an interest in certain lands, and assign it over by the deed, and become bound by bond to perform all the agreements in the deed; if he is not possesfed of such interest, the condition is broken; and though a recital of itself is nothing, yet being joined and considered with the rest of the deed, it is material. And where it is but a recital, that before the indenture the parties were agreed to do such a thing, it is a covenant, and the deed itself confirms it. The recital of one leafe in another, is not a sufficient proof that there was such a leafe as is recited. But the recital of a leafe in a deed of release, is good evidence of a leafe against the releflee, and those who claim under him. A new revocracy leafe shall commence from the delivery, where an old leafe is recited, and there is none, &c. *A* recites that he hath nothing in such lands, and in truth he has an eftate there, and makes a leafe to B for years; the recital is void, and the leafe good.

In this case, if the recital were true, the leafe would not bind.

*Recitation*, the act of reciting, or delivering a discourse, either in the way of narration, rehearsal, declamation, or the like.

*Recitativo*, It., *Recitative*. The Cursi Dictonary gives no more early authority for the use of this word, as a musical term, than that of Batifta Doni, de Preilt. Mus. Veteris, published in 1647; who defines it, "a musical composition in an andante or plain style, different from air; it is used in narrative poetry, in imitation of reciting on the stage."

Roulleau's definition is more full and clear. He terms it "a discourse, or speech, in musical and harmonical tones. It is a melody nearly approaching to common speech; a musical declamation, in which the musician ought to imitate, as much as possible, the inflections of voice in declaiming. This melody is called recitative, because it resembles a narration, a recital; and is used in the dialogue of musical dramas."

We have presented our readers, under the article *Opera*, with extracts from the prefaces of the poets and composers by whom recitative was invented, as well as from contemporay writers, who thought its origin of sufficient importance to be recorded.

Giovanni Batifta Doni, about the middle of the 17th century, (Op. Om. tom. ii. in Firenze, 1763, folio,) a learned and elegant writer on music, though extremely warped in his judgment by a predilection for the music of the ancients, in a dissertation on the Origin of Stage-singing, during his own time, gives so curious and instructive an account of the first operas that were performed at Florence, that we shall translate a part of it.

"Some kind of cantilena, or melody, has been introduced in
in dramatic representations, at all times, either in the form of intermezzi (interludes), between the acts; or, occasionally, in the body and burthen of the piece. But it is still fresh in the memory of every one, when the whole drama was first set to music, and sung from the beginning to the end.”

The revival of theatrical music was brought about by the invention of recitative, as we have already itated in our article Opera.

“The beginning of this century (1600) was the era of musical recitation on the public stage at Florence, though it had been used there in several private exhibitions before. There reeded in that city, during these times, Signor Gio. Bardi de Conti di Verno, who was afterwards called to the service of pope Clement VIII., by whom he was tenderly beloved, and made his madrigal di camera. This most accomplished nobleman was particularly attached to the study of antiquity, and to the theory and practice of music, to which he had applied himself for many years so closely, that he became, for the time in which he lived, a correct and good composer. His house was the constant rendezvous of all persons of genius, and a kind of flourishing academy, where the young nobility often assembled to pass their leisure hours in landable exercises and learned discourse; but particularly on musical subjects, when it was the wish of all the company to recover that art of which the ancients related such wonders, as well as other noble inventions, which had been ruined by the irritations of barbarians.

“During these discussions, it was universally allowed that as modern music was extremely deficient in grace, and the expression of words, it became necessary, in order to obviate these objections, that some other species of cantilena, or melody, should be tried, by which the words should not be rendered unintelligible, nor the verse destroyed.”

Euridice was the first musical drama after the invention of recitative. It was written by Ottavio Rinuccini, set by Jacopo Peri, and performed at Florence in 1600, on occasion of the marriage of Mary of Medicis with Henry IV. of France. The poem and the music were published separately the same year. The poet, in his dedication to the queen of France, says, “It is generally imagined that the tragedies of the ancient Greeks and Romans were entirely sung; but this noble kind of singing had not till now been revived, or even attempted, to my knowledge, by any one; and I used to think, that the inferiority of our music to that of the ancient was the cause; till hearing the compositions of Jacopo Peri to the fable of Daphne, I wholly changed my opinion. This drama, written merely as an experiment, pleased so much, that I was encouraged to produce Euridice, which was honoured with full more applause, when sung to the music of the same composer Jacopo Peri, who with wonderful art, unknown before, had merited the favour and protection of the grand duke our sovereign, it was exhibited in a most magnificent manner at the nuptials of your majesty, in the presence of the cardinal legate, and innumerable princes and nobles of Italy and France.”

Such is the abridged history of recitative. The only printed copy of the music to this primitive opera was in the library of the marchese Rinuccini, a descendant of the poet at Florence: in examining and making extracts from which, we observed that it was printed in fcore, and barred; two very uncommon circumstances at the time of its publication; that the recitative seemed to have been not only the model of subsequent composers of early Italian operas, but of the French operas composed by Lulli, a native of Florence; and that the time was as frequently changed as in the old French operas.

The confusion arising from all the parts singing different words at the same time, together with some other circumstances, mentioned under Opera, account for the necessity of a recitative, or a musica parlante, a speaking music, and for solo singing in general on the stage: besides, poetry was injured, and rendered unintelligible in fugues, canons, and in choruses, full of imitations and contrivances, all unfit for narration and dialogue.

To describe the characteristic difference of recitative from air, and common speech; it is not air, as no time is kept; it is not speech, as every inflexion of voice is in tune with some one note of the instrument by which it is accompanied; and as to the length or shortness of the notes that are written, the accompanier watches for the accents or termination of phrasal, or lines in the verse, to give the chord to which the note that is sung belongs.

It is sometimes accompanied by the orchestra with ritornelli, or interlithical symphonies; but then a regular time must be kept. This only happens in solemn scenes of dignity or diffuseness, and in folellos.

No flats or sharps are placed at the clef in recitative; these are all regarded as accidental; nor is Italian recitative ever confined to any one key.

After recitative was found, it was long ere any thing like an air appeared in these musical dramas. (See Opera, Air, Motivo, and Measure.) Roussel has treated the article recitative at large, with great intelligence and good taste.

Recitative Style, is the way of writing accommodated to this sort of music.

RECIV, LA, in Geography, a well-fortified town of Brazil, in the jurisdiction of Ferneambuco.

RECKENITZ, a river which separates the duchy of Mecklenburg from Pomerania, and runs into a lake, which communicates with the Baltic near Ribnitz.

RECKHEIM, or REKUM, a town of France, in the department of the Lower Meuse, which gives name to a county, situated on the W. side of the Meuse, and surrounded by the bishopric of Liege; 7 miles N. of Maestricht.

RECKLING, in Rural Economy, a provincial word, signifying the tail of the farrow or brood of pigs, poultry, or other farts of domestic birds.

RECKLINGHAUSEN, in Geography, a town of Germany, fortified by a castle, and capital of a county of the same name, which is situated between the bishopric of Munster, the duchy of Cleves, and the county of Mark; 16 miles S.S.W. of Munster.

RECKON, in Rural Economy, a term sometimes applied to a pair of pot-hooks of a certain make, occasionally employed in dragging wells, ponds, &c.

RECKONING, in Navigation, the act of estimating the quantity of a ship's way; or of the distance run between one place and another.

Or, more generally, a ship's reckoning is that account, by which at any time it may be known where the ship is, and on what course or courses she is to steer to gain her port. See Log-Board, Log-Book, and Journal.

This is usually performed by means of the log-line; the manner of applying which, see under its proper article, Log-Line.

Yet this is liable to great irregularities. Vitruvius advices an axis to be passed through the sides of the ship, with two large heads projecting out of the ship, in which are to be included wheels touching the water, by whose revolution the space passed over in any given time may be measured. The fame has since been recommended by Snellius; but
but there are few who have written of navigation, that have not shown the insufficiency of this method.

RECKONING, Dead. See Dead Reckoning.

RECKSON, in Geography, a town of Bengal; 6 miles E. of Calcutta.

RECLAIMING, or Reclaiming, in our Ancient Customs, the action of a lord purifying, professing, and reclaiming his vassal, who had gone to live in another place, without his permission.

Reclaiming is also used in a similar sense, for the demanding of a person or thing to be delivered up, or surrendered, to the prince or state it properly belongs to; when, by any irregular means, it has come into the possession of another.

Reclaiming, in Falconry, is the calling of a hawk, or bird of prey, back to the fill.

The sparrow-hawk, goshawk, &c. are reclaimed with the voice; the falcon only by flaking the lure. So that the term turling, with regard to the falcon, is more proper than reclaiming.

The partridge is also said to reclaim her young ones, when she calls them together upon their scatttering too much from her.

Reclaiming is also used for taming animals that are wild by nature.

Reclaiming, in a monastic fenne. See Religious.

Reclaiming Lands, in Agriculture, the business of refloping and bringing them into a state of cultivation and improvement. There are various kinds and flates of land, which admit of this fort of amelioration and improvement; as among the wet forts, all thofe of the bay or elfuary description, which are washed and occasionally covered by the sea or other waters; different defcriptions of fent lands, and thofe of the more firm marchy nature, and thofe in more interior situations, which are of a loofe swampy or watery quality, as marshy and boggy grounds. And among thofe of the more dry, hard, watery, and wild defcriptions; all the varieties of the rough rocky forts of unimproved lands; the many different kinds of rough woody grounds; and the numerous forts of moory lands, as well as other varieties, which are now and then to be met with in particular circumfiances and situations.

The fill of the wet or watery forts of land, noticed above, are far from being always ready, or in a ripe flate for admitting improvement of this nature; yet in different ficulties and circumfiances, they occasionally permit of its being accomplished, withoUt any great difficulty or trouble. See Embankment, and Embanking against the Sea.

The fanny and marshy lands, where, in the former, they are wholly or only in a partial manner overgrown by ufelefs aquatic plants; and in the latter, become fo firm as to bear a pattering flock, and to afford nutritional herbage for their growth and fupport, but are notwithstanding flill liable to be overflowed by high tides, or land floods; are, of coarse, capable of very great improvement in the above ways, as well as by many other means. See, Fen, Fenney Lands, Marshy Land, and Salt Marsh.

These forts of watery lands are not incident to the flat bays and inlets of the sea-coasts, or the mouths of the larger rivers, in a particular manner; but are met with in the more inland circumfances of the country, accompanying the larger rivers and waters in the more central parts of the kingdom: consequently such forts of improvement must be very extensive in their nature, and of very great importance to the nation.

The other kinds of swampy watery lands, which are liable to be covered with that fluid during wet feafons; thofe on the fides of lakes and ponds; the morasses which are choked and grown up with aquatic vegetation, fo as to have some fort of hardifh crust formed upon them; and the soft boggy lands, formed in somewhat familiar ways, are all capable of allowing great improvement, by fuitable draining, and other methods of management. See Spring and Surface Draining, Swamp, Bog, and Morass.

Lands of the above kinds are mostly met with on the lower flopes, or at the feet of hilly grounds; being caufed by the flagration of water in their internal parts, which has the effect of chilling and rendering them too moif for the production of a nutritious and useful herbage, as well as of promoting the growth of coarse plants of the aquatic nature, though their circumfances may occasionally have some degree of relative height.

There are many valuable tracts of land of thofe kinds, in many different parts of the illand, which have been already reclaimed by thofe methods of proceeding; which fhoul have the effect of stimulating the owners of fuch lands in other places, where they flill remain unimproved, to exert themselves in getting them reclaimed.

Among the more dry kinds of unimproved lands, the fill, or thofe of a rough, itony, waite quality, are all thofe in the vallies of hilly or mountainous tracts, on the skirts or lower parts of mountainous heights, and the rough itony lands, fit for cultivation, in other circumfances. They are the most readily reclaimed and improved, in the lefs hilly forts of lands and circumfiances. In fome caves, where the surfaces of the ground were in a great meafure covered by large rocks and itones of great fizes, very hard in their qualities, and of fcarcefly any value, the lands have been reclaimed, and brought into an arable state, and let for high rents: the itones which were removed paying, in a great degree, the expences of the labour; they being exported and fold as paving-tones, and for other ufe to the metropolis. And though this cannot always be done, it fhews what is capable of being performed by industry and perfeverance; and that, where surface itones can be turned to ufeful purpofes, the most rugged and barren lands may be reclaimed with advantage, under proper modes of management. In fuch circumfances, instead of leaving the surfaces of the grounds in worfe ftates than they were before, by being taken up with pits, and heaps of ufelefs rubbifh, which buried the better moulds, as is common in working superficial quarries, the pits and other hollows were levelled, and filled up to fome height, with the coarse and rubbifh materials produced in the courfe of the works, and the finer mould from other parts thrown back upon the above rubbifh materials, fo as to form an even top-foil; the larger spaces of the ground being trenched over to a good depth, leaving the belt foil on the surface. It is fuggested, that by following fimilar easy methods of management, in carrying on other undertakings of the fame kind, lands of a value in proportion to that of the materials which are removed, may commonly be created, without incurring any very great expence. Hence it is thought to behave thofe who have the direction and management of landed eftates, that comprehend grounds of thofe forts, to examine and consider well whether the itony materials which they contain, and encumber their surfaces, cannot be turned or converted to some profitable purpofe, by the means of roads, iron railways, canals, or fome other easy mode of conveyance for fuch heavy substances.

It must be noticed, however, that the method of levelling and trenching over the lands by the fpade, in fuch circumfances, can only be practifed in a very few cafes, where labour is particularly cheap.

There is another description of itony lands, of a much less
lefs formidable nature, which frequently stands in need of being reclaimed, and in which the surface is lefs encumbered than the interior parts of the soil. In these cases, the interrupting materials are rather large stones than rocks, though the latter may sometimes in part form them. The means which are best suited to the bringing of these into a profit-
able state of cultivation, are to be found in the more northern parts of the island, in the practice and exertions of particular spirited individuals. The plan of the improvement is perfectly simple, but it is expensive in its performance; the whole of the lands being turned over by means of the spade, to a proper depth, as from one to two feet. The stones which are not wanted for use are thrown into pits, and the hollow parts, to contribute to their being made level, and sometimes into the deep trenches formed in digging, being first covered over with the worst of the earthy materials, upon which the better moulds and turfy sub-
stance, which are flirred in the work, are spread out as a foil, by which the whole is rendered very suitable for agricul-
tural purposes.

The cost of reclaiming lands in this way depends, in some measure, on the ease of surface in the lands, the nature of the interrupting matters, and the depth of the earthy sub-
fstances to be removed, in raising a sufficiency of mould for forming the surface foil: but from five to twenty pounds the acre may be considered as the limits of the charges.

And this, it is supposed, leaves an ample profit in the sale of such lands, or otherwise, in these situations where tythes are not taken, and where the rates and taxes are so very few and trifling, and where labour and living is so cheap. It can now, however, be done in this manner in but few instances, as has been already noticed.

It is, notwithstanding, believed that there are very many lands, not only in these northern parts, but in England and Wales, that would more than repay the expenses of this spirited mode of improvement. It may be remarked, that where the stones are very large, or where fragments of rocks are met with, in these undertakings, they may be got rid of either by blasting, or rendering their upper parts, or by linking them in the foil, so as to allow the plough to pass over them with safety.

The former method is more suited to the soft sorts of stones; the latter to those of the harder kinds.

Such rocky grounds as are common in hilly and moun-
tainous situations, which, on account of their climate, and the compact nature of the rocky materials, as well as their quantity, are incapable of being cleared as corn-lands, or so as to admit the plough, may often be reclaimed and improved as pastures lands for sheep, &c. or sometimes as hay lands. The plan of proceeding, in these cases, is that of removing the flinty matter from the surface, and allowing it entirely to the growth of grassy herbage; the means of accom-
plishing which are similar to those already noticed, but the cost considerably less: the main intention here being merely the smoothing of the surface ground, for the pur-
poses of pasturing or mowing: but the more the flinty sub-
fstances are covered with good earthy mould, the better and greater will be the quantity of produce. See Til-
lage.

There are many rough woody tracts of ground, of the shabby or other kinds, which may be cleared and reclaimed with vast advantage to their proprietors, as well as the com-
munity in general, as corn-lands, or for other uses. The most usual method of accomplishing this sort of improve-
ment has been to dig out the whole of the roots, whether of low woods or timber woods, at the time of removing the tops, so as to admit the plough immediately. In perform-
ing this in this way, however, where the flooris are of the timber kind, numerous and large, deep breaking of the ground is often necessary, which is laborious and expensive; and rotten wood, mould, leaves, and other surface matters, are apt to be left in mixture with the fertile or poisonous sub-sera. As lands, cleared and reclaimed in this manner, have been known to remain in a raw unprofitable condition, for several years, although limed, dunged, and raised in sharp ridges, in order to its amelioration.

This improper practice has consequently been highly disadvantageous, injurious, and ruinous, and thrown much difficulty and interruption in the way of clearing and reclaiming such waste lands for the growth of corn, however suit-
able they may be for the purpose in the nature of their soils and situations, thereby tending to propagate and support the notion, that such sorts of land will not repay the ex-
penses and trouble of being improved.

But from attending to what has naturally happened to the cleared parts of wood-lands, it will be seen that a depth of fertile mould, resting on lefs fertile substanstes, form a regular foil and sub-foil, which are free from the roots of trees, ready to receive the plough, and afford corn crops in due succetion. This is supposet to take place somewhat in this way. The trees having been suffered to become decayed, or more properly cut down in due season, and the brash or underwood cut and cleared away from time to time by the occupiers, while such commons or other places were fully or too much stocked with cattle and sheep, the young shoots were of course browsed off and nibbled away, quite to the stumps, consequently weakenet, and at length finally destroyed. The roots and other parts of them followed this course, and pulled into a foilte of vegetable mould, in-
creating and enriching the foil at the same time. Nay, this may, in the natural state, it is supposet, be, in some me-
asure, effected alone by the grazing animals, as it is essential to their exilence.

This natural process, however afflieted in this way, is flow, requiring a length of time for its completion; yet by proper means of art, well applied, it may be accomplished in a few years; the larger roots being extracted from the ground, instead of waiting for their reduction by a slow decay, without any unnecessary disturbance of the sub-foil; and then filling in the pits by the rough buried of the natural surface; by which means the cleared ground will be smoothed, and made fit in due time for being cultivated. Where the surface is much encumbered with leaves and rotten woody matters, they are to be raked up, and put into heaps to decay; or they may be burnt, and the ashes spread out over the surface of the land. Proper draining and fur-
ther levelling multt likewise take place, where necessse; as well as harrowing or hacking the surface (ward, so as to fow it with proper grafts seed; again raking off any rubbish that may arise, and then rolling the whole quite smooth for mowing. It should be stocked hard, especially with sheep, mowing off occasionally any woody shoots that may be per-
mitted to arise; keeping the whole in the state of clofe pat-
turage, until the smaller roots, which were left, be so decayed as to become obedient to the plough-share. At this period, but not before, such pasture ground may be broken up for grain crops in proper succession.

The proceeds might be haled by the use of lime, or other calcaeous matters in union with the vegetable sub-
fstances which were removed, as they would be sooner dis-
folved or reduced, and the compost be more rich. And by sreading them out on the land a simitar effect might be produced, and a finer sort of herbage be encouraged, which would cause a clofer bite, and sooner bring the land into a more
more thick let state of sward, which is the prolific matrix for corn crops.

The really necessary expense of reclaiming and bringing these kinds of wooded lands into a state of cultivation, by these means, is inconsiderable, particularly where fuel is dear. Where the timber wood is properly cut down by the axe, and the underwood taken off rather below the surface, the larger roots, and the stumps which are left, will, in some instances, more than repay the cost of the clearing and levelling the surface. And the other expenses will be repaid by the immediate production of a suitable ground, the value of which is constantly increasing without any further charge, until it may probably be worth two or three times what the lands were while they were in the woody condition.

In cafes where fuel is cheap, and particularly when the timber wood is rapidly fallen, as in the barking lea, they may be cut off by the law level with the surface of the land; the tools and large superficial roots being after that carefully diskarded to some inches within the ground, so as to prevent their throwing out shoots to injure the surface and keep the roots alive. In this way the tools will be so decayed in a few years as to be capable of being removed with little trouble or expense. See Tillage.

In clearing and reclaiming moory lands where they are too wet, the first step is that of properly draining them; they are afterwards brought into cultivation and to their full value by other means, such as in large undertakings, by suitable divisions of the lands into fields proper for the farm or farms to which they are to be let, and so ditched that the surface water may be effectually taken off, without having deep, open, expensive troublesome drains in other parts; the surface of each field being adjusted in such a manner as to shoot off the rain water into the intersecting ditches, in order to prevent injury from happening, in that way, so as to impede the cultivation for any length of time.

As the surfaces of these kinds of land are mostly rugged and uneven, as well as of a loose spongy texture, which unfit them for the tillage processes, without previous affluence from hand labour; where the moory earth, or vegetable mould, is deep, and rises to the surface uncovered by fossil matters, some length of time is requisite to bring it to that solidity and firmness of texture which is suited to the common arable purposes. Hence the general principle of improving deep moory lands, where there is no fossil covering, is supposed to be the same as that advised for bringing woodlands into cultivation; namely, that of converting them to a profitable state of herbage, before corn crops are attempted to be produced.

The process must be guided and regulated by the nature and situation of the tract to be improved. Where the surface is very irregular, full of inequalities, and of an abrupt nature, it must first be adjusted so as to admit the means of tillage when they can be properly had recourse to, and for carrying away the surface waters in the manner already noticed. Then to pare off the lesser hillys and risings, as the tufts and hillocks which were formed during its wet state, and more or less of its general surface, so as to remove the coarse plants and flake mould which occupy it, and thereby produce a fresh face in the whole.

In dry seasons, when the surface has sufficient firmness to bear the tread of animals, the paring may be done by the plough for that purpose, but in other cafes by the breast-plough or paring-fpade. When the surface has been cut over in this manner, and any part has the appearance of being too wet, as may be judged of by the colour of the mould, in some degree, covered drains are to be formed in such places, which may commonly be made in a cheap and durable manner by the firm fibrous tufts collected from the surface. The rest of the roots and mould which were pared off should be burnt, and their ashes spread evenly over the surface, being immediately raked or harrowed into the soil. At this period of the improvement almost any kind of fossil material can be thrown over the ashes at a little expense; and a full quantity of different fossil seeds be covered in with it; leaving the surface to take on a sward without any further trouble or outlay of money.

Afterwards the grassy herbage is to be kept closely fed down when the weather will permit, first by sheep and then by heavier farts of stock, until the surface becomes firm and the soil is well bound together by the fibrous roots of the herbage, so as to be capable of affording corn crops in proper succession.

It has been objected to this summary mode of bringing the land into the state of herbage, that there are no immediate gros returns for the money laid out in reclaiming and bringing it into the cultivable state. But although corn cannot be raised on such raw loose-textured forts of land at first, potatoes are found to answer well, and rape with still more advantage in its culture, the labour attending it, and the profit which it affords. See Moor, Moory-Land, Spring and Surface Draining, &c. See also the Inverness-shire Agricultural Report.

The reclaiming and bringing lands of these several different descriptions into a state of cultivation and improvement is evidently a work of very great importance, particularly in a country where the population is getting too numerous for the produce, as by such means the extent of agricultural territory may be suitably laid to be increased. Extensive improvements of these kinds have lately taken place in Cornwall, and some other southern districts.

Reclaiming Plantations and Timber Woods, in Rural Economy, the restoring of such as have grown into a wild, neglected, and improper state from some fort of mismanagement, or want of attention. The caufes which have a tendency to produce this effect are very numerous, and have been the means of vall individual as well as national loss. One material and very frequent cause is the neglect of their boundary fences; another is the mistaken notion of its being the best practice to leave them entirely to nature after they are once properly planted; a third is the very absurd supposition, that nothing should be done to them for a length of time after planting, in the way of rendering the trees more thin among themselves, or in their branches; and lastly, an universal carelessness and disregard of them, frequently from the narrow conceptions of expense being incurred without the chance of any immediate return of profit. It is, on the whole, much too common to take great care in first forming the plantations, without ever thinking or taking any fort of interest in their after-management. But the business is by no means accomplished in the simple act or operation of planting out the trees. Good examples of this kind of management are indeed few, but they occasionally exist, and much has been written on the matter, so that information may be readily obtained. And there is every inducement to get it; as well prepared, inclosed, planted, cultivated and managed plantations, will far outgrow others that have existed for a much longer time, but have been otherwise treated, often affording more than woods of three times their length of standing.

In directing the proper management in all cafes of this nature, some attention must be paid to the particular kinds of the plantation which they may be, in the first place; after which, the means of reducing them to their appropriate states, or to some other in the most easy and convenient manner, Vol. XXIX.
manner, may be taken into consideration. It may often happen that their proper originally intended states cannot be attempted, but that which has been gradually acquired must be promoted. With a view to the accomplishment of these intentions, plantations may be considered as consisting either of hard woods only, of evergreen or resinous trees only, or of both these sorts of trees in mixture.

In the first of these kinds, or those which are composed solely of the hard-wooded sorts of trees and plants, where they are to be brought to the state of woods, as timber and underwoods, and the latter to be used only as fuel, the good trees of such kinds as are suitable to the soil, and the probable demand of the vicinity and other parts, should be fixed upon, and left as standard trees; the whole of the others being cut over by the surface of the ground, so that they may become tools for supplying the under-growths. When this has been performed, the ground, where necessary, should be dug, hoed, or trenched over, as circumstances may direct; but where the trees and underwoods have been much crowded, these kinds of work will seldom be required. However, if, instead of the common underwood, oak be required, then after pitching upon the most proper and suitable standard trees for remaining, the whole of the rest are to be taken up by the roots, the land dug over, and acorns planted out upon it; which, when they are grown up, must be kept clean and free from weeds for some years, in order to promote their healthy growths and rising to the state of young trees.

Where the whole is to be reduced to the state of copse wood for fuel only, the belt way is to cut over every part by the surface of the ground; and when for bark, to root out the whole, only referring the oaks, and planting with acorns, as already noticed.

In the second sorts of plantations, where they have remained, after planting, without being in any way thinned, for a great many years, they are often, in a great measure, incapable of being remedied, as they are, for the most part, so impoverished by other causes, that their growth is suspended; whereas any thinning takes place, the trees all around are destroyed. In these cases it is the advice of some to have the whole grubbed up by the roots and replanted, after the ground has been properly prepared by fallowing and repeated corn crops. But as there may sometimes be much loss in this way, it may be proper to try the cautious thinning of them, which should be done during the latter summer months in a careful manner, as success has occasionally attended this method.

With natural plantations of this kind under twenty years' growth, and artificial ones under ten, much advantage has been gained by suitable cautious thinning and retrenching. In all these cases there is no necessity whatever for the cultivation of the ground, as the trees suffer few or no plants to rise below them, and besides, injury may be done to their superficial roots.

The management in the last or mixed kinds of plantations, where the evergreen trees are in such proportions as not to admit of either of the above modes, is to reduce them to the grove plan only, or to this in some parts and the wood kind in others; the modes of accomplishing both of which have been already laid down. However, in each of these methods, it will frequently happen that the tree or trees which are the most advantageous and defirable in the parts where the plantations exist, are either very deficient, or wholly wanting. In all such instances it is probably the best and most beneficenti practice to grub up nearly the whole of such trees, and replant the ground with the proper sort or sorts; care being taken to leave such a number of the old trees, either in a scattered manner, or in narrow stripes and screens, for sheltering and protecting the young trees, plants, and feeds, which have been put in, planted, or sown. See PLANTATION and Wood.

It may be noticed that in reclaiming all kinds of wild and neglected plantations in lands which are inclined to the retention of moisture; the first thing which is necessary is invariably that of the removal of the flagrant wet woods, as where this is not properly performed, the other operations will be of but little avail, however well they may be executed. In many extensive tracts of this nature, the injury which is sustained by this fort of neglect is scarcely to be calculated. There are many thousands of acres, in different situations in this country, which would by this means alone be brought to twenty times and more their present value. And as this fort of work in such cases can, for the most part, be accomplished by open cuts or gutters alone, at a very trifling expense in comparison of that for arable and some other sorts of land, it should never be neglected where good management is in the least degree attended to. See SPRING and SURFACE Draining.

It is a material point in reclaiming all these sorts of plantations and timber woods, to keep the surrounding ditches and fences well up and in a proper safe state, as large tracts are often completely ruined in a very short time by inattention in this respect, from the cropping, rubbing, and defraction in other ways produced by the entrance of cattle of different kinds into them. There is hardly anything so injurious to the more young timber plantations as cattle being suffered to get into them. See FENCE.

The retrenching of old ill-managed plantations of these kinds should con tinually be done in a very gradual manner, having due regard to their length of standing, the nature of the trees, the quality of the land, the situation and exposure, as well as some other points. Their outside parts are in general to be left more thick and close, than those which are more in the interior, and the parts of the foil which are of a bad thin quality, should be left less thick of trees and plants than where it is of greater depth and richness. And open exposures should be kept more thick and close than where they are more warm and sheltered.

In retrenching the branches of the different trees, the work should be performed according to the length of time the trees have been growing, their particular growths and sizes, the difference of kind, and the uses, purposes, and intentions for which their wood or other parts are designed. It is always proper to stop rather short, than to carry it to an extreme, as there is sometimes danger in the latter case. See PRUNING.

It is always necessary and essential to reclaim these old wild sorts of plantations as soon as possible, as the forming of new tracts of this kind chiefly benefit poltery, while the ameliorating and improving of the other, by these means, are an immediate and direct gain to the present proprietors, of very great national importance at the present time, and which would otherwise be complete losses to both.

No forts of woods of the timber kind should indeed ever be suffered to remain any great length of time without being properly looked over and put into such states as that they may go on in the most beneficent and profitable manner, as
where they are in any way or by any means restricted or impeded in their growths, there is a constant and continual loss taking place, and the ultimate disadvantage is prodigiously great, as the timber never becomes either so good or in such quantity; of course it is of inferior value in both respects, which makes a difference of much consequence to the proprietors as well as to the nation at large. See Wood.

RECLINATION of a Plane, in Dialling, the number of degrees which a dial-plane leans backwards, from an exactly upright or vertical plane, i.e. from the zenith.

The reclusion is easily found, by means of a ruler, and a quadrant; for having drawn an horizontal line on the plane by a level or quadrant, and to it another line at right angles, apply a ruler, so that one end of it may hang over, or reach beyond the plane; then will a quadrant, applied to the under edge of the ruler, shew the degrees and minutes of the plane's reclusion; counting from that side of the quadrant that is contiguous to the edge of the ruler.

RECLINATUM Folium, in Botany, a leaf whose point is curved downwards, below the level of the base. See LEAF.

RECLINATUS CAULIS, a reclined stem, is bent towards the earth, as in many species of Ficus, Salis, Rubus, &c.

RECLINER, or RECLINING Dial, is a dial whose whole plane reclines from the perpendicular; i.e. leans from you when you stand before it.

When this reclusion is equal to the height of the pole, the dial is said to be equinoctial. See DIAL.

RECLINER, Declining, or Declining reclining dial, is a dial which neither stands perpendicular, nor opposite to one of the cardinal points. See DIAL.

RECLUSE, among Religious, a person close shut up in a very narrow cell of an hermitage, or other religious house; and cut off, not only from all conversation with the world, but even with the house.

The word is chiefly used for such as thus imprison themselves out of devotion, to do penance. It is sometimes also applied to incessant wives, whom their husbands procure to be thus kept in a perpetual prison in some convent.

Recluses were anciently very numerous; they were then a kind of solitaries who shut themselves up in some little cell, with a vow never to stir out of it.

None were admitted to this oath until they had given sufficient proofs of their abstinence, and had leave from the bishop, or the abbot of the monastery where they were shut up; for the cells of the recluses were always to join to some monastery.

The prelate's permission being obtained, they were tried for a year in the monastery; out of which, during that time, they never flirted.

They were then admitted to their vow of stability in the church before the bishop; which being done, and the recluse having entered his little cell, the bishop set his seal on the door.

The cell was to be very small, and very exactly closed. The recluse was to have every thing within it necessary to life; and even, if he were a priest, an oratory consecrated by the bishop, with a window which looked into the church, through which he might make his offerings at the masts, hear the singing, sing himself with the community, and answer those who talked to him. But this window was to have curtains before it, both within and without; so that the recluse might neither see, nor be seen.

Indeed he was allowed a little garden in his reclusion, to plant a few herbs, and take fresh air; adjoining to his cell was that of his disciples, which he was very rarely without; with a window, through which they served him with necessaries, and received his instructions.

When it was judged proper to have two or three recluses together, their cells were made contiguous to each other with windows of communication; if any woman would confute them, or confess to them, it was to be in the church, and in the face of all the world.

Where there were two or three reclues together, they were never to hold any conference, but on spiritual matters, and to confes to each other; where there was but one, he was to confes and examine himself.

If the recluse fell sick, his door was opened for people to come in and affilt him; but he was not allowed to stir out on any pretence whatever.

These articles are extracted from the rule, compiled for the reclues, by Grimlaic, a priest in the ninth century.

There were also women reclues, who led the same life, in proportion. St. Viborade lived a recluse at St. Gall, and was there martyred by the Hungarians in 825.

RECLUSION, the state of a recluse; or the cell and other appurtenances of it.

F. Helyot gives a particular account of the ceremonies practiced in the reclusion of a woman, in that of mother de Cambrai, infallitrix of the order of the representation of Nôtre Dame. A cell being built for her in 1625, adjoining to the church of St. Andrew, in Tournay, the bishop waited for her early in the morning at the church-door. Upon her arrival, prostrating herself at the feet of that prelate, he gave her her benediction; conducted her to the grand altar; and there blessing a mantle, veil, and cappaular, he put them on her, and gave her a new name.

Having here made her vow, and the bishop having arranged the people in praiue of the new recluse, he conducted her processional to her reclusion; the clergy all the way singing Veni, Sponfa Christi, &c.

Here the bishop, blessing her aforehand, consecrated the reclusion, and shut her up in perpetual confinement.

RECOGNISANCE. See RECOGNIZANCE.

RECOGNITION, Recognitio, denotes an acknowledgment. The word is particularly used in our law-books, for the title of the first chapter of the tit. 1. Jac. I. by which the parliament acknowledged the crown of England, after the death of queen Elizabeth, to have rightfully descended to king James.

RECOGNITIONS of Clement, in Ecclesiastical History, a suppedititious or apocryphal book, ascribed to St. Clement, but really composed by some learned and eloquent man in the second century. Rufinus, who translated the ten books of Recognitions out of Greek into Latin, in whose translation only we now have them, plainly supposes them to have been written by Clement of Rome; but that the copies, in his time, had been corrupted in some places. The first ecclesiastical writer who has mentioned this work is Origen, by whom it is cited twice; but he does not seem to have held it in high estimation. Eusebius, who is supposèd to mention the Recognitions under the title of "The Acts of Peter," which made part of them, rejects them, and owns no work for St. Clement, but his epitoke to the Corinthians. Epiphanius mentions "The Travels of Peter" as written by Clement, but corrupted by the Ebionites, so that little was left that is genuine. St. Jerome's opinion of the works of Clement coincides with that of Eusebius. This book is, for a large part of it at least, says the learned Dr. Lardner, a fiction or romance, in which divers things concerning the Christian religion are represented in a philosophical manner, in order to render them more agreeable to the Greeks. It
is called the "Circuits," or "Travels and Acts of Peter," from its subject, as it contains an account of the apostle Peter's disputes with Simon Magus, and his discourses to other people, and his miracles. It is called the "Recognitions," from Clement's recognizing his father, and mother, and brethren, who had been long separated from each other.

Mr. Whilton, though he allows that this work was not written by Clement himself, supposes that it was the production of some of the hesers of Clement, and other companions of the apostles; but Dr. Lardner is of opinion, that it must be reckoned to Clement's, or to be suppliational. With regard to the age of this work, Lardner further adds, that the arguments here urged against Heathenism seem to imply, that the Christian was not yet the prevailing established religion. And the author often speaks of the power of Christians to heal diseases, and to expel demons, as if it was common in his time. That such gifts were enjoyed by many Christians in the second, and in the beginning of the third, century, we are assured by Irenæus, Tertullian, Origen, and others; after which time, or however after the end of the third century, they were not so common, if they did not quite cease. Mr. Whilton's opinion of this book is, that if it be not, in some fene or other, itself a sacred book, yet it ought certainly to be esteemed in the next degree to that of the really sacred books of the New Testament. But in the opinion of many other learned men, it is a worthless piece, of little or no use. It contains, however, as Dr. Lardner admits, some excellent sentiments, and fine passages, intermixed with very great faults, for which no excuse can be made. This book contains passages of our four gospels, though it has been doubted whether he used the four, or some one gospel containing in all these. Its author seems to own the first epistle of St. John, and the book of the Revelation. He was also well acquainted with the book of the Acts of the Apostles; but it is not certain how far he owned it. The passages from St. Paul's epistles are not sufficient to prove, that they were esteemed by this writer to be of authority. The author does not seem, indeed, to have any great kindness for the apostle Paul, and on this account he made little use of his epistles, and of the Acts of the Apostles. From his hasty infinuations, and injurious reflections upon St. Paul, it may be suspected that he was a mere Ebionite; the ancients alluring us, that this sect of Christians rejected the authority of that apostle and his epistles. The author bears testimony to many principal facts of the New Testament. He gives an account of our Lord's temptation; he mentions the choice of the 12 apostles, and afterwards of other 72 disciples. In one place he speaks of the 12 apostles in such a manner as if he intended to exclude Paul from the honour of the apostleship, and even to deny him the character of a sufficient and faithful "preacher of Christ's word." We have also, in this book, relations of the miracles of our blessed Lord's ministry, and of his death and resurrection, and the extraordinary signs attending these events. Grabbe's Preface to the Writings of St. Clement in his "Spicilegium." Coteler apud Patr. Auct. tom. i. p. 484. Lardner's Works, vol. ii. p. 342, &c. See Clementin Homilies.

RECOGNITION, in the Drama. See DISCOVERY.

RECOGNIZO, aduallanda per vivum et duritiam factis, in Lexis, is a writ to the judicet of the common bench, for sending a record touching a recognizance, which the recognizor fugglest has to be acknowledged by force and hard dealing; that, if it to appear, it may be annulled. See TRANSCRIPTIO.
along the cylinder, is to the length of the cannon diminished by the space behind the ball, as the weight of the ball is to the weight of the cannon. Let a twenty-four pounder of ten feet be 6400 pounds weight, and when the ball quits the piece, the cannon will have recoiled \( \frac{4}{5} + \frac{1}{5} \times 10 = \frac{1}{5} \) of a foot, less than half an inch.

The greater the charge, *cæteris paribus*, the greater the rebound. By an experiment made before the Royal Society, and related in the Philosophical Transactions, it was found, that cannons, charged to a certain degree, throw the ball from right to left of their own direction; but that the cannons themselves recoil from left to right.

Some of the gentlemen of the French academy doubting the justness of the observation, M. Caffini, the younger, undertook to repeat the experiment; which he did by means of a machine, as like that used in England as he could: and that tried over and over again.

The result was, that the ball, when the gun had liberty to recoil, was always thrown to the right of the point to which it was thrown when the gun was fixed without a possibility of rebounding; but then the recoil was always made the same way, viz. to the right; and he never found that contrariety of directions between the ball and the rebound, observed in the English experiment. See Hilt. Acad. R. Scienc. A. 1703. p. 120, &c.

The cause of the phenomenon seems very difficult to assign; for supposing the guns of a common make, with the touch-hole on the top, we cannot so much as guess what cause should conduce to determine the ball from right to left; unless some very material circumstances be omitted in the report they have given us in the experiment.

Guns whose vents are a little forward in the chase recoil most. To lessen the recoil of a gun, the platforms are generally made sloping towards the embasure of the battery. See Projectiles.

RECOLATION, a method of fining the decoctions of vegetables, &c. by repeated percolation, or straining them several times successively through a linen or woollen bag.

RECOLLECTION, a mode of thinking, by which those ideas, fought after by the mind, are with pain and endeavour found, and brought again to view. See Memory and Imagination.

RECOLLETS, a congregation of reformed Franciscans, called also friers minor of St. Francis, of the strict observance. They were established about the year 1532, when some religious of the order of St. Francis being willing to keep his rule to the letter, Clement VII. gave them houses, whether they might retire, and receive such as were disposed to follow them. The same year he approved the reform; and in 1564, it was carried from Italy into France, where these religious had already been established, in the towns of Tulle in Limousin, and Murat in Auvergne. They had a convent at Paris in 1603; and since they have erected no less than a hundred and fifty in the whole kingdom, where they are divided into seven provinces.

RECOLOGNE, in Geography, a town of France, in the department of the Doubs; eight miles W. of Besançon.

RECOMMENDATI. See Affidavit.

RECOMMENDATION, in a Military Sense, denotes a certificate, flating an individual to be properly qualified for a situation in the army. This certificate must be signed by a field-officer in the regulars, addresed to the commanding officer of the regiment, by whom it is forwarded to the commander-in-chief, who lays the name of the person recommended before the king.

RECOMPOSITION, in Chemistry, the compounding of bodies from their separated parts, or principles, so as to compose the original whole again. This is extremely difficult to effect universally, but in some cases it may be done, and that so perfectly, that the recomposed body shall not be distinguishable by the senses from that which had never been separated by the fire. If the art of chemistry were perfect, we should thus be able, at least in some degree, to recompose all the bodies we divide; but this is far from being the case at present. We can by no means do this in vegetable and animal bodies, where there is a vaelular structure, and therefore we are carefully to distinguish between the regeneration of organised, and that of unorganised bodies.

RECONCILIARI, in our Law Books, &c. A church is said reconciliari, to be reconciled, when it is consecrated afore, after having been polluted or profaned; as by the profefsion of pagans, heretics, &c.

RECONCILIATION, in Church History, See Poenitentes.

RECONNOITRE, in War, implies to view and examine the state of things, in order to make a report of them. The word is French, signifying, literally, to know, recollect.

We say to reconnoitre the coasts, to reconnoitre a port, &c. A body of horse was sent to reconnoitre their camp, the ground, the condition of the roads, rivers, &c.

Parties ordered to reconnoitre, are to observe the country and the enemy; to remark the routes, conveniences, and inconveniences of the first; the position, march, or forces of the second. In either case, they should have an expert geographer, capable of taking plans readily; he should be the bell mounted of the whole, that in case the enemy happen to scatter the escort, he may have his works and ideas.

All parties that go for reconnoitring only, should be but few in number; never more than twelve or twenty men. An officer, be his rank what it will, cannot decline going with to few under his command: the honour is amply made up by the importance of the expedition, frequently of the most interisting consequence, and the proper to recomend the prudence, bravery, and address of any officer that has the fortune to succeed.

It is previously necessary that the officer ordered on this duty should be as well acquainted with the country, the roads, and the diftance of the enemy. His party must consist of men of approved fidelity, part of whom should be dismounted. This detachment must march off in the night. The men must have strict orders neither to smoke tobacco, make a noise, nor speak. The officer must be provided with two guides, who are to be strictly interrogated, but are to remain ignorant of the route you intend to take. A detachment of this kind should be furnished with suficiency for two or three days. The horfes are to be fed every two or three leagues, for it is absolutely necessary that they should be always fresh and fit for duty. The officer will take care never to halt, but at a distance from any road, and also take every precaution to prevent his being surprized, while his horfes are feeding, &c.

RECONNOITRE is also used at sea. To reconnoitre a vessel, a fleet, &c. is to approach near enough to examine the rate and burden of a vessel, &c. the force it may have aboard, what nation it is of, &c.

To reconnoitre a land, or shore, is to observe its situation, in order to find what land it is.

RECORD, Recordium, in Law, an authentic testimony of any thing in writing, contained in rolls of parchment, and preferred in a court of record. See Court, and Custom. Records
Records are said to be "vetustatis & veritatis vox origo." So early as the Conquest we find the "prerogativa memoriae eventorum" reckoned up as one of the chief qualifications of those who were held to be "leges patriae optimae instituti." For it is an established rule to abide by former precedents, where the same points come again in litigation; as well to keep the scale of justice even and steady, and not liable to waver with every new judge's opinion, as also because the law in that case being solemnly declared and determined, what before was uncertain, and perhaps indifferent, is now become a permanent rule, which it is not in the breach of any subsequent judge to alter or vary from, according to his private sentiments; he being sworn to determine not according to his own private judgment, but according to the known law and custom of the land; not delegated to pronounce a new law, but to maintain and expound the old one. Yet this rule admits of exception, where the former determination is most evidently contrary to reason; much more if it be clearly contrary to the divine law. But even in such cases the subsequent judges do not pretend to make a new law, but to vindicate the old one from misrepresentation. For if it be found that the former decision is manifestly absurd or unjust, it is declared, not that such a sentence was "bad law," but that it was "not law," that is, that it is not the established custom of the realm, as has been erroneously determined. An act committed to writing in any of the king's courts, during the term in which it is written, is alterable, being no record; but that term once ended, and the act enrolled, it is a record, and of such credit as admits no alteration, or proof to the contrary.

It is a settled rule and maxim that nothing shall be averred against a record (see Court) nor shall any plea, or even proof, be admitted to the contrary. (Co. Litt. 260.) And if the existence of a record be denied, it shall be tried by nothing but itself; that is, upon bare inspection whether there be any such record or no; else there would be no end of disputes. But if there appears any mistake of the clerk in making up such record, the court will direct him to amend it. Courts of record, or repositories for the public records of the kingdom, were first established by Edward I., our English Jusfrinius, some of which are more ancient than the reign of his father, and those were by him collected.

Lawyers reckon three sorts of records: viz., a judicial record, as attaint, &c.; a ministerial record upon oath, as an office of inquisition found; and a record made by conveyance and content, as a fine, or deed enrolled, and the like.

Record, Affurances by matter of, are such as do not entirely depend on the act or content of the parties themselves; but the fact of a court of record is called in, to substantiate, prove, and be a perpetual testimony of the transfer of property from one man to another; or of its establishment, when already transferred: of this nature are private acts of parliament, the king's grants, fines, and common recoveries.

Record, Court of. See Record, supra, and Court.

Record, Debt of, is a sum of money, which appears to be due by the evidence of a court of record. Thus, when a specific sum is adjudged to be due from the defendant to the plaintiff, on an action or suit at law, this is a contract of the highest nature, being enrolled by the sentence of a court of judicature. Debts upon recognizances, together with statutes merchant, and statutes fleape, &c., if forfeited by non-performance of the condition, are also debts of record; the contract, on which they are founded, being witnessed by the highest kind of evidence, viz. by matter of record.

Records, Imbezzling of. See Imbezzle.

Record, matter, mulct, exer., prisoner upon matter of, see Matter, Muster, Over, and Prisoner, &c.

Record, Trial by, is used only in one particular instance; where a matter of record is tried. The party litigant as a fine, a judgment, or the like; and the opposite party pleads "null and record," that is, there is no such matter of record existing: upon this, if true is tendered and joined in the following form, "and this he or she may be enquired of by the record, and the other doth the like," and hereupon the party pleading the record has a day given him to bring it in, and proclamation is made in court for him "to bring forth his record, or he shall be condemned!" and, on his failure, his antagonist shall have judgment to recover. The trial of this issue is, therefore, merely by the record; for, as Sir Edward Coke observes (1 Inst. 117. 260), a record or enrolment is a monument of so high a nature, and imputed in itself such absolute verity, that if it be pleaded there is no such record, it shall not receive any trial by witnesses, jury, or otherwise, but only by itself. Thus, titles of nobility shall be tried by the king's writ or patent only, which is matter of record. (6 Rep. 53.) Also in case of an alien, whether alien, friend, or enemy, shall be tried by the league or treaty between his sovereign and our's; for every league or treaty is of record. (9 Rep. 31.) And also whether a manor be held in ancient demesne or not, shall be tried by the record of Domesday in the king's exchequer. Blackft. Com. book iii.

Record, among Fowlers. A bird is said to record, when it begins to tune or sing within itself; or to form its notes and diploze its organs for ringsing.

The cock thrush is distinguished from the hen in recording; the first being more loud and frequent in it than the second.

Influences have been known of birds beginning to record when they were not a month old. This first melody does not seem to have the least rudiments of the future song; but as the bird grows older and stronger, one may perceive what the setting is aiming at. A young bird commonly continues to record for ten or eleven months, when he is able to execute every part of his song, which afterwards continues fixed, and is scarcely ever altered. The term record is probably derived from a musical instrument, formerly used in England, called a recorder, which seems to have been a species of flute, and was probably used to teach young birds to pipe tunes. Lord Bacon describes this instrument (in his second Century of Experiments) to have been straight, to have had a lefser and greater bore, both above and below, to have required very little breath from the blower, and to have had what he calls a sipple or ropper.

Recordari facias legatum, in Law, a writ directed to the sheriff to remove a caufe depending in an inferior court, as hundred-court, county-court, court of ancient demesne, &c. to the king's bench, or common pleas, &c.

It is thus called, because it commands the sheriff to make a record of the proceedings either by himself, or others; and then to fend up the cause.

Recordes, Robert, in Biography, an early English physician, of Welsh origin, commenced his education at Oxford about the year 1521; and in 1531 was elected fellow of All-Souls College. Devoting his studies to physic, but where, or under what masters, we are not told, he was created doctor in that faculty at Cambridge in 1545. Both before and after this period he is said to have taught arithmetic at Oxford, and to have excelled all his predecessors.
ors in rendering this branch of knowledge clear and familiar. He is likewise mentioned as remarkably skilful in rhetoric, astronomy, geometry, music, mineralogy, and every part of natural history. He was well acquainted with the Saxon language, and made large collections of historical and other ancient manuscripts. To these various studies he joined that of divinity, and was attached to the principles of the Reformers. But notwithstanding he was justly deemed a prodigy of learning and talents, it does not appear that he met with encouragement at all adequate to his merits; since all that we know further of him is, that he died in the king's bench prison, where he was confined for debt, in the year 1558.

He was author of several works, some of which were several times reprinted, on the following subjects.

"The Ground of Arts, teaching the Work and Practice of Arithmetic, both in whole Numbers and Fractions," 1540. This was dedicated to king Edward VI. "The Whitstone of Wit," a second part of the former. "The Pathway to Knowledge, containing the first Principles of Geometry." "The Castle of Knowledge, containing the Explanation of the Sphere." "The Urinal of Physick," 1547, which was reprinted in London in 1582, 1590, and 1665; and in the last mentioned year, the title of "The Judicial of Urines" was given to it. This book contains a description of urinary vessels with figures. It is a short, but very methodical treatise, full of divisions and subdivisions relative to the different kinds of urines, and the prognostics to be deduced from them. Nevertheless he candidly acknowledges at the beginning, that the judgment to be formed in difeases from the urine is not so certain as some have represented; and indeed the perplexity and variety of opinions concerning this subject are sufficiently apparent from his treatise. His other works were, "Of Anatomy?" "Of Auricular Confession?" "Of the Eucharist?" and "The Image of a true Commonwealth." Aikin's Biog. Memoirs of Medicine.

RECODER, Recodator, a person whom the mayor, or other chief magistrate of any city, or town corporate, having jurisdiction, and a court of record, within their precincts, does associate with him, for his better direction in matters of justice, and proceedings according to law. He is usually a counsellor, or other person, versed and experienced in the law. In some towns, which have their particular affizes within themselves, and no mayor, the recorder is the judge.

The recorder of London is one of the justices of oyer and terminer, and a justice of peace of the quorum, for putting the laws in execution for preserving the peace and government of the city; and being the mouth of the city, he delivers the sentences and judgments of the courts therein, and also certifies and records the city customs, &c. He is chosen by the lord mayor and aldermen, and attends the business of the city, on any warning by the lord mayor, &c.

RECODER, in Majic. See RECORD, supra.

RECORDO & procella mittendis, in Law, is a writ to call a record, together with the whole proceedings in the cause, out of an inferior court into the king's court.

RECOVERY, in a legal sense, an obtaining of any thing by judgment, or trial at law; answering to reverts among the civilians.

There is a true and a feigned recovery.

Recovery, True, is an actual or real recovery of any thing, or of the value of it, by judgment. As if a man sue for any land, or other thing, and have a verdict or judgment for him.

Recovery, Feigned or Common, is a sort of fictio juris, being a certain form or course prescribed by law to be observed for the better affuring of lands and tenements to us; the end and effect of which is, to discontinue and destroy entails, tail, remainders, and reversions, and to bar the tails of them.

Thee common recoveries were invented by the ecclesiastics to chide the statutes of mortmain; and afterwards encouraged by the fines of the courts of law in 12 Edw. IV. in order to put an end to all fettered inheritances, and bar not only entail, tail, but also all remainders and reversions expectant thereon.

A common recovery is so far like a fine (which fee), that it is a suit or action, either actual or fictitious; and in it the lands are recovered against the tenant of the freehold; which recovery, being a supposed adjudication of the right, binds all persons, and vails a free and absolute fee-simple in the receiver.

This recovery is either with a single or double voucher; and sometimes a treble or farther voucher, as the exigency of the case may require.

As a recovery is in the nature of an action at law, not immediately compromised like a fine, but carried through every regular stage of proceeding, its form and method are not easily understood by those who are unacquainted with the course of judicial proceedings. Judge Blackstone has, therefore, stated its nature and progress as clearly and concisely as possible; avoiding, to the utmost of his power, all technical terms and phrases not before interpreted. Of his luminous statement we shall avail ourselves in the sequel of this article.

Let us (says he), in the first place, suppose David Edwards to be tenant of the freehold, and desirous to suffer a common recovery, in order to bar all entail, remainders, and reversions, and to convey the same in fee-simple to Francis Golding. To effect this, Golding is to bring an action against him for the lands; and he accordingly sues out a writ, called a precipe good redatt, because those were its initial or most operative words, when the law proceedings were in Latin. In this writ the demandant, Golding, alleges, that the defendant, Edwards, (here called the tenant) has no legal title to the land; but that he came into possession of it after one Hugh Hunt had turned the demandant out of it. The subsequent proceedings are made up into a record or recovery roll, in which the writ and complaint of the demandant are first recited; whereupon the tenant appears, and calls upon one Jacob Morland, who is supposed, at the original purchase, to have warranted the title to the tenant; and thereupon he prays, that the said Jacob Morland may be ordered to defend the title, which he so warranted. This is called the voucher, vocatio, or calling of Jacob Morland to warranty; and Morland is called the voucher. Upon this, Jacob Morland, the voucher, appears, is impleaded, and defends the title. Whereupon Golding, the demandant, defires leave of the court to per aspir, or confer with the voucher in private; which is (as usual) allowed him. And soon afterwards the demandant, Golding, returns to court; but Morland the voucher disappears, or makes the default. Whereupon judgment is given for the demandant, Golding, now called the recoveror, to recover the lands in question against the tenant, Edwards, who is now the recoveror: and Edwards has judgment to recover of Jacob Morland lands of equal value, in recompense for the lands so warranted by him, and now lost by his default; which is agreeable to the doctrine of warranty. This is called the recompense, or recovery in value. But Jacob Morland having no lands of his own, being usually the cryer of the court
court (who, from being frequently thus vouched, is called the common voucher) it is plain that Edwards has only a nominal recompense for the lands so recovered against him by Golding; which lands are now absolutely vested in the said recoveror by judgment of law, and fein thereof is delivered by the sheriff of the county. So that this collusive recovery operates merely in the nature of a conveyance in fee-simple, from Edwards the tenant in tail, to Golding the purchaser.

The recovery, here described, is with a single voucher only; but sometimes it is with double, treble, or farther voucher, as the exigency of the case may require. And indeed it is now usual always to have a recovery with double voucher at the least; by firft conveying an estate of freehold to any indifferent person, against whom the præcipe is brought; and then he vouches the tenant in tail, who vouches over the common vouchee. For, if a recovery be had immediately against tenant in tail, it bars only such estate in the premises of which he is then actually feised; whereas if the recovery be had against another person, and the tenant in tail be vouched, it bars every latent right and interest which he may have in the lands recovered. If Edwards therefore be tenant of the freehold in possession, and John Barker be tenant in tail in remainder, here Edwards doth firft vouch Barker, and then Barker vouches Jacob Morland the common vouchee; who is always the last person vouched, and always makes default; whereby the demandant, Golding, recovers the land against the tenant Edwards, and Edwards recovers a recompense of equal value against Barker the firft vouchee; who recovers the like against Morland the common vouchee, against whom such ideal recovery in value is always ultimately awarded.

This suppos'd recompense in value is the reason why the issue in tail is held to be barred by a common recovery. For if the recoveror should obtain a recompense in lands from the common vouchee (which there is a possibility in contemplation of law, though a very improbable one, of his doing) these lands would supply the place of those so recovered from him by collusion, and would defend to the issue in tail. This reason will also hold with equal force, as to unfit remainder-men and revivers; to whom the possibility will remain and revert, as a full recompense for the reality, which they were otherwise entitled to: but it will not always hold; and therefore, as Pigott says, the judges have been even æquiti, in inventing other reasons to maintain the authority of recoveries. And, in particular, it hath been said, that, though the estate-tail is gone from the recovery, yet it is not destroyed, but only transferred; and still subsists, and will ever continue to subsist (by construction of law) in the recoveror, his heirs, and assigns: and, as the estate-tail so continues to subsist for ever, the remainders or revivers expectant on the determination of such estate-tail can never take place.

To such awkward shifts, such subtle refinements, and such strange reasoning, were our ancestors obliged to have recourse, in order to get the better of that stubborn statute de donis. The design, for which these contrivances were first on foot, was certainly laudable; the univeting the fetteres of estates-tail, which were attended with a legion of mischiefers to the commonswealth; but, while we applaud the end, we cannot but admire the means. Our modern courts of justice have indeed adopted a more manly way of treating the subject; by considering common recoveries in no other light, than as the formal mode of conveyance, by which tenant in tail is enabled to alienate his lands. But, since the ill consequences of fettered inheritances are now generally feared, and of course the utility and experience of setting them at liberty are apparent; it hath often been wished, that the proceeds of this conveyance was shortened, and rendered less subject to niceties, by either totally repealing the statute de donis; which perhaps by reviving the old doctrine of conditional fees, might give birth to many litigations; or by vesting in every tenant in tail of full age the same absolute fee-simple at once, which now he may obtain whenever he pleases, by the collusive fiction of a common recovery; though this might possibly bear hard upon those in remainder or revivers, by abridging the chances they would otherwise frequently have, as no recovery can be suffered in the intervals between term and term, which sometimes continue for near five months together: or, lastly, by empowering the tenant in tail to bar the estate-tail by a solemn deed, to be made in term time and enrolled in some court of record; which is liable to neither of the other objections, and is warranted not only by the usage of our American colonies, and the decisions of our own courts of justice, which allow a tenant in tail (without fine or recovery) to appoint his estate to any charitable use, but also by the precedents of the statute 51 Jac. I. c. 19, which, in case of a bankrupt tenant in tail, empowers his commissioners to sell the estate at any time, by deed indented and enrolled. And if, in so national a concern, the emoluments of the officers, concerned in palling recoveries, are thought to be worthy attention, those might be provided for in the fees to be paid upon each enrolment.

The force and effect of common recoveries may appear, from what has been said, to be an absolute bar not only of all estates-tail, but of remainders and revivers expectant on the determination of such estates. So that a tenant in tail may, by this method of assurance, convey the lands held in tail to the recoveror, his heirs and assigns, absolutely free and discharged of all conditions and limitations in tail, and of all remainders and revivers. But, by statute 34 and 35 Hen. VIII. c. 20. no recovery had again tenant in tail, of the king's gift, whereof the remainder or reviver is in the king, shall bar such estate-tail, or the remainder or reviver of the crown. And by the statute 11 Hen. VII. c. 20. no woman, after her husband's death, shall suffer a recovery of lands settled on her by her husband, or settled on her husband and her by any of his ancestors, and by statute 14 Eliz. c. 8. no tenant for life, of any fort, can suffer a recovery, so as to bind them in remainder or reviver. For which reason, if there be tenant for life, with remainder in tail, and other remainders over, and the tenant for life, is desirous to suffer a valid recovery; either he, or the tenant to the præcipe by him made, must vouch the remainder-man in tail, otherwise the recovery is void; but if he does vouch such remainder-man, and he appears and vouches the common vouchee, it is then good; for if a man be vouched and appears, and suffers the recovery to be had against the tenant to the præcipe, it is as effectual to bar the estate-tail as if he himself were the recoveror. Salk. 571.

In all recoveries it is necessary that the recoveror, or tenant to the præcipe, as he is usually called, be actually feised of the freehold, else the recovery is void. (Pigott, 28.) For all actions to recover the fein of lands, must be brought against the actual tenant of the freehold, else the suit will lose its effect; since the freehold cannot be recovered of him who has it not. And, though these recoveries are in themselves fabulous and fictitious, yet it is necessary that there be altera fabula, properly qualified. But the nicety thought by some modern practitioners to be requisite in conveying the legal freehold, in order to
to make a good tenant to the praecipe, is removed by the provisions of the statute 14 Geo. II. c. 20, which enacts, with a retrospect and conformity to the ancient rule of law, that, though the legal frehold be vested in lieges, yet those who are entitled to the next frehold estate in remainder or reversion may make a good tenant to the praecipe, that, though the deed or fine which creates such tenant be subsequent to the judgment of recovery, yet, if it be in the same term, the recovery shall be valid in law; —and that, though the recovery itself do not appear to be entered, or be not regularly entered, on record, yet the deed to make a tenant to the praecipe, and declare the uses of the recovery, shall after a postrion of twenty years be sufficient evidence, on behalf of a purchaser for valuable consideration, that such recovery was duly suffered. And this may suffice to give the student a general idea of common recoveries, the last species of assurances by matter of record.

For an account of deeds to lead, or declare, the uses of fines, and recoveries; see Uses.

In some manors, by special custom, recoveries may be suffered of copyhold (Moor, 637;) but as these differ in nothing material from recoveries of free land, excepting only that they are not suffered in the king's courts, but in the court baron of the manor, we shall refer this subject to the article SURRENDER. In this place we shall observe, however, that a fine or recovery had of copyhold lands in the king's court may, if not duly reversed, alter the tenure of the lands, and convert them into frank-fee, which is defined in the old book of tenures to be "land payable at the common law;" but upon an action on the case, in the nature of a writ of "deceit," brought by the lord in the king's court, such fine or recovery will be reversed, the lord will recover his jurisdiction, and the lands will be restored to their former state of copyhold. Black. Com. b. ii.

Clerk of Inrollments of Recoveries and Fines. See Clerk.

Recovery, Fort, in Geography, a fort of America, in the Indiana territory, situated on a branch of the Wabash river, about 25 miles from Greenville. It consists of two block-houses, and barracks with curtains, sufficient for 60 men.

Recontre, French; formed of re, and couper, to cut again, in Law, to rebate, or discont.

Thus, if a man have ten pounds illuing out of certain lands, and he deteiles the tenant of the land; in an affidavit brought by the defier, if he recover the land and damages, the defier shall recover the rent due in the damages.

Recontre also denotes a quick, sharp reply, to a peremptory demand. See Repartee.

Recreant, in our old Law-Books, implies cowardly, faint-hearted.

Hence recreant. See DRAVEN and CHAMPION.

Re created was in reproachfull a word, that Granville would not describe it. Recreated equi, is used by Plut. lib. ii. cap. 2. for dull, jaded horses.

RECREATION ISLAND, in Geography, a fertile island in the Southern Pacific ocean, discovered by Roggevin in the year 1722. Some of the ship's company obtained a quantity of antiscorbutic herbs; but upon venturing into the country, they were assailed by the natives, who, by cutting fomes at them, killed four, and wounded almost all. Many of the islanders were killed by the fire-arms in return. The soil produces sugar-canes, cocoa-nuts, pomegranates, Indian figs, &c. The inhabitants were well made, robust, and very lively; their bodies were painted, and they were armed. S. lat. 16°. W. long. 148°.

Recrement, in Medicine, some superfluous matter separated from some other that is useful.

In which sense, it amounts to much the same with facces, or excrement.

Recrements of vegetables are useful as manure.

Recrement is sometimes also used to denote such secreted juices in the body, as are afterwards of use in the economy; as the lymph, gall, &c. which are thus called, in contradistinction to excrement, which are expelled out of the body, as of no further use.

Recrimination, a posterior accuasation brought by the accused against his accuser, upon the fame fact.

When two parties have made their mutual complaint at the same time; the business is, first, to determine who shall be the accuser, and who the accused, i.e. on whom shall fall the recrimination.

By the French laws, recrimination is of no force till the criminal hath been purged legally.

Recrevuscence, Recrudescencia, in Medicine, is a relapse, when a disease that has gone off returns again.

Recruits, in the Military Art, new men raised to supply the places of such as have loft their lives in the service, or are rendered unserviceable by age or wounds. See Listing.

Recruit-Horses, are the horses brought up for completing the regiments of horse or dragoons every year.

Rectangle, in Geometry, called also oblong, and long square, a quadrilateral rectangual figure M L I K, (Plate XII. Geometry, fig. 3.) whole opposite fides, M L and I K, as well as M I and L K, are equal.

Or, a rectangle is a parallelogram, whose sides are unequal, but its angles right.

To find the area of a rectangle, see PARALLELOGRAM.

If from the same point A, (fig. 4.) be drawn two lines, one of which, A D, is a tangent to a circle, the other a fectant A B; the squire of the tangent A D will be equal to the rectangle under the fectant A B, and that part of it without the circle A C. If two or more fectants, A a, A B, &c. be drawn from the same point A; the rectangles, under their wholes, and their parts without the circle, will be equal. If two chords intersect each other, the rectangles under their segments will be equal. The rectangles under equal lines are equal. The sum of all the rectangles contained under a given line, and all the parts of another any how divided, is equal to the rectangle contained under the two whole lines. If from any point, within a rectangle, to the angles of a rectangle, four lines be drawn, the sums of the squares of those drawn to the opposite angles will be equal. The rectangles contained under the corresponding fides of equiangular triangles, taken alternately, are equal. The rectangle under the two fides of any triangle is equal to the rectangle under the perpendicular to its base, and the diameter of the circumference of the circle. The squire of a line bisecting any angle of a triangle, and terminating in the opposite side, together with the rectangle under the two segments of that side, is equal to the rectangle of the two fides, including the proposed angle. The rectangle of the two diagonals of any quadrilateral inscribed in a circle, is equal to the sum of the two rectangles contained under the opposite sides.

Rectangles, Similar. See SIMILAR.

Rectangle, in Arithmetic, is the same with product or factum.

Rectangled, Right-angled, Triangle, is a triangle, one of whose angles is right, or equal to 90°. See Triangle.
There can be but one right angle in a plain triangle; therefore a rectangled triangle cannot be equilateral.

RECTANGULAR, in Geometry, is applied to figures and folids which have one or more angles right.

Such are squares, rectangles, and rectangled triangles, among plain figures; cubes, parallelepipeds, &c, among folids.

Solids are also said to be rectangled with respect to their situation: thus, if a cone, cylinder, &c, be perpendicular to the plane of the horizon, it is called a rectangled or right cone, cylinder, &c.

The ancient used the phrase rectangled section of a cone, to denote a parabola; that conic section, before Apollonius, being only considered in a cone, whole section by the axis would be a triangle, right-angled at the vertex. See Conic Sections.

Hence it was that Archimedes entitled his book of the quadrature of the parabola, by the name of "Rectanguli Coni Secatio."

RECTANGULAR Barometer. See Barometer.

RECTANGULAR Windsmills. See Windsmills.

RECTIFICATION, compounded of rectus, right, direct, and fac, I became, the act of rectifying, i.e. of correcting, remedying, or redressing, some defect or error, in respect either of nature, art, or morality.

Rectification, in Chemistry, is the repeating of a distillation or sublimation several times, and generally with a less degree of heat than at first, in order to render the substance purer, finer, and freer from aqueous and earthy parts.

Rectification is a reiterated deputation of a distilled matter, e.g. brandy, spirits, or oils, by distilling them over again, to render them more subtils, and exalt their virtues.

That the rectification of spirits may, in all cases, proceed with the greatest exactness, a due regard to it must be had even from the first fermenting the substance from which they are to be made, and continued through all the stages of distillation, the low wines, proof spirit, and alcohol. The management of the fermented liquor, to this purpose, is principally the letting it stand to subside after the fermentation is over, and the drawing it off clear and thin, not too rich for the still. The still is not to be overfulled with this.

Great care must be taken to prevent its burning, and the fains that run last must be kept separate, not mixed with the rest of the liquor distilled, which is now called the low wines. In the rectifying of these into proof spirit, great caution must be used that the fire be kept regular, not raised by fudden spirits, which always throw up the oil in large quantities, which is to be left behind. In the succeeding rectification of the proof spirit into alcohol, the fire cautious management of the fire is necessary; and, in both this and the last, the fains are not to be suffered to run in among the spirit, but to be faved separate. They may be all mixed together at last, and reduced to a spirit fit for burning in lamps; but the keeping out of the rectified liquor will keep away the coaled and most flinking part of the oil of the ingredients.

By these easy means, without any additional trouble or charge, we might be furnished with a spirit greatly exceeding what we commonly meet with. And in general, the art and mystery of our fellers of the severall sorts of English brandies, seem to consist in this prudent management, and in the adding a little of the oleum vini, or oil of wine-leas, to the spirits thus procured pure; this gives the flavour of foreign brandies, and is so extensive in its use, that half an ounce of it is sufficient for a hoghead of pure spirit.

Malt spirit is that which principally requires all this care, in the rectification, because its oil is more nauseous and offensive than that of any other spirit; but all others will be greatly the better for being treated in the same manner, and it is indeed necessary that they should for some particular uses.

It is remarkable, that no one method of combinatory rectification, that is, of the rectification performed by means of salt, and other additions, is suited to all the several kinds of spirits; scarcely indeed will any one way serve for any two spirits: but this method, by simple and careful distillation, is equally suited to all. Molasses-spirit, cider-spirit, wine-spirit, or brandy, run, and arrack, are all improved by it; and all of them are then known to be perfectly rectified, when, in the state of alcohol, they not only prove, totally inflammable in a little vesel floating upon cold waters, but when poured into the purest spring water they have not the least power of making any change in it, nor leave any marks of oiliness, or that unctuosity which, on the mixture of the leas pure spirits, float on the top, and in certain lights gives the rainbow colours. See Shaw's Essay on Distillation. See Alcohol and Distillation.

Fixed salts are rectified by calcination, distillation, or filtration.

Metals are rectified, i.e. refined, by the coppel; and regu- lapse by repeated fusions, &c.

In a word, all rectifications are founded upon the same principle; and consist in separating substances more volatile from substances less volatile; and the general method of effecting this is to apply only the degree of heat which is necessary to cause this separation.

RECTIFICATION of vitriolic Acid. See Concentration.

Rectification, in Geometry, is the finding of a right line equal to a proposed curve, or simply finding the length of a curve line; a problem which, even in the present advanced state of analysis, is attended in many cases with considerable difficulty; and was, in all, totally beyond the reach of the ancient geometers, who were not able to allign the length of any curve line whatever; though they could, in a few instances, determine the area of a curvilinear space. See Quadrature.

The first rectification of a curve line was effected by Mr. H. Neal, as we are informed by Dr. Wallis, at the conclusion of his Treatise on the Cylind. This curve was the semicubical parabola, and Neal's rectification of it was published in July or August, 1657; and two years after, viz. in 1659, the fame was done by Van Haureat in Holland. See Schooten's Commentary on Descartes' Geometry.

It is, however, to the doctrine of fluxions that we owe the complete rectification of curve lines, in finite terms, when they admit of it; and in others by means of infinite series, circular arcs, logarithms, &c; of which method we shall give a general view in the present article.

Let A M O (Plate XIII. Analysis, fig. 10.) be a curve of any kind, whose ordinates are parallel to one another, and perpendicular to the axis A H; and let the fluxion of the abscissa A P be denoted by P p or M R, and R m be taken to represent the corresponding fluxion of the ordinate P M, then will the tangent M m be the line which the generating point of the curve would describe, if its motion were to become uniform at M; consequently this line will truly express the fluxion of the space A M. Hence putting P A = x, P M = y, and A M = z, we have z = M m = \sqrt{(M R\text{'} + R m)} = \sqrt{(x^2 + y^2)}; from which, and the equation of the curve, the value of y may be determined. But if all the ordinates of the proposed curve A R M (fig.) be referred to a centre C; then, putting the tangent R P, intercepted by the perpendicular C P, = i, the arc B N of a circle described about the centre C, = x, the radius...
RECTIFICATION.

radius CN (or CB) = a, &c. (see Quadrature of Curves, Café 2.) we shall have \( z : y : y (CR) : t (RP) \);
and consequently, \( z = \frac{y^2}{t} \); whence the value of \( z \) will be found, if the relation of \( y \) and \( t \) is given.

I. To find the length of the semi-cubical parabola, of which the equation is \( ax^3 = y^3 \), or \( x = \frac{y^2}{a^2} \).

Here \( x = \frac{3y^2}{a^2} \) or \( x^2 = \frac{9y^2}{4a^2} \); substituting, therefore, this value of \( x^2 \) in the general expression
\( z = \sqrt{y^2 + x^2} \), we have
\( z = \sqrt{\left(\frac{9y^2}{4a^2} + y^2\right)} = \frac{\sqrt{y^2}}{2a^2} \sqrt{(y + 4a)} \); the fluent of which is
\( z = \frac{1}{27a^2} \times (y + 4a)^{3/2} + C \), correction.

Now when the arc = 0, then \( y = 0 \); therefore
\( 4a^2 + C = 0 \), or \( C = -\frac{4a^2}{27a} \);
whence the complete fluent is
\( z = \frac{(y + 4a)^{3/2} - 4a^2}{27a} \),
which is the length of the curve, answering to any length of the ordinate \( y \).

II. To rectify the common parabola; or to find the length of any parabolic arc AM (fig. 11.) Let the parameter = \( a \), the absciss \( = AP = x \), &c. as above. From the well known property of this curve, \( ax = y^2 \); and \( a \times = 2y/2 \); consequently \( x = 2y/a \), and \( x^2 = \frac{4y^2}{a^2} \), which substituted for \( x^2 \) in the general expression for the length of the curve, makes \( z = \left(\frac{4y^2}{a^2} + y^2\right)^{3/2} = \frac{y^2}{a} \times (a^2 + 4y^2)^{3/2} \);
which, thrown into an infinite series, becomes
\( \left(\frac{2y^2}{a} - \frac{2y^2}{a^2} + \frac{4y^6}{a^4} \right) \), i.e., \( z = \frac{2y^2}{a} \times \frac{4y^6}{a^4} \), &c.

The fluent of this series is \( z = y + \frac{2y^4}{3a^2} - \frac{2y^2}{5a^2} + \frac{4y^6}{7a^2} \), &c., = the length of the curve AM required.

Otherwise: the above \( z = \frac{y}{a} \times (a^2 + 4y^2)^{3/2} = \frac{1}{a} \times (a^2 + 4y^2)^{3/2} \), &c. But the fluent of the first of these
two terms is \( \frac{3y^2}{2a} \times (a^2 + 4y^2)^{3/2} = \frac{y}{a} \times (\frac{3}{4} a^2 + y^2) \);
and the fluent of the last of the two terms is \( \frac{1}{2} a \times (\frac{3}{4} a^2 + y^2)^{3/2} \); therefore
\( z = \frac{y}{a} \times (\frac{3}{4} a^2 + y^2)^{3/2} + \frac{3y}{2a} \times \sqrt{(\frac{3}{4} a^2 + y^2)} \).

Hence, if \( AC \) and \( DC \) (fig. 12.) be the conjugate foci-axes of an equilateral hyperbola; and \( AC = a \), \( MP = 2y, QM = x \), then will \( AP = x - a \); and \( x^2 - a^2 = 4y^2 \); therefore \( x^2 = 4y^2 + a^2 \); consequently \( x = \sqrt{4y^2 + a^2} \). If then \( q \) be supposed infinitely near \( QM \), we shall have \( \sqrt{Qq} = s \), and therefore the element of the area \( CQMA = \frac{y}{a} \times \sqrt{(a^2 + 4y^2)} \). Whence it appears, that the rectification of the parabola depends on the quadrature of the hyperbolic space \( CQMA \).

III. To determine the length of an arc of the common hyperbola. Let the rectilinear axis be represented by \( b \), and the foci-conjugate by \( c \), and we shall have \( \frac{b^2 y^2}{c^2} = 2b x + x^2 \), from the nature of the curve (see Hyperbola); and therefore \( x = \frac{b y y}{c \sqrt{(c^2 + y^2)}} - b \); hence \( \dot{x} = \frac{b y y}{c \sqrt{(c^2 + y^2)}} \), and \( \ddot{x} = \sqrt{(y^2 + x^2)} = \sqrt{\left(\frac{b y y}{c \sqrt{(c^2 + y^2)}}\right) + \frac{b^2 y^2}{c^2 \sqrt{(c^2 + c^2 y^2)}}} \); which, by converting \( \frac{b^2 y^2}{c^2 \sqrt{(c^2 + c^2 y^2)}} \) into an infinite series, becomes \( \ddot{x} = \left(1 + \frac{b^2 y^2}{c^2 \sqrt{(c^2 + c^2 y^2)}} - \frac{b^2 y^2}{c^5} \right) \); &c. But still we have the square root to extract: in order to which, let it be assumed \( = 1 + A y^2 + B y^4 + C y^6 + D y^8 \), &c. Then, by squaring, and transposing, there arises
\( 1 + 2 A y^2 + 2 B y^4 + 2 C y^6 + 2 D y^8 \), &c.
\( + A^2 y^4 + 2 A B y^6 + 2 A C y^8 \), &c.
\( + B^2 y^8 \), &c.
\( - 1 - \frac{b^2}{c^2} \times y^2 - \frac{b^2}{c^4} \times y^4 - \frac{b^2}{c^6} \times y^6 - \frac{b^2}{c^8} \times y^8 \), &c.
Hence \( A = \frac{b^2}{2c^2} \); \( B = -\frac{b^2}{c^4} \); \( -\frac{1}{2} A^2 = -\frac{b^2}{2c^4} \); \( C = \frac{b^2}{2c^2} - A B = -\frac{b^2}{2c^4} \); \( -\frac{b^2}{4c^4} + \frac{b^4}{16c^8} \), &c. &c. Therefore \( \ddot{x} = \sqrt{\left(1 + \frac{b^2 y^2}{c^2 \sqrt{(c^2 + c^2 y^2)}} - \frac{b^2 y^2}{c^5} \right) \times \frac{b^2 y}{c^4} \times y^2 + \frac{b^2}{c^8} \times y^4 \), &c. \)

\( = \ddot{x} + \frac{b^2}{2c^4} \times y^2 y^2 - \left(\frac{b^2}{2c^4} + \frac{b^2}{16c^8}\right) \times y^4 y^2 + \left(\frac{b^2}{2c^4} + \frac{b^2}{8c^8}\right) \times y^6 y^2 + \left(\frac{b^2}{2c^4} + \frac{b^2}{8c^8}\right) \times y^8 y^2 + \ldots \)

\[ \frac{b^2}{c^2} \left( \frac{1}{2} \right) \times y^3, \text{ &c.} \]

and consequently \( z = y + \frac{b^2}{c^2} \left( \frac{1}{2} \right) \times y^3, \text{ &c.} \)

By the very same way of proceeding, the arc of an ellipsis may be found, the equations of the two curves differing in nothing but their signs.

IV. To rectify the spiral of Archimedes. The value of \( t \) (A T, f. 15.) being denoted by \( \frac{b}{\sqrt{b^2 + y^3}} \) (see Tangent of the Spiral, &c.), we have

\[ \frac{d}{d} \left( b^2 + y^3 \right) \frac{d}{d} \left( b^2 + y^3 \right) \]

which fluxion being the same as expressing the arc of the common parabola (Prob. II.), by inserting in the expression

\[ \frac{d}{d} \left( b^2 + y^3 \right) \frac{d}{d} \left( b^2 + y^3 \right) \]

fluent will, therefore, be truly represented by the measure of the said arc, or by \( \frac{1}{2} \left( b^2 + y^3 \right) \). The value there found, by making the proposed substitution,

\[ y + \frac{1}{2} \left( b^2 + y^3 \right) \]

the value, there found, by making the proposed substitution.

V. To rectify the involute of a circle, whose nature is such, that the part \( P R \) (fig. 14.) of the tangent intercepted by the point of contact and the perpendicular \( CP \), is every where equal to the radius \( CO \) of the generating circle.

In this case \( \frac{d}{d} \left( \frac{y}{x} \right) = \frac{y}{a} \), which, corrected by making \( y = a = A C \), becomes

\[ \frac{y^3 - a^2}{2a} \left( \frac{C P}{2A C} \right) \]

the true measure of the required arc \( A R \).

VI. To find the length of a circular arc. This may be expressed either in terms of the sine, cosine, versed sine, or any other trigonometrical line, as follows.

Let the versed sine - - of the circle - - radius - - and arc = - - then, by the property of the circle, \( y^2 = 2r x - x^2 \) or, putting tangent = \( t \) and tangent = \( s \), we have

\[ y^2 = \frac{r^2 t^2}{r^2 + s^2} \]

as are readily deduced from the known properties of the circle.

Now, by means of these values of \( y^2 \), or of \( 2r x - x^2 \), and the general equation \( \ddot{z} = \sqrt{(x^2 + \ddot{y})} \), we readily draw the following values of \( \ddot{z} \), viz.

\[ \ddot{z} = \begin{cases} \sqrt{2r x - x^2} = \frac{r \ddot{x}}{r^2 + t^2} \\ \sqrt{(x^2 + \ddot{y})} = \frac{r \ddot{t}}{r^2 + s^2} \\ \sqrt{(x^2 + \ddot{y})} = \sqrt{(x^2 + \ddot{y})} \\ \sqrt{(x^2 + \ddot{y})} = \sqrt{(x^2 + \ddot{y})} \end{cases} \]

the fluents of which can only be found in series, which are as follows; making radius \( r = 1 \), viz.

Having
Having thus laid down his plan of operation, by a few trials he fell upon a number well suited to his purpose, viz., knowing the tangent of $\frac{1}{4}$ of $45^\circ$, or $11^\circ\ 15'$, to be very nearly $\frac{1}{5}$, radius being 1, he assumed for his first arc that whose tangent is $\frac{1}{5}$; then since $\tan\ 2\ a = \frac{2\ \tan\ a}{1 - \tan^2\ a}$,

he had $\frac{5}{12}$ for the tangent of his double arc, and $\frac{120}{119}$ for the double of this, or of four times the first, which being a little greater than $45^\circ$, was well adapted to his views; for by a known trigonometrical property, $\tan\ (a - 45) = \frac{\tan\ a - 1}{\tan\ a + 1}$; that is, the tangent of the small arc, which is equal to the excess of its multiple above $45^\circ$, was $\frac{120}{119} - 1 = \frac{1}{239}$.

He had, therefore, two arcs to compute, the one having for its tangent $\frac{1}{5}$, and the other $\frac{1}{239}$; and then four times the first of these arcs minus the latter, would evidently give the exact arc of $45^\circ$, and both these numbers being such as to converge very well in the general series, the difficulty attending the usual approximation was avoided. Other approximations, however, have since been discovered, which, if not more rapid, their investigation is, at least, more simple, of which, perhaps, that of Euler's is the most deserving of notice. This celebrated geomter observes, that every arc whose tangent is commensurable with the radius, as, for instance, $45^\circ$, may be divided into two arcs, of which the tangents, though much smaller, are still commensurable with the radius; for since

$$\tan\ (a + b) = \tan\ a + \tan\ b,$$

we have also

$$\tan\ a = \tan\ (a + b) - \tan\ a \\tan\ b,$$

where it is obvious that if $\tan\ (a + b)$ and $b$ be rational, $\tan\ a$ will also be rational; thus, if $\tan\ (a + b) = \tan\ 45^\circ = 1$, and $\tan\ b = \frac{1}{2}$, we have $\tan\ a = \frac{1}{3}$, and we shall evidently have a similar result, whatever rational fraction we assume for $\tan\ b$.

We shall find, therefore, by the series which gives the arc in terms of the tangent, each of these arcs, the sum of which will evidently be the measure of the whole arc sought; whether the arcs themselves, which belong to these tangents, be rational or irrational, with respect to the whole arc of which they form the parts. These tangents, substituted in the general series above, give arc to tan. $\left(\frac{1}{2}\right)$ =

$$\frac{1}{2} - \frac{1}{3\cdot2^1} + \frac{1}{5\cdot2^3} - \frac{1}{7\cdot2^5} + \frac{1}{9\cdot2^7} - &c.$$

and arc to tan. $\left(\frac{1}{3}\right)$ =

$$\frac{1}{3} - \frac{1}{3\cdot3^1} + \frac{1}{5\cdot3^3} - \frac{1}{7\cdot3^5} + \frac{1}{9\cdot3^7} - &c.$$

In both which series, the terms diminish much more rapidly than in the original series, and may therefore be computed with tolerable ease.

But it is evident that we may proceed farther in this approximation, by dividing each of these into other two arcs, by which means the convergency will obviously be much more rapid; and though, generally speaking, for every subdivision we double the number of our series, yet the degree of convergency is so much the greater as amply to compensate for the additional number of series. Besides, we may always subdivide our greater arc, so that one of its subdivisions shall be the same as the smaller arc, in which case we do not increase the number of series. Thus; arc to tan. $\frac{1}{2} = \frac{1}{2}\ tan.\ \frac{1}{3} +\ arc\ to\ tan.\ \frac{1}{7}$; therefore arc to tan. $1 = 2$ arc to tan. $\frac{1}{3} +\ arc\ to\ tan.\ \frac{1}{7}$. Again; arc to tan. $\frac{1}{3} =\ arc\ to\ tan.\ \frac{1}{7} + 2\ arc\ to\ tan.\ \frac{1}{11}$; and so on to any extent required, which might in course be published so far as to render the operation as simple and as little laborious as can be expected in such kind of computations. Even with these already mentioned, the circumference of the circle might undoubtedly be computed to 200 places of decimals, with less labour than it cost Vieta to carry them to 10 places, or Romanus to 15.

The reader will observe, that this approximation differs from Machin's in nothing except the simplicity and generality of the investigation; for if we make the successive subdivision of the greater arc, so as always to include in it the smaller one, we shall find in our results the identical formula of Machin.

Let us repeat our former expression

$$\tan\ a = \tan\ (a + b) - \tan\ b,$$

Let $\tan\ (a + b) = \frac{R}{T}$, $\tan\ a = \frac{R'}{T'}$, $\tan\ b = \frac{r}{I}$ and we shall have generally $\frac{R'}{T'} = \frac{R + T'}{T'}$.

Let now $\tan\ (a + b) = 1$, answering to arc $45^\circ$, so that $R = 1$, and $T = 1$; assume also $r = 1$, then, by constantly subtituting, in the general expression, the values found for $R'$, $R''$, $R'''$, &c. and $T'$, $T''$, $T'''$, &c. for $R$ and $T$ respectively, we shall have

$$R' = \frac{t - 1}{t + 1},$$

$$T' = \frac{t^2 - 2t - 1}{t^2 + 2t - 1},$$

$$R'' = \frac{t^4 - 3t^2 - 3t + 1}{t^4 + 3t^2 - 3t - 1},$$

$$T'' = \frac{t^8 + 3t^4 - 3t - 1}{t^8 - 3t^4 - 3t + 1},$$

$$R''' = \frac{t^8 - 4t^6 + 6t^4 + 4t + 1}{t^8 + 4t^6 - 6t^4 + 4t + 1},$$

$$T''' = \frac{t^{16} - 5t^{12} - 10t^{10} + 10t^8 + 5t - 1}{t^{16} + 5t^{12} - 10t^{10} - 10t^8 + 5t + 1}.$$
$$\frac{R^{(n)}}{T^{(n)}} = \frac{t^n - n t^{n-1} + \frac{n (n - 1)}{1 \cdot 2} t^{n-2} + \&c.}{t^n + n t^{n-1} - \frac{n (n - 1)}{1 \cdot 2} t^{n-2} - \&c.}$$

So that, generally, arc to tan. $1 = n \times \arc \tan \frac{1}{t}$ + arc to tan. $R^{(n)}$.

If we take $n = 1$, and $t = 3$, we have arc $t = 1$ = arc tan. $\frac{1}{3} + \text{arc tan.} \frac{1}{2}$. If $n = 2$, and $t = 3$,

we have arc tan. $2 = 2 \times \text{arc tan.} \frac{1}{3} + \text{arc tan.} \frac{1}{7}$. If $n = 4$, and $t = 5$, we have arc tan. $4 = 4 \times \text{arc tan.} \frac{1}{5}$.

arc tan. $\frac{1}{239}$; which is the formula of Machin, and by giving other values to $n$ and $t$, a variety of other formulae might be found, though it would, probably, be difficult to find one more convergent than the last. The reader will examine this on more at length in Dr. Hutton’s Tracts.

We shall conclude this article by giving the circumference of the circle to 15 places, as given by Zach, from a manuscript, which he has in the Ratcliff library at Oxford, differing from the periods of the several approximations of different authors mentioned in the preceding part of this article, and the article Quadrature.

The diameter of a circle being 1, the circumference will be a b c d
e 3.14159 0.6535 2.05893 2.3846
f 2.6433 0.3279 0.50288 4.1971
h 0.69399 3.7510 5.8209 7.4944
i 0.9230 7.1646 0.6286 2.0899
j 8.6280 3.4825 3.4511 7.0679
g 8.2148 0.6651 3.2243 0.6647
h 0.6938 4.6905 5.0829 2.3172
i 0.5359 0.8128 4.802.

* This figure is a 7 in Lagney’s approximation, but Vega, in the revision of the computation, alters that it ought to be an 8, as we have given it.

RECTIFIED Spirits, &c. are such as have undergone the operation of rectification, or have been distilled over and over, to separate from them any heterogeneous matter, which might have arisen with them in the former distillations.

Hence we say, spirit of wine twice rectified, thrice rectified, &c.

It is the rectification that makes the difference between brandy and rectified spirits of wine. See Spirits.

RECTIFIER, in Navigation, is an instrument used for determining the variation of the compass, in order to rectify the ship’s course, &c.

It consists of two circles, either laid upon, or let into one another, and so fastened together in their centres, that they represent two compases, the one fixed, the other moveable; each is divided into thirty-two points of the compasses, and three hundred and sixty degrees, and numbered both ways, from the north and the south, ending at the east and west in ninety degrees.

The fixed compass represents the horizon, in which the north, and all the other points, are liable to variation.

In the centre of the moveable compass is fastened a silk thread, long enough to reach the outside of the fixed compasses; but if the instrument be made of wood, an index is used instead of the thread.

RECTIFIER, in the Distillery, the person whose employment is to take the coarse malt-spirit of the malt-tillers, and re-distill it to a finer and better liquor. The art of the rectifier might be entirely lost aside, if the malt-tillers could make their spirit perfect at the second operation; which seems very practicable, if the malt-tillers could be induced to forsake their old practice. The great things to be recommended for the improvement of their art, would be, first, the brewing in liquid; and secondly, the keeping of their wash after the manner of flake beer, till it has entirely lost its malt flavour, and acquired a pungent acid vinosity; and then, thirdly, leaving out the lees, to distil with a well-regulated fire. It is scarcely to be thought how pure a spirit is to be obtained from malt this way; but the great art would be, the finding of a method to make malt liquors artificially flake, bright, and flavourful, though otherwise vineous.

Shaw's Lectures, p. 223.

RECTIFYING Curves. See Rectification.

RECTIFYING of the Globe or Spheres, is a previous adjusting of the globe or sphere, to prepare it for the solution of problems. For the method of doing it, see Use of the Celestial Globe.

RECTILINEAR, Right-lined, in Geometry, is applied to figures whose perimeter consists of right lines.

RECTILINEAR Angle, Map, and Superficies. See the sub-

RECTITUDE, Rectitude, Rectum, in matters of philosophy, refers either to the act of judging, or of willing; and therefore, whatever comes under the denomination of rectitude is either what is true, or what is good: these being the objects about which the mind exercises its two faculties of judging and willing.

Rectitude of the mind, considered as it judges, i.e. rectitude of the faculty of judgment, consits in its agreement and conformity to the nature and reason of things, and in its determining and deciding about them according to what their constitutions, properties, uses, &c. really are.

Rectitude of the mind, considered as it wills, called also moral rectitude, or uprightness, consists in the choosing and pursing of those things which the mind, upon due enquiry and attention, clearly perceives to be good; and avoiding those that are evil.

RECTITUDINES, in Law, rights, or legal dues, belonging either to God, or man. See Right.

RECTO, a writ usually called a writ of right; of so high a nature, that whereas other writs in real action are only to recover the possession of the lands, &c. in question, loft by the plaintiff, or his ancestor; this aims to recover both the seisin thus lost, and the property of the thing: so that both rights are here blended together; that of property, and that of possession.

If a man lose his cause upon this writ, he is without all remedy.

There are two kinds of this writ: breve magnum de reso,
or breve de recto patens, a writ of right patent; and recto clauarium, a writ of right clore.

The first is so called, because sent open. It lies only for him that hath fee-simpie in the lands sued for, against the tenant of the freehold at least.

Indeed, the writ of right patent is extended, in practice, beyond its original intention; for a writ of right of dower, which lies for the tenant in dower, is patent; and so in several other cases. Fitzherb.
The writ of right clore, called also breve purum de recto, is directed to the lord of ancient demeine, or the bailiff of the king's manors; and lies for those who hold lands and tenements by charter, in fee-simpie, or in fee-tail, or for term of life, or in dower, if they be ejected out of such lands, or dispossessed. In such case a man, or his heirs, may sue out the writ of right clore, directed to the lord of ancient demeine, commanding him to do him right in his court. This is called a writ fecadum confuetudinem maneri. See Possession, Property, Title, and WRIT. Recto de advocacione ecclesie, a writ of right, lying where a man has right of advowson in fee to him, and his heirs; and, the incumbent dying, a stranger presents his clerk to the church; and he, not having brought his action of quarre impedit, nor darrein presentment, within six months, has suffered the stranger to usurp upon him. See Diffurance of Patronage, Quarre impedit, and Assisa darrein presentment.

Recto de cajfodia terce & baredis, a writ which lies for him whose tenant dying in his nongage, a stranger enters, and takes the body of the heir.

This writ was to lands holden in capite, or by knight's service, is become ufeless by the Stat. 12 Car. II. but not where there is a guardian in socage, or appointed by the laft will of the ancestor. See Guardian.

Recto de dole, a writ of right of dower, which lies for a woman that has received part of her dower, and proceeds to demand the remnant in the same town against the heir, or his guardian. This extends either to part or the whole, and is a more general remedy than that mentioned in the next article.

Recto de dole unde nihil habet, is a writ of right which lies in case where the husband, having divers lands and tenements, has assuied no dower to his wife; and she is thereby driven to sue for her thirds against the heir, or his guardian. See Dower, and Writ of Entry.

Recto quando ou quia dominus renovit, a writ of right, which lies in case where lands or tenements in the fignory of any lord, are in demand by a writ of right.

If the lord hold no court, or, at the prayer of the demandant or tenant, fend his writ to the king's court, to put the caufe thither for that time; this writ suffices for the other party, and has its name from the words comprized, which is the true occasion of it.

Recto de rationali parte, is a writ that lies between privies of blood, as brothers in gavel-kind, or filters, or other coparceners, as nephews and nieces, and for land in fee-simpie.

If a man lease his land for life, and afterwards die, leaving ifiue two daughters, and, after, the tenant for life likewise dies; the one ifiue entering on all the land, and fo deforcing the other, the ifiue so deforced shall have this writ to recover her part.

Recto fur disclaimer, a writ which lies where the lord, in the court of common pleas, does know upon his tenant, and the tenant disclaims to hold of him; upon which disclaimer the lord shall have this writ. This takes place when the tenant upon a writ of affile for rent, or on a replevin, disfouws or disclaims his tenure: whereby the lord lofs his verdict; in which case the lord may have this writ, grounded on this denial of tenure, and shall, upon proof of the tenure, recover back the land itself so helden, as a punishment to the tenant for his false disclaimer. This piece of retaliating justice, whereby the tenant who endeavours to defraud his lord is himself deprived of the estate, as it evidently proceeds upon feudal principles, so it is expressly to be met with in the feudal constitutions: "valalus, qui abnegavit feudum ejus conditionem, expoliatur." Recto folio. See Folio.

RECTOR of a parifh, the parson, or he who has the charge or cure of a parifh church. See Parson.

If the predial tythes of the parifh be inappropriate, i.e. either in lay hands, or in fome of thofe ecclesial communities, then, instead of rector, the parfon is called vicar, (which fee). In England are reckoned 3485 rectories.

The same rector denotes him governor or ruler, quia sanctum jus in ecclefia parochialis habeb, quantum praebuit in ecclefia collegiata.

RECTOR also denotes the chief elective officer in several foreign universities, particularly in that of Paris.

RECTOR is also used in several convents for the superior, or officer who governs the house.

The Jesuits used it for the superiors in fuch of their houses as were either feminaries, or colleges.

RECTORY, or RECTORES, Rectoria, a parifh church, parfonage, or spiritual living, with all its rights, glebes, and tythes.

RECTRICES, in Ornithology, denote the ftrong feathers of the tails of birds.

RECTUM Intestinum, in Anatomy; or in English, simply the rectum; is the laft portion of the large intestine, and of the whole alimentary canal. It begins at the left sacro-iliac symphysis, below the sigmoid flexure of the colon, and ends at the anus. See Intestine.

RECTUM, Abfeffes in the Neighbourhood of. See Fis- TULA in Ano.

RECTUM, Concreations and extraneous Substances lodged in.

The concreations formed in the larger intestines, and especially in the rectum, by the accumulation and protracted lodgment of the feces, may become the caufe of obstinate constipation, which can only be removed by their extraction. Sometimes these malaks of indurated matter include no extraneous subfance; in other instances, their nucleus is a biliary calculus; in a vaft number of cafes, they are merely compofed of the feces in a dry hardened state. It is remarked that women, and persons of advanced age, are most subject to the conftipation arising from the obfruction thus occasioned in the large intestines. Children and adults in the vigour of life are not, however, entirely exempt from the disorder, though they seldom have it, except when the formation of fuch concreations in the bowels has been brought on by swallowing a large quantity of hard indigefible bodies, like cherry and plum-tones. Lastly, excessively hardened malaks of fecal matter have been noticed in patients who have for a long while been confined to bed in the recumbent posture by severe disease.

Whatever may be the caufe of the disorder, whether the defect itself conffits in a mere accumulation of indurated feces, with which the rectum is dilated, and behind which the excrement is detained; or whether the conftipation is not complete, the concretion allowing the liquid part of the feces to pass out between it and the fide of the intestine; the existence of the hardened mass may be known by
by the conpilation which it produces; by the seive of weight which the patient feels about the fundament; and also by the possibility of actually touching the indurated obstructing body, when a finger is introduced up the rectum.

Oily emollient clysters, and carminative draughts, will serve for expelling such concretions as are not of too firm a consistence; but the extraction of them is absolutely necessary when they are particularly hard. The operation is to be done with a spoon, or suitable forceps, properly oiled; and, after the concretion has been removed, an emollient clyster is to be administered, in order to allay any irritation which may have been caused by the introduction of the requisite instruments. When the sphincter ani contracts so forcibly, as the operation is attended with extreme pain and difficulty, we are advised by surgical writers to make a dilatation of the anus, by pricking an incision at its posterior angle. A wound made in this direction cannot do injury to any part of consequence, whilst there would be a risk of wounding the urethra in the male, or the vagina in the female subject, if the cut were made at the anterior angle. An incision, carried laterally, would be apt to injure the pudic vessels. A division of the fibres of the sphincter ani does not produce any material permanent weakness of its action, and a paralysis of this muscle, according to Richerand, can never proceed from such a cause.

Nefografia Chirurgicale, tom. iii. p. 414, edit. 2.

The hard concretions which lodge in the rectum cannot be reached with the finger when they are situated high, and, in this circumstance, the surgeon must use a probe, or found, in order to assure himself positively of their presence, their movableness, and their size.

With regard to foreign bodies lodged in this intestine, some have been swallowed, and have passed through the whole extent of the alimentary canal; whilst others have been pushed up the anus to a greater or lesser height. The extraction of these lumps is generally attended with a great deal of difficulty, and even demands on the part of the operator more than ordinary dexterity, in consequence of the various shapes, the hardnes, and the fragility of these different bodies. Glass phials, instrument cafes, shuttles, &c. have been introduced into the rectum by maniacs. One person of this description put into his rectum a rented flint, which did not admit either of being extracted, or broken, owing to its hardnes, and slippery surface, and which in the end caused the patient to die in the greatest agony, with swelling and gangrenous mischief in the abdomen. Marchetti has recorded an instance, in which a pig's tail, hardened by cold, was forcibly thrust up the rectum of a girl of the town. This extraneous body could not be withdrawn, as the short bristles, which all inclined outward, immediately came into contact with and pierced the inner part of the bowel. It remained in the part fix days, and occasioned a train of alarming symptoms, such as fever, vomiting, swelling of the abdomen, and obliterative constipation. Marchetti failed a ligature to the end of the foreign body, which protruded at the anus, and then pulled the ligature through a long piece of reed, which he introduced up the rectum, in order that the foreign body might be drawn through this tube without the intestine being lacerated. The experiment was completely successful.

In another example a piece of wood, three inches long, and two in width, was introduced into the rectum. Colic, tension of the abdomen, fever, constipation, and difficulty of making water, came on, and lasted fix days. The impossibility of removing the extraneous substance with a pair of forceps, led to the idea of using a borer, which, having been passed up the rectum under the guidance of the finger, was inserted deeply enough into the piece of wood to draw it out. The extraction, however, could not be effected without a great deal of pain. See Mélanges de Chirurgie, par M. Saucorcer, p. 484. Mémoires de l'Académie de Chirurgie, tom. v. p. 605. Laflus, Pathologie Chirurgicale, tom. ii. p. 569, edit. 2.

RECTUM. Congenital and Syphilitic Contractions of its inferior Portion. A contraction of the lower end of the rectum is sometimes an original malformation; but more frequently it arises from what has been considered by various surgical authors to be a vesical thickening of the parietes of this intestine. If this be really a syphilitic disorder, a circumstance which is to be doubted, it is certainly as grievous as any of the more common effects of the vesical disease. Excrecences grow from the mucous membrane at the rectum, and discharge a purulent matter, which is continually oozing from the anus. When a finger is passed within this aperture, the irregularities occasioned by the tumour may be plainly felt. Such writers as believe in the syphilitic nature of this complaint inform us, that the truth of this may be known by the antecedent and co-existent symptoms of the vesical disease. They admit, however, that the disorder almost always lasts after the cure of every other mark of syphilis, and they caution us not to pervert rathly in administering mercury any longer for a disease which cannot be further benefited by it. These circumstances are quite sufficient to prove that there is not much reason for the doctrine, that this fort of contraction of the lower end of the rectum is vesical.

Such writers as consider the complaint to be connected with syphilis, of course recommend the exhibition of mercury, and they further advise the frequent injection into the rectum of a weak solution of the oxymurate of the same mineral. Tents, lined with mercurial ointment, are also recommended to be passed into the bowel. The latter applications are rated to have the advantage : if, of opposing, by mechanical pressure, the further increase of the excrecences; &c., of dilating the contracted part; and, 3dly, of acting on the disease by their medicinal quality.

For our own part, we much doubt the reality of the vesical nature of the foregoing complaint. The language of the advocates for such a doctrine must raise suspicions, that they are influenced in their judgment more by prejudice than reason. "The vesical affection of the coats of the rectum (says one of these writers) almost always lasts after the total extinction of the syphilitic virus. Then, we ought to be content with the employment of dilating mechanical means, without perverting in the use of medicines, which would serve only to ruin the patient's constitution.

An elastic girdle cannis is to be preferred, and it should be of a conical shape, in order that it may be gradually introduced further and further, in proportion as the dilatation of the bowels is effected." Richerand, Nefografia Chirurg. tom. iii. p. 418, edit. 2.

In cases of congenital contraction of the rectum, the only plan which can be adopted, is that of making an incision through the posterior part of the intestine.

RECTUM. Polypi of. Sometimes, though not often, polyopi grow from the mucous membrane of the rectum, and by their size obstruct the passage of the feces. Their existence is at first manifested by an uneasy sense of heaviness, and afterwards they are protruded outwardly in the efforts which the patient makes to stool. The anus contracting after their expulsion, their roots become strangulated, so that they cannot return, and excessive agony is produced.
In this circumstance, the surgeon should take the opportunity of removing them with a knife, after having tied their root, or even without this precaution. The lining of the rectum, freed from the weight of the tumour, immediately retracts, and if the polypus should have received a supply of blood from a large vessel, hemorrhage may ensue. Such accident may be remedied by completely detinding the distended part of the rectum with a large piece of sponge, or with a compres of lint; but as it is easier to prevent the hemorrhage altogether, than to stop it after it has occurred, we would advise surgeons, whenever the exscrecence is of any size, always to tie its root before removing the rest of it with a cutting instrument.

Rectum, Prolapsus of. See Prolapsus Ani.

Rectum, Serratus-contracted. Serratus of the rectum is not uncommon at an advanced period of life. Sometimes it extends over a considerable length of the gut, but generally it is more circumfered. The coats of the bowel become much thicker and harder than in the natural state. The muscular coat is subdivided by membranous septa, and the internal coat is sometimes formed into hard irregular folds. The surface of the inner membrane is occasionally ulcerated, so as to form a cancerous disease. Every vellige of the natural structure is occasionally lost, and the gut is changed into a gritty substance. The cavity of the bowel is always rendered narrow at the serratus part, and is sometimes almost obliterated. When the passage through the gut is much obstructed, the bowel is always a good deal enlarged just above the stoppage, or stricture, from the accumulation of the feces there. As the disease advances, adhesions form between the rectum and adjacent parts, and ulcerations produce communications between them.

The disease is usually not much noticed till somewhat advanced, not being at first very painful. The patient only thinks that he is coughing, and that he voids his stools with a little difficulty. In time, a good deal of pain is felt in the part affected, especially at stool, after which some relief is experienced. Pass and blood may sometimes be noticed with the excrement, particularly when the disease has advanced to the ulcerated state. The patient at length becomes ill at ease, the constitution suffers, and dilatation follows. Severe tenesmus attends the whole course of the disease.

Defect has often seen the disease form a communication between the rectum and vagina, and the feces have passed through the latter part. In the latter stage of the affliction, the rectum, bladder, vagina, uterus, and adjacent parts, are all involved in one common ulceration.

When the disease has attained the ulcerated state, it is probably always incurable. Palliatives can now only be resorted to, such as anodyne and emollient glypters, the warm-bath, &c. with the exhibition of medicines like opium, cucuta, uva ursi, &c. Claudius applied his remedies to the inside of the bowels by means of tents, and did not employ the latter as a mode of curing the disease, when less advanced. Valsalva used to introduce a cannula pierced with numerous holes, when his patient got into the bath, so as to let the fluid enter the intestine. Numerous practitioners, among them Morgagni, made mercureals the base of their treatment, from a supposition that the complaint was of venereal origin.

When the disease is not attended with ulceration, the contraction and thickening of the gut may be diminished by introducing bougies, keeping them for a certain time, every day, so introduced, and increasing their size gradually. The prebure of these instruments seems to lessen the disease, and stop its progress; a proof that its nature differs from that of what is usually understood by serratus. Default used to employ long tents, made of lint, smeared with cerate, and passed into the bowels by means of a probe, with a forked end. This surgeon gradually increased the size of the tents, so as to continue the compression, to which he conceived all the good was owing. Their length was also augmented by degrees. Fresh ones were, at first, introduced twice every day. When any hardnesse were situated on the outside of the anus, Default cured them on the same principle, viz. by making pressure on them with compres and a bandage. This eminent surgeon effected a cure of a serratus-contracted rectum by this method. The woman was taught to pass occasionally the tents herself, so as to prevent a relapse. The disease is said to afflict women more frequently than men: from a comparative table kept at the Hôtel-Dieu, this has been the case there in the proportion of ten to one. See Œuvres Chirurgicales de Default, tom. ii. p. 422.

Rectum, Hemorrhoidal Swellings of. See Hemorrhoids.

Rectum, in Law. See Recto.

Rectum, in our old Law Writers, is also used for a trial or accusation.

Rectum, Commune, denotes a trial at law, or in the common course of law. Stare ad rectam, denotes to fland a trial. Rectum rogare, to petition the judge to do right.

Rectus, in Anatomy, a name applied to several muscles, generally, but not invariably, distinguished by the straightness of their fibres, or of their general direction.

Rectus abdominis. See Obliquus.

Rectus abducens, or externus, &c. muscles of the globe of the eye. See Eye.

Rectus deprimens, or inferior,

Rectus anterior cruris, or femoris, synonymes of the Rectus cruris; Rectus extensor cruris, or femoris, which fee.

Rectus capitis anticus major et minor. See Rectus internus.

Rectus capitis internus major, rectus anticus major, tracheo-tons-occupitien; a muscle of the head, flattened, broader and thicker above than below, occupying the anterior and lateral part of the neck, and reaching from the transverse processes of the sixth cervical vertebra, to the inferior surface of the biliary process of the occiput. Its anterior surface is covered by the carotid artery, the internal jugular vein, the nerve of the eighth pair, the great sympathetic, and the pharynx. The longus colli, the rectus capitis internus minor, the articulations of the occipit and atlas, and of the latter bone, and the second vertebrae, are covered by its posterior surface. The inner edge lies on the longus colli, and is connected to it by cellular substance: the outer is fixed to the front of the transverse processes of the fifth, sixth, fourth, and third cervical vertebrae, and is unattached above the latter. The lower end, very thin and pointed, is fixed to the transverse processes of the sixth cervical vertebra: it ascends with a little obliquity from without inwards, increasing in breadth and thickness: it approaches the muscle of the opposite side, and is attached by its upper end to the biliary process of the occipital bone, in front of the foramen magnum. At the upper part of this muscle is a broad and thin aponoeuros, which depends on the anterior and inner surface; the attachments to the transverse processes are by small tendons terminating in muscular portions. The muscular fibres run obliquely between the last mentioned tendons and the aponoeuros.

This muscle bends the head forwards on the neck; and restores it after it has been carried backwards. The muf-
of one side, acting singly, inclines the head towards its own side.

Rectus capitis internus minor, or rectus anticus minor, tra-chelio-masto-occipitius; a small muscle of the head, lying under the lait, short, narrow, and flattened, and extending from the atlas to the occiput. It is covered in front by the rectus internus major, the internal carotid artery, and the great sympathetic nerve; behind it covers the capsule of the articulation between the atlas and occiput. The outer and inner edges present nothing remarkable. Its lower extremity is fixed to the anterior surface of the lateral portion of the atlas, and to the neighbouring part of its transverse process. Thence it ascends, increasing somewhat in size, and inclined a little inwards, and is fixed to the under surface of the baddary processes of the occiput, behind and a little on the outside of the rectus internus major, and to the cartilaginous mass filling the space between the occipital and temporal bones. It has aponeuroses at its extremities, and very short muscular fibres between these.

Its action on the head is exactly the same with that of the rectus internus major.

Rectus capitis lateralis, le premier transfereur antérieur Winflow, alétoïdo-mastoïden, petit droit latéral; a small muscle of the head, situated at the upper and lateral part of the neck, flattened and quadrilateral, reaching from the transverse process of the atlas to the occiput. It is covered in front by the internal jugular vein; and it covers behind the vertebral artery. The two edges present nothing remarkable. Below it is fixed to the front of the upper surface of the transverse process of the atlas: thence it ascends a little outwards, and is attached above to the rough impression behind the jugular fossa. It is muscular, except jux at the attachments, which are tendinous. Its action, like that of the two last muscles, is to reftore the head, when it has been bent backwards; to bend it forwards; and, when one muscle acts singly, to incline it laterally.

Rectus capitis pfflicosus major, axoïdo-occipitius; a muscle of the head, of a triangular flattened figure, placed at the upper and back part of the neck, and extending from the spinous processes of the second cervical vertebra to the occiput. Its posterior surface is covered by the complexus, and above by the obliquus superior capitis; the anterior surface covers the posterior arch of the atlas, the rectus pfflicosus minor, and the occiput. The inferior extremity, narrow, and almost pointed, is attached to the spinous processes of the second cervical vertebra, thence it ascends, directed outwards, and a little backwards, and gradually increasing in breadth, to be inserted in the inferior surface of the occiput, at about an equal distance from the great external transverse ridge, and the foramen magnum, between the complexus, the obliquus superior, and the rectus pfflicosus minor. The extremities alone are tendinous; the rest being muscular. It reftores the head, when it has been bent forwards; and carries it back on the vertebral column. When one muscle acts singly, it will have the power, from the oblique direction of its fibres, of rotating the head, so as to turn the face towards its own side.

Rectus capitis pfflicosus minor, alétoïdo-occipitius; a small flattened muscle with radiated fibres, and consequently a triangular figure, placed at the upper and back part of the neck, extending from the atlas to the occiput, and lying with its fellow in the interval between the two recti majores. Its posterior surface is inclined downwards and covered by the complexus; the anterior surface corre-sponds to the occiput, and to the interval between it and the atlas. The lower extremity is the narrowest part, and is fixed to the rough impression in the middle of the pos-
terior surface of the posterior arc of the atlas: it ascends parallel to the opposite muscle and directed backwards, and is fixed to the external surface of the occipital bone at a short distance from the foramen magnum. It raises the head when bent forwards; and extends it or carries it back on the neck.

Rectus cruris, rectus extensor or anterior cruris, droit ou grêle antérieur, leu-ro-totailien; a muscle of the thigh, long and flat, broad in the middle, and narrow towards its extremities, occupying the middle and front part of the limb, and reaching from the anterior and inferior spine of the ilium to the patella. It is covered in front by the iliaceus internus, the fatorius, and the facia lata; behind it covers the orbicular ligament of the hip, the great extensores of the knee, and the external or anterior circumflex vessels. The outer and inner margins of the muscle are unattached in their upper three-fourths; they are confluent, in their lower fourth, with the extensores of the knee.

The superior extremity of the rectus cruris presents two tendons, one of which is straight, the other curved. The former is fixed to the anterior and inferior spine of the os innominatum: the latter, curved from before backwards, and from above downwards, is fixed to the outer surface of the os innominatum for about an inch, immediately above the edge of the acetabulum. From this upper attachment the muscle descends vertically in front of the thigh, growing broader to the middle of the limb; it then becomes narrow towards the lower part, and is fixed to the basis of the patella.

The rectus is tendinous at its extremities, and fibrous in the middle. The upper tendon has been already described as divided into two portions; the anterior of these, attached to the anterior and inferior spine of the os innominatum, is the thickest and shortest, and has the same direction as the muscle; the other is longer and curved, and attaches some fibres to strengthen the orbicular ligament of the hip. The two portions soon unite in a common tendon; this spreads out into a broad aponeurosis, which descends about four inches on the front of the muscle, and then dips into its substance. The inferior tendon is broad and flat, and rises from the basis of the patella; its posterior surface is united to the great extensores of the knee, and the edges are strongly connected to the vallate externus and internus. It is broad at the patella, grows a little narrower as it rises, then spreads out again, and forms a broad aponeurosis, covering the back of the muscle above its middle. The superficial fibres of this tendon extend over the front of the patella, to which they are strongly united, and are left below in the tendon which unites this bone to the tibia. The muscular fibres are placed very obliquely between the superior and inferior tendons: they cover the back of the first up to the part where its two portions separate; and they descend on the front of the second to within two inches of the patella.

It extends the knee-joint, either by bringing the leg forwards upon the thigh, or the thigh upon the leg, according as the one or the other part is rendered a fixed point. If the knee be extended, or firmly retained in the bent position by its flexor muscles, the rectus may bend the thigh upon the pelvis: when the leg and thigh are fixed, it can bend the pelvis forwards upon the latter, as in the attitude of stooping to pick up any object from the ground. In the erect attitude it prevents the pelvis from inclining backwards; and reforces it when it has been carried in that direction.

Rectus in curia, in Law, one who stands at the bar, and no man objects any thing against him.
When a man hath revered the outlawry, and can participate of the benefit of the law, he is said to be relictus in curia.

Reculver, in Geography, a village and parish in the upper half hundred of Blean Gate, lathe of St. Augustine, and county of Kent, England, is situated at the distance of 10 miles N.E. by N. from Canterbury. It is noted in history as the site of the Roman Reculver, which was a strait or cause which defended the northern entrance to the celebrated Portus Rutupensis. It is remarkable, that while the ocean has receded from the southern entrance, leaving Richborough (Rutupium) considerably inland, it has gradually advanced upon Reculver. This is proved on the authority of several ancient writers, particularly Leland, who states, that in his time it stood about half a mile from the shore, whereas, at present, the tide washes the walls of many of the village houses, and threatens to overwhelm the whole at no distant period. Reculver was a strait of much importance, as it not only commanded an extensive view of the open sea, but likewise of the mouths of the Thames and the Medway. It was therefore used as a watch-post to discover the approaches of an enemy; and also as a light-house to guide sailors. Its perfect flat is an islet of a square form, with the angles rounded off, and was en-vironed by a ditch exterior to the walls, of which a considerable portion still remains. The extent of the enclosed area from eait to well is about 150 yards, and from south to north about 198 yards. The ancient town was without the islet, and is supposed to have been on the north, on that part of the coast long since swallowed up by the waves: and from the present shore, as far as a place called Black Rock, seen at low water mark, where, according to tradition, a church once stood, there have been found great quantities of tiles, bricks, fragments of walls, tessellated pavements, and other marks of a ruined town; and remains of the household furniture, drefs and equipment of the horse belonging to its inhabitants, are continually met with among the sands; for after the fall of the cliffs, the earthy parts of them being washed away, these metaline substances remain behind. When a part of the cliff here fell down about the conclusion of the fourteenth century, a number of small vaults, arched over, and several cisterns, were discovered. The latter were all of the same figure, namely, square, and measured from ten to twelve feet in length each side, and the same in depth. They were constructed of quarters, driven deep into the ground, with planks two inches thick fixed to them. Their use was evidently the reception and preservation of rain water, which the Romans thought more wholesome than spring water. Vast quantities of Roman coins have been discovered both in the fields and along the shore here; and Du Fresne has produced many, which, from the markings upon them, appear to have been struck at a mint in this place. Britsh and Gaulish coins are likewise occasionally found here; also seals, keys, spoons, gold rings, bracelets, filigree, bullae, belts, bridles, harness, beams of scales or flagiars, and many other articles of which the use has not yet been determined.

When Kent was subdued by the Saxons, Regulbium, became a principal seat of the monks of that dynasty. It was then called Raculf and Raculf-stiger; and hither king Ethelred retired with his court, after his conversion to Christianity by St. Augustine. In the next century, it obtained the name of Raculf-minister, from a Benedictine abbey founded here by Boffa, a priest and nobleman, to whom lands were granted for that purpose by king Egbert, as an atonement for the murder of his two nephews. This abbey was dissolved previous to the Conquest, having probably been destroyed by the Danes. The town, however, continued in a flourishing condition for many years after the event, and had the privilege of a weekly market granted to it in 1513; but this right has been long discontinued. The church here is an ancient and spacious edifice, consisting of a nave, with two aisles, a chancel, and two lofty towers, surmounted by spires at the angles of the west front. The nave is separated from the aisles by five pointed arches, rising from short oblong piers; and from the chancel by three small semi-circular arches, springing from tall round columns, with very singular capitals. In this church kings Ethelbert I. and II. are said to have been buried; and a monument erected to the memory of the first is described by Weever in his "Funeral Monuments," though it has now disappeared. On the floor of the chancel are several brasses of great antiquity. (See Richborough.) Beauties of England and Wales, vol. vii. by E. W. Brayley. History and Antiquities of Reculver and Herne, by W. Battelley, D. D. 8vo.

Recumpado, in Geography, a town of Hindoos, in the circar of Rajamundry; 23 miles N.W. of Rajamundry.

Recuperatores, among the Romans, were commissioners appointed to take cognizance of private matters in dispute, between the subjects of the state and foreigners, and to take care that the former had justice done them.

It came at last to be used for commissioners, to whom the prorog referred the determination of any affair between one subject and another.

Recurrens, in Anatomy, a name under which the inferior laryngeal branch of the par vagum is often described, from the circumstance of its arising in the chest below the point of its distribution to the larynx, and then going back into the neck in a retrograde course. See Nerve.

Recurring Series, is a series so constituted, that each succeeding term is connected with a certain number of the terms immediately preceding it, by a certain and variable law; as the sums or differences of some multiples of those terms. Thus the series

\[ a, b, \gamma, \delta, \epsilon, \theta, \&c. \]

is a recurring series; for these terms being respectively represented by \(a, b, \gamma, \delta, \&c.\) we have

\[ \gamma = 2 \times \beta - \alpha \times 2 \]
\[ \delta = 2 \times \gamma - \alpha \times 2 \]
\[ \epsilon = 2 \times \delta - \alpha \times 2 \]
\[ \theta = \&c. \]

that is, each term is equal to 2 \( \times \) times that which precedes it, minus \( \alpha \times 2 \) times the one preceding the last.

Or, generally, let

\[ a, b, c, \gamma, \delta, \epsilon, \theta, \&c. \]

be any series whose terms are denoted as above, by \(a, \beta, \gamma, \delta, \&c.\) Also, let \(\mu, \nu, \pi, \ldots\) \&c. represent the successive multipliers by which the terms are connected, so that

\[ a = a \]
\[ \beta = \beta \]
\[ \gamma = \mu \times \beta + \nu \times \alpha + \&c. \]
\[ \delta = \mu \times \gamma + \nu \times \beta + \&c. \]
\[ \epsilon = \mu \times \delta + \nu \times \gamma + \&c. \]
\[ \theta = \&c., \&c. \]

then this series is called a recurring series; and \(\mu + \nu + \&c.\) De Moivre calls the scale of relation, which is said to be of one, two, three, \&c. terms, according to the number of multipliers
RECURRING SERIES.

In the above we have used only two, \( \mu \) and \( \nu \), whence \( \mu + \nu \) is called the scale of relation, which is here of two terms; and 1 minus the scale of relation, as \( 1 - \mu - \nu \), is called the same author the differential scale, which is always equal to the denominator of the fraction from which the series is produced.

If, in the above series, the terms had the relation

\[
\begin{align*}
\alpha &= x \\
\beta &= \beta \\
\gamma &= \gamma \\
\delta &= \mu x \cdot \gamma + v x^3 \cdot \beta + \xi x^3 \cdot \alpha \\
\epsilon &= \mu x \cdot \delta + v x^3 \cdot \gamma + \xi x^3 \cdot \beta \\
\theta &= \mu x \cdot \epsilon + v x^3 \cdot \delta + \xi x^3 \gamma \\
&\text{etc. etc.}
\end{align*}
\]

then the scale of relation would be \( \mu + v + \xi \), which is of three terms; and the differential scale, or the denominator of the fraction, is \( 1 - \mu - v - \xi \).

The following problems are naturally connected with the doctrine of recurring series; viz.

1. Any recurring series being proposed, to find the scale of relation, or the law of the series, which is not always obvious on inspection.

2. To find the sum of an infinite recurring series, or the sum of any number of its terms \( (n) \).

3. To find a general expression for any indefinite term of such a series, as, for example, the \( n \)th term.

We shall consider each of these problems under their separate heads.

1. To find the scale of relation in any proposed recurring series.

Let \( a, b, c, d, e, f \), &c. be a recurring series, of which it is required to find the scale of relation.

Assume

\[
\begin{align*}
\beta &= \mu \gamma + \nu \beta + \xi \gamma + \delta \\
\epsilon &= \mu \delta + v \gamma + \xi \beta \\
\theta &= \mu \gamma + v \beta + \xi \delta + \epsilon \\
&\text{etc. etc.}
\end{align*}
\]

Where \( \beta, \gamma, \delta, \epsilon \) are known, and \( \nu, \xi, \gamma \) &c. unknown quantities, whose numerical values are required, and which are readily found by the usual method of elimination. Thus in the above, using only \( \mu \) and \( \nu \), we have

\[
\mu' = \frac{\beta - \gamma + \nu \beta}{\gamma - \nu \beta}, \text{ and } \nu' = \frac{\beta - \gamma}{\beta - \gamma}.
\]

These values of \( \mu' \) and \( \nu' \) will obviously contain in them the powers of the indeterminate quantity \( x \), which being taken out, we shall have the required numerical values of \( \mu \) and \( \nu \).

Let it be required to ascertain the scale of relation in the series

\[
\alpha, \beta, \gamma, \delta, \epsilon, \theta, \text{ &c.}
\]

Here, by substituting the proper values of \( \beta, \gamma, \delta, \epsilon \) &c. in the above equation, we have

\[
\mu' = \frac{35 x^3 - 27 x^5}{26 x^3 - 21 x^5} = \frac{8 x^3}{4 x^5} = 2 x
\]

\[
\nu' = \frac{49 x^3 - 45 x^5}{21 x^3 - 25 x^5} = \frac{4 x^3}{-4 x^5} = \frac{x^3}{-4 x^5}
\]

when \( \mu = 2 \), and \( \nu = -1 \).

The same method may obviously be employed in any other case; but in order to know whether or not we have assumed a scale of relation of a sufficient number of terms, we must repeat the same process upon three other terms, of which one at least was not before employed; and if both give the same values, we may be assured of the truth of our results; or we may otherwise, instead of repeating the operation, examine the several terms, and see whether they agree with the law we have determined, and if not, we must increase the terms in our scale of relation; for it may be observed, that we can never fail of determining them in consequence of having assumed too many terms, as we shall, in that case, have one of our results zero.

Here it is evident, that the whole sum

\[
S = \alpha + \beta + \gamma + \delta + \epsilon + \theta + \text{ &c.}
\]

\[
S = \alpha + \beta + \mu \cdot x (\gamma + v \cdot \beta + \xi \cdot \alpha) + v \cdot x \beta (\gamma + v \cdot \beta) + \xi \cdot x^3 \beta (\gamma + v \cdot \beta) + \delta + \epsilon + \theta + \text{ &c.}
\]

which is a general expression when the scale of relation is of two terms.

When the scale of relation is of three terms, so that

\[
\alpha = \alpha \\
\beta = \beta \\
\gamma = \gamma \\
\delta = \mu x \cdot \gamma + v x^3 \cdot \beta + \xi x^3 \cdot \alpha \\
\epsilon = \mu x \cdot \delta + v x^3 \cdot \gamma + \xi x^3 \cdot \beta \\
\theta = \mu x \cdot \epsilon + v x^3 \cdot \delta + \xi x^3 \gamma \\
&\text{etc. etc. &c.}
\]

it is equally obvious that

\[
S = \alpha + \beta + \gamma + \mu \cdot x (\alpha + \beta + \gamma + \text{ &c.}) + v \cdot x \beta (\gamma + \beta + \gamma + \text{ &c.}) + \xi \cdot x^3 \beta (\alpha + \beta + \gamma + \text{ &c.}),
\]

or

\[
S = \alpha + \beta + \gamma + \mu x (S - \alpha - \beta) + v x^3 (S - \alpha) + \xi x^3 S + \text{ &c.}
\]

whence we have

\[
S = \frac{\alpha + \beta + \gamma - \mu \cdot x (\alpha + \beta) - v \cdot x^3 \cdot \alpha}{1 - \mu x - v x^3 - \xi x^3}
\]

which is the general expression for the sum, when the scale of relation is of three terms.

In the same manner we have

\[
S = \frac{\alpha + \beta + \gamma + \mu x (\alpha + \beta + \gamma) - \mu x^3 \cdot (\alpha + \beta) - \xi x^3 \cdot \alpha}{1 - \mu x - v x^3 - \xi x^3}
\]

for a scale of relation of four terms; and so on.

But as the terms \( \alpha, \beta, \gamma, \delta \) &c. contain in them certain powers of \( x \), we may reduce the above expressions to simpler forms.
RECURRING SERIES.

II.—To find the general term of any proposed recurring series.

From the preceding part of this article it appears, that every recurring series may be considered as arising from the development or expansion of some rational fraction of the form

\[
\frac{a + bx + cx^2 + dx^3 + \&c.}{1 - \alpha x - \beta x^2 - \gamma x^3 - \delta x^4 - \&c.}
\]

Let us, therefore, suppose this fraction to be converted into the infinite recurring series \(A + Bx + Cx^2 + Dx^3 + \&c.\) of which we already know how to determine the co-efficients, and the law of their formation.

Now if this rational fraction be decomposed into its simple fractions by the method explained under the article RATIONAL FRACTIONS, and each of these simple fractions be then converted into a recurring series, it is evident that the sum of all these series ought to be equal to the original series

\[
A + Bx + Cx^2 + Dx^3 + \&c.
\]

Now each of these partial fractions being of the form

\[
\frac{A'}{1 - r x^n}
\]

the series thence arising will have the form

\[
A' + A'r x + A'r^2 x^2 + A'r^3 x^3 + \ldots + A'r^n x^n
\]

of which \(A'r^n x^n\) is the general term. Hence, the several series arising from the partial fractions may be supposed to be

\[
A' + A'r x + A'r^2 x^2 + A'r^3 x^3 + A'r^4 x^4 + \ldots + A'r^n x^n
\]

and since the sum of these series is equal to the original one proposed, we know that the co-efficients of the like powers of \(x\) are all equal, whence we have

\[
A = A' + A'' + A'' + A''' + \&c.
\]

\[
B = A'r + A''r + A'''r + A''''r + \&c.
\]

whence it appears that the co-efficient of any term \(x^n\) of the recurring series is equal to the sum of the co-efficients of the same power of \(x\), which arise from expanding the several simple fractions into which the given fraction is decomposed; and this co-efficient is always equal to the sum of each of the numerators of the several simple fractions, multiplied into the \(n\)th power of the corresponding value of \(r\) in the denominator of the same fraction, at least while the denominator contains no equal factor. But if, among the partial fractions,

\[
\frac{A}{(1 - r x)^n}
\]

is required

there is any one of the form

\[
\frac{A}{(1 - r x)^n}
\]

the general term of this will be \((n + 1) A r^n x^n\); of \(\frac{A}{1 - r x}\), the general term is \(\frac{(n + 1)(n + 2)}{1 \cdot 2} A r^n x^n\); and universally \(\frac{A}{1 - r x} \), the general term is

\[
\frac{(n + 1)(n + 2)(n + 3) \ldots (n + k - 1)}{1 \cdot 2 \cdot 3 \ldots (k - 1)} A r^n x^n
\]

we may, therefore, in all cases wherein the generating fraction of the original series admits of a rational decomposition, arrive very readily at the general term upon the principles above explained.

Thus,
RECURRING SERIES.

Thus, as an example, let there be proposed the recurring series

\[ 1 + 4x + 14x^2 + 46x^3 + 146x^4 + \&c. \]

to find the general term, or the co-efficient of \( x^n \).

The sum of this series is found by the preceding part of this article to be \( \frac{1 - x}{1 - 5x + 6x^2} \).

This rational fraction is equal to \( \frac{1}{1 - 2x} + \frac{2}{1 - 3x} \).

Now the general term of \( \frac{1}{1 - 2x} \) is \( 2^n x^n \); and of \( \frac{2}{1 - 3x} \)
is \( 2 \cdot 3^n x^n \), as shewn above; therefore the general term of the proposed series will be \( (2 \cdot 3^n - 2^n) x^n \).

It may be observed, however, that this method is in some cases very laborious, and not always practicable; it will, therefore, frequently be better to make use of the multinomial theorem, which may be done by putting the generating fraction under the form

\[ (a + b + c x + \&c.) \frac{1}{1 - a x - b x^2 - c x^3 - \&c.} \]

See Multinomial Theorem.

IV.—To find the sum of any number \( n \) terms of a recurring series.

For this purpose it is only necessary to find the co-efficient of the \( n + 1 \)th term of the series. Then, from the sum of the entire series subtract the sum of the series beyond the \( n \)th term, and the difference will obviously be the sum of the first \( n \) terms sought.

Let there be proposed as an example to find the sum of \( n \) terms of the series

\[ 1 + 2x + 3x^2 + 4x^3 + \ldots \ldots nx^{n-1}. \]

The infinite sum of this series readily found \( \frac{1}{(1 - x)^2} \).

In the second case, viz. of the terms beyond \( nx^{n-1} \), the series is

\[ (n + 1)x^n + (n + 2)x^{n+1} + (n + 3)x^{n+2} + \&c.; \]

and in the formula \( s = \frac{a + \beta - \alpha \mu x}{1 - \mu x - \nu x^2} \) we have only to substitute \( a = (n + 1)x^n \), and \( \beta = (n + 2)x^{n+1} \), instead of \( a = 1 \) and \( \beta = 2x^n \), as in the former. Hence we have

\[ s' = \frac{(n + 1)x^n + (n + 2)x^{n+1} + \ldots}{1 - 2x + x^2}, \]

or

\[ s' = \frac{(n + 1)x^n + nx^{n+1}}{1 - x}. \]

and, therefore, \( s = s' \), or the sum of the first \( n \) terms is equal to \( \frac{1 - (n + 1)x^n + nx^{n+1}}{(1 - x)^2} \).

2. Required the sum of \( n \) terms in the series

\[ 1 + 3x + 5x^2 + 7x^3 + \ldots \ldots (2n - 1)x^{n-1}. \]

Here, by trial, we find the scale of relation to be \( \mu = + 2 \), and \( \nu = - 1 \), as before; therefore the infinite sum is

\[ s = \frac{a + \beta - \alpha \mu x}{1 - \mu x + x^2} = \frac{1 + 2x - x^2}{1 - 2x + x^2} = \frac{1 + x}{(1 - x)^2}. \]

After \( n \) terms, the series becomes

\[ (2n + 1)x^n + (2n + 3)x^{n+1} + (2n + 5)x^{n+2} + \&c. \]

which therefore arises from the fraction

\[ \frac{(2n + 1)x^n + (2n + 3)x^{n+1} - 2(2n + 1)x^n}{1 - 2x + x^2} = \]

\[ \frac{(2n + 1)x^n - (2n - 1)x^{n+1}}{(1 - x)^2}. \]

whence the sum of \( n \) terms is

\[ \frac{1 + x - (2n + 1)x^n + (2n - 1)x^{n+1}}{(1 - x)^2}. \]

3. Required the sum of \( n \) terms of the series

\[ (n - 1)x + (n - 2)x^2 + (n - 3)x^3 + \&c. \]

Here again the scale of relation is \( + 2 - 1 \); therefore the infinite sum is

\[ \frac{(n - 1)x + (n - 2)x^2 - 2(n - 1)x^3}{(1 - x)^2}. \]

After \( n \) terms, it becomes \( x^{n+1} - 2x^{n+2} - \&c. \), the sum of which is found in the same manner to be \( \frac{x^{n+1}}{(1 - x)^2} \); therefore \( n \) terms of the series is

\[ \frac{(n - 1)x - nx^n + x^{n+1}}{(1 - x)^2}. \]

Hence, also, \( n \) terms of the series

\[ \frac{(n - 1)x}{n} + \frac{(n - 2)x^2}{n} + \frac{(n - 3)x^3}{n} + \&c. \]

is found to be

\[ 1 + x - (n + 1)x^n + (2n^2 + 2n - 1)x^{n+1} - n!x^{n+2} \]

the scale of relation being \( 3 - 3 \).

In all the preceding examples we have determined the infinite sum of the series, as beginning at the first term, and at the \( (n + 1) \)th term, a more easy method is as follows, which is due to Simpson. Effays, p. 96.

Let \( A + B + C + D + \ldots + K + L + M + N \) be any finite recurring series, of which each term depends upon the three which precede it, the scale of relation being \( p, q, r \), so that

\[ \begin{align*}
  pA + qB + rC &= D \\
  pB + qC + rD &= E \\
  &\ldots intersect.
\end{align*} \]

or, which is the same,

\[ \begin{align*}
  pA + qB + rC + D &= 0 \\
  pB + qC + rD + E &= 0 \\
  pC + qD + rE + F &= 0 \\
  &\ldots intersect.
\end{align*} \]

whence,
whereby, by addition

\[
\rho (A + B + C + \cdots K) + q (B + C + D + L) + r (C + B + D + \cdots M) = 0
\]

or, representing the whole sum by \( S \),

\[
\rho (S - L - M - N) + q (S - A - M - N +) + r (S - A - B - N) = 0
\]

which, by addition and division, gives

\[
\rho (L + M + N) + q (A + M + N) + r (A + B + C) = \rho + q + r - 1
\]

where the sum depends merely upon the three first and the three last terms of the series; and a similiar expression, it is obvious, may be obtained for any other scale of relation.

It may not be amifs to observe, that when the proposed series is wholly numeral, (the sum of which, as we have before observed, is to be found by making \( x = 1 \)); both this formula and the preceding one fail, in the case in which the denominator of the fraction becomes zero, and we must, therefore, in such cases, have recourse to other methods of summation, as given under the article Series.

On this subject the reader should consult De Moivre's Misc. Analyt. and his Doctrine of Chances, and Euler's Analysis Infinitorum, where he will find an explanation of its application to the approximation to the roots of equations. Collon's Comment on Newton's Fluxions. Stirling's Methods Differ. Cramer's Analyse des Lignes Courbes. Bernoulli de Serieb. Inf. &c. See also a chapter on this subject, in vol. ii. of Bonnycastle's Algebra.

RECURVIROSTRA, the Avocet, in Ornithology, a genus of birds of the order Grallae, of which the generic character is; bill deprefed, fubulate, recurved, pointed, flexible at the tip; the feet are palmate, four-toed, the hind toe not connected, very short, and placed high up; the nostrils are narrow, pervious; the tongue is short. There are only three species.

*AVOCET; Scooping Avocet; called also in different parts of this country, butter-clip, scooper, yelper, crooked-bill, &c. This bird is variegated with white and black; the bill is three inches and a half long; irises hazel; crown black; a white spot behind and beneath the eyes; rect of the head, neck, back, exterior part of the wings, lesser quill-feathers, tail, and under part of the body, white; inner scapulars and greater quill-feathers without and at the tips black; legs blueish, and very long; membrane connecting the toes indented. It resides in the temperate parts of Europe, weighing thirteen ounces; and measuring, from the tip of the bill to the end of the tail, eighteen inches. It breeds in the fens of Lincolnshire, and on Romney Marsh, in Kent. The female lays two white eggs, tinged with green, and marked with large black spots. In winter these birds assemble in small flocks of six or seven, and frequent the shores, particularly the mouths of large rivers, in search of worms and marine infests, which they scoop out of the mud or sand. They seem to be particularly fond of the cancer, pales, or loceats. By means of their long legs, they run over shores that are covered five or six inches with water. In their movements they are lively, alert, volatile, and difficult to catch. When the female is frightened off her nest she counterfeits lameness; and when a flock is disturbed, they fly with their necks stretched out, and their legs extended behind, over the head of the spectator, making a shrill noise, and uttering a yelping cry of trit, trit, all the time.

AMERICAN; American Avocet. The head and neck are reddish; back black, beneath it is white. It inhabits North America and New Holland; is fourteen inches long. Bill black; front dusky-white; neck above white; primary and tertial wing-coverts black, the middle ones, and some of the secondary quill-feathers, white.

ALA; White Avocet. This species is white; the lower wing-coverts brownish; bill orange; legs brown. Inhabits Hudson's Bay; fourteen inches and a quarter long. Bill tip with black; edge of the wings, greater quill-feathers, and tail, tinged with yellowish.

RECUSSANTS, in a general sense, persons, whether Papists or others, who refuse to go to church and to worship God after the manner of the church of England. Popish recusants are Papists, who so-refuse; and a popish recusant convict is a Papist legally convicted of such offence. See Papist, Prelumire, and Toleration.

RECUSSION, RECUSSION, an act by which a judge is directed to refrain from judging some certain cause, on account of his relation to one of the parties; or of some capital enmity, or the like.

By the French laws, kindship within the fourth degree is deemed a legal cause of recusation; as also the judge's being godfather, &c. of one of the parties.

By the laws of England also, in the times of Bracton and Fleta, a judge might be refused for good cause; but now the law is otherwise, and it is held that judges or justices cannot be challenged. Co. Litt. 254. See CHALLENGE.

RED, in Physics, one of the simple or primary colours of natural bodies, or rather of the rays of light.

The red rays are those which are of all rays the least refrangible; hence, as Sir Isaac Newton fupposes the different degrees of refrangibility to arise from the different magnitudes of the luminous particles of which the rays consist, the red rays, or red light, is concluded to be that which consists of the largest particles. See COLOUR, LIGHT, and RAY.

Authors differ in the three general kinds of red; one bordering on the blue, as cobaltine, or dove-colour, purple, and crimson; another bordering on yellow, as flame-colour and orange; and between these extremes is a medium, partaking neither of the one nor the other, which is what we properly call red.

Acids generally turn black blue, and violet into red; and red into yellow, and yellow into a very pale yellow.

Alkalies change red into violet, or purple; and yellow into feuillemort, or dead leaf-colour.

Terrestrial and sulphuraceous matters become red by extreme heat; and one, at length, black, as we see in brick, red oak, red chalk, flate, &c. All these, when vitrified by a burning glafs, become black.

Lobsters become red by a moderate fire; and by a violent one, black. Mercury and sulphur mixed and heated over a moderate fire make a beautiful red, called artificial cinnabar.

An acid spirit, as lemon juice, being poured on a blue solution of turpentine, turns it into a beautiful red. Alkali restores it again to its original blue. Filtrating of some reddish wines takes from them all their red colour.

M. De la Hire observes, that a very luminous body viewed through a black one, always appears red; as when the sun is seen shining through a black cloud. He adds, that some people who see all the other colours perfectly well, yet have no idea of red, and only see it as black.

RED, in Cosmetics, a fucus or paint with which the ladies enliven their cheeks and lips.

There
There are two kinds of reds; the one in leaves, called Spanish red; the other a liquor, which is an extract of a scarlet dye.

Red, in Dyeing, is one of the five simples or mother colours of the dyers. Some reckon seven kinds, or calls of red: viz. scarlet-red, crimson-red, madder-red, half-grain-red, half-crimson-red, lively orange-red, and scarlet of cochineal. But they may be all reduced to three, according to the three principal drugs which give the colours; which are kermes, cochineal, and madder.

The fine scarlet, called scarlet of the Gobelins, is given with agaric, bran-water, woad, and scarlet grain, or kermes. Some dyers add cochineal, and others fenugreek; brightening it with bran-water, agaric, tartar, and turmeric. See Kermes and Scarlet.

Crimson-red is dyed with bran-water, tartar, and mellelique cochineal. See Crimson.

Madder-red is dyed with madder; to which some add realgar, or red arsenic; others, common salt, or other salts, with wheat-flour; or agaric with spirit of wine, with galls or turmeric. See Madder.

The half-grain is made with agaric and bran-water, half scarlet grain, half madder, and sometimes turmeric.

The half-crimson is made of half madder, half cochineal. As to the lively orange-red, the stuff must be first put in yellow, then in a liquor made of goat's hair, (which has been boiled several times with madder,) diffused over the fire with certain saline liquors, as urine, tartar, &c.

The scarlet of cochineal, or Dutch scarlet, as the French call it, is made with flame, tartar, and cochineal; after first boiling it with alum, tartar, sal gemma, and aqua fortis in which pewter has been diffused.

Besides these seven reds, which are good and allowed colours, there is also a Drazil red; which is discouraged, as fading easily.

Of the seven good reds, only four have particular calls, or shades; the madder-red, crimson-red, lively orange-red, and scarlet of cochineal.

The calls or shades of crimson are flesh colour, peach colour, carnation rose colour, and apple-tree flower colour. Tho' of madder are flesh colour, onion-peel colour, and flame colour. Tho' of orange are the same with those of crimson. Scarlet, besides the shades of all the reds, has some peculiar to itself, as cherry colour, fire colour, &c. See Dyeing.

Red, in the Manufacture of Glass. See Red Glass.

To make a deep red in glass, the following method is that most practised by the glas-men. Take crytall frit twenty pounds, broken pieces of white glass one pound, calcined tin two pounds; mix these well together, and put them into a pot to melt and purify. When they are melted, take these, calcinations, scales of iron from the smith's anvil, both powders very fine, of each an equal quantity; put ideally an ounce of this mixed powder to the before mentioned metal; mix all well together, and let them stand fix or eight hours in fusion to incorporate; take out a proof after this, and if there be too little of the powder, it will appear of a dusky yellow; then more of the powder must be added, and then add three quarters of an ounce of calcined brasa, ground to a fine powder; mix them thoroughly together, and the mass will be of a blood red; continue fusing the whole together, and frequently taking out proofs of the colour, when it is right, work it immediately, otherwise it will lose its colour and become black. The mouth of the pot must in this process be left open, else the colour will be lost. Neri's Art. of Glass, p. 100.

Red, in Heraldry. See Gules.

Red, in Painting. For painting in oil colours they use a red called cinnamon, or vermilion; and another called lacca. See each in its place.

In liming and fresco, for a violet red, instead of lacca they use reddie, a natural earth found in England; for a brown red, they use burnt ochre, which is a native yellow earth, made red by calcination. It is chiefly brought from Oxfordshire; and burnt by those who prepare it in large ovens. The marks of its goodnese are brightness of colour, and a friable chalky texture, without manifesting any gritty roughness when rubbed between is fingers.

The common Indian red, which is of a hue verging to the scarlet, is much used, on account of its flattening and warm though not bright colour, in finer as well as coarser paintings in oil. It may be prepared by taking of the caput mortuum or ochre left in the iron pots after the distillation of aqua fortis from nitre and vitriol, two parts; and of the caput mortuum or coloquhar left in the long necks after the distillation of oil of vitriol, one part; breaking the lumps found among them, and putting them into tubs with a good quantity of water; and having left them to stand for a day or two, frequently stiring them, then lading off as much water as can be obtained clear from them, and adding a fresh quantity, repeating the same treatment till all the fat be washed out, and the water comes off nearly infusid. The red powder which remains must then be washed over, and, being freed from the water, laid out to dry. When this is designed for nicer purposes, it should again be washed over in basons.

The true Indian red is a native ochreous earth of a purple colour, brought from the island of Otrum, in the Perican gulf; and called, among the authors on these subjects, terra Perica. At present, it is very rarely to be found; but it is certainly very valuable (there being no other uncompounded purple colour in use with oil) as well for the force of its effect, as for the certainty of its spreading. In its genuine state, it needs no other preparation than grinding or washing over. It may be easily distinguished from any fictitious kind, by its being more bright than any other ochre which may be made up; and if it be rendered artificially purple by any addition, the fire will soon betray it; into which the genuine may be put without any hazard of change.

Venetian red is a native red ochre (see Veneta bolus), not much different from the common Indian red, but fouler; and may be easily prepared, by mixing common red ochre with the coloquhar or caput mortuum taken out of the aqua fortis pots, and washed over. As it is generally used by the house painters in imitation of mahogany, it requires no other preparation than to be well ground with the oil with which it is used; but when it is used in miniature painting, it should be carefully washed over.

Red, Blown, in the Porcelain Manufacture, a name given to a peculiarly coloured china ware, of a spangled red, or to the colour alone that spangles it. It is an ornament easily introduced into use in our own manufactories of porcelain ware; and is done in the following manner. The colour is to be prepared of common copperas, calcined to a red colour in a charcoal fire, in a crucible, with another heated on the top of it inverted, and with a hole in its bottom. The signal of the calcination being finisht, is, when the black clouds cease to come up through the hole, and a fine white thin vapour rises in their place. The vessels are to be then suffered to cool, and the red matter in them be to be reduced to a fine powder, while the vessels be to be coloured with this
are yet wet. The operator is to provide a glass pipe, and covering one end of it with a piece of fine gauze, he is to dip this into the powder, and taking it carefully out, with what little is sticking to it, he is to blow against the vessel at some distance from it; thus the finest part of the powder only will reach the vessel, and will be laid on in form of glittering spangles, very small, but all distinct. This is a

fort of colouring much esteemed by the Chinese themselves, and they have a way of using the common blue in the same manner; but few of the vessels thus painted come over to us.

RED Clover, in Agriculture, an useful artificial grafs for arable lands. It has this name in contradistinction to the white and some other forts. There were at first many and very great prejudices against and objections made to the introduction of this plant into cultivation by farmers, which were not surmounted without difficulty, and it prevailed for some length of time in particular districts, as Staffordshire and Worcestershire, before it was known in some other counties, where it is now very predominant and beneficial, as Cheshire, Lancashire, and many more.

In some arable counties red clover is found to fail as a crop when long cultivated, dying away in the winter and spring, which the farmers designate by saying that the land is sick of it. This is a severe inconvenience to them in many cases; and renders such variations in the courses of cropping necessary, as may prevent the recurrence of it so frequently as has hitherto been the case. It is very liable to fail in every part of the county of Essex, but of the cause of which there are different opinions, some think that the land becomes sick of the plant, while others do not ascribe it to any fatuity of this nature, but attribute their modes of cropping that it may not take place so often. About the Belcamps and Booley this is very much the case, some venturing it only once in seven years, and in that case it succeds well. In all the Tendring hundred it is found to decline little on the strong rich lands, but is felt on the lighter forts; on both the cropping is varied in regard to it. In the neighbourhood of Thorndon the lands are sick of it. And at Audley End the land is tired of it, but more in many cases from want of sufficient feed than any thing else. In the vicinity of Hal-lingbury it is very liable to fail, if sown oftener than once in seven or nine years, though theylem thereabouts is crop and fallow.

In the county of Oxford some low red clover twice in ten years, the land being new to it; of course it never fails. On the gravelly loamy soils about Henly it dies from repetition, so that it is alternately omitted in cropping, others being substituted, as white clover, trefoil, and peas. Nothing of this fort was known forty years ago, but now they sow it only once in two rounds. The loams and feme-brash lands around Wood Raton are not in general tired of this plant; some however find it to fail on the latter fort of soil. About Great Tew, where the lands have been inclosed forty years, they are not yet tired of red clover. At Atterbury, where the lands have been inclosed many years, it does not now succeed quite so well as it did fifteen or twenty years ago. In these cases other crops are put in, as tares and early peas drilled.

Some suspect sheep’s dung to be destructive to the red-clover plant, but there are no proofs of the fact.

The most proper management of red clover as a preparation for wheat is a matter of great importance. Some think feeding it off wholly the beast practice; others mowing and feeding; and a few mowing altogether. The method of feeding off the crops altogether, when done in a close manner, is probably the most advantageous in this intention, though there may be some immediate losses and inconvenience; after which that of mowing the first crop and feeding the second in a suitable manner; the third mode, or that of mowing twice, is most to be feared, but upon some forts of land it may be done and answer well for wheat. These methods are all practised and have their advocates in different parts of Essex; and some think that they get as good wheat after white as red clover, as well as that feeding the latter does no injury in this respect.

The farmers in Oxfordshire follow nearly the same practices, and hold much the same opinions in regard to the management of this crop as a preparation for wheat. And the custom of mowing and feeding off the first year, is thought the best practice in some other counties.

But in the county of Lancashire, and some others adjoining it, they know nothing of the land being ever sick or tired of this fort of crop, though they grow it in more frequent succession and in a more full manner than perhaps any where else in the kingdom. Ask the farmers about this, and you will find from one end of the above county to the other, they are all of the same opinion, and appear much surprized at the question, not ever having any conception of such a circumstance. What can be the reason that red clover has been as long and as frequently cultivated in these districts, as in those where it is so liable to fail? Does it depend upon the difference in the nature or quality of the soils, or the management in regard to the quantity of feed and other matters? The circumstance is worthy of further and more close attention and investigation, in consequence of its great importance to the farmer.

There is one particular feature of management in the cultivation of red clover in the county of Oxford, which is that of hand-howing over it from fourteen to fifteen bushels of Newbury peat-ales, that are brought into the Thames, by the Reading canal, on the acre, about the end of March or at the beginning of the following month; which has an immediate effect upon it, seldom failing to produce a crop, except where it naturally declines. The expense is estimated at about ten shillings the acre. These ales do not, however, seem to be employed in this way to the red clover crop in the district where they are found and prepared.

Seeded red clover undergoes two succellive threplings, the first, which only beats off the heads and chaffs containing the feed from the stalks, is called cobbing in some places; the parts thus separated being denominated the red-clover cobh. The work is performed on a thick wooden plank frame for the purpose, and requires much labour to separate the feed, which, when done, is cleaned and passed through different sieves, being ultimately divided into two forts, the primary and secondary. The cost of these operations is very great, amounting to from four to six shillings the bushel, and sometimes much more. It has been concluded by Mr. Middleton, that this plant grows a full crop in all the arable lands of this country, from the sands of Norfolk to the cliffs of Cleveland and Suff. And that various soils that have been exhausted by corn, and not much accustomed to red clover, have been so much restored by it, as to produce a good crop of wheat; but that to do this every means should be used to secure a full crop, as that is an excellent preparation for corn, and seldom fails of ensuring a considerable produce, arising from shade, smoother, and putrefaction, the natural and constant attendants of full-grown red clover. It is supposed advisable, in some cases of poor land, to feed both crops off on the land by sheep and other animals, in some way or other. And sometimes to sow the first and feed the second, or the contrary. In every point of view this is an interesting plant to the farmer. See Clover.
Red Gun, an insect disease on wheat, by which the ears of the grain are deprived of their nutrition, and thereby prevented from perfecting themselves. It is described by Mr. Middleton to be a collection of insects, which are visible to the unaided eye, and which, in the early part of their growth, are of a reddish colour, but become brown with age: the black spots on the straw, blades, and ears of the wheat, are supposed to be the excrement of the insects. The blighted ears are probably rendered so, by the insects piercing the necks of the straw immediately below them, and sucking the saccharine juice, otherwise designed for filling the corn. In those ears which have both perfect and imperfect grains, the insect has perhaps infected its probe at the connection between the corn and the straw, and by drinking up the food of the grains severally, has flamey many of them in such a manner as to cause their destruction and decay. The exact nature of the disease is not, however, yet well ascertained.

Red Hay, a term used to signify such as is mow-burnt, in opposition to such as is green from a moderate heat, and winny hay, or such as is mouldy.

Red Land, a term used by husbandmen to express a sandy soil of a reddish hue, interpenetrated for the most part with pieces of sand-toned of the same colour, or somewhat deeper.

It may be noticed that there are several varieties of this soil: one of which is almost entirely made up of sand; another with an admixture of loam with the sand, the whole making a loose loamy earth; and a third full of fragments of a poor sandy iron ore, and often containing flaking specular of felnite. See Soil.

In some of the more northern parts of the county of Oxford, there is a rich red sandy loam, upon a red grit-toned rock. In some places this land is of more sandy quality than in others; and, in particular instances, a deep red loam, or red clay. The lands are moist of an excellent quality, both for arable purposes and those of grass; but the sandy forts are better than those of the clayey kinds, especially for the former use. The red soils in this district are considered as the boast and glory of the county, as they are deep, found, friable, and yet capable of tenacity; being well suited to almost every sort of plant which can be truffed to them, in the way of cultivation. Soils of this nature prevail more or less in a vast number of counties throughout the kingdom, even from the more southern ones to those far advanced towards the north.

Red Room, a term signifying the red tinge in ripening barley, and sometimes other sorts of grain.

Red Row, a provincial term, applied to the grains of barley, when in a ripening state, or flecked with red. The crop is then said to be in the red row.

Red Antimony, in Mineralogy, an ore of that mineral, of a cherry-red colour, containing, according to Klaproth, 67.5 antimony, 10.8 oxygen, 19.7 sulphur.

It occurs most frequently in minute diverging capillary crystals. It melts and evaporates before the blowpipe, yielding a fulphurous odour. See Antimony.

Red Arsenic. See Arsenic.

Red Chalk. See Reddish, and Ores of Iron.

Red Cobalt, called cobalt crust, and cobalt bloom or ochre, an ore of cobalt, of a peach blossum red colour. See Cobalt.

Red Copper, Ruby copper, an ore of copper, of a cochineal red colour, inclining to a lead-grey. It consists, according to Klaproth, of 91 parts copper and 9 of oxygen. See Copper.

Red Hamalite, Fer oligile facutrenierie of Haüy, an ore of iron, found in kidney-shaped and globular balls. The structure is fibrous, and divergingly radiated, but arranged in concentric curves; the colour is a bluish-grey, intermixed with red. By friction, it acquires a high metallic lustre. It yields from 65 to 70 per cent. of pure iron. (See Iron.) An excellent ore of this kind is procured near Ulverstone, in the north of Lancashire, much valued, as producing an iron of a peculiarly ductile quality, suited for the purposes of the wire-drawers.

Red Lead. See Minium and Lead.

Red Scalpy Iron Ore. Fer oligile flagrant of Haüy. It consists of feally particles slightly cohering; it has an unctuous feel, and flains the fingers. It passes into micaeous iron ore.

Red Schorl. See Ores of Titanium.

Red, or Ruby Silver Ore, Argent antimoniacal sulphure of Haüy. Werner divides this into two sub-species, dark red silver ore, and light red silver ore, distinguished from each other by their colour, and the situations in which they occur. The dark red ore is commonly accompanied by galena, antimonial sulphuret of silver, quartz, calcaceous spar, and pyrites. The colour is between cochineal red and lead-grey. It occurs massive, disintegrated, and crystallized in equiangular six-sided prisms, frequently variously truncated. The form of the primitive crystal is an obtuse rhomboid, whose pole angles are 105° 28' and 75° 32'; the inclination of the faces 105° 28' and 75° 32'. The external luster is pellucid, and in some specimens metallic; internally it is shining, and sometimes semi-metallic and metallic. The fracture is uneven, and in the crystallized varieties imperfectly smooth conchoidal. See Ores of Silver.

The massive varieties are opaque; the crystallized, semi-pellucid and pellucid. The colour of the flesh is a cochineal red. This variety yields easily to the knife; before the blowpipe or charcoal it deceripates, and melts with a slight effervescence, emitting a dense smoke, which colours the charcoal yellow, and leaves a globule of silver. The specific gravity is 7.65 to 5.68.

The light red silver ore is usually accompanied by native arsenic, white cobalt ore, orpiment, and sulphate of barytes. The colour passes from a carmine red to a medium between cochineal red and lead-grey. In most of its characters it agrees nearly with the dark red silver ore; but when fused, it yields an arsienie vapour. Hence some chemists have conjectured that this ore differs from the dark red ore, by the former containing antimony, and the latter arsenic. According to Klaproth, red silver ore contains nearly 60 of silver, 10.5 sulphur, Combined with 29.4 of antimonial kines, 3.2 oxygen, or 5.9 sulphur.

A variety of red silver ore, probably the light red ore of Werner, analyzed by Prout, gave 74 sulphuret of silver, 25 sulphuret of arsene, .6 oxyd of iron.

Red silver ore may be distinguished from cinnabar and red copper ore, by its specific gravity, which is considerably less than the former, and greater than the latter; the specific gravity of red silver ore being 5.6 to 5.8. of cinnabar 7 to 7.5.

Red Copper 3.9.

Red Vitriol, a salt found at Neufohl, in Hungary, in the form
form of transparent crystals of a pale rose-red colour, and more or less transparent. It was discovered by Klaproth to be a sulphate of cobalt. Its solution affords a pale blue precipitate, with carbonate of potash, which tinges borax a pure blue colour.

Red Berr, in Ichthyology. See Charr.

Red Eye, Erythroptalbus, the cyprinus erythroptalbus of Linnaeus, called by some robaus, or rooang, which, in the German language, signifies the lime. It very much resembles the common river bream in shape, but that it is somewhat thicker. The fins are all red, and the whole body of the fish is lined with a very elegant red, but no part of it so much as the iris of the eyes. When the scales are off, the body is of a greenish hue, and it has a yellow spot under the tongue. It much resembles the river mullet in some particulars, but it is of a more beautiful colour, and its eyes are more red. Its largest size feems a foot in length. It is a well-tasted fish; and spawns in April, under cover of the roots of trees. Ray.

This fish is called rudd by some English authors; it is also called ruilus later, rubello flavilletis, and is found very common in many of the rivers of Germany and England, and is in season all the year, except in spawning time, when the male is subject to a great number of white spots on its head, and is more rough than at any other season. Willughby. See cyprinus erythroptalbus.

Red-Breast, in Ornithology, a well-known bird, for the characters of which, see Motacilla Rubecula.

The song of this bird is remarkably fine and soft, and continues through the greatest part of the winter, spring, and summer. Many of the autumnal flogers seem to be the young cock red-breasts of that year. Pennant.

Thompson, in his Scephus, Winter, line 246, has admirably described the annual visits of this guest; and the ancient ballad of "The Babes in the Wood," recording the affection of this bird for mankind, is universally known.

Red Chatterer of Latham, Red-bird from Surinam of Edwards, and Ampelis cornix of Gmelin, a bird of red colours, with an ocular band, and the wing and tail-feathers black at their tips. It is found in New Spain, Guiana, and Surinam.

Red Game, an English name of a bird, common in the mountainous parts of Yorkshire, and some other of our northern counties. See Gorr-cok, Grouse, and Tetrao Lagopus.

Red-Pole, or Linnet. See Fringilla and Linnet.

Red-Pole, Tellow, or Red-headed Warbler. See Motacilla Pechlea.

Red-Head, the name of a water bird, called by authors gallinula erythroptalbus, and calidris; the ilopex calidris of Linnaeus. It is about the size of the common plover. The back is of a greyish or brownish-green, usually spotted with black; its neck grey, and its throat variegated with black and white; the breast is white, with a few loof streaks of black; the wing-feathers are variegated with black, brown, and white; the bill is two fingers breadth long, slender, and shaped like the beak of the woodcock; reddish at the base, and blackish lower down; its legs are of a nice beautiful red, and the hinder toe is very short and small. It breeds in the fens and marshes; is found on mole of our shores; conceals itself in winter in the gutters; and is generally found single, or at most in pairs. When disturbed it flies round its nest, making a noise like a lapwing. It lays four eggs, of a whitish colour tinged with olive, and marked with irregular spots of black, chiefly on the thicker end. Ray and Pennant. See Sclophax.

Red-Star, the English name of the rutilus, or motacilla phoeniceus of Linnaeus, a very beautiful bird. The bill and legs of the male are black; the forehead white; the crown of the head, hind part of the neck, and the back, are of a deep blue-grey; the cheeks and throat black; the breast, rump, and sides, are red; the two middle feathers of the tail brown, the others red; the wings brown. In the female, the top of the head and back are of a deep ash colour; the rump and tail of a duller red than those of the male; the chin white; the lower side of the neck cinereum; and the breast of a paler red.

This bird appears among us only in the spring and summer, and is observed to come over nearly at the same time with the nightingale. It is so shy, that it will forsake its nest, formed with moss on the outside, and hair and feathers within, in hollow trees and the holes of buildings, if the eggs are only touched. It has a very fine soft note; and is remarkable for shaking its tail, and moving it horizontally, as a dog does when baying. Pennant.

Red-Star, Greater. See Lanius Inflatus. See also Turdus Saxatilis.

Red-Star, Indian or Bengal. See Lanius Emuria.

Red-Star, Small American. See Muscicapta Rusticilla.

Red-Star, Grey. See Motacilla Gibratariensis and Erithacus.

Red-Stone Pcll. See Linnet.

Red-Tail. See Motacilla Erithacus and Guianenfts.

Red-Wing, the name of a bird of the turdus, or thrush kind, called also in some places the wind thrush, or fauine pipe; and by Linnaeus and others the turdus iliacus, or thus.

It is a little smaller than the common thrush, and is left spotted. Its back, neck, and head, are of the same colour with those of the common thrush; but its sides under the wings, and the feathers which line the wings, are of an orange colour, or dusky red; its belly and breast are white, and its throat yellowish, with brown spots: the wings are of a sort of chestnut colour, a little variegated. It feeds on insects, as worms, and the like; and is a bird of passage, coming to us in large flocks about the same time with the fieldfare, and leaving us also when that bird does. When the red-wing appears on the coast in autumn, it is certain the woodcocks are near. It is not well known where they breed, though some have guessed it to be in the mountains of Germany and Bohemia. They have a bitterish taste, and are less valued than the fieldfare. With us they have a disagreeable piping note; but in Sweden, during the spring, they sing very finely, perching on the top of fome tree among the feres of maples. They nest in hedges, and lay fix blueish-green eggs spotted with black. Ray and Pennant.

Red Water, a disease in sheep. It has been supposed by farmers to be caused by taking too much watery food, such as turnips, clover, rape, eddie, &c., but it is not peculiar to sheep feeding on turnips or rape, as has been believed by some. Its removal has been attempted by the use of common salt, a tea-spoonful of a tincture of vitriol, and the frequent driving the animal about; and it is ascertained, that the disease may be wholly prevented by having recourse to the use of dry food, in the night time, while the sheep are feeding upon these juicy kinds of food. See Sheep.

In Suffolk the sheep are sometimes affected with this complaint on their being first turned into turnips, which is supposed to be caused by their eating too large a portion of them in wet weather. The disease is also believed to originate in the sheep being let out of the fold, when the ground
is covered with hoar frost; and often from feeding in the oat-erfhes about the beginning of the autumn, when the young oats are strong. It is thought here to be readily obviated by allowing a small quantity of hay fo as to counteract the great waterinfs of the turnip; the quantity of half a pound or even less in the course of the day is believed to be quite enough for each sheep in this intention. It is likewise suspected, that clover, flubble, and folded land, are productive of it in wet weather or moist feasons.

Red Weed, in Botany, a name given to a plant common in the Bermudas, and some other places; and called by our first travellers to that part of the world, the Summer Island red weed. Its berry is of a fine red colour, and affords a tincture little inferior to that of cochineal, and possifling all its virtues in medicine: the only misfortune of this, and some other very fine vegetable colours, is, that they fade soon. The juice of the fruit of the opuntia, or prickly pear, is as fine a dye as can be procured from the cochineal, but it will not fland; the infect feeding on this, however, we find affords a colour of the fame nature that will fland. The fruit of the wild weed is in the fame manner liable to be eaten by insects as that of the prickly pear; and it is worthy a trial, whether the colour obtained at second hand from insects, will not fland as well as the cochineal does, and whether the insects may not be propagated in a fufficient abundance to serve the markets in the fame manner. Phil. Tranf. No. 40.

Red Weed is also a provincial term, signifying the round smooth-headed poppy, a pernicious weed in corn-fields. See Weeds.

Red Worm, in Natural History, the name of an infect very deftuctive to young corn crops. The following defcription of this worm has been given by Mr. W. Baker: after observing, that he has often heard of the havoc which red worms make in young wheat, barley, and oats; and in some few writers upon husbandry has read of them, but never saw them till May 1764; when, to his great mortification, in a few days they defroyed almost totally nine acres of his wheat, for he did not reap above half a barrel per acre; and that the ingenious M. de Chataeuix fpeaks of an infect, which is certainly of the fame kind, if it be not the very infect which he has now under confideration; and in noticing the infts fultained in wheat crops, fays, they found in it many little white worms, which afterwards became of a chefnut colour. They poifon themselves between the blades, and eat the fins. They are ufually found between the firft joint and the roots; every infall which they attacked grew no more, but became yellow and withered. And the fame mortification happened to them in the year 1752. The infts appeared about the middle of May, and made fuch havoc, that the crops were almost defroyed; Stillingfleet, alfo, in the fecond edition of his Miscellaneous Tracts, fpeaks of an infect, which is probably the fame as in Suffolk and in fome parts of Norfolk, where the farmers find it their interest to encourage the breed of rooks, as the only means to free their grounds from the grub, from which the trees or blind-bectle comes, and which in its grub flate defroyes the roots of corn and grafs to fuch a degree, that he has seen a piece of pature land where you might turn up the turf with your feet: he adds, that Mr. Matthews, a very obferving and excellent farmer of Wargrofe, in Berkshire, told him, that the rooks one year, whilst his men were hewing a turnip field, fat down in a part of it, where they were not at work, and that the crop was very fine in that part, whereas in the other part there were no turnips that year; though M. de Chataeuix defcribes this worm as being firft white, and afterwards be-

coming of a chefnut colour, he has carefully fought them at different periods during the past year, but always found them of the fame chefnut colour, never varying in any particuar except that of fize, which he finds to be the cafe at all feasons in which he has seen them; and he obferves, that the infect fpeaks of by Stillingfleet as a grub, which, he fays, defroyes corn and grafs, induces him to believe that it is the fame infect (though the report which he relates from Mr. Matthews seems to contradift it), because he has obferved that the red or chefnut worm never appears voluntarily upon the surface; but when the earth is turned up, either with plough or fpade, the rooks or crows are very bold in their approach to pick them up, a circumstance which, he owns, has in fome degree abated his caution to these birds; he therefore never defroyes or frightens them off his land whilst he is ploughing it; but when he fows, when the corn fires, and when it is ripe, he defroyes or banifhes them as well as he can, because the miftich which they do at these times is intolerable; he has also obferved his lucern to decay in its tops foon after it has been up; and upon examining the roots he has found the red worm which had eat them off; and that, in fuch, this infect seems to be the moft deftuctive. Mr. Needham, in his Difccrptions of the English writers, who have fpeaken of the infect which defroyes the corn in the manner already mentioned, which he thinks undoubtedly the fame, it is called a grub, by others the large maggot, and the rook worm, becaufe the rooks eat it.

These worms are about half an inch long, and about one-tenth of an inch in diameter; they are jointed in their fkins, and are of a very firm texture; they have many short legs, two small black specks, which appear to be their eyes; and two small points springing from their heads, with which, he believes, they eat the corn, and which in that work, he apprehends, act like forceps; and all that he has feen of this species are of a bright chefnut colour. For this reafon, he fhould conceive it would be more defcriptive to call them the chefnut-worms. When they are expofed to the air, by turning up earth which is infetted with them, they will very foon cover themfelves again in the foil, which they are very capable of doing by the strength which their make gives them, although they appear to be a fuggifh infect, and have not the advantage of a fliynefs upon their fkins, which the common large creeping worm has, which enables that inoffenfive worm to penetrate the earth, and get under timber and Bones with ease. The red worm, immediately endeavouring to cover itfelf from the air, is certainly, he thinks, from natural inftinct, as it will foon die when expofed to the air, as will appear by the experiment, No. 10, mentioned below.

It is further flated, that these worms defroy wheat, barley, oats, and lucern, while in an infant flate, in the months of March, April, and May. Late fown barley and oats they will defroy as late as June. He has not yet experienced that they defroy any other crops. The miftich done by them is in dry weather. Rain fufficient to penetrate the ground makes them deffift from defroying the corn; and he fuppofes every thing else which they at any time injure. They eat wheat off just above the crown of the roots; barley and oats in the fame place, and also higher up, upon any part of the flem which is below the surface of the earth. And these worms feem to abound more in ground which is lightly tilled, than in fuch as hath been well tilled; but in lay ground they feem to be more numerous than any where elfe: and the fields upon his farm in which he has found them, are wetter than other fields where they are not; whether that circumftance contributes to their increafe, he cannot fay; but the fol-

following
lowing experiments prove that they will live longer in water than they can when exposed to the open air.

Experiments.

No 1. He put ten red worms into a wine glass with common salt in it. They were all dead in four hours.

No 2. Into a glass with brine in it he put ten red worms. They were all dead in six hours.

No 3. Into a glass with lime in it, which had been flaked for a long time, and exposed to the weather, he put the like number. They were all dead in forty-four hours.

No 4. Into a glass with the above lime, and some water in it, he put the like number. They were dead in twenty hours.

No 5. Into a glass with lime newly flaked, and when cold, he put the like number. They were dead in fourteen hours.

No 6. Into lime water, made with cold water, he put the like number. They were dead in ten hours.

No 7. Into a glass with foot in it, he put the like number. They were dead in four hours.

No 8. Into foot and water he put the like number. They were dead in four hours.

No 9. Into pure water he put the like number. They were dead in fifty-two hours.

No 10. Into a glass, without any thing in it, he put the like number. They were dead in thirty-two hours.

It is stated that by these experiments it is seen that all the articles used will kill this insect in a short time, particularly the salt and foot. He thought it necessary to consider different articles, the better to suit different parts of the kingdom.

Where lime can be conveniently had, and that it is used as a manure, he is apt to believe, from the experiments, that no injury can be sustained from these worms; but he is afraid a small quantity will not effectually destroy them; besides, he should fear, if it were not put on before the sowing of the corn, that it might mingle the blades of the corn; for, from these experiments, it appears that lime newly flaked is more suddenly destructive to them than old lime, and therefore it is to be preferred.

Where lime is used for no other purpose than to destroy this worm, he should conceive, that about eight barrels, regularly sown by hand on an acre of ground, might be sufficient: it must be first flaked and cold before a man can possibly cast it upon the ground with his hand, lime being a very strong caustic; and even when it is cold the man should have a thick glove upon his hand.

Where salt may be used to destroy this worm, it must also be sown upon the ground before the intended crop; for although corn will not vegetate, and receive benefit from salt as a manure, when it is used antecedent to the sowing of the corn, yet if it be added after the corn is growing it will certainly destroy it: therefore it should never be used for this purpose, but before the corn is sown, or at least before it vegetates.

He conceives that where salt is used for this purpose only, about four hundred and a half to an acre will answer the purpose, which is a little more than one ounce to every square yard.

It is seen by the experiments, that foot kills this worm as soon as salt; and as in most places it is to be had at a much less price than salt, he thinks there can be no doubt about preferring it; besides which, it may be safely used after the corn is up.

He had some small parcels of barley under experiments, which these worms began to destroy; and in order to convey the foot as soon as possible to the roots of the plants, he mixed a little of it in water, and poured it on the plants with a garden watering-pot: the consequence was that he did not lose one plant afterwards.

It will hardly be imagined that he means that the same method is to be pursued upon a whole farm: no; the method he would recommend to the practice of the farmer is this; to spread, or cast by hand, as he fosws his corn, about fix or eight barrels of foot on an acre, and let him be careful to choose a calm day for the work, otherwise the wind will carry away a great part of it; and as what remains cannot be regularly dispersed, let him be careful to do it early enough in the spring, that the rain may wash in the foot and convey it to the roots of the plants before the worm begins its mischief; if he does this, he is perfuaded his crop will be preferred.

It is found by the experiments, that these worms will live longer in water, by twenty hours, than when exposed to the open air; but at length, that is in fifty-two hours, they died in the water; perhaps this might be from the effect of drowning; but if so, he might have expected they would have been totally destroyed in his two fields in the winter of 1763 and 1764, by the immediate rains which fell at that season for a long continuance, which often flooded the lands. But they survived that winter, as appeared by the great loss he afterwards sustained by their destroying his wheat; and therefore, whether water be an enemy to them or not, it seems not easy to determine; but if those which died in the glasses of water were really drowned, he thinks we may conclude that water is necessary to their existence in the earth, and probably aids them in getting their food from it: and what seems to confirm this notion is, that when the land is wet, they do not touch the corn, but as soon as ever the land is dry, they begin their mischief. However, this speculation he must submit to the consideration of persons more capable of discovering it than he is.

It is seen by experiment No 10, that they cannot live in the open air, which seems to prove, that, where they abound in land, the oftener it is ploughed, particularly in the summer, when they cannot penetrate the ground so easily as when it is moist, they must be, by such ploughing, greatly diminished; besides which, the frequent ploughing gives the cows more opportunities of picking them up, in which, as he has before said, they are very watchful.

Frequent ploughing has been recommended by some writers as the only means of destroying this worm; and they have recommended the ploughing be stuck with nails, urging, that by those nails the worms are cut to pieces; others have recommended walnut leaves being soaked in water, to sprinkle the land, and strewing dead corn in various liquors, as infallible remedies; but such methods as these are founded upon mistaken principles; they only mislead the farmer, and must disappoint him.

Worldly recommends a strong ley made of fixed salts, but that would be impracticable. Mortimer recommends sea-water, which he believes would answer very well. He says, he used foot once with success, but that it did not succeed with him afterwards. Mr. Baker is persuaded he did not use the foot early enough to have it washed into the ground by rain, or perhaps he used too small a quantity. He concludes by observing, that he would not be thought to arrogate any merit to himself, on account of what he has here offered on this subject, since it appears that other persons have used the articles which he has recommended, against this common enemy; but many persons have been disappointed in their expectations from these remedies,
remedies, which must have arisen, he thinks, from their either having used too small a quantity, or not having observed the necessary precautions; if those which he has recommended shall be put in practice and found to answer, he shall think himself amply rewarded.

This worm undoubtedly does great injury to grain crops in many cases, in particular soils and sorts of land; but a great number of additional facts and experiments are wanting to fully prove its nature, and the ways in which its destructive effects on such crops are produced, as well as the best, most ready, convenient, and effectual ways in which it can be destroyed. See Wire-Worm.

Red Deer, fibr. flar. floris. tartar. See the Substantives.

Red Ink. See Ink and Printing.

Red Notes, in old Mufe, before the invention of printing, were used for diminution. In the MS. at Paris of the Latin and French poems of Guillaume Machaut set to music, chiefly motets for a single voice, some are written in black and red notes, with this instruction to the fingers; "ni grae funt perfectae, et rubra imperfectae;" an admonition worth remembering by those who wish to decipher music of the fourteenth and fifteenth centuries, in which red notes frequently occur. It was an easy expedient of diminution till the invention of the press, when the use of different coloured inks on the same page occasioned the trouble and expense of double printing. See Machaut.

In the Papyri and Kylist at Cambridge, there are examples of the use of red notes for diminution in fragments of music by Joseph Gwine and Robert Davie, who flourished in the time of Edward IV. Morley has given some examples of the use of red notes in his annotations.

Red Banks, in Geography, a part of the United States, on the S.E. side of Delaware river, in the town of Woodbury, Gloucester county, New Jersey; seven miles S. of Philadelphia.

Red Bay, a bay on the N. coast of Spitzbergen. N. lat. 79° 44'. E. long. 10° 42'.—Alfo, a bay on the S.E. coast of Labrador. N. lat. 51° 50'. W. long. 60° 10'.—Alfo, a bay on the N. part of Buffalo’s bay, on the S. coast of Massachusetts, in America.

Red Crab Island, a small island in the East Indian sea, near the coast of Arracan. N. lat. 21° 30'. E. long. 91° 50'.

Red Deer Lake, a lake of North America. N. lat. 55° 10'. W. long. 112°.

Red Flagg Bay, a bay on the N. coast of the island of St. Christopher, E. of Ragged Point.

Red Haven, a bay of Scotland, on the N. coast of the county of Banf; three miles E. of Cullen. N. lat. 57° 39'. W. long. 2° 38'.

Red Head, a cape of Scotland, on the E. coast of the county of Angus; six miles S. of Montrose. N. lat. 56° 33'. W. long. 2° 26'.—Alfo, the N. point of the island of Eda. N. lat. 59° 6'. W. long. 2° 40'.

Red Hills, rocks in the German sea, near the coast of Northumberland. N. lat. 55° 26'. W. long. 1° 17'.

Red Hook, a town of America, in the township of Rhy- nebeck, and Dutchess county, New York, on the E. bank of Hudson’s river; 21 miles S. of Hudson.

Red Horfe, Vale of, a district of England, in the county of Warwick, which owes its name to a horfe cut in a hill, the foil of which is reddish.

Red Island, an island near the E. coast of Labrador. N. lat. 43° 55'. W. long. 55° 30'.—Alfo, an island near the W. coast of Newfoundland. N. lat. 48° 35'. W. long. 59° 10'.

Red Lake, a comparatively small lake of North America, at the head of a branch of the Bourbon river, sometimes called "Red river;" its form is nearly round, and its extent is about 60 miles in circumference. It has on one side an island, close by which a river enters. It lies almost S.E. both from lake Winnepeck, and from the lake of the Woods. N. lat. 41° 5'. W. long. 94° 10'.—Alfo, a lake of North America, in N. lat. 47° 40'. W. long. 95° 15'.

Red Lick, a salt spring of the state of Kentucky; 32 miles E. of Stanford.

Red Point, a cape on the E. coast of New Holland. N. lat. 34° 29'. W. long. 208° 45'.

Red River, a river of Louisiana, which rises in about N. lat. 35°, and W. long. 96°, and runs into the Mississippi, N. lat. 37° 15'. W. long. 91° 48'.—Alfo, a river of Upper Canada, which runs into Lake Superior. N. lat. 47° 51'. W. long. 85° 46'.—Alfo, a river of Tennessee, which runs into Cumberland river, about two miles N.W. of Clarksville. N. lat. 36° 18'. W. long. 87° 46'.—Alfo, a river of Kentucky, which runs into Kentucky river, about nine miles above Boonsborough, N. lat. 37° 45'. W. long. 84° 18'. It is 60 yards wide at the mouth.—Alfo, a river of North America, which rises from Red lake, in N. lat. 47° 40', and runs into Winnipeg lake.—Alfo, a river of Canada, which runs into the Utwaas; 60 miles W. of Montreal. See and Mythotchees.

Red Sea, called by the ancients the "Arabian gulf," forms the grand natural division between Asia and Africa, and extends about 21° or 1470 British miles from the straits of Babelmandeb to Suez; it terminates in two branches, the western being extensive, and the eastern ascending a little beyond the parallel of mount Sinai.

This sea is called, in the Old Testament, the sea of Suph or Zuph, the sea of weeds, on account of the great quantity of algae and fucis, and perhaps the madreporas and coraline substances, anciently supposed to be of vegetable origin, found at its bottom, and near the shores. In scriptural language it is also denominated "the tongue of the Egyptian sea;" in the Greek and Latin geography, it was called the gulf of Heropolis; and by the Arabian geographers, the western arm of the sea of Kolzum, (al Kol- zum, with the article,) which seems to have some affinity with "Clifma," another name by which this gulf was formerly known; Kolzum in Arabic, and Clyfma in Greek, signifying destruétion, in reference, as it is supposed, to the destruétion of Pharaoh’s host. Don John de Castro, vice-roy of the Indies for the king of Portugal, conjectures that it was called the Red sea from the great quantity of coral that is found in it. Pliny says that it obtained this name, in Greek "Erythraea," from a king called Erythros, who reigned in Arabia, and whose tomb was seen in the island Tyrine or Agyris. Several learned men believe, that this king Erythros is no other than Eufau, or Edom; Edom, in Hebrew, signifying red or ruddy, as Erythros does in Greek. But Calmet is of opinion, that Edom never dwelt, either on the shore of the Red sea, or the Persian gulf, which has been sometimes also called the Red sea. His habituation was east of the land of Canaan, towards Bozra; and he inclines to believe, that the name of the Red sea was not given to this gulf till after the Idumeans, descended from Edom, had spread themselves from eait to west as far as the Red sea. At that time it might receive the name of the sea of Edom, which the Greeks rendered by the Red sea, or "thalassa erythrea."

The famous miracle of the passagle of the Red sea by 600,000 Israelites, besides old men, women, and children, recorded in the sacred writings, is well known. Those who have been defirous of explaining this passagle, without
out admitting the miraculous part of the history, have had recourse to a variety of conjectures; both as to the place and the manner in which this passage was effected. As to the place of the passage, there has been a difference of opinion even among those who have not hesitated to acknowledge that it was miraculous. Till of late years it has been generally believed, that the passage of the Israelites was at Baidah, or Bedea, which, according to Niebuhr, is about six German miles from Suez, and where the sea, says Bruce, is something less than four leagues broad, by 50 feet deep. In support of this hypothesis, Dr. Shaw has traced the march of the Israelites to their third encampment before Pihahriroth. Whilst they were removing from the edge of the wilderness of Etham towards this station, they had left the open country and were marching through a narrow path, between the mountains of Gewoubee and Attackah. In these circumstances the Egyptians might well imagine, that they could have no possible way of escape, as the mountains of Gewoubee would obstruct their prospects towards the south, and those of Attackah would impede their advancing towards the land of the Philistines; the Red sea lay before them to the east, whilst Pharaoh closed up the valley behind them, with his chariots and horses. This valley terminates at the sea, in a small bay, made by the eastern extremities of the mountains above-mentioned; and is called "Tiah Beni Isreal," i.e. the road of the Israelites, from a tradition still existing among the Arabs of their having passed through it; and it is also called "Baidah," from the new and unheard-of miracle that was wrought near it, by dividing the Red sea, and destroying it in it, Pharaoh, his chariots and his horses. The encampment of the Israelites, according to Dr. Shaw, was at this bay, before Pihahriroth, betwixt Migdol and the sea, over-again Baal-tzephon, Exod. xiv. 2. Baal-tzephon, as this learned geographer suggests, might have relation to the northern situation of the place itself, or to some watch-tower, or idol-temple that was erected upon it; or it may be taken for the extremity of the mountains of Suez, or Attackah, the most conspicuous of these defeats, as it overlooks a great part of the Lower Thebais, as well as the wilderness that reaches towards, or rather which makes part of, the land of the Philistines. Migdol might lie to the south, as Baal-tzephon did to the north of Pihahriroth. The marches of the Israelites, from the edge of the wilderness, being towards the sea, i.e. towards the S.E., their encampment betwixt Migdol and the sea, or before Migdol, could not well have any other situation. Pihahriroth, or the mouth of Hihroth, or a narrow gullet or defile, may denote the mouth, or the most advanced part of this valley towards the E., or towards the Red sea. But as the Israelites were delivered at this place from their captivity and fear of the Egyptians (Exod. xiv. 13.) we may suppose that Hihroth denotes the place where they gained their liberty, horizon and hiroth being words of the like import in the Chaldee. It may be further urged in favour of this explication, and also of the tradition still preserved, of the Israelites having passed through this valley, that the eastern extremity of the mountain, suppos'd to be Baal-tzephon, is called, even to this day, by the inhabitants of these deferts, "Jibbel Attaakah," or the mountain of deliverance; which appellation, together with the name of Baidah and Tiah Beni Israel, could never have been given or imposed upon these inhabitants at first, or preferred by them afterwards, without some faithful tradition, that such places had been once the actual scene of these remarkable transactions. The sea likewise of Kolsum, i.e. destruction, as the correspondent part of the Red sea is called in the Arabian geography, is a further confirmation of this tradition. Moreover, the Ichthyophagi, who lived in this very neighbourhood, are reported by Diodorus Siculus (l. iii.) to have preferred the like traditionary account from their forefathers, of this miraculous division of the Red sea. There are likewise other circumstances that tend to prove, that the Israelites took their departure from this valley, in their passage through the Red sea; for an account of which we refer to Shaw's Travels, ch. v.

This hypothesis, however, says Geddes, (Crit. Remarks on Exod. xiv.) has been fairly given up by our belated modern critics; and the "Sinus Henoopolitanus," or gulf of Suez, pitched upon as the scene of action. The idea was first suggested by Le Clerc, and since adopted and defended by Michaelis, Niebuhr, and almost all the German commentators. But Mr. Bryant still contends for Bedea (Baidah), and calls the arguments of Niebuhr "prejudice and misconception." Dr. Geddes, whose sentiments concerning Morses and his whole history are singular, denies that there was any thing miraculous in the event; and strenuously maintains, that Suez or its vicinity was the place of passage; for here, he says, at this day, are shallows fordable at low water, and which might, in former times, have been frequently dry. We will show what changes happen in the bed of seas as well as that of rivers, especially where that bed is sand, which is the case with that of the gulf of Suez. The occurrence is thus described by Dr. Geddes. When Moses saw that the Egyptians had found out that the Israelites meant not to return, and were about to pursue him with a force which he could not resist, he wisely took the only course that was most likely to afford him an escape. Acquainted, as he must have been, during his long stay in Midian, with the nature of the Red sea, and its ebbs and flows, he deemed it better to take his chance of passing over some shallow which he knew to be fordable at low water, than to expose himself to be overtaken in a defert, where no stratagem could save him. If he got the start of the Egyptians but for a single day, he would have time to watch the tide, and begin his march as soon as the passage was fordable; and in the space of a few hours might be safe on the other side. The width of the sea at Suez is at present, according to Niebuhr's measurement, 757 double paces, or 3450 feet. It is common for the Arabs to pass on foot over this passage, although not always without danger, as the sea sometimes flows back unexpectedly. At Suez, according to Niebuhr, it is low water, at the full of the moon, at half past six; but as the passage of the Israelites must have happened some days after the full of the moon, the ebb and flow must have been considerably later, and the former must have occurred in the night-time, during which the Israelites were said to have passed. Michaelis was of opinion, that, as a strong wind is said to have accompanied this event, it might have caused a double ebb, as it sometimes does on the coast of Holland and the North Germany; but Niebuhr thinks that no such thing is likely to happen in the Red sea. Be this as it will, the wind might certainly have prolonged the ebb; and, if it happened at the time of the passage, might well be considered as a providential interference, and readily confused into a miracle. Josephus, in recording this transaction, puts a formal speech into the mouth of Morses to the terrified and discontented people, and a prayer to God before he strikes the sea with his rod; yet he tells us that all this he invented as he found it in the sacred books. But he seems not sure, whether to consider it as a miracle or a natural effect. "Let no one," says he, "wonder at this account of a way of safety being opened to those old-world innocent folks, even through the sea, whether by the will of God or naturally; since, of later days, the Pamphylean sea opened a
way for Alexander's army, when God through him had decreed to overturn the Persian empire." (Antiq. l. ii. c. 16. n. 5.) For this he appeals to all Alexander's historians; and, indeed, both Appian and Arrian, who relate the event, seem to have considered it as a sort of divine interposition; but honel Strabo tells us, that Alexander only took the advantage of low water; and, trusting to his good fortune, passed through the strait with his army; but not on dry land; for the water came up to the navel. (Strab. l. xiv.) The same was the case with Scipio's soldiers, who surprised New Carthage by taking the advantage of an ebb; although they waded sometimes up to the knees, at other times up to the navel, in water. (Liv. l. xxvi.) Here, says Geddes, the fame two natural causes, the tide and a strong wind, concurred to make a passage through the water, as accompanied at the passage of the Red sea; and in both cases they were converted into a miracle. Josephus concludes his narrative with these words. "Of such things, let every one think as he pleases;" and the author now cited adopts his language. It has been said, and thus the priests of Memphius explained the history (see Euseb. Prep. l. iv. c. 17.), that Moses taking advantage of the time of the ebb, led the Hebrews over in safety; but the Egyptians, not knowing the nature of the sea, and easily entering it just before the return of the tide, were all swallowed up and drowned.

In opposition to all conjectures for explaining this history, without having recourse to a miracle, we shall content ourselves with appealing to the history itself, Exodus, xiv. 16, 17, &c. from which it appears that the Hebrews traversed the sea from shore to shore, on a large space of dry ground, which was left by the retreating waters; and that they were driven back to overwhelm the pursuing host of Pharaoh. See also Izaiah, lxxvi. 11, &c. Habakuk, iii. 15. Wisdom of Solomon, xix. 7, 8, x. 17, 18.

It is thought, says Calmet, after Eusebius, that the place where the Hebrews passed the Red sea, is two or three leagues below its northern point, at the place called Kofium, or Clyfima. Niebuhr informs us that, wherever on the coast of Arabia, we meet with indications, that the waters are withdrawn; e. g. Mufa, which ancient authors mention as a port of Arabia, is now at many leagues distance from the sea; near Loheta, and Gibid, we see great hills filled with the same kind of shells and corals, as are now found living in the sea; near Suez, are petrifications of all these things. From these and similar circumstances it infers, that some thousand years ago this Arabian gulf was much larger, and extended much farther north, especially that arm of it near Suez, for the shore of this extremity of the gulf is very low. The breadth of the arm of the sea at Suez, he adds, is about 3,500 or 3,500 feet (in its present state). Although it would much shorten the distance of their way, no caravan now crosses this arm, nor could the Israelites have crossed it, without a miracle. The attempt must have been much more difficult to the Israelites, some thousand years ago, the gulf being then probably larger, deeper, and longer toward the north, at the lowest time of the tide. Niebuhr crossed, when returning from mount Sinai, that arm of the sea, over to Kofium, upon his camel; and the Arabs, who accompanied him, were only immerged to their thighs in water. The banks of the Red sea are pure sand from Suez to Girondel; but lower to the south are banks of coral. If the Israelites had crossed the sea upon such banks, they must have been greatly incommoded by them.

The Red sea, notwithstanding the difficulty and danger, and also the tediousness of its navigation, was, for many ages, before the discovery of the passage by the Cape of Good

Hope, the channel of communication between Egypt and other countries, bordering on the Mediterranean, and India. Accordingly, Dr. Robertson observes, in his "Historical Disquisition concerning Ancient India," that navigation made its first efforts in the Mediterranean and the Arabian gulf, and that in them the first active operations of commerce were carried on. Nor are the accounts of the earliest historians in this respect at all improbable, if we consider the position and form of these two great inland seas. They lay open the continents of Europe, Asia, and Africa, and spreading to a great extent along the coasts of the most fertile and most early civilized countries in each, seem to have been defined by nature to facilitate their communication with one another. We find, accordingly, that the first voyages of the Egyptians and Phenicians, the most ancient navigators mentioned in history, were made in the Mediterranean, and, moreover, by acquiring early possession of ports on the Arabian gulf, they extended the sphere of their commerce, and are represented as the first people of the west who opened a communication by sea with India. Selinus, in the course of his reign (if we may give credit to some historians), was able to fit out a fleet of 400 ships in the Arabian gulf, which conquered all the countries stretching along the Erythraean sea to India. The Phenicians, who, by their situation on the Mediterranean, and the imperfect state of navigation, could not attempt to open a direct communication with India by sea, were prompted by the entering spirit of commerce to wrest from the Indus the burns of commerce. The Phenicians and Phoenicians, the nearest port in the Mediterranean to the Arabian gulf. Thither all the commodities brought from India were conveyed over land by a route much shorter, and more practicable, than that by which the productions of the East were carried at a subsequent period from the opposite shore of the Arabian gulf to the Nile. At Rhinocolura they were reloaded and transported by an easy navigation to Tyre, and distributed throughout the world. For an account of the trade which the Jews carried on by the Red sea, we refer to the article EXODUS, and WHERE DID MOSES CROSS THE RED SEA? Of the manner in which the Egyptians carried on their trade with India by means of this gulf, see ALEXANDRIA and BERENICE.

All the commercial transactions of the ancients with the East were confined to the ports on the Malabar coast, or at the farthest extended to the island of Ceylon. To these staplers, the natives of all the different regions in the eastern parts of Asia brought the commodities which were the growth of their several countries, or the product of their ingenuity, in their own vessels, and with them the ships from Tyre and from Egypt completed their movements. While the operations of their Indian trade were carried on within a sphere so circumscribed, the conveyance of a cargo by the Arabian gulf, notwithstanding the expense of land-carriage, either from Elath to Rhinocolura, or across the desert to the Nile, was so safe and commodious, that the merchants of Tyre and Alexandria had little reason to be solicitous for the discovery of any other. During the period in which this mode of carrying on commerce sufficed, the price of goods imported from India into Europe was very much enhanced by the various operations to which the conveyance of them was subject. In Ceylon, or the ports on the Malabar coast to which they were brought from the various countries of Asia by the natives, they were put
put on board the ships which arrived from the Arabian gulf. At Berenice they were landed, and carried by camels 258 miles to the banks of the Nile. There they were again embarked, and conveyed down the river to Alexandria, whence they were dispatched to different markets. But, after the passage to India by the Cape of Good Hope was discovered by Vasco de Gama, at the close of the fifteenth century, its various commodities were purchased at first hand in the countries of which they were the growth or manufacture; and the carriage of mercantile goods by water is much less expensive than by any other mode of conveyance, the Portuguese, as soon as they could import the productions of India in sufficient quantities to supply the demands of Europe, were able to afford them at such a reduced price, that the competition of the Genoese and the Venetians, who had been actively engaged in this commerce, ceased almost entirely; and the full stream of commerce took its natural direction towards the cheapest market. The consequence was, that early in the sixteenth century, the subjects of the Portuguese monarchs became possessed of a monopoly of the trade with India, founded upon the only equitable title, that of furnishing its productions in greater abundance, and at a more moderate price. From the era of the discovery now mentioned, the Arabian gulf or Red sea lost its importance as a channel of communication between the western and eastern parts of the globe; and from this time both its navigation, and the commerce connected with it, have been partial and restricted. An account of its principal ports will be found under their respective articles.

**REDA**, a town of Turkish Armenia, in the government of Erzerum; 36 miles N. of Ipira.

**REDANS**, or **REDDANT** See REDENS.

**REDARIDES**, in Geography, a town of France, in the department of the Mouths of the Rhone; 16 miles S.S.E. of Orangi.

**RED BOOK of the Exchequer** (*liber ruber faccarii*) is an ancient record, in which are registered the names of those that held lands *per baroniam* in king Henry II.'s time. It is a manuscript volume of several miscellaneous treaties, in the keeping of the king's remembrancer, in his office in the exchequer; and hath some things (as the number of the hides of land in many of our counties, &c.) relating to the times before the Conquest. There is likewise an exact collection of the ecuages under king Henry I., Richard II., and king John; and the ceremonies used at the coronation of queen Eleanor, wife to king Henry III. &c.

**REDDAT.** *Precipe quod reddat.* See PRECIPITE.

**REDDENDIS CHARTIS.** See CHART.

**REDDENDUM, in Law,** a clause in a lease, &c. by which a rent is referred to the lefior; which anciently consisted of corn, flesh, fish, and other viands. 2 Rep. 71.

**REDDIDIT &c.,** is where a man procures bail for himself to an action in any court at law; if the party bailed at any time before the return of the seconz *facta facti* against the bail, renders himself in discharge of his bail, they are thereby discharged. 2 Litt. Abr. 430. See BAIL.

**REDDITARIUM,** an ancient law term for a tarry, roll, or rental, in which the rents and services of a manor are set down.

**REDDITION, REDDITO,** a surrendering or restoring. In Law, it also denotes a judicial acknowledgment that a thing in question belongs to the demandant, and not to the persons to surrendering.

**REDDITUS ASSISUS,** a set or standing rent. See ASSISUS.

**REDDELE, Red Ochr, or Red Chalk,** in Mineralogy, the red oxd of iron intermixed with earthy matter. It is Vol. XXIX.

used for crayons, either in its natural state, or pounded and washed, and afterwards mixed with gum, and cast into moulds. The colour of reddele varies from a blood-red to a brown-red; its fracture is earthy; it is soft, friable, and flains the fingers. See *Orce of Iron.*

This is the common English name for the substance called in Latin *rubicularia,* and used in painting, and for marking sheep, &c. There are two kinds of it, a harder and a softer.

The first, or harder kind, is but little in use, except among the turners in wood, as it does not mark so easily, requiring to be first wetted, and then pressed hard upon the substance to be marked. This is dug in Lincolnshire, Hampshire, and Suffolk; and is a hard dry earth, of a somewhat pale red, like the common pale red bricks, and is of a very regular and close texture, and always composed of a number of thin lamina, lying closely and evenly on one another. It is of a rough uneven surface, adheres firmly to the tongue, is not easily broken between the fingers, and flains the hands a little; it is of a very atfrangent taste, and melts pretty readily in the mouth. It is very readily diffusible in water, mouliderng to powder, soon after being thrown into it; and makes no effervescence with acids.

The second, or softer kind, is very common, and put to a number of different uses. It makes simply a very good pale red for the painters, and is very serviceable to them in their mixed colours. It is in constant use in many parts of the kingdom for the marking of sheep; and when washed and separated from its sandy particles, is, by some of our modern druggists, sold under the name of bole armenic.

It is found in many parts of the world; the best in England is that from several parts of Derbyshire, from whence the colour-flops and druggists of London are supplied; many of the latter thinking this a shorter method than the common one of our bole armenic makers, of preparing it from a mixture of tobacco-pipe clay, and the red ochre called Spanish brown.

This soft, or common reddele, is a loose ponderous earth, of a lax texture, and very friable; and of a pale, but tolerably bright red, of a somewhat smooth and glossy surface, soft to the touch, adhering firmly to the tongue, easily broken between the fingers, and flains the hands a little; it is of a very atfrangent taste, and melts pretty readily in the mouth. It is very readily diffusible in water, mouliderng to powder, and makes no effervescence with aqua fortis. Hill.

Some call reddele, *lapis hamatticus*; but the real hamattites is another thing.

**REDEEMABLES, in Law,** are lands, funds, &c. sold with a reservation of the equity of redemption.

Crown lands are redeemable for ever; others only for a certain time.

**RE-DELIVERY,** an yielding or delivery back of a thing; if a person has committed a robbery, and stolen the goods of another, he cannot afterwards purse the offence by any re-delivery. Co. Litt. 69. H. P. C. 72.

**RE-DEMISE.** See DEMISE.

**REDEMPTION, REDENTIO,** a faculty or right of re-entering upon lands, &c. that have been sold, and affigned; upon reimbursing the purchase-money, with legal costs.

Bargains in which the faculty, or, as some call it, the *equity of redemption,* is referred, are only a kind of pignerative contracts.

A certain time is limited, within which the faculty of redemption shall be exercised; and beyond which it shall not extend.

**REDEMPTION, in Theology,** denotes the recovery of man-kind.
kind from sin and death, by the obedience and sacrifice of Christ, who on this account is called the Redeemer of the world. See COVENANT.

REDUCTIONS, Reductions, in our old Law Writers, denote grievous mulcts imposed by way of commutation for the head or life of the delinquent.

REDEMPTION OF THE NATIONAL DEBT. See Fund.

REDEN, or REDYIN, in Geography, a town of Prufia, in the territory of Culm; 20 miles N.E. of Culm.

REDENS, REDANS, or REDANT, in fortification, a kind of work indented in the form of the teeth of a saw, with salient and re-entering angles; to the end that one part may flank or defend another.

It is also called face-work, and indented work. The faces in this flank another.

Redens are frequently used in the fortifying of walls, where it is not necessary to be at the expense of building battlements; as when they stand on the side of a river, a marsh, the sea, &c. But the fault of such fortification, is that the besiegers from one battery may ruin both the sides of the tenaille or front of a place, and make an assault without fear of being enfiladed, since the defences are mined.

The parapet of the corridor also is frequently redented, or carried on by way of redens.

REDES, in Geography, a river of South America, which runs into the gulf of Darien, N. lat. 7° 37'. W. long. 70° 40'.

REDBITION, REDITION, in the Civil Law, an action allowed a buyer, by which to annul the sale of some movable, and oblige the buyer to take it back again, upon the buyer's finding it damaged, or that there was some personal cheat, &c.

The redhibition, or redhibitory action, has a place in several cafes, in the body of the civil law. If a horse was sold that had the glanders, were broken-winded, or foundered, it was a redhibitory cafe; and the seller might be obliged to take him again within nine days.

REDI, Francis, in Biography, an Italian physician, was defended from a noble family, and born at Arezzo, in Tuscany, in the year 1626. He commenced his studies at Florence, and then removed to Pisa, for the prosecution of his philosophical and medical pursuits, where he received the degree of doctor in both these sciences. He had acquired great reputation both in science and literature, and was induced to settle at Florence, where he at length gained the favour of the court, and was appointed first physician to Ferdinand II. duke of Tuscany, and subsequently to Cosmo III. These appointments and his constant professional employment did not, however, prevent him from cultivating his favourite study of the belles lettres. He devoted much of his time to the language of his country, and contributed not a little to the perfection of the dictionary of the academy of La Cruca, of which, and of several other learned bodies, he was a member. Totally free from presumption, and attached to every cultivator of learning and science, he was always ready to give his assistance to them in every way he could, and was universally esteemed and beloved. He displayed both in his practice, and in the prosecution of his inquiries in natural history, a singular acuteness of observation, and a complete incredulity as to the marvellous, which was so prevalent in his time; and he cautioned his friends and pupils against the popular errors in this respect. Although he was afflicted with epileptic fits in his latter years, yet he appears neither to have abandoned his studies, nor his professional business, until his death, which took place in 1697, in his 71st year.

Redi was the author of several Italian poems, which are held in much estimation. His other works were all written in Italian, and his style was deemed to pure and elegant, that the authors of the dictionary of La Cruca have often cited it as a standard. Most of his writings on natural history have been translated into Latin; especially his "Experimenta circa Generationem Infectorum, cum Figuris Axis," his "Observationes de Viperis," his "Experimenta circa diversas Res naturales, specieim illas que ex Indis adferuntur," and his "Observationes de Animalibus viventibus, que intra Animalia viventia reperiuntur." He also published a letter on the Use of Spectacles, and an Essay on Styptics. Eloy Dict. Hist. de la Med.

Redi, in the notes to his "Baco in Torecano," a dithyrambic poem, published in 1685, has given many curious etymologies and explanations of the medical terms used by the Italians in early times.

REDINGA, in Geography, a town of Hindooftan, in the circar of Ellore; 25 miles W. of Ellore.

REDIMICULUM, among the Romans, a girdle, which going about the neck, divided on the breast, and passing down each side, went round, and kept the robe tight to the body.

REDINGA, in Geography, a town of Portugal, in the province of Beira; 14 miles S. of Coimbra.

REDINGA, in Geography, a town of Hindooftan, in the circar of Ellore; 25 miles W. of Ellore.

REDICCATIO, REDINTegraTO, in the Civil Law, the act of restoring a person to the enjoyment of a thing, of which he had been illegally dispossessed.

In France, where a person is deprived of his property, he claims it again by redintegration, or action of restitution. But the redintegration must be demanded within a year and a day, otherwise it is precluded.

Redintegration, in Chemistry, the restoring of any mixed body, or matter, whose form has been destroyed by calcination, corrosion, sublimation, or the like, to its former nature and constitution.

The redintegration of mercury is properly called revivification. Mr. Boyle has an express treatise on the redintegration of sulphur; where he shows, that after reducing it by fluxion into fixed nitre, which is next to kind of salt of tartar in all its properties, he could perfectly redintegrate it, by pouring a sufficient quantity of spirit of nitre on it; i.e. he could re-produce true crystals of the usual form and virtue of sulphur.

It is a strong objection against the chemical principles, that we cannot redintegrate the body they were procured from, by re-mixing them.

This seems to argue, that the body did not properly consist of such elements, or that they were not originally contained in it, but were rather produced by the fire.

REDIPATAM, in Geography, a town of Hindooftan, in Marwar; 18 miles N. of Ramadnapuram.

REDIRE ad Pacem, in Law, is applied to a person, whose outlawry is revocable, and who is restored to the king's peace.

REDisseisIn, a difficulty made by him who once before was found and adjudged to have diffiged the fame man of his lands or tenements; for which there lies a special writ, called a writ of redissetin. See ABSET OF Novel Differsin, DFDerIn, and Post-DiffersIn.

REDIANS, or RADIANs, in Doomsday and other ancient books, are probably the name with rod, or rad-knights; viz. men who, by the tenure or custom of their lands, were to ride with, or for, the lord of the manor, about his business.

REDNITZ, in Geography, a river of Germany, formed by the union of the Upper and Unter Rellat, about 5 miles S. of Reth, in Franconia. After receiving in its course several

1
several streams, it discharges itself into the Maine, a little below Bamberg.

REDDESCO, a town of Italy, in the department of the Mincio; 14 miles W.S.W. of Mantua.

REDON, a town of France, and principal place of a district, in the department of the Ille et Vilaine; 32 miles S.S.W. of Rennes. The place contains 3783, and the canton 11,620 inhabitants, on a territory of 1875.54 square kilometres, in 5 communes. N. lat. 47° 39'. W. long. 2°.

REDONDA, an island in the West Indies, about 10 miles in circumference, without ports, rivers, or towns. N. lat. 16° 55'. W. long. 62° 20'.

REDONDILLA, or REDONDILLA, a town of Spain, in the province of Galicia, near the west coast, defended by a strong castle; 32 miles W.S.W. of Orense.

REDONDO, a rock, about three miles in circumference, between the islands of Montserrat and Nevis, in the West Indies. N. lat. 17° 6'. W. long. 61° 35'.

REDONDO NOVA, a town of Benguela. S. lat. 11° 22'. E. long. 12° 45'.

REDONDOS, O, a town of Portugal, in Alentejo; 14 miles E.E. of Lisboa. N. lat. 38° 33'. W. long. 7° 22'.

REDONDOS, a town of Portugal, in the province of Beira; 17 miles S. of Coimbra.

REDDOUBLE, Fr., in Musie, a doubled interval in the octave above a single interval. The octave of the octave, with us, is called the 15th. See INTERVAL.

REDOUTI, or REDOUTE, Redoutus, in Fortification, a small square fort, without any defence but in front, used in trenches, lines of circumvallation, contravallation, and approach; as also for the lodging of corps de garde, and to defend passages. See Fort.

They are usually figures of three, four, five, or six sides, encompassed with a ditch, and a bank of earth, which consists of two parts, called rampart and parapet.

In marly grounds, redoubts are often made of stone-work, for the security of the neighbourhood; their face consists of from ten to fifteen fathoms; the ditch round them from eight to nine feet broad and deep; and their parapets, which are cut into embrasures and merlons, have the same thickness. See REDUCTION.

The inner sides of square redoubts are usually between the limits of twelve and thirty-two yards; and when they are to be defended by musketry, the number of men necessary to the defence may be thus determined: half the side figured gives the number of troops; and twice the square root of a given number of men, shews the length in yards of the side of a square redoubt proper to contain them.

To construct a square redoubt.—Mark out a square, whose side is adapted to the number of troops allotted for the defence, as A B (Plate VII. Fortification, fig. 5.) for the base of the rampart. About this square, at the distance of ten or twelve feet, describe another square, whose side, C D, is the inner boundary of the parapet; make a parapet of about nine or ten feet thick, whose outline is the line E F; leave a beam about three or four feet broad, whose side is G H; and dig a ditch about sixteen feet wide, and about six or seven feet deep, which should be rounded before the angles of the redoubt. Make the rampart from four feet to nine or ten feet high; let the parapet be six or seven feet higher, and let the footbank be four feet and a half lower than the crown of the parapet. On this side most fucures from the enemy, make a bridge across the ditch, and a palisade through the rampart, about four or five feet broad when the defence is musketry, about nine or ten feet broad when cannon are to be used; and fling up the palisade by a strong gate. If the redoubt is to be defended by cannon, both the rampart and parapet should be at least five or six feet thicker. In order to make the fire pretty nearly equal on all sides, and sufficient for defending the angles of the work, M. Clairac has contrived to cut the inside of the parapet into notches, whose two sides, of a yard each, are at right angles to one another, and make half-right angles with the sides of the work; the manner of which, and its defence, are plainly shewn in the figure, where the lines with dots at the ends represent the fire three different ways from the same side.

For the method of constructing flanked redoubts, see Fort.

A detached redoubt is a kind of work resembling a ravelin, with flanks, placed beyond the glacis; such as B (Plate V. Fortification, fig. 6.) They are made in order to occupy some spot of ground which might be advantageous to the besiegers; and likewise to oblige the enemy to open their trenches farther off than they would otherwise do. Their distance from the covert-way ought not to exceed a hundred and twenty toises, that they may be defended by musket-shot from thence. The gorge, a, b, is forty toises; the flanks, a c, b f, which are perpendicular to the gorge, ten; and the faces, a d, f d, thirty; the ditch before it is fix toises, ending in fleaves at both ends; the covert-way, four; the branches of the covert-way, twenty toises long; the faces of the places of arms, p, y, which are perpendicular to the branches, ten; and the other, which is parallel to them, fourteen. The communication from the covert-way to the redoubt is five or six toises wide; and there is a traverse made just at the entrance, and another in the middle when it is pretty long. The parapets of this communication terminate in a slope or glacis. Robertson's Marine Fortif. p. 20, &c. Muller's Fort. p. 43, &c. See ARROW.

Redoubts are also small works of the same form made in a ravelin.

REDOUTE, Castle or DONJON. See REDUCTION.

REDOUTES en Cremailles, differ from other redoubts by having the inside line of the parapet broken, so as to resemble a pot-hook, or the teeth of a saw; by which a greater fire can be brought to bear upon the defile than if only a simple face was opposed to it, and consequently the passage is rendered more difficult.

REDOUTES de TERRE, Fr. redoubts that are halfly thrown up, and made with earth, for the purpose of securing entrenchments, circumvallations, passageways of rivers, &c.

REDOUTES de Macaronières, Fr. redoubts made of masonry; generally constructed in places where an enemy might derive advantage from establishing himself; they are likewise built upon the fallant angles of the glacis.

REDOUTES Cafematées, Fr. cased redoubts, or such as are arched over and made bomb-proof. Those constructed for the defence of Gibraltar, and for the security of Dover castle, are of this description.

REDOUTES à MACHICOUR, Fr. are those which are made of brick or stone-work several stories high. The highest story juts out about one foot beyond the wall that surrounds or fronts the redoubt.

REDRESSING, the rectifying or setting any thing straight again.

Trees and other plants have a natural faculty of redressing themselves, when, by any external caue, they are forced out of the perpendicular.

In the moral lefe, to redress grievances, is to reform or remove them. The redress of injuries is the objeet with a view to which courts of justice are instituted in every civilized society; in order to protect the weak from the insults of the stronger, by expounding and enforcing those laws, which define rights and prohibit wrongs. This remedy is, therefore,
therefore, to be sought for by application to these courts; that is, by civil suit or action.

To redress a flag, among hunters, is to put him off his changes.

REDDRILL, To, in Military Language, is to put a soldier through the first elements of military training. Every soldier, after his return from long absence, must be redrilled before he is permitted to act in the ranks of a company.

REDRUTH, in Geography, a considerable market-town in the east division of the hundred of Penwith, and county of Cornwall, England, is situated on the road from Launcelton to the Land's-End, at the distance of 262 miles S.W. from London. It occupies the declivity of an eminence in the very centre of the mining district, and derives its support entirely from the mines. Dr. Percy supposes it to have been a town in Saxons times; but if so, the records of its history during that period have been entirely lost. It is first mentioned in the year 1352, when William Basset, the then proprietor of the manor, obtained for the inhabitants the privilege of fairs and markets. In 1502 a similar grant was made in favour of John Basset, Esq.; and in the time of the Cromwellians, the Earl of Morrall procured a charter for a market on Fridays, which was confirmed by king Charles II. At present there are two weekly markets, held on Wednesday and Friday; and three annual fairs, chiefly for cattle and oxer manufactures. The tolls of two of these fairs and the markets belong to the Buller family; and the other fair to lord de Dunstanville, the descendant of the Bassets. The increase of this town, since the commencement of the copper mines in the last century, has been as fast to one, as appears by the average of baptisms. According to the population register of 1801, it contained 664 houses, and 4924 inhabitants; but in 1811 the houses were returned as amounting to 879, and the inhabitants to 5903 in number.

Redruth consists chiefly of one long street. The church, the living of which is a rectory, was built, in 1770, by lord de Dunstanville, in the stead of a more ancient one. This building is situated about half a mile from the town. Here are the remains of a chapel of ease, dedicated to St. Rumon, which has been unroofed for many years. In Redruth are meeting-houses for Quakers and Anabaptists, besides two for Methodists in the town, and a third in the north part of the parish. In 1803, a large school-house was built here by subscription, and a master placed in it by the same means; but the subscription having been discontinued, the school is now kept open by the master on his own account.

Among the numerous mines in Redruth and the contiguous parishes of Gwennap, Kenwyn, and St. Agnes, those denominated the Gwennap mines are considered to be the principal. These lie to the south-east of Redruth, in a part of the county where the tin and copper leads are peculiarly rich, and in some places intersect each other. The country of the united mines Huel-Virgin, Poldice, and Huel-Unity, is schistus; that of Huel-Jewell, Huel-Gorland, and Trefewan, is granite; and it has been remarked, that the metallic veins mostly obey the course of the granite mountains, and run very nearly parallel with them. The united mines employ about 600 men, of whom 400 work under ground. The water is drawn off by four immense steam-engines, one of the cylinders of which is nearly seven feet in diameter. The Huel-Virgin mine is 160 fathoms deep, and is extremely productive; but the Huel-Unity and Poldice mines are still more rich, and are wrought to such advantage, that the proprietors usually flare from 16,000l. to 26,000l. per annum. The depth of the Poldice mine is 170 fathoms; but at present it is not worked at a lower depth than 140. This is one of the oldest mines in the county, and yields a yellowish copper ore, a rosin tin, and a few stones of galena. The Huel-Gorland mine is 120 fathoms below the surface, and is wrought at the expense of about 1000l. a month. The North Down mines, nine in number, occupy an extent of two miles in length, and one in breadth, and have their surplus water carried away by the same long adit which runs through the Gwennap mines to the Cannen-Stream works.

Besides the mines, there are several other objects in the vicinity of Redruth not undervalue of notice. Portreath, about four miles to the north, is a small sea-port for the importation of coals and lime, and the exportation of copper ore to the works in Wales. It is defended by a fort, mounting four guns, and was erected by lord de Dunstanville in the year 1782, and is maintained at his expense. Tehidy park, the ancient seat of the Dunstanville family, adjoins Portreath on the south-west. This manor is first mentioned as being in their possession as early as the year 1200, about thirty years before the marriage of Cecilia de Dunstanville with William Basset, who carried the Dunstanville estates to the Bassets. The present mansion-house is of modern erection, consisting of a centre, and four detached pavilions at the angles, the whole constructed chiefly of Cornish free-stone. The principal rooms are decorated with some good portraits by Vandyke, Kneller, and Sir Joshua Reynolds; and also with a few pieces by Rubens, Carlo Dolci, Bononi de Ferrari, Rembrandt, Borgognone, and others of less note. The park and pleasure grounds attached to this mansion are very extensive; containing about seven hundred acres, finely varied by wood and lawn, and appearing like a well-cultivated garden in the midst of a desert.

Wellward from Redruth, about a mile and a half, is Carn-breh hill, which Dr. Borlase and others contend ought to be regarded as the grand centre of Druidical worship in this county, almost every kind of monument commonly attributed to the Druids being found, as they allege, upon that eminence. How far this opinion is correct, we shall not pretend to decide; but we may observe, that several late writers maintain, that a part of the supposed monuments of religion, viz. the caves, are in fact the result of natural convulsion. No doubt, however, some of them are artificial, and probably belonged to the Druids; and what seems to corroborate this idea is, the circumstance of Redruth being a corruption for Dre-Druith, which signifies the Druids' town. On the summit of this hill is a circular fortification, called the Old Castle, which appears to have been formerly surrounded by a strong wall; and about 300 yards to the eastward, on a ledge of flinctum rocks, stands Carn-breh castle, part of which lays claim to a very high antiquity, but the remainder is of comparatively modern date. The rocks upon which this structure is erected not lying at all contiguous to each other, are connected by five circular arches thrown over the cavities.

On the south-west side of Carn-breh hill is Pendarves, the seat of John Stackhouse, Esq. It is a large handsome building, situated on an eminence commanding extensive views over the western parts of the county. In a field contiguous is a large cromlech, composed of three upright stones, and an impost. Clowance, situated about three miles further to the south-west, has been for several centuries a seat of the family of St. Aubin. The house is deeply embosomed in wood; and contains, besides several pictures of curiosity and value, a large collection of rare and choice prints, accumulated in the portfolios of its present possessor.

RED

REDSEAR. See Iron.

REDSTONE, in Geography, a town of Pennsylvania, on the Monongahela; 53 miles N.W. of Pittsburg.

REDUBBORS, those who buy stolen clothes, &c. and, to the end they may not be known, turn them into some other fashion, &c. See Frippery, and Rejuvenator.

REDUCE, in Chemistry. See Reduce.

To Reduce a Place, in Military Language, is to oblige the governor to surrender it to the besiegers by capitulation.

To Reduce the Circle, is to restore or bring back a battalion or company which has been formed in circle to its original position in line.

To Reduce the Square, is to restore a battalion or battalions which have been formed in a hollow or oblong square to their original situation in line or column.

REDUCED CHART. See Chart.

To be Reduced, in Military Language, is to be taken off the establishment, or cease to receive pay as soldiers. When a regiment is reduced, the officers are generally sent upon half pay. Sometimes, as at the close of a war, the corps are reduced, and the officers remain upon full pay. Hence are derived the expressions in and out of the break. In the break denotes the liability of being reduced: out of the break signifies the certainty of being kept upon the establishment.

To be Reduced to the Ranks, is to be taken from a superior appointment in a regiment, and to be ordered to the duty of a common soldier. This sometimes happens by way of punishment, when a sergeant or corporal misbehaves. A sergeant, however, cannot, at present, be reduced, except by sentence of a regimental court-martial.

REDUCING SCALE, is a thin broad piece of box, with several lines and scales of equal parts upon it; for turning chains and links into acres and rods, by inspection.

It is used by surveyors to reduce maps and draughts from one dimension to another; it is sometimes also called a surveying scale.

REDUCT, REDUIT, or Reduce, a military term, signifying an advantageous piece of ground, intrenched and separated from the rest of the place, camp, &c. for an army, garrison, &c. to retire to, in case of a surprize. Reduits have been sometimes made for the purpose of securing different posts in a town independent of its citadel. They were propounded by the celebrated Vauban. See Donjon.

Reduct, in Building, a kind of recess, or little place, taken out of a larger, to make it more uniform and regular; or for some other convenience, as for a little cabinet above of a chimney, for alcoves, &c.

Reduct, or Redux, among Chemists, is a powder by which calcined metals and minerals are reduced again to their regular, or pure substance.

REDUCTION, Reductio, in the Schools, a manner of bringing a term or proposition, which before was opposite to some other, to be equivalent to it.

Reduction is effected by the addition or retraction of a negative particle. Thus, to reduce this proposition, no man is an animal, to be equivalent to its opposite, every man is an animal, I drop the negative, and say, man is an animal. After the like manner might the term every man be reduced, by adding the negative and saying, there is no man.

Reduction of Propositions is used in a more general sense, for any expression of one proposition, by another proposition equivalent to it.

To a reduction, therefore, there are two propositions required, the reduced, and the reducing; which are considered as the extremes of it, and to be connected in the reduction by means of the particle that is, which here has the effect of a copula.

As here, only animals think; that is, animals think, and nothing besides animals thinks. Where the proposition preceding the particle is reduced, and the subject of the reduction; that following the particle reduces, and has the effect of the predicate of the reduction, and the particle that is acts as a copula, importing, not barely that the proposition is expounded by another, but by another equivalent one, or, as it were, the same.

Reduction of Syllogisms, is a regular changing or transforming of an imperfect syllogism into a perfect one. Or, it is a change of a syllogism in respect of form, by which the necessity of the implication, or inference, is made more evident.

Reduction obtains in syllogisms of the second and third figure; as also in the indirect modes of the first. By it these are all brought to the first.

There are two kinds of this reduction; the one direct, or often, performed merely by a conversion of one or both the premises, or by a transposition of them; as when callus is reduced to capital: the other indirect, called per impossibile, or ad absurdum; by which the person who denies the good-ness and legitimacy of an imperfect syllogism, is reduced to affirm something absurd and impossible, or contradictory to some other thing maintained by him.

Suppose, e. gr. a person granting the premises of the following syllogism, denies the conclusion: All fraud is prohibited; but some trading is not prohibited; therefore some trading is not fraud. We thus proceed against him if the syllogism be not good, the antecedent is just, but the consequent false; and, therefore, the contrary of the conclusion must be true: now I take the contrary of the conclusion, which you thus give, viz. all trading is fraud; and of that, with the other premise of the former syllogism, viz. the major, which you likewise grant, make a new syllogism; thus, All fraud is prohibited; all trading is fraud; therefore all trading is prohibited. But this proposition, all trading is prohibited, and the other, some trading is prohibited, which you granted me in the first syllogism, are contradictions.

Reduction, in Arithmetic, is the converting of monies, weights, or measures, into the same value in other denominations; e. gr. pounds into shillings and pence; or shillings and pence into pounds.

The reductions of the principal monies, coins, weights, and measures, ancient and modern, foreign and domestic, are found under Coin, Weight, Measure, Pound, Foot, &c.

Reduction is of two kinds: 1. Descending, when a quantity is to be brought from a higher denomination to a lower.

This is done by considering how many of the next less denomination are contained in the next greater before, and by that number multiplying the greater.

Thus pounds are reduced into shillings, by multiplying by 20; shillings into pence, by multiplying by 12; and pence into farthings, by multiplying by 4.

Troy pounds are reduced into grains, by multiplying by 12, 20, and 24: and avoirdupois hundreds into ounces, by 4, 28, and 16.

2. Ascending, when a lower denomination is to be reduced to a higher.

In order to this, the business is to divide the least by so many of its denomination as are contained in the next greater: thus, 24720 pence, divided by 12, and the quotient by 20, gives 103 pounds.

If there remain any thing in each division, it is respectiv-

red

R

ive either odd pence, or shillings; thus, 67½ pence reduced, give £27 l. 19s. 5d. cut off the half, the rest are the pounds required.

To expedite the practice, several compendious ways of reduction have been invented. See Practice.

Thus, yards are turned into ells by subtracting a fifth; and into ells Flemish by adding a fifth. Ells Flemish are reduced into yards by subtracting a quarter. Ells Flemish reduced to Ells by multiplying by 6, and cutting off the right-hand figure.

Great pounds of firk of twenty-four ounces are reduced to pounds of sixteen ounces by adding one-half; and pounds of sixteen ounces into pounds of twenty-four by subtracting one-third.

Reduction of Decimals. See Decimals.

Reduction of Fractions. See Fractions.

Reduction of Ratios. See Ratios, Reduction of.

Reduction of Surds. See Surds.

Reduction of Equations. Various algebraical operations are called under this head by different authors; some considering it to be the same as is otherwise, and more properly, called the solution of equations, or the finding of their roots; some define it to be the taking away or exterminating all the unknown quantities except one, otherwise called elimination; others again, under this head, treat of what is more usually termed the transformation of equations; and others again apply it to the furthering of an equation, or the reduction of it to another of lower dimensions, which latter seems to us the only operation that can properly be treated of under the above designation. See Solution, and Transformation.

There are but few cases in which the reduction of an equation can be effected, viz. only when a known relation has place amongst any of its roots, in which case the equation will admit of being reduced as many degrees lower, as there are independent conditions known to have place. So that if the relation be only between two roots, which is one condition, the equation may be reduced two degrees; if the relation extend to three roots, it may be reduced three degrees; and so on.

The conditions or relations more commonly considered, are those in which the roots of an equation form an arithmetical or geometrical progression, and when an equation has any number of equal roots. The two former relations seem rather objects of curiosity than utility, as it is not probable that an equation should have such relations obtain between its roots; but with regard to equal roots they may frequently arise in the solution of various problems. When any geometrical or physical problem is proposed, the number of its possible solutions is generally limited, and therefore the ultimate result arising out of such investigation ought to be an equation, the number of whose roots agree with the limited number of solutions. But it may happen that the analyst, by not pursuing the best mode of operation, is led to an equation of higher dimensions than is requisite, in which cases, upon investigation, it will always be found that his refuting equation has some number of equal roots, which being taken away, will reduce the equation to one of lower dimensions, which gives the proper number of solutions to the original problem. As to the cases in which the roots of an equation form a geometrical progression, they occur almost exclusively in the solution of binomial equations, having prime indices, a property which M. Gaufi has turned to a good account in the solution of these equations. See Polygon, and Reciprocal Equations.

Nearly all other relations between the roots of equations are feigned for the purposes of framing questions, and excising the ingenuity of authors and their students.

1. To ascertain whether a proposed equation has any equal roots.

Let \( x^n + \alpha x^{n-1} + \beta x^{n-2} + \gamma x^{n-3} + \&c. = 0 \), be any equation whose roots are \( a, b, c, d, \&c. \) then from the known theory of equations we have

\[
\begin{align*}
(x - a) (x - b) (x - c) (x - d) & \ldots & \ldots \\
(x - a) (x - b) (x - c) & \ldots & \ldots \\
(x - a) (x - b) & \ldots & \ldots \\
(x - a) & \ldots & \ldots \\
& \ldots & \ldots \\
& \ldots & \ldots
\end{align*}
\]

And it may be shown also, that the equation \( m x^n + (m - 1) x^{n-1} + (m - 2) x^{n-2} + \&c. = 0 \), and

\[
\begin{align*}
(x - a) (x - b) (x - c) & \ldots & \ldots \\
(x - a) (x - b) (x - c) & \ldots & \ldots \\
(x - a) (x - b) & \ldots & \ldots \\
(x - a) & \ldots & \ldots \\
& \ldots & \ldots \\
& \ldots & \ldots 
\end{align*}
\]

that is, it is equal to the sum of all the \( m \) equations that can be formed by the different combinations of the \( m \) first roots, taking \( m - 1 \) at a time. (See Waring’s Meditationes Algebraicae, cap. 3.) Now if we suppute the first equation to have two equal roots, as, for example, \( a = b \), the above products will become

\[
\begin{align*}
x^n + \alpha x^{n-1} + \beta x^{n-2} + \gamma x^{n-3} + \&c. &= \]

\[
\begin{align*}
(x - a) (x - a) (x - c) (x - d) & \ldots & \ldots \\
(x - a) (x - a) (x - c) & \ldots & \ldots \\
(x - a) (x - a) & \ldots & \ldots \\
(x - a) & \ldots & \ldots \\
& \ldots & \ldots \\
& \ldots & \ldots 
\end{align*}
\]

where it is obvious that both the one and the other of these equations have the same factor, viz. \( (x - a) \).

If the equation had three equal roots, it is equally obvious that both equations would have the common factor \( (x - a)^3 \); and generally, if the equation had \( p \) equal roots, they would both have the common factor \( (x - a)^p \).

Therefore, when it is proposed to find whether a given equation have equal roots, we must from the proposed equation draw the derived equation as above, (which, it will be observed, is the same as would arise from the taking of the fluxion of the first, leaving out of course the \( x^2 \))s) and find by the usual methods, whether these two functions have any common measure; which, if they have, will furnish us with the equal root sought; and consequently the original equation may then be reduced by division to another of two degrees, lower dimension for two equal roots; of three degrees, lower for three, and so on.

Exam. 1.—It is required to find the equal roots of the equation \( x^5 - 48x - 128 = 0 \).

Here the derived equation is \( 3x^4 - 48 = 0 \), and the common measure of these two functions is \( x + 4 \); whence \(-\frac{3}{2} \) and \(-\frac{7}{2} \) are the equal roots; the third root being \( 8 \).

Exam. 2.—It is required to ascertain whether the equation

\[
x^5 + 3x^4 - 14x^3 - 12x + 40 = 0
\]

have equal roots, and what they are.

Here the derived equation is

\[
4x^3 + 9x^2 - 28x - 12 = 0
\]

and the common divisor of the two is \( x - 2 \), whence \( x = 2, 2 \), which are two of the equal roots. Divide now the original equation by \( x^2 - 4x + 4 \), and we have

\[
x^3 + 7x + 10 = 0
\]

whole
whose roots are $-2$, and $-5$; therefore, the four roots of the proposed equation are $2$, $2$, $-2$, $-5$.

If the roots of an equation be equal, but with contrary signs, the operation is more simple. For, in this case, we have only to change the signs of the roots in the proposed equation, by changing the alternate signs of its coefficient; and we shall thus have two equations, having necessarily a common quadratic factor of the form $x^2 - a^2$, which may be found, and the equation depressed as before.

Exam. 3.—Required the roots of the equation $x^4 + 3x^3 - 7x^2 - 27x + 18 = 0$, two of which are equal, but with contrary signs.

By changing the signs of the alternate terms, we have $x^4 - 3x^3 - 7x^2 + 27x + 18 = 0$, the common quadratic divisor of which is $x^2 = 9 = 0$; whence the equal roots with contrary signs are $3$, and $-3$. Now dividing the proposed equation by $x^2 - 9$, we have $x^2 + 3x + 2 = 0$;

whence $x = \frac{-3 \pm \sqrt{1}}{2} = -2$, and $-1$, which are the other two roots.

On this subject the reader should consult Waring's Meditationes Algebraicae, cap. 3. See also Bonnycastle's Algebra, vols. i. and ii.

Reduction of Interest of the Public Debt. See Fund.

Reduction of Curves. See Curve.

Reduction of a Figure, Design, or Draught, is the making a copy of it, either larger or smaller than the original, thus preserving the form and proportion.

The great use of the proportional compasses is in the reduction of figures, &c. whence they are also called compasses of reduction.

There are various methods of reducing figures, &c.; the most easy is by means of the pentagraph (which see), or parallelogram; but this has its defects. The best and most usual methods of reduction are as follow:

To reduce a figure, as A B C D E (Plate XII. Geometry, fig. 5.) into a lesser compasses.—About the middle of the figure, as $z$, pitch on a point; and from this point draw lines to its several angles, A, B, C, &c. then drawing the line $a b$ parallel to AB, be parallel to BC, &c. you will have the figure $a b c d e$ similar to A B C D E.

If the figure $a b c d e$ had been required to be enlarged, there needed nothing but to produce the lines from the point beyond the angles, as $z D$, $z C$, &c. and to draw lines, viz. D C, B C, &c. parallel to the sides $d e$, $e b$, &c.

To reduce a figure by the angle of proportion.—Suppose the figure A B C D E (fig. 6.) required to be diminished in the proportion of the line A B to $a b$ (fig. 7.); draw the indefinite line G H (fig. 8.), and, from G to H, let off the line A B; on G describe the arc H 1; let off the line $a b$ as a chord on H 1, and draw G I. Then with the angle I G H you have all the measures of the figure to be drawn. Thus to lay down the point $e$, take the interval B C, and upon the point G describe the arc K L; also on the point G make a perpendicular on G M; and upon a, with the distance G M, describe an arc cutting the preceding one in $e$, which will determine the side $d e$. And after the same manner are all the other sides and angles to be described. The same process will also serve to enlarge the figure.

To reduce a figure by a scale.—Measure all the sides of the figure $e$, gr. A B C D E, by a scale, and lay down the same measures respectively, from a smaller scale in the proportion required.

To reduce a map, design, or figure, by figures.—Divide the original into little squares, and divide a fresh paper of the dimensions required, into the same number of squares; which are to be larger or less than the former, as the map is to be enlarged or diminished.

This done, in every figure of the second figure, draw what you find in its correspondent one in the first.

Reduction to the Ellipse, in Astronomy, is the difference between the argument of latitude, as N P (Plate XIX. Astronomy, fig. 10.) and an arc of the ecliptic N R, intercepted between the plane of a planet and the node N.

To find the reduction.—The angle of inclination P N R, and the argument of latitude N P, being given, find, by the doctrine of spherics, the arc N R; subtract N R and N P from each other, the remainder is the reduction.

Reduction into first Matter, is a term which alchemists formerly used, when they found their substances putrefy, and grow black.

Reduction was particularly used for the conversion of a dry matter into a liquid, particularly into water; which by the alchemists was held the principle of all things.

The reduction of metals into their first matter, or principles, according to these philosophers, can only be effected by mercury; nothing else being able to loosen the fixed sulphur of metallic bodies, which binds them together.

Reduction, in Metallurgy, is the decomposition of a metallic oxyd, so as to leave the metal in a state of greater or les purity, and exhibiting the lustre which is so essentially characteristic of metallic bodies.

Reduction is, for the most part, effected by charcoal and a high temperature, either with or without the assistance of fluxes. For the various modes of reduction in actual practice, see the articles of the different metals.

Reduction, in Surgery, denotes an operation by which a dilated, luxated, or fractured bone is restored to its former place. Reduction, or reposition, is always to be performed before any remedy be applied.

Reduit, in Military Affairs. See Reduct.

Redundancy, or Redundance, a fault in discourse, confining in the use of a superfluous word; Words perfectly synonymous are redundant, and ought to be abridged. Redundancy necessarily makes the style weak and languid. See Pleonasm.

Redundant Hyperbola, in Geometry, is a curve of the higher kind, thus called, because it exceeds the conic section of that name in the number of its hyperbolic legs; being a triple hyperbola, with six hyperbolic legs.

Redundant Interval, in Music, is used for an interval exceeding the truth by a comma.

Some apply redundant to an interval exceeding a diatonic interval by a semitone minor; but this is more usually called a superfluous interval. See Interval and Second.

Reduplication, in Rhetoric, a figure by which a verce begins with the same word as the preceding one ends with. See Anadiplosis.

Reduplication, in Logic, is a kind of condition expressed in a proposition, indicating or alluding the manner in which the predicate is attributed to the subject.

The usual reduplicative words are guatentus, as, so far as, considered as, inasmuch as, &c. Hence.

Reduplicative Propositions, are such in which the subject is repeated, with some circumstances or condition. Thus, Men, as men, are rational; kings, as kings, are subject to none but God.

Redutea, in Botany, so called by the late M. Ventenat, in honour of his friend M. P. J. Redouté, one of the most accurate and intelligent botanical draughtsmen, and perhaps the finest botanical painter, ever known. He is the author of a splendid coloured work in folio, on the Liliaceous
liaceous tribe, including some other beautiful plants allied thereto, which has already extended to the seventh volume; and it is to his pencil that the perfection of most botanical works that have appeared in France, for near thirty years past, particularly the publications of L’Héritier and Ventenat, is owing.—Ventenat, Jard. de Cels, t. 11. Poiret in Lamarek Dict. v. 4. 87.—Clafs and order, Monodelphia Polyandria. Nat. Ord. Columnifera, Limn. Malasses, Jull. Gen. Ch. Cal. Perianth inferior, double, permanent: the outer of many minute leaflets: inner much larger, of one leaf, in five very deep segments. Cor. Petals five, roundish kidney-shaped, imbricated obliquely, united at the base to each other, and to the column of the filaments. Stam. Filaments numerous, united below into a conical tube, subdivided and branched above; anthers kidney-shaped. Pffl. Germen superior, ovate, simple; stye thread-shaped, swelling upwards, about as long as the filaments; stigmas three, obtuse. Peric. Capsule ovate, of three cells and three valves, the partitions from the middle of each valve. Receptacles of the seeds three, inserted into the base of the capsule, alternate with the valves, and nearly equal to them in length, linear, bearing seeds on each edge. Seeds fix or eight in each cell, obovate, minutely stalked, inserted in two rows on the receptacle, each clothed with dense wool. 

Eff. Ch. Calyx double; the outer of many minute leaves; inner in five deep segments. Stigmas three. Capsule of three cells and three valves. Seeds enveloped in wool. Receptacles three, linear, unconnected with the valves. 

Obf. Ventenat considers the three distinct receptacles, as affording the most essential diftinction, between this and every other malvaceous genus. The woody feeds, moreover, distinguishing it from all except Gossypium, whose large three-leaved outer calyx is abundantly different from Reduetia. 

The only known species is

1. R. heterophylla. Various-leaved Reduetia. Vent. Jard. de Cels, t. 11.—Discovered by Riedlé in the island of St. Thomas, and raised in M. Cels’s garden at Paris. The plant is herbaceous and annual, and M. Ventenat seemed to think it might serve to decorate our flower-borders, like other annuals of very hot climates, in the open air, being, we suppose, raised on a hot-bed in the spring. Every part of the herbage is bespangled with small, white, fringed scales, readily seen with a magnifying-lens. The root is spindle-shaped, yellowish. Stem erect, twelve or fifteen inches high, about the size of a goose-quill, angular, pithy, branched, leafy, dark green, many-flowered. Leaves alternate, on longiflalks, spreading widely, ovate, undivided or three-lobed, entire, an inch or inch and half long; paler beneath. Stipulas minute, awl-shaped, deciduous. Flowers large, hand-like, sulphur-coloured, with a dark purple radiating spot at the base of each petal, solitary, erect, on long,imple, axillary flanks. Segments of the inner calyx nearly linear, half as long as the petals. Style hairy. Capsule the size of a filbert. Wood of the seeds of a dirty grey.

We have not heard of this plant in any English collection.

REDUVIA, in Surgery, a word used by some for a whitlow, and by others for a painful crack, or other disorder about the nails, either of the fingers or toes.

REDUX, in Chemiftry. See REDUCT.

REDWAETH BAY, or Treath Coeb, in Geography, a bay on the N. coaft of the island of Anglefey. N. lat. 53° 17’, W. long. 4° 25’.

REDWITZ, a town of Bavaria, in the bishopric of Bamberg; 4 miles N.W. of Künfadt. 

REDWITZ, a town of Germany, in the principality of Cülmach; 4 miles N. of Bayreuth.

REDWOOD RIVER, a river of America, which runs into the Wabash, N. lat. 40° 16’. W. long. 82° 15’. RED, or RE, in Commerce. See Mollusca.

REE, Lough, in Geography, an expansion of the waters of the river Shannon, in Ireland, between the county of Roscommon and the counties of Longford and Meath, reaching from Langborough nearly to Athlone, with several islands, and in some places three miles broad.

REED, in Botany. See ARUNDO.

The root of the arundo donax of Dioscorides, attracts any matter lodged in wounds, if powdered and applied to them with wine; or if it is taken fresh and reduced to powder with an onion, or mixed with honey. (Oribas de Morb. Cur. lib. ii. cap. 32.) It also removes pains arising from dislocation of limbs, and carries off pains in the hips. The green leaves cut and applied, are said to cure the erysipelas. Poor people boil the flowers in water or in beer, which they mix with honey, and drink, after being filtrated, to cure coughs, oppriffions of the breast, and consumptions. The ancients made flutes and other musical instruments of the reed. James’s Med. Dict.

REE, Barr. See SPARGANiUM.

REE, Indian flowering. See CANNA.

REE Mace. See TYPHA.

REE, in Agriculture, the name of an aquatic plant, infelting boggy lowlands or meadows on the sides of rivers.

The best method of destroying reeds, is by draining the land; for if the drains be cut deeper than their roots it will take away their nourishment, and, consequently, destroy them. Aches, or foot, will likewise sometimes kill them; and so will ploughing up the land, and laying it in high ridges. They always indicate a deep good moift soil, as a bad one will not nourish or support them. There are many different sorts of reeds, but those of the more vigorous and tall kinds are often of much ufe in thatching the different sorts of farm buildings, where other better kinds of coverings are scarce, and these abundant. There is also a sort of reed found in Huntingdonshire, and some of the adjoining counties, that is very valuable for the purpose of laying plaster floors with. In other situations, reeds of the other kinds may be met with, that may be found ufeful for different purposes either of the farmer or in the arts. In such situations they may be cultivated with advantage as an article of profit: and it may often be more beneficial than to have them destroyed, especially where they are of a valuable nature, and where the land is of too moift and boggy a quality to be ever fully reclaimed and brought into either the state of good arable or meadow ground. Slips on the sides of large rivers or brooks are likewise, frequently, the most advantageously, conveniently, and profitably kept under reed eeps, as the overflow of the waters prevent their being usefully managed in any other manner. There are other situations, as those about the borders of large ponds, lakes, and other waters, where they may be preferred with far greater propriety than having them destroyed, provided even that can be accomplished without difficulty, as not any thing more valuable can in general be raised in such places. They are, however, by no means to be continued wherever any better crop will grow and succeed.

REE is also a term applied to such straw of the wheat or rye kinds as has not been bruised by threshing or in any other way.

REE, Hedge, in Gardening, that sort of hedge fence which is formed from reeds. They are a sort of temporary internal fences made with these dried materials which may be had cheap, and be expeditiously formed into hedges by the affil-
R E E

ance of polt and railing, being of great utility for occasional use in gardens, to inclose particular internal spaces of ground, so as to afford shelter to certain feather plants, both in nurseries and large kitchen gardens; and in some nurseries, to form places of shelter for many sorts of feeding trees and shrubs, &c., which being tender whilst young, require the shelter of a fence in winter to break off severe or cutting blasts two or three years, till they gradually gather strength and a greater degree of hardiness. They are also useful in training several sorts of wall-fruit-trees against, to form them for rows, or what are called trained trees; adorning of planting trees against each side of them, fix, eight, or ten feet afunder. See Nursery.

And in large open kitchen-gardens they are occasionally made use of to inclose the melonary, or place for raising early melons and cucumbers in, and often as cross internal fences, under which to form warm borders for the purpose of raising various early crops of esculents.

The proper sort of reeds for these fences are the dried stems of the common marsh reed, which grows in great plenty by river sides, and in lakes, and marshy places, furnishing a crop of items annually fit to cut in autumn, when they should be bound in bundles, and stacked up, or houfed, to remain for use.

These fences are sometimes erected in fixed ranges, and sometimes formed into movable panels. In the first mode, some flat poles should be placed fix or eight feet afunder, and five or six fix, and from post to post carry two or three ranges of flat thin railing, one range near the bottom, another near the top, and a third in the middle; against this railing, the reeds must be placed about two inches thick, having other railing fixed directly opposite; so that the reeds being all along between the double railing, the bottom refting either upon a plate of wood, or let into the ground, but the former is preferable; and as soon as one panel is formed, the railing should be nailed as close as possible, driving some long spike-nails through each double railing, or binding them with strong withy bands, or tar rope-yarn, but railing is the best, in order to bring them as close as may be, to secure the reeds firmly in the proper position; the top should be cut even afterwards.

In the better method, a frame-work of railing should be prepared as above, each panel fix or eight feet long, and the reeds fixed therein as before directed; then, where they are intended to be placed, poles must be ranged fix or eight feet distant to support the different panels. Or sometimes the panels may be placed inclining against the wall or other fence, in time of severe weather, when the borders are narrow. These sorts of fences are now however in much less use in gardening than formerly.

Reed Ronds, in Rural Economy, a provincial word, signifying plots or beds of reed, or the swamps in which they grow.

Reed, Ezekiel's. See Ezekiel's Reed.

Reed, Calamus, likewise denotes a Jewish measure, otherwise called commea.

Reed, in the Manufactury of Tapestry. See Tapestry.

Reed Sparrow, in Ornithology. See Emberiza Schoeniclus.

Reed Point, in Geography, a cape on the W. coast of the island of Antigua. N. lat. 15° 12'. W. long. 61° 36'.

REEHAM. See REEPHAM.

REEDS, in a Fire-ship, are made up in small bundles of about twelve inches in circumference; cut even at both ends, and tied each with two bands. There are two kinds of them; the long, which are four feet; and the short, which are two feet five inches in length. Some of them are singly dipped, i.e., at one end, the reed are dipped at both ends, in a kettle of melted composition. After being immersed about seven or eight inches in this preparation, and then drained, they are sprinkled over with pulverized sulphur upon a tanned hide. See Fire-ship.

REEDSBOROUGH, in Geography. See REEDSBOROUGH.

REEDSTOWN. See STRONG.

REEDY CREEK, a river of New Jersey, which runs into the Atlantic, N. lat. 39° 55'. W. long. 74° 16'.

Reedy Island, an island of America, in the Delaware river, 50 miles below Philadelphia, and 20 miles from Bombay Hook, about three miles long and not more than one-fourth of a mile wide. This island was formerly banked in, but is now under cultivation, and overflowed in high tides. It is the rendezvous of outward-bound ships in autumn and spring; waiting for a fair wind. Here is a secure harbour at Port Penn, where piers have been erected by the State of Pennsylvania. On each side of the island is a channel; but veils, especially of the larger kind, choose to keep the eastern side.

Reedy River. See Saluda.

Reedy River Shoal, a post-town of America, in Greenfield county, South Carolina.

REEF (reef, Dutch), in Navigation, denotes a certain portion of a fail, comprehended between the top or bottom, and a row of eyelet-holes parallel to it. The intention of the reef is to reduce the surface of the fail in proportion to the increase of the wind; for which purpose there are several reefs parallel to each other in the superior fails, by which they may be still farther diminished, in order to correspond with the several degrees of the gale. The top-fails of ships are usually furnished with four reefs, parallel to the yard; and there are always three or four reefs parallel to the foot of those main-fails and fore-fails which are extended upon booms; a circumstance common to many of the small veils.

Falconer.

A bag-reef is the fourth, or lower, reef of a top-fail. A balance-reef crossed boom-main-fails diagonally, from thenock to the end of the upper reef-band on the after-larch. This is used to contract the fails in a block. Reef also denotes a chain of rocks, lying near the surface of the water.

Reed-Band, in Sea Language, a piece of canvas, fewed across the fail, to strengthen it in the place where the eyelet-holes of the reefs are formed.

Reef-Hanks, short pieces of log-line or other small line, fastened at certain distances to form the reefs of boom-fails.

Reef-Tackle, is a rope which passes from the deck to a block at the top-mast head, and thence to another block at the top-sail-yard-arm, where it communicates with another rope, called its pendant, that runs downwards through a hole in the yard, and is afterwards attached to a cringle, a little below the lowest reef. It is used to pull the skorts of the reefs clofe up to the extremities of the top-sail yards, in order to lighten the fail, the weight of which would otherwise render it very difficult to perform this operation.

Falconer.

Reef Island, in Geography, a small island in the East Indian sea, about 50 miles from the W. coast of Sumatra. S. lat. 4°. E. long. 101° 3'.—Albo, a small island in the East Indian sea, near the N. coast of the island of Celebes. N. lat. 5° 8'. E. long. 122° 48'.

Reefing, in Sea Language, the operation of reducing a fail, by taking in one or more of the reefs, which is performed by lines, points, or knittles. The top-fails are always
REEL, to reel ropes on from a six-thread ratline to a two-inch rope, have four ribs fixed at each end in a flat circular piece of wood; and round the edges are blades, or handles, to turn them: one of the circular pieces is called the head, and is made to slide off for taking the coil away. They turn on an iron spindle, and are from ten to thirty-six inches long, and from twelve to eighteen inches diameter. The Beach-reel used by fail-makers is similar to a spinning-wheel, and is used to expedite winding the twine from the skins to the twine-reel. Log-reels have several ribs fixed in a circular piece of board at each end, and turn or run upon a spindle, having a handle at one end. (See Log.) Twine-reels, used by fail-makers, are short cylindrical pieces of wood, hollowed in the middle to receive the twine, with a hole through the middle for the spindle. Those used by rope-makers have four oak bars, about eighteen inches long, framed together at the ends on a wooden spindle; one of the bars slides, for the convenience of taking off the twine. The Turn-reel consists of a circular board fastened horizontally on the middle of a piece of oak four inches square, and sixteen long, with a hole through its middle to receive a bolt, on which it turns as its axis, and is used to wind spun-yarn off the coil. The Hand-reel is a narrow board, with three or four holes at each end, in which pegs are fixed for reeling marline and other lines.

REELFOOT, in Geography, a small navigable river of America, in Tennessee, which discharges itself into the river Missippis, about 35 miles S. of the Ohio. It is 50 yards wide seven miles from its mouth. One of its branches rises on the borders of Kentucky.

REELING, in the Manufactories, the winding of thread, flax, cotton, or the like, into a skain, or upon a bottom, to prevent its entangling. It is also used for the charging or discharging of bobbins, or quills, to use them in the manufacture of different stuffs, as thread, flax, cotton, &c.

Reeling is performed different ways, and by different engines.

REEM, in Zoology. See RHINOCEROS UNICORNIS.

REEMING, a term used by caulkers for opening the seams of the planks with reeming-irons, that the oakum may be more readily admitted. To make any hole larger is also termed reeming.

REEMING-IRONS, are the largest irons used by caulkers in opening the seams.

REEMSTOWN, or REAMSTOWN, in Geography, a small poft-town of America, in Lancaster county, Pennsylvania, situated on a stream which runs into Calico creek, a water of Coneloga, which falls into the Susquehanna; 26 miles N.E. of Lancaster.

REEN, a river of Norway, in the province of Drontheim, which runs into the Glomme; 20 miles N. of Opfahl.

REIEN Mofa, a name used by some for the mountain coralloids, or rein-deer moss.

REENBERG, Theocarus, in Biography, a celebrated Danish poet, was born at Viborg in 1656, where he was educated. In 1680 he fell out on his travels into foreign countries, after having undergone an examination by the theological faculty, and he returned to Denmark in 1682. In 1723 he was appointed fourth judge in Jutland. In 1730 he became councillor of justice, and he died in 1742. His poetical works were published at Copenhagen in 1769, by his grandson Tichmann, with a preface by Kofod Anker, and annotations by Luxdorph. Gen. Biog.

REENS KLOSSER, in Geography, a town of Norway; 12 miles N.N.W. of Drontheim.

REEK, in Rural Economy, a term provincially used for flack. See Stack and Rick.

REEK-Stafford, a term applied to a frame of wood placed on flone, on which the mow or flack is railed. It is sometimes written Reek Stafford.

REEL, in the Manufactories, a machine serving for the office of reeling.

There are various kinds of reels; some very simple, others very complex. Of the former kinds, those most in use are,

1. A little reel, held in the hand, consisting of three pieces of wood, the biggest and longest whereof (which does not exceed a foot and a half in length, and a quarter of an inch in diameter,) is traversed by two other pieces disposed different ways.

2. The common reel, or windlace, which turns upon a pivot, and has four flights, traversed by long pins, or ficks, on which the skin to be reeled is put, and which are drawn clover or opened wider, according to the skin.

Other reels used in particular arts, are explained under their particular articles; as the reel used in milling of flax, under the article Milling; and that in the reeling or winding of flax, under the article Silk, &c.
RE-ENTERING ANGLE, in Fortification. See Angle, and Construction, according to M. Vauban's first method.

RE-ENTRY, in Law, the refuming or retaking that possession which any one had lately forgone.

As, if I make a leaf of land or tenement, I do thereby forego the possession; and if I condition with the leffe, that for no-payment of rent at the day, it shall be lawful for me to re-enter; this is as much as if I conditioned to take again the lands, &c. into my own hands, and to recover the possession by my own act, without the assistance of judge or other process. But words in a deed give no re-entry, if a clause of re-entry be not added. (Wood's Inft. 140.) All persons who would re-enter on their tenants for no-payment of rent, are to make a demand of the rent; and, to prevent the re-entry, tenants are to tender their rent, &c. (1 Inst. 201.) If there is a lease for years, rendering rent, with condition, that if the leffe affigns his term, the leffer may re-enter; and the leffe affigneth, and the leffer receiveth the rent of the affignee, not knowing or hearing of the affignment, he may re-enter, notwithstanding the acceptance of the rent. (3 Rep. 65. Cro. Eliz. 553.) See RENT. A feoffment may be made upon condition, that if the feoffor pay to the feoffee, &c. a certain sum of money at a day to come, then the feoffor to re-enter, &c. Litt. § 322. See Entry and Use.

REEPHAM, in Geography. See REPHAM.

REESE, REES, in Geography, a small island of Denmark, in the great Belt, near the coast of Zealand. N. lat. 54° 32' E. long. 11° 7'.

REESES, REIS, or REAS, in Commerce, monies of account in Portugal, 1000 of which make a milress or milrei.

In the notion of accounts, the milreis are separated from the rees by a crossed cypher, called "Cifraon," and the milreis from the millions by a colon; thus Rs. 2 : 700 500, means 2700 mil. and 500 rees. The cruafdo of exchange, or old cruafdo, is 400 rees; the new cruafdo, 480 rees; the telfoon, 100; the vintin or vintem, 20 rees. Thus the milrei is 31/2 old cruafdos, 2½ new ditto, 10 telfoons, or 50 vintins. The gold pieces, coined before 1722, are now 20 per cent. higher than their original value; so that the old dobras, coined at 20,000 rees, are worth 24,000; the librionnomes or mordeiros, coined at 4000 rees, are worth 4800; and the halves and quarters in proportion; but few of these coins are now in circulation. The gold coins, struck since 1722, are the dobra of 12,800 rees; the meia dobra, Joaenfe, or Portugal piece of 6400 rees; the half Joaenfe, of 3200; the dezefees telfoons, of 1600; the caratino, of 1200; the oito telfoons, of 800; the old cruafdo, of 400, now very scarce; and the new cruafdo, of 480 rees. The silver coins are new cruafados, of 480 rees; halves, quarters, and eighths, or pieces of 240,120, and 60 rees; telfoons of 100, and halves of 50; and vintins of 20 rees. There are also copper pieces of 10, 5, 3, and 1½ rees. The pieces coined in Brazil, called patacas, of 600 and 640 rees, are current only in that country, and their intrinsic value is 10 per cent. less than that of the Portugal coins. There is, besides, a gold milrei, struck for the Portuguese pofflfeffions in Africa, and also a silver coin, of the value of 12 macantas, or 600 rees; the macanta being a money of account, worth 50 rees. The Spanish patacas, or dollar, are reckoned at Lisbon at 830 rees, more or less.

Portuguese gold coins are 22 carats (the mark fine being 24 carats), wrought gold is 20½ carats, and gold dust from 21½ to 22 carats fine. The fineffes of silver is exprifed in dinheiros and grains, the mark fine being 12 dinheiros, and the dinheiro subdivide into 24 grains. Silver coins are

10 dinheiros 19 grains fine, and wrought silver 10½ fine.

The rate of coinage of gold and silver coins is as follows: 8 dobras of 12,800 rees, 16 Joanefes of 6400 rees, 32 half 10 Joanefes of 3200 rees, 64 dezfees teloons, 128 oito teloons, or 256 old cruafados, are to weigh a Portuguifhe mark of gold, 22 carats fine. Hence (the mark being 3542½ English grains) the dobra contains 442½ grains; the piece of 6400 rees 22½ grains of English fandard gold, and the other pieces in proportion. These coins, moreover, are not, in general, exactly 22 carats fine; but there is a remedy which amounts from 2½ to 3½ of a carat; and the new cruafados are found to be only 21½ carats fine. The silver coin is 10½ as above; and the mark is coined into 13½ new cruafados; hence the new cruafdo weighs 345½ Portuguese grains, or 265½ English grains; halves, quarters, and eighths, in proportion. It, therefore, contains 258½ grains of English fandard silver. The gold piece of 6400 rees is worth 355½ id. fterling; and the old cruafdo, 2½ id.; and thus the milrei, valued in gold, is worth 67½ fterling. The new filver cruafdo is worth about 2½ fterling; and, therefore, the milrei, valued in filver, is worth 69½ fterling. Gold is to filver as 16 to 1.

At Bombay each quarter of a rupee is divided into 100 rees. See Rupee.

REES, in Geography, a town of the duchy of Cleves; 8 miles E. of Cleves. N. lat. 51° 37'. E. long. 6° 20'.

Reesul Ain, or Refafna, a town of Asiatic Turkey, in the province of Daribekir; 80 miles S. of Daribekir.

REETZ, a town of the New Mark of Brandenburg; 50 miles N.E. of Cnutrin. N. lat. 53° 18'. E. long. 15° 56'.

REEVE, in Ornithology, the name of a bird which is the female of the avus pugnax; the male of which, from the long feathers round his neck, is called the ruff. See Tringa Pugnax.

Revee of a Church, is the guardian of it, or the churchwarden.

So fibre-reg is the sheriff, or guardian of a county; and port-reve, the warden of a port or haven.

REVEE-LAND. See Reveland.

REEVING, in the Sea Language, is the putting a rope through any hole, as the channel of a block, &c. Hence, to pull a rope out of a block, is called unreeving.

RE-EXCHANGE, in Commerce, a second payment of the price of exchange, or rather the price of a new exchange, due upon a bill of exchange that comes to be perfected; and to be refunded the bearer, by the drawer or indorser. See Exchange.

The occasion of re-exchange is, when the bearer of a bill of exchange, after protelting it, for want of either of acceptance, or of payment, borrows money on his own promise, bond, or the like; or draws a bill of exchange in the place where the payment was to be made, on the person who furnished the first for which he pays a second exchange; which, being added to the first already paid, the drawer of the first bill is answerable for two exchanges, properly called exchange and re-exchange.

The bearer of a protelfed bill has a right to recover both the one and the other on the drawer. Yet the simple protelation which the bearer makes in the act of protel, that he will take up a like sum at re-exchange, for want of his bill being accepted or paid, is not sufficient to entitle him to demand the reimbursement of his re-exchange, unless he makes it appear, that he has actually taken up money in the place on which the bill was drawn.

Otherwise the re-exchange will only amount to the restitution of the first exchange, with interest, the expenses of protelation, and those of the journey, if there have been any.
It a bill of exchange, payable to the bearer or order, come to be protested, the re-exchange is only due upon the drawer for the place where the remittance was made, not for those places where it may have been negociated; at least the drawer has a right to be refunded his re-exchange for those places by the indorser.

Indeed, the re-exchange is due from the drawer upon all places where a power of negociation is given by the bill; and upon all others, if the power of negociating be indefinite.

Lastly, the interest of the re-exchange, of the expenses of the protest, and the journey, are only due from the day of the demand.

It is supposed to be the Bibeliers driven out of Italy by the faction of the Guelphs, and sheltered at Amsterdam, who first established the custom of re-exchange, on pretense of the interrells, damages, and expences they underwent, when the bills given them for the effects they had been obliged to abandon, were not accepted, but came to be protested.

REFLECTORY, REFECTIO, among monks and ecclesiastics, a spare meal or repast, full sufficing for the support of life. Refection is also used, in Ancient Authors, for a duty or service incumbent on any person to provide meals for ecclesiastics, or even for princes.

REFECTORY, or REFECTUARY, Refftorium, a spacious hall in convents, and other communities, where the monks, nuns, &c. take their refestions or meals in common.

The refectory of the Benedicines of St. George at Venice, designed by Palladio, is one of the finest in the world.

Davier.

REFERENCE, in Writing, &c., a mark relative to another similar one in the margin, or at the bottom of the page, where something, omitted in the text, is added; and which is to be inserted either in reading or copying. A copyist must be very expert at taking references.

References are also used in books, where things being but imperfectly handled, the reader is directed to some other part or place where they are more amply explained.

Dictionaries are full of references, denoted by see or vide.

By means of these references the dictionary writer ferttles a correspondence between the several parts of his work, and may give his dictionary moiit of the advantages of a continued treatise.

Indices or tables are only references to the several parts of the work where the several matters are handled.

REFERENCE, in Law, denotes the sending of any matter by the court of chancery to a matter; and by the courts at law to a prothonotary, or seconday, to examine and report to the court. (2 Litt. Abr. 432.) If a matter in difference be referred to the seconday, and one of the parties will not attend at the time appointed, after notice given, to hear the business referred; the other party may proceed in the reference alone, and get the seconday to make his report without hearing of the party not attending. (2 Litt. 342.)

If a question of mere law arise in the course of a cause in chancery, or, whether, by the words of a will, an estate for life or in tail is created, or whether a future interest devised for a tail or tuller shall operate as a remainder on an executory devise: it is the practice of that court to refer it to the opinion of the judges of the court of king's bench, or common pleas, upon a cause stated for that purpose, in which all the material facts are admitted, and the point of law is submitted to their decision; who thereupon have it solemnly argued by counsel on both sides, and certify their opinion to the chancellor: and on such a certificate the decree is usually founded. It seems that the matter of the rolls, fitting for the chancellor, may make such reference; but not when fitting at the rolls. 2 Bro. C. C. 88.

The court of exchequer is both a court of law and of equity: therefore, if a question of mere law arises in the course of the exercise of its equitable jurisdiction, the barons will decide upon it in that suit, without referring it to another jurisdiction. Bl. Comm. 3.

REFERENDARY, REFERENDARIUS, in Ancient Customs, an officer who exhibited the petitions of the people to the king, and acquainted the judges with his commands.

An officer of this kind, Spelman observes, we had in England, in the time of the Saxons. The like office was afterwards discharged by others, called malters of requests.

REFINING, in Metallurgy and Assaying. In the former it signifies the metals of obtaining metals from their ores, and from any other impurities, natural or artificial: for which see the metals under their respective heads. In the latter it is employed for ascertaining the quantity of the noble metals in the different alloys; for which see CEPFL; where the methods of refining in the furnace are fully treated. And for the humid procès called paring, see GOLD.

It may be proper here to observe, that although the processes of paring by nitric acid is still practised, we are inclined to recommend the method proposed by Bergmann, which consists in dissolving the alloy of gold and silver in nitro-muriatic acid. The silver falls to the bottom in the estate of muriate of silver, and the gold is precipitated by the green sulphate of iron. The gold, by this means, is obtained perfectly pure, which is seldom the case in the processes of paring. The trouble of telling to know what silver to add to the alloy, to make the gold equal to one-fourth of the silver, will be baved, and, with heat, the nitro-muriatic acid dissolves the gold quite as soon as the silver is dissolved in the common method. The muriate of silver, which is easily separated by washing, may be readily reduced by heating it with soda in an iron crucible. The soda combines with the muriatic acid, and is sublimed in white fumes.

REFINING of Sugar. This operation is begun by several strong liquors or leys of lime-water and eggs, flulls and all, mixed and beaten together.

The first refining is performed in the Caribbees, and other places, where the sugar-canes are cultivated; and only serves to make the brown or coarse sugars.

When these are imported into Europe, the sugar-bakers take them up, and refine them farther, by a second operation, or rather a repetition of the first.

To render the sugar very fine, fit for confections, &c. they give it a third refining; in which they only use the whites of eggs and their shells beaten together, and thrown into the melted sugar; which is called clarifying the sugar. See SUGAR.

REFINING of Salt-petre. The salt being put into an earthen or iron vessel, as much spring-water is poured on it as suffices to dissolve it. The vessel is then put over a gentle fire; and as soon as the water begins to boil, alum powder is thrown into it: the proportion is, one pound of alum to one hundred and twenty-eight pounds of salt-petre; and a little vinegar is added. As it boils, the scum is to be taken off; and it is to be evaporated till a pellicle appears on it, and then set to coagulate. For
REF

For the refining of other matters, as camphor, cinnabar, sulphur, falt, borax, &c., see CAMPHOR, CINNABAR, SULPHUR, SALT, &c.

REFRITION VOE, in Geography, a bay on the E. coast of the island of Yell. N. lat. 65° 58'. W. long. 1° 25'.

REFITTING, in SEA LANGUAGE, denotes the repairing of any damages which a ship may have sustained in her sails and rigging, by battle or tempestuous weather.

REFLECTED RAY. See RAY.

REFLECTED VISION. See REFLEX and VISION.

REFLECTING, or REFLECTIVE DIAL, is a sort of dial, which shews the hour by means of a thin piece of looking-glass plate, duly placed to cast the sun's rays to the top of a ceiling, on which the hour-lines are drawn.

REFLECTING MICROSCOPE. See MICROSCOPE.

REFLECTING LEVEL. See LEVEL.

REFLECTING TELESCOPE. See TELESCOPE.

REFLECTION, or REFLEXION, in Mechanics, the return, or regressive motion of a moveable, occasioned by the reftance of a body, which hindered its pursuing its former direction.

It is controverted whether there be any moment's reft or interval between the incidence and the reflection. For the affirmative stand the Peripateticians, and all who conceive the reflected motion to be different from the incident one of the same body. The motion of incidence, according to these authors, is wholly loft, and destroyed, by the reftance of the obstacle struck against; and the moveable is thus rendered absolutely quiecent in the point of contact; till a new motion of reflection is produced in it, from a contrary cause.

The Cartesians affect the negative; absolutely denying any reft at all between the incidence and reflection; urging, that if the motion were once destroyed, though but for a moment, there would be nothing to excite it again; but the body would perforce in that new state, as much as if it had been at reft a thousand years.

Accordingly Rohault, and others, define reflection to be no other than a change of determination; or a continuation of the former motion in a new direction.

As, say they, a pendulum, when arrived at its greatest sweep, does not stop; so a hard body, by striking on another hard one, does not reft, but pursues its motion the contrary way, according to the established law of nature; and this from the immediate influence or impulse of the cause that first moved it. But this doctrine is now generally set aside.

Reflection is conceived, by the late Sir Babbage, as a motion peculiar to elastic bodies, whereby, after striking on others which they cannot remove, they recede, or turn back by their elastic power.

On this principle, it is asserted, that there may be, and is, a period of reft between the incidence and the reflection; since the reflected motion is not a continuation of the other, but a new motion, arising from a new cause or principle, viz. the power of elasticity.

It is one of the great laws of reflection, that the angle a reflected body makes with the plane of a reflecting obstacle, is equal to that in which it struck on that obstacle. For the several laws of motion observed in the reflections of bodies, see PERCUSSION.

Reflection of the rays of light, in Optics, is a motion of the rays, by which, after impinging on the solid parts of bodies, or rather, after a very near approach to them, they recede, or are driven from them.

When rays of light arrive at a surface, which is the boundary of two mediums not homogenous, they continue their progress without deviating from those planes in which their former paths lay, and which are perpendicular to the surface of the mediums, but they no longer retain the same direction, a part of them, and sometimes nearly the whole, being reflected back from the surface, while the remaining part is transmitted and refracted, or bent. No instance occurs of the abrupt change of the density of a medium, without a partial reflection of the light passing either into the denser, or into the rarer medium; and the more obliquely the light falls on the surface, the greater, in general, is the reflected portion. No body is so black as to reflect no light at all, and to be perfectly invisible in a strong light; although at the surface separating two very rare bodies, as two kinds of gas, the reflection is too faint to be perceptible; but in this case the separation is seldom perfectly abrupt. The quantity of light reflected, when other circumstances are equal, appears to be always greater when the difference of the optical or refractive density of the two substances is the greatest. Thus, the reflection from the common surface of glass and water is much weaker than from a surface of glass exposed to the air. Metals, in general, reflect a great proportion of the light falling on them; and even the reflection from the common surface of glasses and mercury appears to be but little weaker than the reflection from the surface of mercury immediately exposed to the air, so that the optical density of the metals must be exceedingly great. It appears, also, that a portion of the light falling on a reflecting surface, is always transmitted to a certain depth, notwithstanding the apparent opacity of any large masses of the substance. Thus, if we cover a small hole of a window-shutter with the thinnest leaf-gold, we shall find that it transmits a greenish light, which must have passed the reflecting surface, but which, if the gold had been one ten-thousandth of an inch thick, would have been wholly interrupted, and probably in the same manner as by passing through 700 feet of water. See LIGHT and REFRACTION.

The reflection of the rays of light from the surfaces of bodies, is the means by which bodies become visible.

And the disposition of bodies to reflect this, or that kind of rays most copiously, is the cause of their being of this or that colour.

The reflection of light from the surfaces of mirrors, makes the subject of CATOPTRICS; which see. See also MIRROR.

The reflection of light, for Isaac Newton has shewn, is not effected by the rays striking on the very parts of the body; but by some power of the body equally diffused throughout its whole surface, by which it acts upon the ray, attracting or impelling it without any immediate contact.

This power he shews to be the same, by which, in other circumstances, the rays are refracted; and by which they are at first emitted from the lucid body. See REFRACTION.

The arguments he produces to prove this are as follow: 1. Because the surfaces of polished glasses, which to the eye appear smooth, are yet, in reality, very rugged and uneven (polishing being nothing but the gratting, etching, and breaking off the coarser protuberances, by means of sand, glasses, putty, tripoli). If the rays of light, therefore, were reflected by striking on the solid parts of the glass, the reflections would never be so accurate as we find they are; but the rays would even be as much scattered by the most polished glasses, as by the roughest. It remains, therefore, a problem how glasses, polished by fretting substances, can reflect light so regularly as it does; which problem is fiercely otherwise to be solved, than by saying, that the reflection of a ray is effected, not by a single point of the
REFLECTION.

If the colours, separated by a prism placed at the entrance of a beam of light into a darkened room, be successively cast on a second prism placed at a greater distance from the former, in such manner as that they all fall alike, or with an equal obliquity, upon it; the second prism may be so inclined to the incident rays, that those which are of a blue colour shall be all reflected by it; and yet those of a red colour pretty copiously transmitted. Now, if the reflection were caused by the parts of the air or glafs, we would ask, why, at the same obliquity of incidence, the blue should wholly impinge on those parts so as to be all reflected; and yet, the red find pores enough to be, in a great measure, transmitted.

3. Where two glases touch one another, there is no sensible reflection; and yet we see no reason why the rays should not impinge on the parts of the glases, as much when contiguous to other glases, as when contiguous to air.

4. When the top of a water bubble, by the continual subliming and exhalation of the water, grows very thin, there is such a little, and almost in infinitely small quantity of light reflected from it, that it appears intensely black; whereas round about that black spot, where the water is thicker, the reflection is so strong, as to make the water seem very white. Nor is it only at the least thicknesses of thin plates or bubbles, that there is no manifest reflection, but at many other thicknesses, gradually greater and greater. For, in one of our author’s observations, the rays of the same colour were, by turns, transmitted at one thicknes, and reflected at another thicknes, for an intermediate number of successions: and yet, in the superficial of the thinned body, where it is of one thicknes, there are as many other parts for rays to impinge on, as where it is of any other thicknes.

5. If the red and blue rays, separated by a prism, fall successively on a thin plate of any pellucid matter, whose thicknes increases in continual proportion, (such as a plate of air between two glases, the one plane, and the other a little convex,) the same plate will, in the same manner, reflect all the rays of one colour, and transmit all those of the other; but, in different parts, will reflect the rays of one and the same colour at one thicknes, and transmit them at another; and thus alternately, and in infinitum. Now, it can never be imagined that at one place the rays, which, for instance, exhibit a blue colour, should happen to strike on the solid parts, and those which exhibit a red, to hit on the void parts of the body; and at another place, where the body is either a little thicker, or a little thinner, that, on the contrary, the blue should hit on the pores, and the red upon the solid parts.

In the passage of light out of glases into air, there is a reflection as strong as in its passage out of air into glases, or rather a little stronger, and by many degrees stronger than in its passage out of glases into water. Now, it seems improbable, that air should have more reflecting parts than water or glases: but if that should be supposed, yet it will avail nothing; for the reflection is as strong, or stronger, when the air is drawn from the glases by the air-pump, as when it is adjacent to it. If any should here object, on Descartes’s hypothesis, that, though the air be drawn away, there is a subtle matter remaining to supply its place, which, being of a denser kind, is better fitted for the reflection of light than any other body; besides that we have elsewhere shown such subtle matter to be fictitious, and that, supposing its existence, and its reflecting power, no light could ever have been propagated, but must have been all reflected back to the lucid body, immediately after it was first emitted, the following experiment does evidently convict it of fallacy.

7. If light, in its passage out of glases into air, strike more obliquely than at an angle of forty or forty-one degrees, it is then wholly reflected: if less obliquely, it is in great measure transmitted. Now, it is not to be imagined, that light at one degree of obliquity should meet with pores enough in the air to transmit the greater part of it; and at another degree should meet with nothing but parts to reflect it wholly; especially considering, that, in its passage out of air into glases, how oblique ever be its incidence, it finds pores enough in the glases to transmit a great part of it. If any suppo, that it is not reflected by the air, but by the utmost superficial parts of the glases, there is still the same difficulty: besides, that such a supposition is unintelligible, and will also appear to be false, by applying water behind some part of the glases, instead of air; for in a convenient obliquity of the rays, suppose of forty-five or forty-six degrees, at which they are all reflected, where the air is adjacent to the glases, they shall be in great measure transmitted where the water is adjacent to it; which argues, that their reflection or transmission depends on the constitution of the air and water behind the glases, and not on the striking of the rays upon the parts of the glases, the rays not being reflected until they have reached the last part of the surface, and have begun to go out. For if, in going out, they fall upon a surface of oil and water, they proceed, the attraction of the glases being balanced by an equal force the contrary way, and prevented from having its effect by the attraction of the liquor adhering to it; but if the rays, in passing out of this last surface, fall into a vacuum, which has no attraction, or into air, which has but little, not enough to counterbalance the effect of the glases in this case, the attraction of the glases draws them back, and reflects them.

This will appear still more evident by laying two glases prims, or the object-glases of two telescopes, the one plane, and the other a little convex, upon each other, so as they may neither touch, nor yet be too far apart; for that light which falls on the hinder surface of the first glases, where the glases are not above the part of an inch apart, will be transmitted through the surface, and through the air or vacuum between the glases, and will pass into the second glases; but if the second glases be taken away, then the light passing out of the second surface of the first glases into the air or vacuum, will not proceed, but will return into the first glases, and be reflected.

Whence it follows, that the rays are drawn back again by some force in the first glases, there being nothing else to occasion their return. And hence too it follows, that the reflection is not effected, by means of any subtle matter contiguous to the hinder surface, according to the principles of Descartes; since that matter ought to reflect them when the glases were nearly contiguous, as well as when the second glases was quite removed.

Lastly, if it be asked, how some of the rays come to be reflected, and others transmitted; and why they are not all alike reflected, supposing the reflection owing to the action of the whole surface? the same great author shews, that there are, both in the rays of light, and in the bodies themselves, certain vibrations (or some such property) impressed on the rays, by the action either of the luminary that emits them, or of the bodies that reflect them; by means of which it happens that these rays, in that part of their vibration which
which conspires with the motion of the parts of the body, enter the body, are refracted and transmitted; but those in a contrary part of their vibration are reflected.

Add, that every ray of light, in its passage through any refracting surface, is put into a certain transient constitution or state, which, in the progress of the ray, returns at equal intervals, and is deflected by the ray, at each return, to be easily transmitted through the next refracting surface; and between each return, to be easily reflected by it.

These alternate deflections, which Sir Isaac Newton calls a fit of easy reflection, and of easy transmission, he accounts for by supposing, that they are occasioned by the vibrations of a subtle fluid, in which the ray paffes, which happening to move fatter than the rays, when a ray is in that part of the vibration which conspires with its motion, it paffes through; but when in the contrary part of the vibration, it is beat back again: whence every ray is successively deflected to be easily reflected, or easily transmitted, by every vibration which overtake it.

He also thought that these vibrations might be excited by the mutual action and re-action of light, of bodies and of this medium, at the instant of reflection or refraction; so that, in fact, he supposes two causes of this deflection to be reflected or transmitted, when rays of light arrive at any new surface. One of them is the regular vibration of the etherial medium, affecting them through the whole of their progress from the luminous body; and the other the irregular motion, or irregular vibration of the same medium at the surfaces of bodies, occasioned by the action and re-action between light and them: for this last cause can hardly be supposed to affect the whole etherial medium equally, and produce the regular returns of these fits in every ray.

M. Boscovich supposes with Newton, that the fits of reflection or transmission affect the rays themselves, in the whole of their passage from the luminous body, but that they arise from an alteration in their form, by means of the elasticity of their component parts, having been originally driven from the luminous body by a force which acted more strongly on the hinder parts than on the rest of the mass, and thereby put them into a vibratory motion. He also supposes, that the intervals of the fits of easy reflection and transmission may be different in different rays, on the three following accounts. 1. The rays that are differently refrangible have different velocities, at least after refraction; so that, though the fits should return at equal intervals, it will affect different rays in different parts of their progress. 2. The unequal action between the points that compose the same particle of light may make a difference in their oscillations, at the time of changing their medium. And lastly, rays coming in different inclinations to the new surface, the internal motions of these points will be in different directions with respect to the surface, and consequently the whole mass of the medium will act upon all the points differently.

Upon the whole, says Dr. Priestley, is it not more probable that the rays of light are transmitted from the sun, with an uniform disposition to be reflected or refracted, according to the circumstances of the bodies on which they impinge; and that the transmission of some of the rays under the same circumstances, apparently, with others that are reflected, is owing to the minute vibrations of the small parts of the surfaces of the mediums through which the rays pass; vibrations that are independent of action and re-action between the bodies and the particles of light at the time of their impinging, though probably excited by the action of preceding rays. As to the transmission or reflection of certain kinds of light only, producing colours in thin plates, the cause may be this; viz. that every particle of the medium has a great number of equal alternate intervals of attraction and repulsion, relatively to the particles of light; but that these intervals are of different magnitudes, according as the particles of light are of different colours. Now the thickness of any transparent medium in which the particles of matter are uniformly placed is such, that the attracting intervals of the extreme particles, as well as the repelling intervals, coincide with one another, i.e. attracting with attracting, and repelling with repelling, in regard to any one kind of rays, e.g. the red; by the united force of their extremes, (all the intermediate particles of the medium mutually destroying each other's effects,) these rays will be reflected. But where the plate is of an intermediate thickness between this and the next thickness, where the attracting intervals coincide, attracting with attracting, and repelling with repelling, the attracting intervals will coincide with the repelling ones, and the repelling ones with the attracting ones, and these mutually destroying one another's effects, these rays will pass on freely, and be transmitted. But as the intervals of attraction and repulsion are different for differently coloured rays, the thicknesses of the plates at which these coincidences will or will not happen, in the differently coloured rays, will be different. So that it appears probable, says Dr. Priestley, in conformity to a doctrine first suggested to him by Mr. Michell, that the whole mystery of coloured plates depends upon the attractions and repulsions of the particles of the bodies that compose them, affecting different rays in a different manner, according to their thicknesses. See Colours, &c. of Light and Colours, p. 309, &c. See Colours of thin Lamins, &c. and RINGS OF Colours.

Sir Isaac Newton concludes his account of the reflection of light with observing, that if light be reflected not by impinging on the solid parts of bodies, but by some other principle, it is probable that as many of its rays as impinge on the solid parts of bodies are not reflected, but filleted and lost in the bodies. Otherwise, he says, we must suppose two kinds of reflection; for should all the rays be reflected which impinge on the internal parts of clear water or crystal, thole substances would rather have a cloudy colour than a clear transparence. To make bodies look black, it is necessary that many rays be stopped, retained, and lost in them; and it does not seem probable, that any rays can be stopped and filleted in them, which do not impinge on their parts: and hence, he says, we may understand, that bodies are much more rare and porous than is commonly believed. However, M. Bouguer disputes the fact of light being filleted or lost by impinging on the solid parts of bodies. See Absorbing.

For other facts and observations relating to the subject of this article, see Light. See also RAYS OF LIGHT, and RAYS OF HEAT.

Reflection, in Catoptrics, is the return of a ray of light from the polished surface of a speculum or mirror, as driven thence by some power refiding in it.

The ray, thus returned, is called a reflex, or reflected ray, or a ray of reflection; and the point of the speculum, whence the return commences, is called the point of reflection.

Thus the ray A B (Plate I. Optics, fig. 3.), proceeding from the radiant A, and striking on the point of the speculum B, being returned thence to C, B C represents the reflected ray, and B the point of reflection; in respect of which A B represents the incident ray, or ray of incidence, and B the point of incidence.

Again, a line CG drawn from any point, as C, of the reflected
Reflection.

Reflected ray \( BC \), perpendicular to the speculum, is called the cathetus of reflection, or cathetus of the eye: as a line \( \text{AF} \), drawn from the radiant perpendicular to the speculum, is called the incidence.

Of the two angles which the reflected ray \( BC \) makes with the mirror, the smalleft, \( CBE \), is called the angle of \text{reflection} as of the two angles the incident ray makes with the speculum, the smalleft, \( ABD \), is called the angle of \text{incidence}.

If the mirror be either concave or convex, the smalleft angles the ray makes with the tangent to the point of reflection and incidence, are the angles of reflection and incidence.

The angle \( CBH \), which the reflected ray makes with a perpendicular to the point of reflection, is called the inclination of the reflected ray: as the angle \( A BH \) is called the inclination of the incident ray.

Reflection, general laws of.—I. If a ray of light be reflected from a speculum of any form, the angle of incidence is ever equal to the angle of reflection. This law obtains in per- cussions of all kinds of bodies; and consequently must do so in those of light. See \text{Laws of Percussion}; see also Angle.

It might therefore be here assumed as an axiom: but it is of that importance, and its demonstration is beautiful, that we cannot omit it. Suppose, then, \( \text{DC} \) (Plate XVII. \text{Optics}, \text{fig.} 14.) an incident ray, propagated from the radiant \( D \): here, though the motion of the ray be simple, yet its determination in the line \( \text{DC} \), being oblique with respect to the oblique, is really compounded of two determinations; one along \( DE \), the other along \( D G \).

The force along \( \text{DC} \), therefore, is equal to the two forces along \( DG \) and \( DH \). But the oblique \( GF \) only opposes one of the determinations; viz. that along \( DG \) (for it cannot oppose a determination parallel to itself, as \( DE \)): therefore, only the force along \( DG \) will be lost by the stroke, that along \( DH \) or \( GC \) remaining entire. But a body perfectly elastic (such as we suppose the ray of light) will recover by its elasticity the force it lost by the shock.

The ray, therefore, will recover the force \( DG \) or \( CH \); thus, retaining both its forces, and both its former determinations \( HC \) and \( CF \), after percussion, it will be impelled along \( CF \) and \( CH \) by the fame forces as before along \( DH \) and \( DG \). By its compound motion, therefore, it will describe the right line \( CE \), and that in the same time as \( DC \); and \( HE \) and \( DH \) will be equal, as being described by the same force. Now, the two triangles \( DCH \) and \( CHE \) are equal, and consequently their similar angles are equal. Since then \( HCA = HCF \); \( DCA \), the angle of incidence, is equal to \( ECF \), the angle of reflection. Q. E. D.

This law is confirmed in light by an easy experiment. For a ray of the sun falling on a mirror, in a dark room, through a little hole, you will have the pleasure to see it rebound, so as to make the angle of reflection equal to that of incidence. See \text{Camera Obscura}.

The fame may be shewn various other ways: thus, e.g. placing a femeircle \( FG \), (Plate I. \text{Optics}, \text{fig.} 3.) on a mirror \( DE \), its centre on \( B \), and its limb perpendicular to the speculum; and assuming equal arcs, \( FA \) and \( GC \), place an object in \( A \), and the eye in \( C \); then will the object be seen by a ray reflected from the point \( B \). And if \( B \) be covered, the object will cease to be seen.

For the conclusions drawn from this general doctrine of reflection, see the \text{doctrine of Mirrors}, &c.

II. Each point of a speculum reflects rays falling on it, from each part of an object. See the \text{doctrine of Mirrors}, &c.

III. If the eye \( C \), and the radiant point \( A \), change places, the point will continue to radiate upon the eye, in the same course or path as before.

For if the object be removed from \( A \) to \( C \), it will still radiate on its former point of reflection, \( B \); but there can be but one right line drawn between the two points \( G \) and \( D \); and the rays are right lines. Therefore, that which was before the ray of reflection, will now be the ray of incidence; and since it will be reflected under the same angle as that under which it fell, that which was before the ray of incidence, will now be the ray of reflection. So that the object removed to \( C \), will radiate on the eye placed in \( A \), by the right lines \( CB \) and \( BA \). Q. E. D.

Hence, an object is seen by the reflected ray \( AB \), with the eye placed in \( A \), the same as if the eye were in \( C \), and the object in \( A \).

The truth of this theorem is so easily confirmed by experiment, that some, with Euclid, assume it as a principle, and demonstrate the great law of reflection from it. Thus: suppose the angle of incidence a little greater than the angle of reflection, then will the angle \( AFB \) be greater than \( CBE \). Wherefore, changing the places of the eye and the object, the angle \( CBE \) will become the angle of incidence; and therefore \( CBE \) greater than \( AFB \), by the supposition. So that the same angle \( AFB \) will be both greater and smaller than the other, \( CBE \); which being absurd, \( AFB \) cannot be greater than \( CBE \). The same absurdity will follow, if you suppose the angle of incidence less than the angle of reflection. Since then the angle of incidence can neither be greater nor less than that of reflection, it must be equal to it.

IV. The plane of reflection, that is, the plane in which the incident and reflected rays, and also the angles of incidence and of reflection, are found, is perpendicular to the surface of the speculum; and in spherical specula, it passes through the centre.

Hence the cathetus, both of incidence and reflection, is in the plane of reflection.

That the plane of reflection is perpendicular to the speculum, is affirmed by Euclid, Alhazen, and others, as a principle, without any demonstration; as being evident from all observation and experiment.

V. The image of an object seen in a mirror is in the cathetus of incidence. This the ancients affirmed as a principle; and hence, since the image is certainly in the reflected ray, they inferred, it must appear in the point of concourse of the reflected ray, with the cathetus of incidence; which indeed holds universally in plane and spherical mirrors, and usually also in concave ones, a few cafes only excepted, as is shewn by Kepler.

For the particular laws of reflection, arising from the circumstances of the several kinds of specula, or mirrors, plane, concave, convex, &c. see them laid down under the article \text{Mirror}.

Reflection, Caustic by. See \text{Caustic Curve}.

Reflection of Heat. See \text{Heat}, and \text{Rays of Heat}.

Reflection of Cold. See \text{Cold}.

Reflection of Sound. See \text{Sound}.

Reflection of the Moon, is a term used by some authors for what we otherwise call \text{her variation}, being the third inequality in her motion, by which her true place out of the quadratures differs from her place twice equated. See \text{Moon and Variation}.

Reflection is also used, in the Copernican system, for the distance of the pole from the horizon of the disc; which
Reflection is also used figuratively for an operation of the mind, by which, turning as it were upon itself, it makes itself, and its own operation, its object; and considers or contemplates the manner, order, and laws, which it observes in perceiving, reasoning, willing, judging, doubting, believing, &c. and frames itself new ideas of the relations discovered in them.

Reflectoire Curve. See Curve Reflectoire.

REFLECTOR for Light-houses, a combination of a number of square plane glass mirrors, resembling those with which Archimedes is said to have burnt the Roman fleet at the siege of Syracuse. (See Burning-Glafs.) Each of these mirrors is about an inch square; and they are all arranged close to each other in the concave of a parabolic segment formed of stucco, which has been found to answer the purpose best. The idea of thus illuminating light-houses, instead of using coal-fires, in this country, without any previous knowledge of a similar method practiced in France, was first suggested by Mr. Ezekiel Walker, of Lynn Regis, who made, and fixed up reflectors under his direction, in a light-house on the coast of Norfolk, in the year 1779. Accordingly, in the year 1787, at the request of the trusts appointed by act of parliament for erecting four light-houses in the northern parts of Great Britain, he instructed Mr. Thomas Smith, tin-plate worker, of Edinburgh, to whom the original invention was erroneously ascribed in the supplement to Encyclopædia Britannica, in this mode of constructing light-houses. His parabolic moulds are from three to five or six feet in diameter; and in the centre or apex of each is placed a long hollow lamp of tin-plate, filled with whale-oil. In each lamp are fix cotton-wicks, almost contiguous to one another, disposed as to burn without trimming for six hours. The light of these is reflected from each mirror spread over the concave surface, and is thus multiplied, as it were, by the number of mirrors. The stucco moulding is covered on the back with tin-plate, from which a tube, immediately over the lamp, proceeds to the roof of the light-room, and serves as a funnel, through which the smoke escapes without fullying the faces of the mirrors. The light room is a cupola or lantern of from eight to twelve sides, composed entirely of glass, fixed in cast iron frames or sashas, and roofed with copper. On circular branches passing round the inside of this lantern, at about 18 inches from the glass frames, are placed the reflectors with their lamps, so as that the concave surfaces of two or three of the reflectors from every point of the compass, throw a blaze of light in all directions. In the roof, immediately over the centre of the room, is a hole, through which pass all the funnels already mentioned, and which serves likewise to admit fresh air to the lamps. This light-room is firmly fixed on the top of a round tower, so as to be immovable by the weather; and the number of the reflectors, and the height of the tower, arc less or greater according as it is intended that the light should be seen at a less or a greater distance. Experience, it is said, has obviated several objections to which light-houses of this kind were thought to be liable; and it has been found that light-houses, with lamps and reflectors, are, in every point of view, preferable to those with fires burning in the air. They are supported at a much less expense; their light is more brilliant, and seen at a greater distance, whilst it can never be obscured by smoke, or beaten down, on the ice, by a violent gulf of wind; and they may be so variously placed, that one light-house cannot be mistaken for another. Besides, the lamps do not need trimming so often as open fires require fuel, and the man who attends them is never exposed either to cold or wet in the performance of his duty, so that they are less likely to be neglected in stormy weather than those with open fires.

It has been proposed to make the concave surface of the parabolic one speculum of metal, instead of covering it over with a number of plain glass mirrors; or to diminish the size of each mirror, if it be thought best to retain them instead of introducing the speculum. To this proposed alteration it has been objected, that the brightest metal does not reflect such a quantity of light as well foliated clear glass; and by diminishing the size of the mirrors, the number of joinings would be increased, in each of which some light is lost, not merely in the beam, but from its being almost impossible to foliate glass perfectly at its edge.

REFLEX, REFLECT, in Painting, is understood of those places in a picture which are supposed to be illuminated by a light reflected from some other body represented in the same piece.

Or, reflexes may be defined those places which, beside the general light that illumines the whole piece, receive some particular light from their situation with respect to some more illuminated polished body, that reflects part of the rays it receives upon them.

Reflexes are scarcely sensible, except in the shadowed parts. The management of the reflexes requires great accuracy and skill. All reflected light is supposed to carry with it part of the colour of the body which reflects it; so that those places which receive this light, must have their colour mixed or tinged with that colour. But the same place may receive reflexes from different objects, differently coloured, and those again receive reflexes from others. The painter, therefore, must have a view to every circumstance of the colour, light, and position of each figure; he must consider what effect each has on others, and pursue nature through all the variety of mixtures. See CLAIR-OBSCURE, and LIGHT.

REFLEX VISION, or REFLECTED VISION, is that performed by means of rays reflected from the polished surfaces of objects to the eye.

Reflex vision is the subject of catoptrics. Under reflex vision come all the phenomena of specula or mirrors of all kinds.

REFLEXIBILITY of the Rays of Light, is that property by which they are disposed to be reflected. See Reflection.

Or, it is their disposition to be turned back into the same medium, from any other medium on whole surface they fall; hence those rays are said to be more or less reflexible, which are returned back more or less easily under the same incidence.

Thus, if light passes out of glass into air, and by being inclined more and more to the common surface of the glass and air, begins at length to be totally reflected by that surface, those sorts of rays which at like incidences are reflected most copiously, or the rays which, by being inclined, begin soonest to be totally reflected, are the most reflexible rays.

That rays of light are of different colours, and endowed with different degrees of reflectibility, was first discovered by sir Isaac Newton; and is shewn by the following experiment.

Applying a prism D F E (Plate XVII. Optics, fig. 15), whose angles are each 45°, to the aperture C of a darkened room, in such manner that the light is reflected from the base in G; the violet rays are seen first reflected into H G; the other rays continuing still refracted in I K. After the violet the blue are all refracted, the green, &c. (See
REFRANGIBILITY. See Reflection.

REFLEXION. See Reflection.

REFLEXITY, a term employed by Mr. Brougham to denote a property of light, which causes the different rays to be acted upon by bodies, and to begin to be refracted, reflected, refracted, and deflected, at different distances. This property observes the same law with the other optical properties of light; the red ray having most reflectivity, and the violet the least. (See Phil. Trans. for 1797, p. 360.) Mr. Brougham has expressed this property by the three words, "refraction," "reflexity," and "flexity," but the power being the same, if such a property exist, different names seem to be unnecessary.

REFLUX of the Sea, the ebbing of the water; or its return from the shore. It is thus called, as being the opposite motion to the flood, or flux. See Tide.

REFORM, a re-establishment, or revival of former neglected discipline; or a correction of some reigning abuses in it.

The term is much used in a monastic sense, for the reducing or reformation of religious to the ancient severity of the rule from which it had gradually swerved; or even for the improving on the ancient rule and institution itself, and voluntarily making it more severe.

In this sense the order of St. Bernard is said to be only a reform of that of St. Benedict.

To Reform, in a Military Sense, is, after some evolution or manoeuvre, to bring a line to its natural order, by aligning it on some given point. See Battalion.

To Reform, is also to reduce a company, regiment, or other body of men, either by disbanded the whole, or only breaking a part, and retaining the rest; or sometimes by incorporating them with other regiments. Hence, REFORMADO, or Reformed officer, one whole troop or company is suppressed in a reform, whilst he is continued either in whole or half-pay, doing duty in the regiment. A reformed captain of foot follows the company, and affixes the standing officer as a second; but he still maintains his degree and precedence.

REFORMATION, Reformatio, the act of reforming, or correcting an error, or abuse, in religion, discipline, or the like.

The reformation of religion, called, by way of eminence, the Reformation, was begun by the elector of Saxony, at the solicitation of Luther, about the beginning of the sixteenth century. See Luther and Lutheranism.

There were many circumstances which concurred at this time to bring about that happy reformation in religion, which rescued one part of Europe from the papal yoke, mitigated its rigour in the other, and produced a revolution in the sentiments of mankind, the greatest as well as the most beneficial that has happened since the publication of Christianity. How far the sale of indulgences, published by Leo X., contributed to this event, we have already seen under the article Luther. We shall here observe, that the fame corruptions in the church of Rome which Luther condemned, had been attacked long before his appearance, and the same opinions which he propagated had been published in different places, and supported by the fame arguments. Waldus in the 12th century, Wickliffe in the 14th, and Hufa in the 15th, had inveighed against the errors of Popery with great boldness, and confuted them with more ingenuity and learning than could have been expected in those illiterate ages in which they flourished. But all these premature attempts towards a reformation proved abortive. Many powerful causes contributed to facilitate Luther's progress, which either did not exist, or did not operate with full force in their days: the principal of these we shall here enumerate. The long and scandalous schism which divided the church, during the latter part of the 14th, and the beginning of the 15th centuries, had a great effect in diminishing the veneration with which the world had been accustomed to view the papal dignity. The proceedings of the councils of Constance and Basil spread this disrespect for the Romish see still wider, and by their bold exertion of authority in depoping and electing popes, taught the world that there was in the church a jurisdiction superior even to the papal power, which they had long beloved to be supreme. The wound given on that occasion to the papal authority was fearcely healed, when the pontificates of Alexander VI. and Julius II. both able princes, but detestable ecclesiastics, raised new scandal in Christendom. Besides, many of the dignified clergy, secular as well as regular, neglected the duties of their office, and indulged themselves, without reserve, in all the vices to which great wealth and idleness naturally give birth; and gross ignorance and loud debauchery rendered the inferior clergy as contemptible as the others were odious. So that we find, long before the 16th century, that many authors of reputation give such description of the dilolute morals of the clergy, as seems almost incredible in the present age. The scandal of those crimes, which very generally prevailed, was greatly increased by the facility with which such as committed them obtained pardon. The exorbitant wealth of the church, the vast personal immunities of ecclesiastics, and their encroachments on the jurisdiction of the lay, and their various devices to secure their usurpations, created much dissatisfaction among the people, and disposed them to pay particular attention to the invectives of Luther. Besides these causes of his rapid progress, we may also reckon the invention of the art of printing, about half a century before his time, the revival of learning at the same period, and the bold spirit of inquiry which it excited in Europe; so that many were prepared to embrace his doctrines, who did not really with success to his undertaking. In the writings of Reuchlin, Hutten, and the other revivers of learning in Germany, the corruptions of the church of Rome are censured with an acrimony of style little inferior to that of Luther himself. The railery and oblique cen
tures of Erasmus in particular, upon the errors of the church, as well as upon the ignorance and vice of the clergy, prepared the way for Luther's invectives and more direct attacks. To all which we may add, that the theological doctrines of Popery were so repugnant to the spirit of Christianiety, and so detestable; any foundation in reason, in the word of God, or in the practice of the church, that this circumstance combined in favouring the progress of Luther's opinions, and in weakening the resistance of his adversaries. The rise of the reformation in Switzerland was a least as early as in Germany; for Ulric Zwingli had, in the year 1516, begun to explain the scriptures to the people, and to confute, though with great prudence and moderation, the errors of a corrupt church. He had very noble and extensive ideas of a general reformation, at the time when Luther retained almost the whole system of Popery, indulgences excepted; and he had actually called in question the authority and supremacy of the pope, before the name of Luther was known in that country. In the year 1524, Nuremberg, Franckfort, Hamburg, and several other cities in Germany, of the first rank, openly embraced the reformed religion, and by the authority of their magistrates abolished the
the masts, and the other superstitious rites of Popery. The elector of Brandenburgh, Saxony, the marquis of the landgrave of Hesse, the dukes of Brunswick and Luneburgh, and prince of Anhalt, became avowed patrons of Luther's opinions, and countenanced the preaching of them among their subjects. The reformers derived great advantage from the transactings of the diet at Nuremberg, which preferred to the pope a catalogue of a hundred grievances, which the empire imputed to the iniquitous dominion of the papal see. The progress of the reformation in Germany was likewise promoted by the proceedings of the diet held at Spire in the years 1526 and 1529. See Luther and Protestants.

During these transactings in Germany, the dawn of truth arofe upon other nations. The light of the reformation spread itself far and wide; and at length all the European states welcomed its salutary beams, and exulted in the prospect of an approaching deliverance from the yoke of superstition and spiritual despotism. Some of the most considerable provinces of Europe had already broken their chains, and openly withdrawn themselves from the discipline of Rome and the jurisdiction of its pontiff. The reformed religion was propagated in Sweden, soon after Luther's rupture with Rome, by Olaus Petri, one of his disciples, who was countenanced and encouraged by the valiant and public-spirited prince Gustavus Vasa Ericson, to whose firmness and magnanimity it was owing, that from the year 1527 the papal empire in Sweden was entirely overthrown, and Gustavus declared head of the church. The light of the reformation was also received in Denmark fo early as the year 1521, in consequence of the ardent desire discovered by Christian and Christian II., for purposes of mere ambition, of having his disciples instructed in the doctrines of Luther. His successor Frederic, duke of Holstein and Silicia, contributed greatly to the progress of the reformation, by his successful attempts in favour of religious liberty, at the assembly of estates that was held at Odensee, in the year 1527, when he procured the publication of the famous edict which declared every subject of Denmark free, either to adhere to the tenets of the church of Rome, or to embrace the doctrine of Luther; that no person should be molested on account of his religion; that a royal protection should be granted to the Lutherans; and that ecclesiastics of every order should be allowed to marry. But the honour of accomplishing this glorious work was reserved for Christian III., a prince equally distinguished by his piety and prudence. The religious doctrine, discipline, and worship of this kingdom, were settled according to a plan laid down by Bugenhagius. And the assembly of the estates at Odensee, in 1539, gave a solemn sanction to all these transactions, and thus the work of reformation was brought to perfection in Denmark.

In France, the auspicious patronage of Margaret, queen of Navarre, sister to Francis I., encouraged several pious and learned men, whose religious sentiments were the same with her own, to propagate the principles of the reformation, and even to erect several Protestant churches in that kingdom. It appears, that, so early as the year 1523, there were many, and even persons of rank, and some of the episcopal order, who had conceived the utmost aversion both against the doctrine and tyranny of Rome. But the wavering and inconsistent conduct of Francis I. rendered the situation of the Protestants in this country always precarious, often disconcerted. Upon the whole, we may observe, that, before the diet of Augsburg, the doctrine of Luther had made considerable, though perhaps a secret, progress in Spain, Hungary, Bohemia, Britain, Poland, and the Netherlands, and had, in all these countries, many friends, of whom several repaired to Wittenberg to improve their knowledge, and enlarge their views under such an eminent master. At this diet, held in 1530, the Augsburg or Augsburg Confession was presented to the emperor Charles V. and after many debates between the friends of liberty and the vassals of Rome, the latter prevailed; and the diet, in compliance with the opinion and remonstrances of Campeggio, the papal nuncio, issued a decree, condemning most of the peculiar tenets held by the Protestants; forbidding any person to protect or tolerate those who taught them; enjoining a strict observance of the established rites; and prohibiting any further innovation, under severer penalties. Those who refused to obey this decree were declared incapable of acting as judges, or of appearing as parties in the imperial chamber, the supreme court of judicature in the empire. The Protestants, alarmed at the severity of the decree, assembled at Smalcald, and concluded a league of mutual defence against all aggressors, by which they formed the Protestant states of the empire into one regular body; and they resolved to apply to the kings of England, France, and Denmark, to implore them to affift and patronize this new confederacy. After various negotiations between the emperor and the Protestant princes, terms of pacification were agreed upon at Nuremberg, and ratified solemnly in the diet of Ratibon, in the year 1532. In this treaty it was stipulated, that universal peace should be established in Germany; until the meeting of a general council, the convocation of which, within six months, the emperor threatendeavour to procure; that no person should be molested on account of religion; that a stop be put to all proceedings begun by the imperial chamber against Protestants; and the sentences already passed to their detriment be declared void. On their part, the Protestants engaged to assist the emperor with all their forces in repulsing the invasion of the Turks. Thus the Protestants, by their firmness, unanimity, and dexterity in availing themselves of the emperor's situation, obtained terms which amounted almost to a toleration of their religion.

But neither the emperor nor the pope were disposed to abide by the unbiased sense of a general council, assembled, as the Protestants wished, within the limit of the empire, but determined to decide their religious debates by the force of arms. After many evasions and delays, it was proposed, in the year 1545, to assemble a council at Trent, which was vigorously opposed by the Protestants. The emperor and the pope had mutually agreed to destroy all who should dare to oppose this council. The meeting of that assembly was to serve as a signal for their taking arms; and accordingly its deliberations were speedily begun, in the year 1546, when the Protestants perceived undoubted marks of a formidable union to overthrow and crush them by one blow. The fathers, assembled in the council of Trent, promulgated
their decrees; and the Protestant princes in the diet of Ratisbon protected against their authority; and were, in consequence of this, proscribed by the emperor, who raised an army to reduce them to obedience. Thus commenced the war of Smalcald, which was prosecuted with various successes on both sides, till, in the year 1552, Charles was surprised at Inpruck by Maurice of Saxony, and was constrained to conclude at Passau the famous treaty of pacification, (which fee,) with the Protestants, which is confined by those of Germany as the basis of their religious liberty; and to promise in six months to assume a diet, in which all the tumults and dissensions, that had been occasioned by a variety of sentiments in religious matters, should be entirely removed. This diet, though not assembled at the stipulated time, met, however, at Augsburg, in the year 1555, and terminated those deplorable scenes of bloodshed, delusion, and discord, that had so long afflicted both church and state by that religious peace, as it is commonly called, which secured to the Protestants the free exercise of their religion, and established this inestimable liberty upon the firmest foundations. For, after various debates, the following memorable acts were passed; that the Protestants who followed the confession of Augsburg, should for the future be considered as entirely exempted from the jurisdiction of the Roman pontiff, and from the authority and superintendence of the bishops; that they were left at perfect liberty to enact laws for themselves, relating to their religious sentiments, discipline, and worship; that all the inhabitants of the German empire should be allowed to judge for themselves in religious matters, and to join themselves to that church whose doctrine and worship they thought the purest and most consonant to the spirit of Christianity; and that all those, who should injure or persecute any person under religious pretences, and on account of their opinions, should be declared, and proceeded against, as public enemies of the empire, invaders of its liberty, and disturbers of its peace.

In the year 1553, Henry VIII. king of England, who, in the beginning of these troubles, had opposed the doctrine and views of Luther with the utmost vehemence, partly because he had spoken with contempt of Thomas Aquinas, the king's favourite author, having sued for a divorce from Catharine of Aragon, his brother's widow, at the court of Rome, for almost six years, during which period Clement VII. negotiated, promised, retracted, and concluded nothing, determined to apply to another tribunal for that decree which he had unsuccessfully solicited at Rome. Cramer, archbishop of Canterbury, by a sentence founded on the authority of universitieS, doctors, and rabbies, who had been consulted with respect to the point, annulled the king's marriage with Catharine; and Anne Boleyn, whose charms had captivated the king, was acknowledged as queen of England. Clement, apprehensive lest England would revolt from the holy see, determined to give Henry such satisfaction as might still retain him within the bosom of the church. But the violence of the cardinals precipitated him, in 1534, to issue a bull revoking Cramer's sentence, confirming Henry's marriage with Catharine, and declaring him excommunicated, if, within a time specified, he did not abate the wife he had taken, and return to her whom he had defected. Enraged at this unexpected decree, Henry kept no longer any measures with the court of Rome; his subjects sided his rebellion; an act of parliament was passed, abolishing the papal power and jurisdiction in England; by another the king was declared supreme head of the church, and all the authority of which the popes were deprived was vested in him; the monasteries, (which fee,) were suppressed, and their revenues applied to other purposes.

The people had been gradually prepared for this great innovation. Each succeeding feccion of parliament had made some retrenchment from the power and profits of the Roman pontiff. Care had been taken, during some years, to teach the nation that a general council was much superior to a pope. But now a bishop preached every Sunday at Paul's Cross, in order to inculcate the doctrine, that the pope was intitled to no authority at all beyond his own diocese.

The laws passed during this session (1534) sufficiently evince, that the king was determined not to surrender any part of his afoomed prerogative. All payments made to the apostolic chamber: all provisions, bulls, dispensations, were abolished: monasteries were to be subjected to the regulation and government of the king alone: the law for purifying heresies was moderated: the ordinary was prohibited from imprisoning or trying any person upon suspicion alone, without presentment by ten lawful witnesses; and it was declared that to speak against the pope's authority was no hereby: bishops were to be appointed by a couc el d'elire from the crown, or, in case of the dean and chapter's refusal, by letters patent; and no recourse was to be had to Rome for bulls, bulls, or provisions. Campeggio and Ginucci, two Italians, were deprived of the bishoprics of Salisbury and Worcester, which they had hitherto enjoyed: the law which had been formerly made against paying annats, or first fruits, but which had been left in the king's power to suspend or enforce, was finally established: and a submision which was exacted two years before from the clergy, and which had been obtained with great difficulty, received this session the sanction of parliament. In this submision, the clergy acknowledged that convocations ought to be assembled by the king's authority only: they promised to enact no new canons without his consent: and they agreed that he should appoint 32 commissioners, in order to examine the old canons, and abrogate such as should be found prejudicial to his royal prerogative. An appeal was also allowed from the bishop's court to the king in chancery. But the most important act passed this session, was that which regulated the succession to the crown: the marriage of the king with Catharine was declared unlawful, void, and of no effect: the primacy of the see annulling it was ratified; and the marriage with queen Anne was established and confirmed. The crown was appointed to descend to the issue of this marriage, and falling there, to the king's heirs for ever. An oath was likewise enjoined to be taken in favour of this order of succession, under the penalty of imprisonment during the king's pleasure, and forfeiture of goods and chattels: and all fander against the king, queen, or their issue, was subjected to the penalty of misprision of treason. These several acts, so contemptuous towards the pope, and so destructive of his authority, were passed at the very time that Clement pronounced his bolly sentence against the king. The king found his ecclesiastical subjects as compliant as the laity. The convocation ordered that the act against appeals to Rome, together with the king's appeal from the pope to a general council, should be affixed to all the doors of all the churches in the kingdom; and they voted that the bishop of Rome had, by the laws of God, no more jurisdiction in England than any other foreign bishop; and that the authority which he and his predecessors had there exercised, was only by usurpation, and by the suffrance of English princes. The bishops went so far in their complaisance, that they took out new confirmations from the crown, in which all their spiritual and episcopal authority was expressly affirmed to be derived ultimately from the civil magistrate, and to be entirely dependent on his good pleasure.
Henry, however, with the caprice peculiar to his character, continued to defend the doctrines of the Romish church as fiercely as he attacked their jurisdiction. He alternately persecuted the Protestants for rejecting the former, and the Catholics for acknowledging the latter.

Nothing more forwarded the first progress of the reformers, than the offer which they made, of submitting all religious doctrines to private judgment, and the pamphlets given every one to examine the principles formerly imposed upon them. And what can be more just and reasonable? and yet the multitude, says Mr. Hume, were totally unqualified for this undertaking, though they were highly pleased with it. They fancied that they were exercising their judgment, while they opposed to the prejudices of ancient authority more powerful prejudices of another kind. The novelty itself of the doctrines; the pleasure of an imaginary triumph in dispute; the fervent zeal of the reformed preachers; their patience, and even acacity, in suffering persecution, death, and torments; a disgust at the restraints of the old religion; an indignation against the tyranny and interested spirit of the ecclesiastics:—these motives, says the same historian, whilst, as some may imagine, he is depreciating the principles of the reformation, were prevalent with the people; and by such considerations were men so generally induced, during that age, to throw off the religion of their ancestors. In proportion, says the same author, as the practice of submitting religion to private judgment was acceptable to the people, it appeared, in some respects, dangerous to the rights of sovereigns, and seemed to destroy that implicit obedience on which the authority of the civil magistrate is chiefly founded. When some Englishmen, such were Tindal, Joyce, Conulantine, and others, retired to Antwerp, through fear of the exertion of the king's authority, they employed themselves in writing English books against the corruptions of the church of Rome; against images, relics, and pilgrims; and they excited the curiosity of men with regard to that question, which is the most important in theology, the terms of acceptance with the Supreme Being. These books, having been secretly conveyed to England, began to make converts everywhere; but it was a translation of the scriptures by Tindal that was esteemed the most dangerous to the established faith. Against Wolly, a favourite minister of Henry VIII., it was one article of impeachment, that, by his connivance, he had encouraged the growth of heresy, and that he had protected and acquitted some notorious offenders. Wolly was succeeded in the office of chancellor by Sir Thomas More, who, irritated by polemics, became so superstitiously attached to the ancient faith, that few inquisitors have been guilty of greater violence in their prosecution of heresy. Several persons were not only brought into the courts for heretical offences, such as teaching their children the Lord's prayer in English, for reading the New Testament in that language, or for speaking against pilgrimages; and others were charged with the capital offences of harbouring persecuted preachers, neglecting the faits of the church, and declaring against the vices of the clergy. Some were tried, condemned, and committed to the flames. Notwithstanding the inconstant conduct of Henry, his subjects having been encouraged, by his example, to break fome of their fetters, were so impatient to shake off all that remained, that in the following reign, under his son Edward VI., with the general applause of the nation, a total separation was made from the church of Rome in articles of doctrine, as well as in matters of discipline and jurisdiction. (See Articles.) In 1553, his death retarded the progress of the reformation; and his fifty Mary, who succeeded him, imposed a new arbitrary laws and tyrannical yoke of Rome upon the people of England. But the execution of a great number of persons, who were burnt for the Protestant faith in the five years of her persecuting and bloody reign, so alienated the people from Popery, that Queen Elizabeth, her sister, found it no hard matter to deliver her subjects from the bondage of Rome, and to establish that form of religious doctrine and ecclesiastical government, which had subsisted in England.

The seeds of the reformation were very early sown in Scotland, by several noblemen of that nation, who had retired in Germany during the religious disputes that divided the empire. The first and most eminent opposer of the Papal jurisdiction was John Knox, a disciple of Calvin, who set out from Geneva for Scotland in 1559, and in a little while prevailed with the greatest part of the Scotch nation entirely to abandon the superfluities of Rome, and to aim at nothing less than the total extirpation of Popery. In the following year, viz. 1560, the parliament ratified a confession of faith, agreeable to the new doctrines, and passing a statute against the mass, not only abolished it in all the churches, but enacted, that whoever, any where, either officiated in it, or was present at it, should be cast out, for the first offence, with confiscation of goods, and corporal punishment, at the discretion of the magistrate; for the second, with banishment; and for the third, with loss of life. A law was also voted for abolishing the Papal jurisdiction in Scotland; the Presbyterian form of discipline was settled, leaving only at first some shadow of authority to certain ecclesiastics, whom they called superintendants. From that period to the present times the form of doctrine, worship, and discipline, that had been established at Geneva by the ministry of Calvin, has been maintained in Scotland with invincible obstinacy and zeal; and every attempt to introduce, into that kingdom, the rites and government of the church of England, has proved impotent and unsuccessfull. See Presbyterians.

The cause of the reformation in Ireland underwent the same vicissitudes that had attended it in England. When Henry VIII., after the abolition of the Papal authority, was declared supreme head of the church of England, George Brown, a native of England, and a monk of the Augustinian order, whom that monarch had created, in the year 1535, archbishop of Dublin, began to act with the utmost vigour, in conformance of this change in the hierarchy. He purged the churches of his diocese from superfluity in all its forms, pulled down images, destroyed relics, abolished absurd and idolatrous rites, and, by the influence as well as authority he had in Ireland, caused the king's supremacy to be acknowledged in that nation. Henry heard soon after, that this supremacy was not a vain title; for he banished the monks out of that kingdom, confiscated their revenues, and destroyed their convents. In the reign of Edward VI., farther progress was made in the reformation, but the accession of Mary retarded it, in conformance of which Brown and other Protestant bishops were deprived of their dignities in the church. When Elizabeth ascended the throne, the Irish were again obliged to submit to the form of worship and discipline established in England.

The reformation had not been long established in Britain, when the Belgic provinces, united by a respectable confederacy which still subsisted, withdrew from their spiritual allegiance to the Roman pontiff. The means which Philip II., king of Spain used to obstruct the reformation, promoted it: the nobility formed themselves into an association, in the year 1566, and roused the people; who, under the heroic conduct of William of Nassau, prince of Orange, seconded by the succours of England and France, delivered this state from
from the Spanish yoke; and consequence of which the reformed religion, as it was professed in Switzerland, was established in the United Provinces; and, at the same time, an universal toleration granted to all those religious ten- 

tments were of a different nature, whether they retained the 
faction of Rome, or embraced the reformation in another form, 

in, provided that they made no attempts against the authority 
of the government, or the tranquillity of the public.

Whilst Mr. Hume attributes the quick and surprising 

growth of the reformation in part to the late invention of 

printing, and revival of learning, he denies that reason had 

any considerable share in opening men's eyes with regard to 

the impurities of the Roman church; alleging that philo- 

sophy had made little progress, at least not this long after 

the period of the reformation, and that no instance occurs in 

which argument has ever been able to free the people from 

such enormous bias of prejudice with which superstition has 

every where overwhelmed them: to which he adds, that the 

rapid advance of the Lutheran doctrine, and the violence 

with which it was embraced, prove sufficiently that it owed 

not its force to reason and reflection. The art of printing, 

and the revival of learning, it continued its progress in 

another manner. Examples of tis art, the books of Luther 

and his followers, full of vehement declaration, and a rude 

disquisition, were propagated more quickly, and in great 

numbers. The minds of men, somewhat awakened from the profound slum of so many centuries, were prepared 

for every novelty, and furnished hands to carry in any manifold 

path which was opened to them. And as copies of the 

hieroglyphics, and other ancient monuments of the Christian 

ranks, became more common, men perceived the innovations 

which were introduced after the first century; and though 

argument and reasoning could not give conviction, an histori- 

cal fact, well supported, was able to make impression on 

their minds. In the reformation, the pope, the councils, 

which would not agree to punish their privileges, though ancient; and to almost every political establishment in Europe, that matters 

of civil right, which must might render valid, but appeared 

in a divine right, they thus tempted men to look to their 

principal charter, which, with little difficulty, they could 

perceive to be in truth and authenticity. Besides, 

Luther and his followers, not satisfied with opposing the 

prerogative of the Roman church, and defending the 

temporal inconveniences of that establishment, proceeded to 

trick the religion of their ancestors, the duodecems, 

and damnum; forebode by fear, wept itself, as the source 

of all wickedness and pollution. They demonstrated the 

pope antichrist, called his consecration the scarlet whore, 

and gave to Rome the appellation of Babylon; expulsions 

which, however applied, were to be found in Scripture, 

and which were better calculated to operate on the multitude 

than the most世俗 arguments. Exalted by contest and 

permanence on the one hand, by success and applause on the 

other, many of the reformers carried to the greatest 

extremities their opposition to the church of Rome; and in 

contradiction to the multiplied superstitions with which 

that communion was loaded, they adopted an enthusiastic form of 

dissent, which admitted of no obtrusions, rites, or 

ceremonies, but placed all merit in a sylph-like species of 

faith, in inward vision, rapture, and ecstasy. The new 

tenets, joined with this spirit, were intolerable in the 

propagation of their doctrine, and set at defiance all the 

anathemas and punishments with which the Roman pontiff 

endeavored to overawe them.

Thus, in terms which appear to us too disparaging, does 

our historian describe the origin and progress of the reformation; but does he pay due respect to the principles on which
with such vehemence, that the most vigilant attention of the civil magistrate, the highest claims of pontifical authority, and all the rigour of the inquisitorial jurisdiction, were requisite to check or extinguish it. The defection of so many opulent and powerful kingdoms from the papal see was a fatal blow to its grandeur and power, and produced a very considerable diminution of its revenues. It likewise obliged the Roman pontiffs to adopt a different system of conduct towards the nations which continued to recognize their jurisdiction, and to govern them by new maxims, and with a milder spirit. They became afraid of venturing upon any such exertion of their authority as might alarm or exasperate their subjects, and excite them to a new revolt. Hence it happens, that the popes, from the era of the reformation, have ruled rather by address and management than by authority. They have been obliged not only to accommodate themselves to the notions of their adherents, but to pay some regard to the prejudices of their enemies. In process of time, and before the convulsions which have lately agitated Europe, they sunk almost to a level with the other prince of Italy; and they hardly retain any shadow of the temporal power which they anciently possessed. Nevertheless, whilst the reformation has been fatal to the power of the popes, it has contributed to improve the church of Rome both in science and in morals. Many motives have arisen out of the reformation, and the existence of two rival churches, which have served to engage the Catholic clergy to apply themselves to the study of useful science, and to pay a diligent attention to the manners of their clergy. In those countries where the members of the two churches have mingled freely with each other, or have carried on any considerable intercourse, either commercial or literary, an extraordinary alteration in the ideas, as well as in the morals, of the Popish ecclesiastics is manifest. The beneficial influence of the reformation has not only been felt by the clergy, and the inferior members of the Roman Catholic church; but it has extended to the see of Rome, and to the sovereign pontiffs themselves, whose character, at a later period, has been very different from that of several of their predecessors. Many of them have been conspicuous for the virtues becoming their high station; and by their humanity, their love of literature, and their moderation, have made some atonement to mankind for the crimes of those who in former times occupied their places. Thus the reformation has eminently contributed to increase purity of manners, to diffuse science, and to inspire humanity. With the progress of the reformation we may also connect a variety of other important benefits, both to individuals and to society; and as they pertain to the improvement of science, to the promotion of liberty both civil and religious, to the diffusion of knowledge and virtue, and to the advancement of the best interests of mankind. But the details of the advantages resulting from the reformation to nations and private persons, to religion in general, and genuine Christianity in particular, would far exceed the limits to which we are confined.

See, on the subject of this article, Robertson's Hist. of Charles V. vol. ii. p. 113, &c. vol. iii. p. 44, &c. Moheim's Eccl. Hist. Eng. ed. 8vo. vol. iii. Burnet's Hist. of the Reformation, passim. For a comprehensive, and, upon the whole, a just sketch of the predisposing causes, and beneficial consequences of the reformation, we refer the reader to a work which obtained the prize proposed by the National Institute of France, 15th of Germinal, in the year X. viz. "What has been the influence of the reformation by Luther on the political situation of the different states of Europe, and on the progress of knowledge?"

The work is entitled "An Essay on the Spirit and Influence of the Reformation by Luther," by C. Villars. We have two English translations, one by B. Lambert, and the other by James Mill, 8vo. 1825.

Reformation, Right of. See Reformatio.

Refracted Angle, in Optics, the angle contained between the refracted ray and the perpendicular.

Refracted Diaf, are such as shew the hour by means of some refracting transparent fluid. See Di&;s, Refracted Ray, or ray of refraction. See Ray and Refraction.

Refracted Vision. See Vision.

Refracting Telescope. See Telescope.

Refraction, Refraction, in Mechanics, the deviation of a moving body from its direct course, by reason of the different density of the medium it moves in; or a species of change and determination, occasioned by a body's falling obliquely out of one medium into another of a different density.

Thus a ball A (Plate XXXVI. Mechanics, fig. 14.) moving in the air in the line AB, and falling obliquely on the surface of the water CD, does not proceed straight to E, but deviates, or is refracted, to F. Again, if the ball, moving in water in the same line AB, should fall obliquely on a surface of air CD, it will not proceed straight to E, nor yet deflect to F, but to G. Now the deviation in each case is called the refraction: and the two cases are distinguished by means of the perpendicular M I; that is being called refraction towards the perpendicular, or to the axis of refraction; and the other BE, refraction from the perpendicular, or from the axis of refraction.

These refractions are supposed to arise hence, that the ball arriving at B, in the first case, finds no refraction or opposition on the one side O, i.e. from the side of the water, than it did from the side P, or that of the air; and in the latter more resistance from the side P, which is now the side of the water, than the side O, which is that of the air.

The great law of refraction, then, which holds in all bodies, and all mediums, is that a body, falling obliquely out of a medium which resists it more, is refracted towards the perpendicular; and in passing out of a medium which opposes it less into another which opposes it more, it is refracted from the perpendicular.

Hence the rays of light falling obliquely, or from water into air, are refracted towards the perpendicular; whereas a ball thrown into water is refracted from it, because water, which resists the motion of light less than air, resists that of the ball more; or, to speak more truly, because water, by its greater attraction, accelerates the motion of the rays of light more than air does; for that this is the true cause of refraction, at least in light, shall be shewn under Refraction of light.

To have a body refracted, it is necessary that it should fall obliquely on the second medium. In perpendicular incidence there is no refraction.
Vossius indeed, and Snellius, imagined they had observed a perpendicular ray of light undergo a refraction; a perpendicular object appearing in the water nearer than in reality it was; but this was to attribute that to a refraction of the perpendicular rays, which was owing to the divergence of the oblique rays after refraction, from a nearer point.

Yet there is a manifest refraction even of perpendicular rays found in \textit{Iceland Crystal}, which fees.

Rohault adds, that though an oblique incidence be necessary in all other mediums we know of, yet the oblique must not exceed a certain degree; if it do, the body will not penetrate the medium, but will be reflected instead of being refracted.

Thus cannon-balls, in sea-engagements, falling very obliquely on the surface of the water, are observed to mount aloft again, and frequently to sweep the men off from the opposite decks; and the like happens to the little stones with which children make their ducks and drakes.

The ancients confounded refraction with reflection, and it was for Isaac Newton who first taught us the just difference between them. He shews likewise, that there is a good deal of analogy between them, and particularly in the case of light.

The laws of refraction of the rays of light in mediums differently terminated, \textit{i.e.} whose surfaces are plain, concave, convex, &c. make the subject of \textit{dioptrics} which fees.

By refraction it is, that convex glasses, or lenses, collect the rays, magnify objects, burn, &c. and hence the foundation of microscopes, telescopes, &c.

By refraction it is, that all remote objects are seen out of their real places; particularly, that the heavenly bodies are apparently higher than they are in reality, &c.

The refraction of the air has many times so uncertain an influence on the places of celestial objects, very remote from the zenith, that wherever refraction is concerned, the conclusions deduced from observations that are much affected by it, will always remain doubtful, and too precarious in many cases to be relied upon. See Dr. Bradley, in Phil. Trans. No. 485.

See \textit{Atmospherical Refraction}.

\textbf{Refraction of Light, in Optics,} is an inflection or deviation of the rays from their rectilinear course upon falling obliquely out of one medium into another, of a different density.

The term refraction is derived from the distorsion which it occasion in the appearance of an object viewed in part only by refracted light; thus, an oak, partially immersed in water, appears to be bent, on account of the refraction of the light, by which its lower part is seen, in its passage out of the water into the air.

Although no sensible light can penetrate more than 700 feet deep into the sea, and a length of leven feet of water has been found to intercept one-half of the light which enters into it; yet in transparent substances (no medium being, strictly speaking, absolutely transparent,) the greater part of the light penetrates to all depths with little interruption, and all rays of the same kind, thus transmitted by the same surface, form with the perpendicular an angle of refraction, which is ultimately in a certain constant proportion to the angle of incidence; that is, for instance, one-half, three-fourths, or two-thirds, according to the nature of the surface.

Thus, if the refractive properties of the substance were such, that an incident ray, making an angle of one degree with the perpendicular, would be so refracted as to make an angle of only half a degree with the same line, another ray, incident at an angle of two degrees, would be refracted, without sensible error, into an angle of one degree. But when the angles are larger, they vary from this ratio, their lines only preferring the proportion with accuracy; for example, if the angle of incidence at the supposed surface were increased to 90°, the angle of refraction would be 35° only, instead of 45°.

It does not appear that, before Descartes, any person attempted to explain the physical cause of the refraction, and also the refraction of light, which he undertook to do by the revolution of forces, on the principles of mechanics: in consequence of which he was led to suppose that light passes with more ease through a dense medium than a rare one; thus the ray \textit{A B} (Plate XVIII. Optics, \textit{fig.} 10.) falling obliquely on another medium at \textit{B}, is supposed to be acted on by two forces, one of them compelling it in the direction \textit{A C}, and the other in \textit{A D}, which alone can be affected by the change of medium; and since, after the ray has entered the denser medium, it approaches the perpendicular \textit{B H}, it is plain that this force must have received an increase, whilst the other continued the same; for if \textit{B E} be taken equal to \textit{B D}, or \textit{C A}, the consequence of the angle \textit{E B H} being less than \textit{A B C} will be, that \textit{B H} must be longer than \textit{B C} or \textit{A D}.

The first person who questioned the truth of this explanation of the cause of refraction was M. Fermat, who asserted, contrary to Descartes, that light suffers greater resistance in water than in air, and greater in glass than in water; and he maintained that the resistance of different mediums, with respect to light, is in proportion to their densities. M. Leibnitz adopted the same general idea; and they reasoned upon the subject in the following manner. Nature, they say, accomplishes her ends by the shortet methods; light, therefore, ought to pass from one point to another, by either the shortet road, or that in which the least time is required. But it is plain that the line in which light passes, when it falls obliquely upon a denser medium, is not the most direct or the shortest; so that it must be that in which the least time is spent. And, whereas it is demonstrable, that light falling obliquely upon a denser medium (in order to take up the least time possible, in passing from a point in one medium to a point in the other) must be refracted in such a manner, that the lines of the angles of incidence and refraction must be to one another, as the different facilities with which light is transmitted in those mediums; it follows that, since light approaches the perpendicular when it passes obliquely from air into water (so that the line of the angle of refraction is less than that of the angle of incidence), the facility with which water suffers light to pass through it is less than that of the air; so that the light meets with greater resistance in water than in air. This method of arguing from final causes could not satisfy philosophers. Dr. Smith observes that it agrees only to the case of refraction at a plain surface; and that the hypothesis is altogether arbitrary. If he had endeavoured to accommodate his principle to concave and convex surfaces, as he had once propo'd, he would soon have perceived its insufficiency. The easiest way for a ray to pass from a given point in any refiting medium into a vacuum, is in a perpendicular to the refracting surface, this being the shortest way, through any difficulty or resistance whatever; but this being reduced to nothing at the refracting surface, it may then take any other course in vacuo, without any further difficulty; and, on the contrary, in returning back from the vacuum into the dense medium, it must take the shortest course through the same perpendicular as before.

Thus, when the sun shines upon the atmosphere, all his rays should be refracted into lines tending to the centre of the earth, as being the shortest and caifiers way through the atmosphere, and then we should see the sun exactly over our heads, in all places and at all times. Such is the strange
consequence that follows from an hypothesis so arbitrary.

Descartes, in order to explain the law of refraction, supposes that every ray of light is composed of several smaller rays, which adhere to one another; and that they are refracted towards the perpendicular, in passing into a denser medium, because one part of the ray meets with more refilience than another part: so that the former traverses a smaller space than the latter; in consequence of which the ray must necessarily bend a little towards the perpendicular. This hypothesis was adopted by the famous Dr. Barrow, who, as some say, was the author of it. On this hypothesis, it is plain that mediums of a greater refractive power must give greater refilience to the passage of the rays of light than mediums of a less refractive power, which is contrary to fact.

The Bernouillus, both father and son, have attempted to explain the cause of refraction on mechanical principles; the former on the equilibrium of forces, and the latter on the same principles with the supposition of ethereal vortices; but neither of these hypotheses have gained much credit. M. Mairan supposes a subtle fluid, filling the pores of all bodies, and extending, like an atmosphere, to a small distance beyond their surfaces; and then he supposes that the refraction of light is nothing more than a necessary and mechanical effect of the incidence of a small body in those circumstances. There is more, he says, of the refracting fluid in water than in air, less in water than in glass, and in general less in a denser medium than in one that is rarer. M. de Maupertuis supposes that the course which every ray takes, in passing from one medium into another, is that which requires the least quantity of action, which depends upon the velocity of the body, and the space it passes over; so that it is in proportion to the sum of the spaces, multiplied by the velocity with which bodies pass over them. From this principle he deduces the necessity of the sine of the angle of incidence being in a constant proportion to that of refraction: and also all the other laws relating to the propagation and reflection of light.

Dr. Smith (in his Optics, Remarks, p. 70.) observes, that all other theories for explaining the reflection and refraction of light, except Sir Isaac Newton's, supposes that it strikes upon bodies, and is reflected by them, which has never been proved by any deduction from experience. On the contrary, it appears by various considerations, and might be shewn by Mr. Molyneux's and professor Bradley's observations on the parallax of the fixed stars, that their rays are not at all impelled by the rapid motion of the earth's atmosphere, nor by the object-glasses of the telescope through which they pass. And by Sir Isaac Newton's theory of refraction, which is grounded on experience only, it appears, that light is so far from being reflected and retarded by reflection into any denser medium, that it is twiftered there than in vacuo, in the ratio of the sine of incidence in vacuo to the sine of refraction into the denser medium. From these considerations, we are led to suppose, says Dr. Young (Left. Phil. vol. i. p. 460.) that the velocity of light must be smaller in a denser than in a rarer medium; and supposing this fact to be established, the existence of such an attractive force as for Sir Isaac Newton supposes could no longer be allowed; nor, he says, could the system of the emanation of light, in opposition to that of the undulation of an ethereal medium, be maintained by any one. Priestley's Hist. of Light, &c. p. 102, &c. p. 333, &c.

The refraction of light, Sir Isaac Newton shews, is not performed by the very rays falling on the surface of bodies; but it is done without any contact, by the action of some power belonging to bodies, and extending to a certain dis-tance without their surfaces; by which same power, acting in other circumstances, they are also emitted and reflected.

Admitting that certain powers of attraction and repulsion belong to bodies, and extend to a certain distance beyond their surfaces; and supposing also that light consists of particles emitted from luminous bodies, sir Issac Newton demonstrates, in his "Principia," that the sine of the angle of incidence must always be to the sine of the angle of refraction in some certain ratio. For, as he proves geometrically, if two similar mediums be separated from each other by a space terminated on both sides by parallel planes, and a body, in its passage through that space, be attracted or impelled perpendicularly towards either of those mediums, and not agitated or hindered by any other force; and if the attraction be every where the same, at equal distances from either plane, taken towards the same hand of the plane, the sine of incidence upon either plane will be to the sine of emergence from the other plane in a given ratio.

In a corollary to this proposition he also shews, that if, instead of one parallel space, bodies be surrounded with several, or an infinite number of them, the attractive power of each of which differs from the next, increasing or decreasing, still, the ratio respecting any two contiguous ones being given, the ratio of the extremes will be given. He also demonstrates, that, if the cause of refraction be the attraction of the refracting medium, the velocity of light before its incidence will be to its velocity afterwards, as the sine of the angle of refraction is to the sine of the angle of incidence; so that light, in pasling from a rarer medium into a denser, receives an increase of velocity. The same things being supposed, he shews, that if the velocity before incidence be greater than afterwards, so that the angle of emergence must always increase, in consequence of the repulsive power prevailing over the attractive one, the body will at length be reflected; and that, in this case, the angle of refraction must necessarily be equal to the angle of incidence.

That light does not consist of any mode of action upon a fluid medium, he concludes from having demonstrated that pressure cannot be propagated through a fluid in rectilinear directions, unless where the particles of the fluid lie in a right line, but must diverge into the unmoved spaces; and that every tremulous body, in an elastic medium, propagates the motion of the pulses on every side straight forwards. Admitting this, there is hardly any hypothesis that will agree with the phenomena of light, but that of particles emitted from the luminous body, affected by the attractions and repulsions of other bodies.

The same arguments by which we have proved, that reflection (which fee) is performed without immediate contact, will go a great way towards demonstrating the fame of refraction: to which may be added the following ones.

1. Because, if when light falls out of glass into air with the utmost obliquity it will be transmitted at, it be then made to fall a little more obliquely, it becomes wholly reflected, for the power of the glass, after it has refracted light emerging as obliquely as possible, supposing the rays to fall still more obliquely, will be too strong to let any of the rays pass; conseqentially, instead of being refracted, they will all be reflected.

2. Because in thin lamelle, or plates of glass, light is reflected and transmitted several times alternately, as the thicknes of the lamelle increases in arithmetical progression; for here it depends on the thicknes of the lamina which of the two the glass shall do, whether reflect it, or let it be transmitted.

3. Because, whereas the power of other bodies both to reflect and refract light are very nearly proportional to their densties;
Refractive forces; yet unctuous and sulphureous bodies are found to\nreflect more strongly than according to their mere densities; for as the rays act more strongly on these bodies to\nkindle them than on others, so do they again, by their mutual\nattraction, act more strongly on the rays to reflect them.

Lastly; Because not only those rays transmitted through\nglass are found to be refracted, but also those passing in the\nair, or in a vacuum near its extremities, or even near the\nextremes of many opaque bodies, e. gr. the edge of a knife,\nundergo a similar refraction, from the attraction of the body. See \nLight; and also Infection.

The manner in which refraction is performed by mere\nattraction, without contact, may be thus accounted for: sup-
pose H I (Plate XVIII. Optics, fig. 11.) the boundary of two\nmedia, N and O; the first the rarer, e. gr. air; the\nsecond the denser, e. gr. glass; the attractions of the\nmediums here will be as their densities. Suppose \nPS to be the\ndistance to which the attracting force of the denser medium\nexists itself within the rarer. Let now a ray of light A a\nfall obliquely on the surface which separates the media,\nor rather on the surface PS, where the action of the second\nand more refitting medium commences. All attraction being\nperformed in lines perpendicular to the attractive body, as\nthe ray arrives at a, it will begin to be turned out of its\nrectilinear course by a superior force, with which it is attracted\nby the medium O, more than by the medium N, i.e. by\na force with which it is driven towards it in a direction perpendicular\nto its surface: hence the ray is bent out of its\nright line in every point of its passage between PS and RT,\nwithin which distance the attraction acts. Between those\nlines, therefore, it describes a curve ABb; but beyond RT,\nbeing out of the sphere of attraction of the medium N, it\nwill proceed uniformly in a right line, according to the di-
rection of the curve in the point b.

Again, suppose N the denser and more refitting medium,\no the rarer, and HI the boundary, as before; and let \nRT be the distance to which the denser medium exerts its\nattractive force within the rarer: even when the ray has palled\nthe point B, it will be within the sphere of superior attraction\nof the denser medium; but that attraction acting in lines\nperpendicular to its surface, the ray will be continually\ndrawn from its straight course BM perpendicularly towards\nHI: thus, having two forces or directions, it will have\na compound motion, by which, instead of BM, it will de-
scribe BM, which in its line of rimness is a curve.

Lastly, after it has arrived in m, being out of the\ninfluence of the medium N, it will perfit uniformly in a right\nline, in the direction in which the extreme of the curve\nleaves it.

Thus we see how refraction is performed, both towards\nthe perpendicular, and from it.

But note, the attraction of the denser medium, e. gr. N,\nis continually diminishing, as the ray proceeds from B, to-
wards the limit of attraction RT; because fewer and fewer\nparts still come to act at HI, e. gr. all the parts between\nthat and PS attract; but at RT, none but those in the line\nHI. Note also, that the distance between PS and RT\nbeing small, when we consider refractions, no notice is taken\nof the curve part of the ray, but we consider it as consisting\nof two straight lines, CB, or AB, or m B, A B.

Sir Isaac Newton, not content with ascribing the reflec-
tion, refraction, and inflection of light to powers of attrac-
tion and repulsion, extending beyond the surfaces of bodies\nand producing effect in the manner above explained, propo-
ses a conjecture concerning the phyletic cause of this attrac-
tion and repulsion; but his hypothesis is no less liable to\ndifficulties and objections than the hypothesis of the me-
chanical production of the motion of light without attrac-
tion or repulsion. Does not the refraction of light, he says,
arise from the different density of an ethereal medium in\ndifferent places, the light always receding from the denfer\nparts of the medium? And is not the density of it greater\nin free and open spaces void of air, and other grofs bodies,\nthan within the pores of water, glass, crystal, gems, and\nother compact bodies? For when light passes through glass\nor crystal, and falling very obliquely upon the farther su-
face, is all reflected, the total refraction ought to arise rather\nfrom the density and vigour of the medium without and be-
\nground; than from the rarity and weaknesses of it.

Does not the ethereal medium, in passing out of water, glass,\ncrystal, and other compact and dense bodies, into empty\nspaces, grow denser and denser by degrees, and by that\nmeans reflect the rays of light, not in a point, but by bend-
ing them gradually in curve lines? And does not the\ngradual condensation of this medium extend to some dis-
tance from the bodies, and thereby cause the inflections of\nthe rays of light, which pass by the edges of the dense\nbodies, at some distance from the bodies?

Refration, in Dioptrics, is the inflection or bending of\nthe rays of light, in passing the surfaces of glasses, lenses,\nand other transparent bodies of different densities.

Thus a ray, as AB (Plate XVIII. Optics, fig. 11.) falling\nobliquely from the radiant A, upon a point B, in a dia-
phantous surface, HI, rarer or denser than the medium\nalong which it was propagated from the radiant; has its\ndirection there altered by the action of the new medium;\nand instead of proceeding to M, it deviates, e. gr. to C.

This deviation is called the refraction of the ray; BC the\nrefracted ray, or line of refraction; and B the point of\nrefraction.

The line A B is called the line of incidence, or ray of in-
cidence; and, in respect of it, B is also called the point of\nicidence.

The plane in which both the incident and refracted rays\nare found, is called the plane of refraction; a right line BE,\ndrawn in the refracting medium perpendicular to the refra-
flecting surface, in the point of refraction B, is called the axis of\nrefraction; and a right line DB, drawn perpendicular to the\nrefracting surface, in the point of incidence B, along the\nmedium through which the ray fell, is called the axis of\nicidence.

The angle A BI, included between the incident ray and\nthe refracting surface, is called the angle of incidence; and\nthe angle ABD, included between the incident ray and the\naxis of incidence, is called the angle of inclination. The\angle M BC, which the refracted ray makes with the inci-
dent, is called the angle of refraction; and the angle CBE,\nwhich the refracted ray makes with the axis of refraction, is\ncalled the refracted angle.

Refration, general laws of. 1. A ray of light in its\npassage out of a rarer into a denser medium, e. gr. out of air\nto glass, is refracted towards the perpendicular, i.e. towards\nthe axis of refraction.

Hence, the refracted angle is less than the angle of incl-
ination; and the angle of refraction less than that of inci-
dence; as they would be equal were the ray to proceed\nstraight from A to M. Hence, also, a ray perpendicular\nto the refracting surface, will pass through without being\nrefracted, as it cannot be refracted to the perpendicular.

The physical cause of which is, that the attraction of the\ndenser medium, which, in an incidence oblique to its sur-
face acts perpendicularly to that surface, draws the ray\nout of its course; this attraction, we say, in a perpendi-
cular incidence, acts in the direction of the ray.

2. The ratio of the sine of the angle of inclination, to the sine of the angle of refraction, is equal to the ratio of the sine of the angle of incidence, to the sine of the angle of refraction.
Refraction.

The refraction angle, being fixed, and constant; viz. if the refraction be out of air into glass, it is found greater than as 114 to 76, but less than 115 to 76; that is, nearly as 3 to 2.

This ratio, assigned by Huygens, agrees with another of Sir Isaac Newton, who makes the angle of inclination to the angle of the refracted one, as 31 to 20; which is, likewise, nearly as 3 to 2. Indeed, there is some difference in the quantity of refraction, in different kinds of glass; but in physical matters, precipitation is not necessary. In rain-water, Descartes found the ratio of the angle of inclination, to the angle of the refracted one, as 250 to 187, that is nearly as 4 to 3; which agrees with Sir Isaac Newton's observation, who makes it as 529 to 396.

In spirit of wine, the same great author makes the ratio as 100 to 73; which is not far from the sequequitarian ratio. In air, he makes it as 3201 to 3200; and as to air, he shews, that a ray of light, in traversing quite through the atmosphere, is refracted the same as it would be, were it to pass with the same obliquity out of a vacuum into air of equal density with that in the lowest part of the atmosphere.

See the following table, in which the proportion of the refractions of several bodies; the densities of the bodies, estimated by their specific gravity; and their refractive power, in respect of their densities, are set down in separate columns.

Newton's Optics, edit. 3. p. 247.

M. Euler the younger, pursuing a scheme suggested by his father for ascertaining the refractive powers of transparent liquors, made use of two Menisces glases, which they put together when they were plunged in the fluid, the refractive power of which he wanted to determine: the edges of these glases being ground flat, they immediately cohered, so that none of the fluid could escape; and then they might both together be wiped, and used as one object-
glas in a long tube, which he could lengthen or shorten at pleasure; and applying an eye-glas to it, the whole observation he had to make was to measure the exact length of his tube, when he could see through it most distinctly a turret, which was at a considerable distance from him. Or, when the focal distance was less than a foot, he only observed, at what distance from a wall the image of an oppo-
site window was the most distinct. Ac. Berlin. 1762, p. 302.

The refractive power of the fluids which he examined in this manner, he expressed in the following tables.

See Priestley's Hist. of Light, &c. p. 479. &c.

Whence the different refractive power in different fluids arises, is not determined. Sir Isaac Newton shows, that in many bodies, of glafs cristal, a felenites, pseudo-topaz, &c. the refractive power is proportionable to their denitities; only in sulphureous bodies, as camphor, linseed oil, olive, amber, spirit of turpentine &c. the power is two or three times greater than in other bodies of equal denity; yet even these have the refractive power with respect to each other nearly as their denitities.

Water has a refractive power in a middle degree between those two kinds of substantias, and is, probably, of a middle nature. Salts and vitirols have refractive powers in a middle degree between those of earthy substantias and water, and accordingly are compos'd of those two sorts of substantias. Spirit of wine has a refractive power in a middle degree between those of water and oily substantias; and accordingly seems to be compos'd of both, united by fermentation. It appears, therefore, that all bodies seem to have their refractive powers proportional to their denitities, or very nearly, excepting so far as they partake of more or less sulphureous oily particles, and thereby have their refractive powers made greater or less. Whence it seems reasonable to attribute the refractive power of all bodies...
bodies chiefly, if not wholly, to the sulphureous parts with which they abound.

From the observations of M. Euler it appears, that there is no fluid, and probably no transparent substinance of any kind, the refractive power of which is less than that of rain-water, or distilled water; and betwixt air and rain-water there is no substinance that has an intermediate refractive power.

After rain-water immediately follows well-water; but there are probably as many varieties in its refractive power as there are different wells. We may, however, conclude, that the ratio of refraction from air into well-water is contained between the limits of 1.3.16 to 1, and 1.3.37 to 1.

Spirituous liquors have a greater refractive power in proportion to their strength; but the ratio of refraction from air into any spirituous liquor is never less than 1.3.4; nor greater than 1.3.7.

There is, probably, no kind of salt, but what, being dissolved in water, increases its refractive power.

The solutions of salt of urine and of vitriol have the least refractive powers, and those of rock-salt and salt amnonic the greatest; but the ratio of refraction from air into any saline solution, preferring the proportion of one ounce of salt to twelve of water, will be contained between the limits of 1.3.4 to 1. and 1.3.5 to 1.

Distilled vinegar, and the solution of gum arabic, have nearly the same refractive power with common French wine; and the refractive power of white of egg is the same as that of rectified spirit of wine.

Mineral alkali saturated, seems to have the same refractive power with very strong brandy.

Spirit of nitre and oil of tartar per deliquium have a medium refractive power between spirituous liquors and oils.

The refractive powers of oils approach the nearest to that of glafs, especially oil of turpentine, which had the greatest refractive power of all the fluids on which he had made experiments.

Sir Isaac Newton suspected that different degrees of heat might have some effect on the refractive power of bodies, but his method of determining the general refraction was not sufficiently accurate to ascertain this circumstance; but happily this method of M. Euler's proved to be well adapted to this purpose.

From his experiments made for this purpose, he infers, that the focal distance of a single lens of glafs diminishes with the heat communicated to it; and this diminution of the focal distance is not owing to the increase of bulk in the glafs by heat; for the effect of this change is both inconsiderable, and of a contrary nature. There can be no doubt, therefore, but that this alteration in the focal distance is owing to a change in the refractive power of the glafs itself, which, as well as, probably, that of all other transparent substances, is increased by heat, and diminished by cold.

It may seem surprizing that the focal distance of a single lens should decrease with heat, and yet that of the meniscus filled with any fluid, should increase with heat; but M. Euler observes, that it by no means follows from hence, that these fluids are affected by heat in a manner different from glafs; and, after computing the effect of every circumstance of this complex experiment, of the two glasses, and the fluid combined, he concludes, that heat increases the refractive power of water, and of other fluids, as well as that of glafs.

He farther observes, that as 66 degrees of heat diminished the focal distance 1/4th part, 33 degrees ought to have diminished it 1/8th part; whereas the diminution in this case was 1/9th. From hence, says he, one may perhaps conclude, that when it is very cold, the same change in the thermometer has a greater effect on the refractive power of the glafs than when it is very hot. But he acknowledges that experiments of this kind are not capable of so much precision as one could wish, and that, perhaps in reality, the 66 degrees made a change of 1/8th, and the 33 degrees of 1/9th; but he imagined that a great number of experiments, made in different temperatures of the air, might decide this question, especially if object-glasses of a very great focal distance were made use of. Ac. Berl. 1762.

The duke de Chauntes, not satisfied with the methods used by Newton and others for determining the refractive power of glafs, proposed another mode of doing it, which is very ingenious, and, when well conducted, promising facs. He formed the glafs into plates, the surfaces of which were truly plane and parallel, and having placed small objects on each of them, he found, by means of a compound microscope, to which he applied the most exquisite micrometer, the different distances at which they were distinctly visible, and compared them with the thicknesses of the glafs. This, he says, gives the proportion of the fines of the angles of incidence and refraction in that kind of glafs directly. In this method he ascertained the mean refractive power of 15 kinds of glafs. Ac. Par. 1767. See Priestley's Hist. of Light, &c. p. 483; &c.

Dr. W. H. Wollaston has proposed a new method of examining refraction as well as dispersive powers, by prismatic refraction. This method was suggested by a consideration of Sir Isaac Newton's prismatic eye-glasses, the principle of which depends on the reflection of light at the inner surface of a dense refracting medium.

Since the range of inclination, within which total reflection takes place, depends not only on the density of the reflecting prismatic, but also on the rarity of the medium adjacent to it, the extent of that range varies with the difference of the densities of the two media. When, therefore, the refractive power of one medium is known, that of any rarer medium may be learned, by examining at what angle a ray of light will be reflected from it.

For instance, when any object is laid under a prism of Flint-glasses, with air alone interposed, the internal angle of incidence at which the visual ray begins to be totally reflected, and at which the object ceases to be seen by refraction, is about 30° 16'. But when the object has been dipped in water, and brought into contact with the glases, it continues visible, by means of the higher refractive power of the water, as far as 56° 52' of incidence. When any kind of oil, or any refrinous cement, is interposed, this angle is still greater, according to the refractive power of the medium employed; and, by cements that refract more strongly than the glases, the object may be seen through the prism, at whatever angle of incidence it is viewed.

In examining the refractive powers of fluids, or of fusable substances, the requisite contact is easily obtained; but, with solids, which in few instances be made to touch to any great extent, this cannot be effected without the interposition of some fluid, or cement, of higher refractive power than the medium under examination. Since the surfaces of a Flattum fork interposed are parallel, it will not effect the total deviation of a ray passing through it, and may therefore be employed without risk of any error in consequence.

Thus, resin, or oil of saffron, interposed between plate-glasses and any other prism, will not alter the result.

If, on the same prism, a piece of selenite and another of plate-glasses be cemented near each other, their powers may
be compared with the same accuracy as if they were both in absolute contact with it.

For such a mere comparison of any two bodies, a common triangular prism is best adapted; but, for the purpose of actual measurement of refractive powers, Dr. Wollaston has preferred the use of a square prism, because, with a very simple apparatus, it shews the fine of refractive power sought, without the need of any calculation.

Let A (Plate XVIII. Optics, fig. 12.) be a square or rectangular prism, to which any refractance is applied at $b$, and let any ray of light parallel to $cb$ be refracted through the prism, in the direction $bc$.

Then, if $ef$ and $ed$ be taken proportional to the lines that represent the refractive powers of the prism and of air, $fg$, which is intercepted between $f$ and the perpendicular $eg$, will be the corresponding line to represent the refractive power of the medium $b$. For since $edg$ (opposite to $ef$) is the angle of refraction, $efg$ (opposite to $ed$) must be equal to the angle of incidence $bdb$; and $ef:fg::bd:db$.

All, therefore, that is requisite for determining the refractive power of $b$, is to find the means of measuring the line $fg$. On this principle, the instrument in fig. 13 is constructed. On a board, $ab$, is fixed a piece of flat deal $c$, to which, by a hinge at $d$, is joined a second piece $d$, 10 inches long, carrying two plane flames at its extremities. At $e$ is a second hinge, connecting $ef$, 15.83 inches long; and a third at the other extremity of $ef$, by which $fg$ is connected with it. At $i$ alio is a hinge, uniting the radius $ig$ to the middle of $ef$; and then, since $g$ moves in a semicircle $egf$, a line joining $e$ and $g$ would be perpendicular to $fg$.

The piece $ef$ has a cavity in the middle of it, so that, when any refractance is applied to the middle of the prism $P$, it may continue to rest horizontally on its extremities. When $ed$ has been so elevated, that the yellow rays in the fringe of colours (observable where perfect reflection terminates) are seen through the flames, the point $g$, by means of a vernier which it carries, shews by inspection the length of the sign of refraction sought.

The advantages which this method possesses above the usual mode of examining refractive powers, are greater than they may at first sight appear. The usual practice has been, to form two surfaces of the refractance under examination, so inclined to each other that the deviation occasioned by them might be measured. The inclination of these surfaces to each other must also be known; and thence the refractive power might be computed. But, in the method here proposed, it is sufficient to have only one surface, and the result is obtained at once, without computation.

The facility of determining refractive powers is consequently such as to render this property of bodies a very convenient test in many philosophical inquiries.

The following table exhibits a series of refractances, arranged according to their refractive powers.

REFRACTION.

Alcohol
White of an egg
Æther
Vitreous humour of an eye
Water
Atmospheric air (Haukhee)

From the law laid down in the beginning of this article, it follows, that one angle of inclination, and its corresponding refracted angle, being found by observation, the refracted angles, corresponding to the several other angles of inclination, are easily computed. Now, Zahnius and Kircher have found, that if the angle of inclination be 70°, the refracted angle will be 38° 50'; on which principle Zahnius has constructed a table of refractions out of air into glafs, for the several degrees of the angle of inclination; a specimen of which follows:

<table>
<thead>
<tr>
<th>Angle of Inclination</th>
<th>Refracted Angle</th>
<th>Angle of Refraction</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.000032</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Hence it appears, that if the angle of inclination be less than 20°, the angle of refraction out of air into glafs is almost one-third of the angle of inclination; and, therefore, a ray is refracted to the axis of refraction, by almost a third part of the quantity of its angle of inclination. And on this principle it is that Kepler, and most other dioptrical writers, demonstrate the refractions in glafs; though in estimating the law of these refractions, he followed the example of Alhazen and VitelHio, and sought to discover it in the proportion of the angles, and not in that of the lines.

The true law of refraction was first discovered by Willebrand Snellius, professor of mathematics at Leyden; who found by experiment that the facets of the complements, or co-facets, of the angles of incidence and refraction, are always in the same ratio. It is vulgarly attributed, however, to Descartes; who having seen it in Snellius's MS., first published it in his Dioptrics, without naming Snellius; as we are informed by Huygens. The form in which Descartes gives this law is different from that of Snellius, and in general more commodious; but it might have been easily deduced from it. According to him, the sine of the angle of refraction always bears the same proportion to the sine of the angle of incidence. Indeed, as the rays of light are not all of the same degree of refrangibility, this constant ratio must be different in different kinds. The ratio, therefore, observed by authors, is to be understood of rays of the mean refrangibility, i.e. of green rays. The difference of refraction between the leaf and most refrangible rays, that is, between violet and red rays, for Isaac Newton fHews is about the 27th part of the whole refraction of the mean refrangible; which difference he owns is so small, that there seldom needs to be any regard paid to it.

3. When a ray paffes out of a denser into a rarer medium, e, gr. out of glafs into air, it is refracted from the perpendicular, or from the axis of refraction. And hence the angle of refraction is greater than the angle of inclination.

Hence, also, if the angle of inclination be less than 30°, MBC (Plate XVIII. Optics, fig. 11.) is nearly equal to one-third of MBE; therefore MBC is one-half of CBE; consequently, if the refraction be out of glafs into air, and the angle of inclination less than 30°, the ray is refracted from the axis of refraction by almost one-half part of the angle of inclination. And this is the other dioptrical principle used by most authors after Kepler, to demonstrate the refraction of glafs.

If the refraction be out of air into glafs, the ratio of the sine of inclination to the sine of the refracted angle is as 3 to 2, or, more accurately, as 17 to 11; if out of air into water, as 4 to 3; therefore, if the refraction be the contrary way, viz. out of glafs or water into air, the ratio of the sines, in the former case, will be as 2 to 3, or 11 to 17, and in the latter as 3 to 4.

Hence, if the refraction be from water or glafs into air, and the angle of incidence or inclination be greater than about 48° in water, or greater than about 40° in glafs, the ray will not be refracted into air, but will be reflected into a line, which makes the angle of refraction equal to the angle of incidence; because the lines of 48° and 40° are to the radius as 3 to 4, and as 11 to 17 nearly, and therefore when the ratio has a greater proportion to the radius than as above, the ray will not be refracted.

4. A ray falling on a curve surface, whether concave or convex, is refracted after the same manner as if it fell on a plane which is a tangent to the curve in the point of incidence.

For the curve and plane surface touching it, have an infinitely small part common to them both (each being originally generated by the flux of a point). But a ray is refracted in such a little part; therefore it is the same as if it were refracted in such a plane.

5. If a right line EF (Plate XVIII. Optics, fig. 14.) cut a refracting surface, GH, at right angles; and if, from any point in the denser medium, as D, be drawn DC parallel to the incident ray AB; this will meet the refracted ray in C; and will be to it as the sine of the refracted angle to the sine of the angle of inclination.

For = x; but if BC pafs out of a denser medium into a rarer, y > x; and out of a rarer into a denser, y < x; therefore, in the former case, y > o, in the latter y < o; consequently, in the former, o + y < y + u; in the latter y + u < o + u. But in the one case o + u, and in the other y + u, are equal to two right angles; therefore, o + u is in this, and y + u in the other, are less than two right angles, and consequently DC will meet BC. But since o = o, or the angle of inclination, and y is the refracted angle, it is evident that CB is to CD as the sine of the angle o to the sine of the angle y, or in the ratio of the sine of the angle of inclination to the sine of the refracted angle.

Hence, if BC pafs out of glafs into air, it is in a subfequaltere ratio to CD; if, on the other hand, it pafs out of air into glafs, it is in a sequequaltere ratio to CD.

Hence, also, if light pafs out of water into air, CB is in a subfalsaquaterian ratio to CD; if out of air into water, in a falaquiterian. See figs. 14 and 15.

REFRACTION in plane surfaces, locus of. 1. If parallel rays be refracted out of one transparent medium into another of a dif-
a different density, they will continue parallel after refraction. The physical reason is, that, being parallel, their obliquity, or angle of incidence, is the same; but, at equal obliquities, we have shewn the refraction is equal; consequently the parallelism, which they had before the refraction, will be retained after it.

But this may be also demonstrated geometrically; thus, if the rays be perpendicular to the refracting surface, they will pass without any refraction; consequently being parallel before their passage, they will be so after it. If they fall obliquely, as A B and C D (fig. 16.), the angles of incidence $\alpha$ and $\omega$, and, consequently, also the angles of inclination $\alpha$ and $\omega$, will be equal. But the sines of the angles of inclination $\alpha$ and $\omega$ have the same ratio to the sines of the refracted angles $m$ and $n$; therefore the refracted angles $m$ and $n$ and also the angles $\alpha$ and $\omega$, are equal; consequently the refracted rays are parallel.

Hence a glass, plane on both sides, being turned directly to the sun, the light passing through it will be propagated after the same manner as if the glasses were away; for the rays being perpendicular, will pass without refraction. If the glasses be turned obliquely to the sun, the light, after refraction, will be of the same intensity as before, the intensity depending on the spiltitude or closeness of the rays, and on the angle with which they strike the object, or the eye; both of which are here unvaried.

2. If two rays D C and C P (fig. 17.) proceeding from the same radiant C, and falling on a plane surface of a different density, so that the points of refraction D and P are equally distant from the catheus of incidence G K, the refracted rays D F and P Q have the same virtual focus, or the same point of dispersion G.

Hence, 1. Since, in rays very near each other, the distance from the catheus is the same as to sense, very near rays will diverge from the same point G, i.e., they have the same virtual focus G.

And hence, 2. When refracted rays, falling on the eye placed out of the catheus of incidence, are either equally distant from the catheus, or very near each other, they will flow upon the eye, as if they came to it from the point G; consequently the point C will be seen by the refracted rays as in G.

3. If a ray C D fall obliquely out of a thinner into a denser medium, having a plane surface, the distance of the radiant point C K will have a less ratio to the distance of the point of dispersion, or virtual focus, K G, than the sine of the refracted angle to the sine of the angle of inclination. But if the distance of the point of refraction, from the catheus of incidence K D, be less than the eleventh or nineteenth part of the distance of the radiant point C K; and if in the former case the tenth, and in the latter the hundredth, part of it be so small, that it cannot be alligned, or need not be minded, then will C K be to K G, as to sense, in the ratio of the sine of the refracted angle, to the sine of the angle of inclination.

Hence, 1. If the refraction be out of air into glass, the distance of the point of dispersion of rays near the catheus is isequiangular of the radiant point; of more remote rays greater than isequiangular. But if the refraction be out of air into water, the distance of the same point will be isequiangular, when the rays are near the catheus; and when more remote, greater than isequiangular.

Hence, 2. If the eye be placed in a dense medium, objects in a rarer will appear more remote than they are; and the place of the image, in any given case, may be determined from the ratio of the refraction. Thus, to fishes swimming under water, objects out of the water must appear farther distant than in reality they are.

4. If a ray D G fall obliquely out of a denser into a rarer medium A B, the distance of the radiant point G K has a greater ratio to the distance of the point of dispersion K C, than the sine of the refracted angle has to the sine of the angle of inclination. In the other case of the preceding theorem, K G will be to K C, as to sense, in the sine of the angle of the refracted angle, to the sine of the angle of inclination.

Hence, 1. If the refraction be out of glass into air, the distance of the point of dispersion of the rays near the catheus of incidence is subsequaler than the distance of the oblique point; that of the more remote rays is less than subsequaler.

But, 2. If the refraction be out of water into air, the distance of the point of dispersion of rays near the catheus is subsequaliter; of those more remote, less than subsequaliter.

And, 3. The eye, therefore, being placed in a rarer medium, objects, placed in a denser, appear nearer than they are; and the place of the image may be determined in any given case by the ratio of refraction. Hence, the bottom of a vessel full of water is raised by refraction to a third part of its height, with respect to an eye perpendicularly over the refracting surface; and hence fishes, and other bodies under water, appear nearer than they really are.

5. If the eye be placed in a rarer medium, an object seen in a denser medium, by a ray refracted in a plane surface, will appear larger than it really is. If the object be in a rarer, and the eye in a denser medium, the object will appear less than it is. And, in each case, the apparent magnitude is to the real one in a ratio compounded of the distance of the point to which the rays tend before refraction, from the refracting surface D E (fig. 18.) to the distance of the eye G L from the same; and of the distance G M of the object A B from the eye, to its distance F M from a point F, to which the rays tend before refraction.

Hence, 1. If the object A B be very remote, F M will be physically equal to G M; and, therefore, the real magnitude M B is to its apparent one M H, as G L to F L, or the distance of the eye G from the refracting plane to the distance of the point of convergence F from the same plane.

Hence, 2. Objects under water, to an eye in the air, appear larger than they are; and to fishes under water, objects in the air appear less than they are.

REFRACTION. Law of, in spherical surfaces, both concave and convex. 1. A ray of light D E (fig. 19.) parallel to the axis of a denser sphere, after a single refraction in E, falls in with the axis in the point F, beyond the centre C.

For the semidiameter C E, drawn to the point of refraction E, is perpendicular to the surface K L, and is therefore the axis of refraction; but a ray out of a rarer into a denser medium, we have shewn, is refracted towards the perpendicular, or the axis of refraction; therefore the ray D E will converge to the axis of the sphere A F; and will, therefore, at length concur with it, and that beyond the centre C, in F; because the angle of refraction F E H is less than the angle of inclination C E H.

2. If a ray D E fall on a spherically convex surface of a denser medium, parallel to its axis A F; the semidiameter C E will be to the refracted ray E F in the ratio of the sine of the angle of refraction, to the sine of the angle of inclination; but the distance of the focus, or point of concurrence from the centre C, is to the refracted ray F E, in the ratio...
ratio of the sine of the refracted angle, to the sine of the angle of inclination.

3. If a ray D E fall on a denser spheric surface K L, parallel to the axis A F, the distance of the focus from the refracting surface F B must be to its distance from the centre F C, in a ratio greater than that of the sine of the angle of inclination, to the sine of the refracted angle. But if the rays be very near the axis, and the angle B C E be very small, B F will be to C F very nearly in the ratio of the sine of inclination, to the sine of the refracted angle.

Hence, 1. If the refraction be out of air into glass; in the case of rays near the axis, F B : F C :: 3 : 2; in the case of rays more remote from the axis, F B : F C :: 3 : 2 ; consequent, in the former, B C : F C :: 1 : 2. And hence, in the latter, B C : F C < 1 : 2.

Hence also, 2. If the refraction be out of air into water; in the case of rays near the axis, F B : F C :: 4 : 3. In the case of rays more remote from the axis, F B : F C > 4 : 3 ; consequent, in the first case, B C : F C :: 1 : 3. And hence, in the latter, B C : F C > 1 : 3.

And hence, 3. Since the point of refraction F is farther from the centre C, if the refraction be in water than in air, rays will be less deflected in the latter case than in the former.

8. If the ray H E (fig. 20.) fall parallel to the axis A F, from a denser upon the surface of a spheric concave rarer medium, the refracted ray will concur with the axis A F, in the point F; fo that the distance of the point of confluence from the centre C F, may be to the refracted ray to E, in the ratio of the sine of the refracted angle, to the sine of the angle of inclination.

9. If a ray H E fall parallel to the axis A F on the concave surface of a rarer medium out of a denser, the distance of the focus from the centre F C will be to its distance from the refracting surface F B in a greater proportion than the sine of the refracted angle, to the sine of the angle of inclination. But if the rays be very near the axis, F C will be to F B in the proportion of these lines.

Hence, 1. If the refraction be out of glass into air; in the case of rays near the axis, F C : F B :: 3 : 2; in the case of rays more remote from the axis, F C : F B > 3 : 2 ; whence, in the former case, B C : F B :: 1 : 2.

2. If the refraction be out of water into air; in the case of rays near the axis, F C : F B :: 4 : 3; in the case of rays more remote, F C : F B :: 4 : 3 ; whence, in the former case, B C : F B :: 1 : 3. For the demonstration of these several laws of refraction, we refer to Wollaston's Elem. Math. &c. tom. iii. p. 179, &c. See also, LENS.

Refraction in a glass prism. If a ray of light D E (fig. 21.) fall obliquely out of air on a prism A B C; being refracted towards the perpendicular, instead of proceeding to F, it will decline to G, i.e. towards a line H I, drawn perpendicular to the surface A B in the point of refraction E. Again, since the ray E G, passing out of the glass into air, falls obliquely on C B, it will be refracted to M, fo as to recede from the perpendicular N G O. And hence arises the various phenomena of the prism. See COLOUR and REFRANGIBILITY.

Refraction in a convex lens. If parallel rays, A B, C D, and E F (fig. 22.) fall on the surface of a lens 2 B 3 K, the perpendicular ray A B will pass unrefracted to K, where it will proceed straight to G. But the rays C D and E F, falling obliquely out of air into glass, in D and F, will be refracted towards the axis of refraction (i.e. towards lines H I and L M, drawn perpendicular to the refracting surface in the points of refraction D and F) and decline to Q and P. Again, emerging obliquely out of the glass into the surface of the air, they will be refracted from the perpendicular, and, therefore, D Q will not proceed to X, but to G; and F P, not to V, but to G; thus, likewise, might all the other rays, falling on 4 F the
the surface of the glass, be shewn to be refracted so as to
meet the ref about the point G. See Focus and Lens.
Hence the great property of convex glasses; viz., that they
collect parallel rays, or make them converge into a point.

Refraction in a concave lens. Parallel rays A, B, C, D,
and E (fig. 23.) falling on a concave lens G B H I M K,
the ray A B, falling perpendicular on the glasses at B, will
pass unaltered to M; where being still perpendicular, it
will pass into the air without refraction, to L. But the
ray C D, falling obliquely on the surface of the glass, will
be refracted towards the perpendicular N D O, and proceed to
Q; and the ray D Q, again falling obliquely out of the
glasses upon the surface of air, will be refracted from the
perpendicular Q R S, and proceed to V. After the same
manner might the ray E F be shewn to be refracted to V,
and thence to Z.

Hence the great property of concave glasses; viz., that they
disperse parallel rays, or make them diverge. See Lens and
Mirrors.

Refraction in a plane glass. If parallel rays E F, G H,
I L (fig. 24.) fall obliquely on a plane glasses A B C D, the
obliquity being the same in all, by reason of their parallelism,
they will be all equally refracted towards the perpendicular;
and accordingly, being still parallel at M, O, and Q, they
will pass out into the air equally refracted again from the
perpendicular, and still parallel.

Thus will the rays E F, G H, and I L, at their entering
the glasses, be inflected towards the right; and in their going
out as much inflected to the left; so that the first refraction
is here undone by the second; though not so as that the ob-
ject is seen in its true place. For the ray B Q, being produced
back again, will not coincide with the ray L I, but will fall
to the right of it; and this the more as the glass is thicker;
however, as to matter of colour, the second refraction does
really undo the first. See Colour.

Refractive of Heat. See Heat, Light, and Rays of
Heat.

Refractive in Iceland or Island glass. See Iceland
Crystal. Dr. Young, who maintains that radiant light
consists in undulations of the luminiferous ether, takes
occasion to make some remarks on Sir Isaac Newton’s theory
of the peculiar refraction in Iceland crystal. Newton, he
says, has advanced the singular refraction of the Iceland
crystal, as an argument that the particles of light must be
projected corpuscles; since he thinks it probable that the
different sides of these particles are differently attracted by
the crystal, and since Huygens has confuted his inability to
account, in a satisfactory manner, for all the phenomena.
But contrary to what might have been expected from New-
ton’s usual accuracy and candour, he has laid down a new
law for the refraction, without giving a reason for rejecting
that of Huygens, which Mr. Hâyi found to be more
accurate than Newton’s; and, without attempting to deduce
from his own system any explanation of the more universal
and striking effects of doubling spars, he has omitted to ob-
serve, that Huygens’s most elegant and ingenious theory per-
fectly accords with these general effects, in all particulars,
and of course derives from them additional pretensions to
truth; this he omits, in order to point out a difficulty for
which only a verbal solution can be found in his own theory,
and which will probably long remain unexplained by any
other.

Dr. Wollaston, in his paper on the oblique refraction
of Iceland crystal, confirms the experiments of Huygens on
this subject, with additional evidence, deduced from the
superiority of his mode of examining the powers of re-
fration. He observes that Dr. Young has already applied
the Huygenian theory with considerable success to the ex-
planation of several other optical phenomena, and that it
appears to be strongly supported by such a coincidence of
the calculations deduced from it, with the results of these
experiments, as could have scarcely happened to a false theory.

In ordinary cases, the incident undulations are of a sphé-
rical form; but in the Iceland crystal light appeared to Huy-
gens to proceed as if the undulations were portions of an ob-
late spheroid, of which the axis is parallel to the short dia-
gonal of an equilateral piece of the crystal, and its centre
the point of incidence of its ray. From this spheroidal
form of the undulations, he deduces the obliquity of refra-
tion; and lays down a law observable in all refractions, at
any surface of the spar, whether natural or artificial, which
bears the clearest analogy to that which obtains, universally,
at other refractory surfaces; for as, in other cases, the ratio
is given between the sine of incidence and sine of refraction,
(or ordinate of the spheroidal undulation propagated,) in the
Iceland crystal, the ratio between the sine of incidence
and ordinate of refraction (in any one section of the sphenoi-
ral undulation) in a given ratio, but different in different
planes.

Dr. Wollaston observes, that though we do not fully
understand the existence of a double refraction, and are
utterly at a loss to account for the phenomena occurring
upon a second refraction, by another piece of the spar, yet
that the oblique refraction, when considered alone, is nearly
as well explained as any other optical phenomenon. Phil.
Trans. for 1801 and 1802.

Refractive, Partial laws of, in different kinds of
leaves; see Lens.

Refractive, Atmospheric, is generally considered under
two distinct heads; viz., astronomical refraction, which is
that relating to the refraction of the moon, stars, and other
celestial bodies; and terrestrial refraction, or that which
takes place in terrestrial observations.

It appears, from the article Refraction, that a ray of
light is refracted in passing obliquely out of one medium into
another of different density; and as the atmosphere may be
considered as composed of an infinitude of strata, whose
density increase as they are poluted nearer the earth, the lu-
minous rays which pass through it are acted on as if they
palled successively through media of increasing density, and
are therefore refracted more and more towards the earth, as
the density augments, that is, as they approach the eye of
the observer. In consequence of this it is, that rays from
objects, whether celestial or terrestrial, proceed in curves
which are concave towards the earth; and since the mind al-
ways refers the place of objects to the direction in which
the rays reach the eye, that is, to the direction of the tan-
gent to the curve at that point, it follows, that the apparent
or observed elevation of objects is always greater than the
true one, at least with the exception of some few remark-
able anomalies which sometimes, in terrestrial observations,
produce a contrary effect, and of which we have stated a
few particular instances under the article Mirages, and on
which subject some other curious facts are recorded in a me-
moire of professor Vince’s, in the Phil. Trans.; in Nicholson’s
Philosophical Journal, 4to; and more particularly by M. Monge,
in vol. i. of the “Decade Egyptienne.” Ref-
erring the reader therefore to those works, to which we
ought also to add the memoir by M. Biot, in vol. 8. of the
National Institute, for an account and explanation of those
phenomena, we shall confine our present observations to those
cases only, in which an uniform law is supposed to have place,
and which, as we have seen, has a constant tendency to aug-
ment the observed altitude of both terrestrial and celestial
objects.
objects. In order to submit the phenomena of refraction to strict mathematical investigation, it must be observed that, in consequence of the inconsiderable height of the atmosphere, and its spherical form, a luminous ray impinging upon it, even in the most unfavourable case, that is directly in the horizon, traverses only a small quantity of this medium; and in this case, if the atmosphere be calm, the density of the air at equal heights above the level of the sea is everywhere the same. Therefore, in supposing the earth spherical, a supposition which may be admitted, in the present case, without any sensible error, we may consider the atmosphere as composed of successive spherical concentric shells, or strata, of which the density diminishes from the surface of the earth upwards.

Let us conceive, now, a luminous ray, coming from a distance, to penetrate into one of the supposed spherical shells; then, if through the common centre of these shells, which is the same as the centre of the earth, we suppose a plane to pass in the direction of the luminous ray, the spherical beds of the atmosphere will be found divided into two equal portions, which acting equally upon the ray, can produce no deviation of it from that plane; whence it follows, that the effect of refraction is entirely produced in a vertical direction, and in such a manner as to augment the apparent altitudes of the heavenly bodies, and consequently to diminish their zenith distances.

But the intensity of these effects will not be the same at all heights, for we know that in all cases the quantity of refraction depends upon the obliquity of incidence, and therefore the refraction in the zenith is equal to zero, and increases from that point to the horizon, where it is the greatest.

If now, we knew the law by which the density of the air is diminished in ascending from the earth, that is, if we knew the difference in the density of any two consecutive strata, it would be comparatively a direct and easy problem to find the whole amount of refraction for any given angle of observation; but unfortunately the uniformity of decrease in the density of the atmosphere, which, according to theory, is in geometrical progression, is so much interrupted by the multitude of causes which may tend to produce this effect, that it is found that the quantity of refraction computed on this principle will by no means agree with that deduced from actual observation. It has been, however, demonstrated, that the quantity of refraction, in all cases exceeding 10 or 12 degrees of elevation, is not sensibly affected by any irregularity in the law of density, in the strata of which we have suppos'd the atmosphere to be composed, but that it depends simply upon its pressure and temperature at the time and place of observation, which are indicated at the time by the barometer and thermometer.

It was formerly thought, also, that refraction was influenced by the degree of humidity and dryness of the air; but from a great variety of interesting and accurate experiments, carried on by M. M. Biot and Arrago, it appears indubitably established, that no sensible effect is thence produced. See a memoir on this subject by the former author, in vol. x., of the National Institute.

But before we proceed farther on this interesting subject, it will be proper to give a sketch of the several improvements which the theory has experienced in the hands of different celebrated astronomers; in doing which we shall avail ourselves of a memoir, published by Dr. T. S. Evans in the Philosophical Magazine, which contains a minute and circumstantial detail of many important particulars connected with this subject. There appears to be but little doubt that the astronomic refraction was known to the ancients, since it is expressly mentioned by Ptolemy, although not made use of in his calculations. He says, near the end of the 8th book of the Almagest, that in the rising and setting of the heavenly bodies, there are changes which depend upon the atmosphere, and he mentions it more at length in a work on optics, which, unfortunately, has not been handed down to us. Alhazen, an Arabian writer, who is generally supposed to have lived about the year 1000, and to have taken the greater part of his optics from the works of Ptolemy, speaks also decidedly of it, and shews the manner of convincing ourselves of it by experiment. "Take," says he, "an armillary, which turns round its poles, and measure the distance of a star from the pole of the world when it passes near the zenith in the meridian, and when it is rising or setting near the horizon, and you will find the distance from the pole less in the latter case." He then demonstrates that this must arise from refraction, but he does not state its quantity.

In the collection of observations made by Bernard Walter, and published by Willebrode Snell in 1618, it is stated, that the observations were so exact, that they pointed out to Walter the quantities by which the altitudes of the stars and planets were increased on account of the refraction.

Tycho Brahe, however, appears to be the first who, with any degree of accuracy, that the refraction elevates the heavenly bodies rather more than half a degree when on the horizon. (See Progymn. p. 15.) But either his instruments or his observations were not sufficiently correct to determine it with certainty for all degrees from the zenith to the horizon; and, accordingly, where these failed, the result was supplied by conjecture. He believed that the sun's refraction was 34" in the horizon, and that it became sensible at 45° of altitude. For the stars, however, he ascribed an entirely different quantity, viz. 30" in the horizon; but this, according to him, terminated at only 20° of altitude.

The following is the manner in which it is related (Encly. Method.) that Tycho made this discovery. He had determined, with one or two instruments, extremely well made, the latitude of the place by observations of Polaris above and below the pole. He determined it also by the sun's altitude in both solstices, and found it four minutes less in the latter. At first he doubted the goodness of his instruments, and therefore constructed, with the utmost care, as many as ten others, of different sizes and forms, but they all gave nearly the same results. He could, therefore, no longer attribute this difference in the two determinations of the latitude to any defect in the observations, but endeavoured, by an attentive consideration of the subject, to find out the cause of this singular phenomenon. At length he suppos'd it could only arise from the refraction which elevated the sun at the winter solstice, having then only 11° of elevation above the horizon. This result agreed very well with the principles of optics; but still Tycho Brahe could scarcely persuade himself that the refraction was sufficiently large to produce so great a difference. On this account, he made other observations of the ten feet diameter, whole axes corresponded exactly with the pole of the world, and with these he measured the declination of the stars out of the meridian. He then found, that even in summer the refraction, although sensible at the meridian altitude of the sun, was very considerable near the horizon, and amounted to half a degree in the horizon. See Progymn. p. 79-104. Street's Alfr. Carol. p. 119.
REFRACTION.

Tycho Brahe’s table of refraction is as follows:

In this state the refraction remained for many years. Even Riccioli, in 1665, supposed it nothing at about 26° of altitude; but he thought the moon had only 20″ of horizontal refraction in summer, the sun 30°, and the stars 3° 37″. It was not till after the year 1672, that a tolerably near table of refraction made its appearance, when the elder Caffini took the subject into consideration. (Mem. de l’Acad. tom. v. p. 81.) What led to this was the voyage of Richer to Cayenne in that year, upon the utility of which some very excellent remarks were made by Caffini, shewing how far observations made in a situation so near the equator tended to confirm or disprove certain theories derived from observations made in Europe. Several very useful deductions were drawn from a comparison of those made both at Paris and Cayenne; among others, the refraction was settled upon much more accurate elements than hitherto, and a new table computed, for the first time, of its quantity, for all degrees, up to the zenith; an abridgment of which is given below:

</table>

From the relation of his grandson it appears, however, that Caffini had at one time computed three tables of refraction for all altitudes; one for winter, another for summer, and a third for spring and autumn; but several doubts having been suggested to him respecting this arrangement, although in appearance conformable to nature, and principally the observations of Richer at Cayenne, where the refraction was found little different from that at Paris, he changed his opinion; and judging, that since the great difference of heat of the torrid zone from that of the temperate zone, which we inhabit, does not cause sensible differences in the refraction; therefore the greatest heat or cold of our climate could not change it much; and he then fixed upon one table, which was that used by the astronomers of the Royal Observatory of Paris up to the year 1745.

It was always thought, before the time of Caffini, that the refraction did not extend its influence higher than 45° of altitude; and he is generally considered as the first who proved that it reached all the way to the zenith. He also supposed that near the equator the horizontal refraction was less than in our climate by about one-third; that this difference decreased as far up as 60°, after which it was the same nearly for both climates.

From this discovery it followed, as a natural consequence, that the refraction must be greater near the pole than at Paris; and this was shortly afterwards proved to the Academy by the publication of a work expressly on that subject. (Refraction, folia inedita, &c. Holmiae, 1695.) The king of Sweden, being, in 1692, at Tornes, in West Bohemia, near the latitude of 65° 45′, and observing that the sun did not set there in the summer solstice, sent the following year some mathematicians to make more certain and exact observations of this curious phenomenon. They are contained in this book, and Meffrs. Caffini and Del la Hire concluded from them, that in the latitude of 65° 45′, the horizontal refraction must be 58′, or nearly double of that at Paris.

According to an observation made by some Dutchmen who passed the winter of 1596—7, in Nova Zembla, in latitude 76° north, the sun, which had entirely disappeared the 14th of November, began to rise again the 24th of January, viz. fix days sooner than was expected, according to astronomical calculations. If so, when the sun has been two or three months under the horizon, as the Dutchmen observed in 1597, the cold becomes dreadful, and perhaps the refraction increases prodigiously. M. le Monnier affirms us, that he found by the observations printed in 1599, that on the 24th and 25th of January 1597, there were more than 45 degrees of refraction; that he could neither explain these observations, reject them as doubtful, nor suppose any error, as was done by most of the other astronomers, Kepler, Caffini, Scotto, and, lastly, M. le Gentil, in his Voy. dans les Mers des Indes, tom. i. p. 395, tom. ii. p. 532, who maintained that there were errors in the observations, and accordingly read a memoir on the subject. If it were not so difficult a task to winter in these high latitudes, we might expect such observations as would remove all doubt on the subject; and, perhaps, bring others to light of as great or greater importance.

The refraction of the north being so considerable, is very useful to the inhabitants, who are deprived of the sun’s light during many months; as it makes the sun rise much earlier, and set much later to them, than it otherwise would.

About the year 1725, Mr. Flamsteed, the English astronomer royal, published his table computed from his own observations: and this was the one commonly used in England for many years afterwards.

Sir Isaac Newton also constructed one from theory, which was first published by Dr. Halley in the Philosophical Transactions, N°. 568, for 1721. He made the horizontal refraction 33° 45′; whereas Mr. Flamsteed’s was only 33° 00′.

But although the refraction might be determined within a few seconds at all altitudes by observation; yet, the law of its increase from the zenith to the horizon was a subject that occupied the principal mathematicians and astronomers for more than a century. Newton having discovered the general principles of attraction, found that the refraction was a consequence of this law of gravity; and that it arose from the attraction of the atmosphere on the particles of light. On this principle the curve which a ray of light describes might be determined: since it is successively attracted
The refraction of the variation of density in the atmosphere, as indicated by the barometer and thermometer, is due to Neîfss, Lotthorpe and Haukseb; the former of which, in 1698, proved by a very simple experiment, in the presence of the Royal Society, that the refractive power of air is directly proportional to its density: and the latter, by repeating and extending the same course of experiments in the year 1708, with the machinery pointed out by the former, found that the variations of refraction, depending on the barometer, are proportional to the alteration of height of the mercury in the tube: and by a series of these experiments, he furnished us with a table of the corrections which it is necessary to make on account of the changes of heat indicated by the thermometer. These experiments, although not quite conclusive on the subject, were yet made with as much accuracy and care as the nature of the machinery, and the rate of experimental philosophy of that time, would admit. An example is also given, towards the end of his paper, on the mode of applying them to correct the refraction. By these, Haukseb found that a volume of air expressed by unity, when the thermometer was at 180° above zero, became, at 50° below, one-eighth more dense: or, which is the same thing, that the air lost one-eighth of its density, for an elevation of 180° of Fahrenheit's thermometer; which is exactly the difference of heat between melting ice and boiling water. But although this one-eighth, as will be shewn hereafter, was too small; yet it laid the foundation for other experiments, since made by several philosophers, by which the quantity of expansion has been determined more accurately.

We have already shewn that the refraction near the pole is greater than in our climate; the degree of cold being more intense. It was also found to be less in the torrid zone, where the heat is greater than in Europe. Bouger made a variety of observations at Peru, the result of which he has given us. In 1740, he came down into an island situated in the river of Emerals, called Isla de Inca, where he determined the refraction from 1° to 7° of altitude; and the table which he afterwards computed shews the refraction to be about one-seventeenth less than in Europe. The horizontal refraction he found to be 27'; but at 6° of altitude it is 7° 45': and at 9° it is 4° 54'. Bouger then gives a table for Quito, which is much more elevated above the level of the sea. M. le Gentil found it greater at Pondicherry in India, although in the torrid zone.

The refraction diminishes when we are elevated above the level of the sea. Bouger observed the quantity of it at Chimbapora, 2388 toises above the level of the sea, and found it in the horizon only 192'. At the croots of Pitcairia, 2044 toises above the sea, he found it 20° 45'; at Quito, 1479 toises above the sea, 22° 50'; but at the level of the sea 27°. These observations, when joined with the theory, produced the following rule: viz. if we take the excess of 5158 toises above the elevation of the place, with regard to the level of the sea, the refraction will be as the square root of this excess. Thus the square root of 5158 toises above the elevation of the place, with regard to the level of the sea, the refraction will be as the square root of this excess. Thus the square root of 5158 above the elevation of the place, with regard to the level of the sea, is 7° for the horizontal refraction, at the level of the sea, in the torrid zone: and the square root of the excess of 5158 above the elevation of the place will be its horizontal refraction. The quantity 5158 is the height above which the refractive matter no longer produces any sensible effect, at least in the torrid zone.

But although by this time considerable attention had been paid to the subject, yet great differences were to be found in the tables then most in use. Thus at the altitude of 50°, according to Flamstead, the refraction was 1° 23'; Newton, 1° 30'; Cassini, 1° 42'; and de la Hiere, 1° 55': leaving an uncertainty of more than half a minute: and it must have been very mortifying to an observer, after having taken the utmost
REFRACTION.

utmost pains to avoid errors of two or three seconds, to
find his reduced observations liable to so great an error, ac-
cording to the choice of his table of refraction

It is indeed rather extraordinary, that in a memoir pub-
lished by Caffini de Thury, among those of the Academy,
for 1745, he attempted to reconcile a number of observa-
tions with each other, by considering the rate of the thermometer
only, without at all noticing that of the barometer; al-
though at that time Hankkée's experiments had been
published about 37 years.

He concludes his paper, as is very natural to suppose,
without being able to make the observations agree; for
it does clearly appear that the French noticed the above-
mentioned experiments made by Hanskée till about the
year 1749. It is also worthy of remark, that although the
necessity of introducing corrections on account of the alter-
ations of the barometer and thermometer were likewise
shown to be absolutely necessary by Dr. Halley (Phil. Trans. 
N° 364), and the circumstance mentioned, and in some de-
gree admitted by Le Monnier (Hist. Celest.), yet it does not
appear that he followed the advice of his illustrious con-
temporary, but merely endeavoured, as Caffini did, to
reconcile his observations with the rate of the thermostat
at the time of making these observations, without taking the
barometer into account.

It would be endless to notice the different opinions re-
flecting both the terrestrial and the astronomic refraction
which are to be met with in the writings of various authors
on the subject: and it would be equally useless to notice all
the tables of its quantity given by them, some of which dif-
fer very much from others. It will be sufficient to mention
those only who made some considerable advances towards
obtaining it with greater accuracy.

The next of these in order was La Caille (Mem. de l'Ac. de 
Sc. 1755, p. 547.), who in determining it certainly bellowed
very great pains, by making and reducing an immense number
of observations, and afterwards comparing them with others
made at Greenwich by Dr. Bradley, at Gottingen by Mayer,
at Bologna by Zanotti, and by La Lande, who was then at Berlin.
From these it appeared that the refraction at 45° of altitude was
1' 51"; but this, as will hereafter be seen, was too great by five
seconds. In his paper on the subject, which is divided into four parts, he proves, first,
that the mean refractions are very nearly the same for the
same apparent altitudes throughout the whole extent of the
temperate zone; since those which were observed at Paris
did not exceed those observed at the Cape of Good Hope
but by 1" at most. In the second he determines the abso-
lute quantity of the mean refraction for the apparent height
of the pole at Paris, and gives the result of his observations
with regard to the latitude of Paris and of the Cape of
Good Hope. In the third he gives his table of mean re-
fraction, and another of corrections depending upon the
rate of the barometer and thermometer; concluding with
some reflections on its construction and use. In the fourth
he compares his new table with the most celebrated of those
that had before that time been in use among astronomers;
and he then shews how it agrees with the observations
of Bradley, Zanotti, and Mayer.

But by La Caille's memoir it appears, that previous to
this time M. Mayer had formed and communicated to him a
table of astronomic refractions which he computed by means
of an algebraic formula, the coefficients of which he de-
duced from his own observations, and took into account the
variations relative to those of the barometer and thermometer.
He found the alteration of refraction for a depression
of 15 minutes in the barometer, the same as for a rise of 10°
in the thermometer, and the variation for each degree of
the latter, according to his table, 1/4 of the whole mean
refraction, which he adopted for 28 inches of the barometer,
and 5° of the thermometer. This proportion takes place
down to 30° of zenith distance. Mayer considered also
that the mean refraction is the same for all parts of the earth;
and that the only variation which takes place depends on
the changes of the weight and temperature of the
atmosphere.

La Caille, in comparing Mayer's table with observations,
found that his correction for the thermometer was a little
over-rated; and accordingly, for his new table, altered it
at 45° for each degree. And here it may be observed that
La Caille did not correct his altitudes above 35° at Paris,
and 30° at the Cape; firstly, because he only noted the baro-
meter and thermometer in the night, when he observed stars
below 30° of altitude. Secondly, because, at 36° of altitude,
where the mean refraction is about 1/4 minute, the variation
which belongs to 10° of the thermometer only amounts to 3/4
seconds; a quantity about equal to the limits of the errors of observations made with an instrument
of six feet.

The formula given by Euler (Mem. de l'Ac. de Berlin, 
1754, p. 131.), appeared also about this time. It took into
account the variation of the refraction depending upon
the thermometer and barometer, but was certainly too
complicated to be generally adopted. He shews, however,
that in very different hypotheses the refraction will be suf-
ficiently exact, if taken in the inverse ratio of the degrees
of heat, when the star or planet is not too near the
horizon, but the precise quantity of this ratio was unknown
to him.

In this state the refraction stood when Dr. Bradley took
the subject into consideration, and began to find its quantity
from his own observations. The rule which he adopted,
although a very elegant one, he neither lived to complete
nor to present to the world; but it was published after his
death by Dr. Markelyne, (Pref. to fold. vol. of Obs. 1765,
Phil. Trans. 1764 and 1787, p. 157. Req. Tables, &c.),
and has commonly been used in England up to the present
time. He found the mean refraction at 45° of altitude
57°, and, that at all other altitudes, it was equal to 57°
multiplied by the tangent of the zenith distance, diminished
by three times the refraction. Then supposing the mean
flats of the atmosphere to be at 29.6 inches of the baro-
meter, and 30° of Fahrenheit's thermometer, he made the
true or corrected refraction equal to 57° × t, (Z. D. − 3r)
barom. × 29.6 330 + ther., where it is to be understood
that the mass of air is supposed to increase in bulk 3/4
for each degree of Fahrenheit's scale.

A variety of experiments has been made at various
times to ascertain the increase in bulk or a quantity of air
represented by unity for a certain number of degrees of rise
of the thermometer. The following is a list of some of them:

The refraction deduced from Bradley's very neat and simple formula was, in a few years, adopted by nearly all the astronomers of eminence throughout Europe. The extreme facility with which it might be computed, and the corrections applied, whether from the formula itself, or from tables ready calculated for that purpose, was a powerful recommendation in its favour; but its near agreement with observation soon established it.

We must now, without entering farther into detail of minor improvements, proceed at once to the chapter given by La Place on this subject, in his "Mécanique Céleste," vol. iv. p. 234, where he has drawn, from an investigation which we cannot undertake to exhibit in this place, the following general formula, for expressing the refraction for all angles of elevation above 12 decimal, or 10.8 sexagesimal degrees, viz.

\[ r = \frac{a \rho \cdot \tan \alpha}{0.76 \left(1 + \frac{0.00125354}{\cos^2 \alpha}\right) - 0.76 \cdot \cos^2 \alpha} + \frac{0.5 a' \sin \tan \alpha}{\left(1 + \frac{0.00125354}{\cos^2 \alpha}\right) \tan \alpha} \]

where all the quantities are known except \( r \) and \( \alpha \); which latter represents a constant co-efficient; viz. \( r \) is the observed zenith distance under the barometric pressure \( \rho \), in metres, and \( \alpha \) the temperature of the centigrade thermometer, \( r \) being the refraction; all, therefore, that is required for determining \( r \), is the value of the unknown co-efficient \( a \), which is to be drawn from observations on the circumpolar stars, in the following manner.

Let \( Z \) be the distance of one of these stars from the zenith, in its superior meridian passage; \( Z' \) this distance at the inferior meridian passage, observed from the same point of the terrestrial surface; \( r \) and \( r' \), the corresponding refractions. Now all the other quantities, except \( a \), being known, we may, for the sake of simplicity, put the above formula for both passages under this form,

\[ r = A a + B a', \quad r' = A' a + B' a' \]

where \( A, B, A', B' \) are all known quantities. Writing for \( Z \) and \( Z' \), for the observed zenith distances, the true zenith distance, \( D \), corrected for refraction, will be

\[ Z + A a + B a', \quad Z' + A' a + B' a' \]

which are, therefore, now equal to each other; consequently, by addition, we have

\[ Z + Z' + (A + A') a + (B + B') a' = 2 D \]

in which all the quantities are known, except \( a \) and \( D \). But by repeating similar observations on some other star, and denoting by \( Z'', Z''', A'', A''', B'', B''' \), the similar quantities before referred to by \( Z, Z', A, A', B, B' \), the following two equations will be obtained:

\[ Z'' + Z''' + (A'' + A''') a + (B'' + B''') a' = 2 D \]

from which it is obvious, the constant co-efficient \( a \) may be obtained by the usual methods of elimination.

In the above operation, however, we have supposed the polar distances of the same star to be the same for its superior and inferior passage; whereas we know that, in consequence of the effect of precession, nutation, and aberration, this distance is constantly varying; and we ought, therefore, to introduce these variations into the above equation. But our object being merely to give a general view of the principles made use of for the determination of the co-efficient \( a \), we have not thought it necessary to enter so triflingly into the minutiae of the computation. It appears from the above, that the constant co-efficient \( a \) may be determined by means of four observations on two different circumpolar stars; and, consequently, that every such set of observations ought to produce the same result, or the same value of \( a \). Considering, however, the extreme accuracy required in such cases, both in the instruments and the application of them, some little disagreement is to be expected; and indeed one is surprised to see it so small, as it has been found to be in various observations undertaken for this purpose, and the mean of which we have every reason to consider as perfectly correct; and which is stated by M. Biot, who has interested himself very much on this subject, at 187.42, for the decimal division, or 60.9666 for the sexagesimal division.

But now, in order to simplify our first formula, by taking \( \rho = 0.76 \) metres, and \( \alpha = 0 \), this may be put under the form,

\[ r = a \tan Z \left(1 - \frac{0.00125354}{\cos^2 \alpha}\right) + \frac{0.5 a' \sin \tan \alpha}{\cos^2 \alpha} \]

wherein, substituting for \( \cos^2 \alpha \), its value \( \frac{1}{1 + \tan^2 \alpha} \), and the proper numerical value of \( a \), as above found, as also of \( \tan \alpha \), the whole is reduced to the following form, viz.

\[ r = 0.99918761 \cdot a \tan Z - 0.001105823 \cdot a \tan^2 Z \]

which latter form M. Biot has shown to be equivalent to

\[ r = 187.42 \cdot \tan (Z - 3.25) \]

for the decimal division;

\[ r = 60.9666 \cdot \tan (Z - 3.25) \]

for the sexagesimal division.

But the reduction of it to this form would occupy more space than can be allowed for this article. This last form is as simple as can be desired, from which the following rule in words may be deduced, viz. The refraction under the same barometric pressures, and the same degree of temperature, is proportional to the tangent of the apparent zenith distance of the star, diminished by 3.25 times the refraction.

It must be remarked, however, that the formula \( r = A \tan (Z - 3.25) \), though it exhibits the law of refraction in as simple a form as can be desired, is not well adapted for calculation, in consequence of \( r \) entering on both sides of the equation; and astronomers have, therefore, given different methods of rendering the above formula more commodious. In order to which, it is first put under the form,

\[ \tan n r = \tan n R \tan (Z - n r) \]

\( R \) representing the refraction, answering to \( Z = 90^\circ \). Let us now add successively to both sides of this equation, the quantities \( + \tan n r \tan n R - \tan n R \tan n r \), and we shall have,

\[ \tan n r (1 + \tan^2 n R) = \tan n R \left[ \tan (Z - n r) + \tan n r \right] \]

\[ \tan n r (1 - \tan^2 n R) = \tan n R \left[ \tan (Z - n r) - \tan n r \right] \]

Now, dividing these equations, member by member, \( n r \) will be eliminated, and we obtain

\[ \frac{1 + \tan^2 n R}{1 - \tan^2 n R} = \frac{\tan (Z - n r) + \tan n r}{\tan (Z - n r) - \tan n r} \]

whence we draw

\[ \tan (Z - 2 n r) = \cot 2 n R \cdot \tan Z \]

Now
REFRACTION.

Now Z and its length being known, we may compute the second side of this equation; whence the arc $Z - 2 \tan r$ is known, and consequently $2 \tan r$; which, divided by $2 n$, will give $r$, as required. But it may be found still more simply by the formula,

$$\tan r = \frac{\tan n R \tan \frac{1}{2} n}{\tan n}$$

where $n$ is the refraction at the Earth's surface, and $R$ is the refraction of the Earth's atmosphere.

On the principle above explained, the following table of refractions has been computed, agreeing with the temperature of the centigrade thermometer, and under a pressure of 0.76 metres of the barometer; which is the same as 57.2 Fahrenheit, and 29.022 English inches. And for any other temperature and pressure, the corresponding corrections must be made as indicated in Tables II. and III., where tables are computed by means of the general formula given in the preceding part of this article.

We had intended to give here a short abstract of a very interesting paper on this subject, published by Mr. Groombridge, in the Philosophical Transactions for 1810; but having already exceeded our usual limits, we can only refer the reader to the volume itself, where he will find several neat and useful formulæ.

Having thus given a sketch of the method of determining the quantity of astronomical refraction for all angles of elevation, and under various degrees of temperature and barometric pressure, let us add a few words on the subject of terrestrial or horizontal refraction; for the determination of which, the following method has been successfully practised in the English Trigonometrical Survey.

Let $A, A'$ (Plate XIX, Astronomia, fig. 11.) be two elevated places on the surface of the Earth; $B, B'$, the left or right angles of the Earth's surface; $C$, the centre of the Earth; $A H, A' H'$, the horizontal lines at $A, A'$, produced to meet the opposite vertical lines $C H, C' H$. Let $a, a'$, represent the apparent positions of the objects $A, A'$; then is $a A A'$ the refraction observed at $A$, and $a A' A$ the refraction observed at $A'$; and half the sum of these angles will be the horizontal refraction, if we assume it equal at each station.

Now an instrument being placed at each of these stations $A, A'$, the reciprocal observations are made at the same instant of time, which is determined by means of signals or watches previously regulated for that purpose; that is, the observer at $A$ takes the apparent depression of $A'$, at the same moment that the other observer takes the apparent depression of $A$. Then, in the quadrilateral $A C A' B$, the two angles $A, A'$, are right angles, and consequently the angles $A$ and $A'$ are together equal to two right angles; but the three angles of the triangle $A A' C$, are together equal to two right angles; and consequently the angles $A$ and $A'$ are together equal to the angle $C$, which is measured by the arc $B D$. If, therefore, the sum of the two depressions $H A a, H' A a$, be taken from the sum of the angles $H A' A$, and $H' A' A$, or, which is equivalent, from the angle $C$, (which is known, because its measure $B D$ is known,) the remainder is the sum of the two refractions. Hence this rule, “Take the sum of the two depressions from the measure of the intercepted terrestrial arc, and the remainder is the refraction.” If, by reason of the minute errors of the contained arc $B D$, one of the objects, instead of being depressed below the tangent $A H'$, appears elevated, as supposes $A$ to $a'$, then the sum of the angles $a A A'$, and $a A' A$, will be greater than the sum $I A A' + I A' A$, or than $C$, by the angle of elevation $a A A'$; but if from the former sum there be taken the depression $H A A'$, there will remain the sum of the two refractions, so that in this case the rule becomes as follows: “Take the depression from the sum of the contained arc and elevation, and half the remainder is the refraction.”

The quantity of this terrestrial refraction is estimated by Dr. Maltecky at one-tenth of the distance of the object observed, expressed in degrees of a great circle. Where the distance be 10,000 fathoms, its 10th part, 1000 fathoms, is the 65th part of a degree, or one minute, which, therefore, is the refraction in altitude of the object at that distance. But Le Gendre is induced, by several experiments, to allow only one-fourteenth part of the distance for the refraction in the altitude, so that on the distance of 10,000 fathoms, the 14th part of which is 714 fathoms, he allows only 44" of terrestrial refraction, so many being contained in 714 fathoms. (See his Memoir on the Trigonometrical Operations.) Again, Delambre makes the quantity of terrestrial refraction to be one-twelfth part of the arc of distance. And the English measurers, from many very exact observations, determine the quantity of the medium refraction to be a twelfth part of the said distance. The mean of all these is about $0.8\%$ of the intercepted arc, which is probably not very far from the truth; this quantity, however, it must be observed, is found to vary very considerably with the different latitudes of the weather and atmosphere, from one-seventh to one-eighth of the contained arc.

Table
TABLE I. Of Refraction.

Barometer 29.922 Inches = 0.76 Metre; Thermometer Centigrade, 14°; Fahrenheit's, 57°.2; Reaumur's, 11°.2.

To
To observe the Refraction of a Star, &c. 1. Observe the meridian altitude of a star near the zenith; whence the latitude of the place being known, the true declination of the star is easily had, the star being now void of any sensible refraction. 2. Observe the altitude of the same star in any other degree, and note the time by a pendulum. 3. For the given time of observation, from the declination of the star compute its true altitude.

This being thus found less than the altitude observed, subtract the one from the other; and the remainder is the refraction for that moment, in that degree.

Refraction of Altitude, is an arc of a vertical circle, by which the altitude of a star is increased by the refraction.

Refraction of Declination, is an arc of a circle of declination, by which the declination of a star is increased or diminished by the refraction.

Refraction of Ascension and Declension, is an arc of the equator, by which the ascension and declension of a star, whether right or oblique, is increased or diminished by means of the refraction.

Refraction of Longitude, is an arc of the ecliptic, by which the longitude of a star is increased or diminished by means of the refraction.

Refraction of Latitude, is an arc of a circle of latitude, by which the latitude of a star is increased or diminished by means of refraction.

Refraction, in Commerce, is a term sometimes used by merchants, where there has been an oversight in an account, to the prejudice of a person; who thereupon demands restitution of so much, added or omitted by mistake.

You must make me a refraction of five pounds forgot in your account. I will deduct or make you a refraction of 30s. charged inadvertently in my bill.

REFRACTORY, in Chemistry. See an explanation of the term under APYRIOUS.

REFRAIN, Fr., in Musique, the termination of every verse or stanza of a song, by the same words and the same melody. (See BURDEN.) The word, according to Menage (Dict. Etym.) is derived from the Spaniel refrain.

REFRAN, Span., a proverb; the burden of a song in that language, being usually sententious, and including some moral precept.

REFRANGIBLE, whatever is capable of being refracted. See REFRACTIBILITY.

REFRACTIBILITY of Light, the disposition of the rays to be refracted.

A greater or less refrangibility is a disposition to be more or less refracted, in passing at equal angles of incidence, into the same medium.

That the rays of light are differently refrangible, is the foundation of Sir Isaac Newton's whole theory of light and colours. The truth of the principle, which was inveighed against and established by our great philosopher in the year 1666, will appear from the following experiments.

1. Let EG (Plate XIX. Optics, fig. 1.) represent the window-shutter of a dark room, and F a hole in it, through which the light is transmitted to the prifm ABC, which refracts it towards PT, where it appears in an oblong form; its length being about five times greater than its breadth, and exhibiting the various colours of the rainbow. In fig. 2, ag b represents a second prifm, which refracts the light back again to Q, where the image is round; whereas, without the interposition of this second prifm, the light would have proceeded to PT; and, consequently, been oblong, as before. In this experiment Sir Isaac Newton took care that the plane ag was placed exactly parallel to BC, and also bg to AC, that the rays might be equally refracted, though in contrary ways, by both prifs. He also observed, that both prifs must be placed very near to one another; for if their distance be so great, that colours begin to appear in the light, before its incidence on the second prifm, those colours will not be destroyed by the refraction of that prifm.

2. Having placed one of two boards behind the prifm at the window, so that the light might pass through a small hole made in it for the purpose, and fall on the other board at the distance of about twelve feet, a hole being made in it to admit the passage of the incident light, he then placed another prifm behind the second board, so that the light which was transmitted through both the boards might pass through that also, and be again refracted before it arrived at the wall. This being done, he took the first prifm in his hand, and turned it about its axis so much, as to make the several parts of the image, cast on the second board, successively to pass through the hole in it, that he might observe to what places on the wall the second prifm would refract them; and he saw, by the change of those places, that the light tending to that end of the image, towards which the refraction of the first prifm was made, did, in the second prifm, suffer a refraction considerably greater than the light which tended to the other end. The true cause, therefore, of the length of that image was discovered to be no other, than that light is not similar or homogeneal, but that it consists of rays, some of which are more refrangible than others; so that without any difference in their incidence on the same medium, some of them shall be more refracted than others; and therefore, that according to their particular degrees of refrangibility, they will be transmitted through the prifm to different parts of the opposite wall.

To make this capital experiment, which Sir Isaac Newton himself justly calls the experimentum crucis, let SF (fig. 3.) represent a ray of the sun, which, after passing through a hole in the window-shutter F, is received by the prifm in ABC, close behind which is placed a board D E, with a hole in it at G, to admit any of the rays after they have been separated by the prifm; then de will represent the other board, placed at a considerable distance from the former, with a hole in it, g, to receive any part of the light transmitted through the other board. Behind this second board is placed another prifm, a bc, through which different rays of light, falling upon it in the very same place, and with precisely the same angle of incidence, will be refracted higher or lower, on the opposite wall MN. This experiment was conducted with the utmost circumspection and accuracy; and it is observed, that neither the different magnitude of the hole in the window-shutter, nor the different thicknesses of the prifm, at the place where the rays passed through it, nor the different inclinations of the prifm to the horizon, nor the different matter of the prifms, made any sensible change in the length of the image.

3. In order farther to establish this famous hypothesis of the different refrangibility of the rays of light, he held a prifm in a beam of the sun, which was transmitted into the room through a hole in the window-shutter, so that its axis might be perpendicular to that beam; and having turned the prifm about its axis to make the image ascend and descend, and when it seemed to be stationary between these contrary motions, he fixed the prifm so that the refractions of both sides might be equal to each other. In this situation he looked at the hole through the prifm, and observed the length of its refracted image to be many times greater than its breadth: the most refracted part of it was violet, the least refracted red, the middle parts blue, green, and yellow, in order. The same thing happened when he removed the prifm.
out of the sun’s light, and looked through it upon the hole
shining by the light of the clouds beyond it.

4. Considering that if the image of the sun should be
drawn into an oblong form, either by a dilatation of every ray,
or by any other casual inequality of the refractions, the fame
oblong image would, by a second refraction, made sideways,
be drawn out as much in breadth, he placed a second prism
immediately after the first, in an oblique position with regard
to it, that it might again refract the light of the beam of
the sun’s light, which came to it through the first prism; so that
in the first prism, the beam would be refracted upwards, and
in the second sideways. But he found that the breadth of
the image was not increased by the refraction of the second
prism, but only its upper part, which in the first prism suf-
fcred the greatest refraction, and appeared violet and blue,
did again, in the second prism, suffer a greater refraction,
than the lower part of it, which was red and yellow, and
this without any dilatation of the breadth of the image.
Thus let S (fig. 4.) represent the fun, F the hole in the
window, A B C the first prism, and D H the sec-
cond. If Y represent the round image of the sun, made
by a direct beam of light, when the prisms are taken
away, P T will be the oblong image of the sun, made
by the same beam passing through the first prism only, and
P I will be the image made by the crofs refractions of both
prisms together. Sometimes he placed a third prism after
the second, and sometimes a fourth after the third; by
all which the image might be often refraffed sideways, but
the rays which were more refracted than the reit in the first
prism, were also more refracted in all the others, and that
without any dilatation of the image sideways; and, there-
fore, these rays, on account of their confluence of a greater
refraction, he called the more refrangible ones. He obser-
ves, in order to render the meaning of this experiment more evi-
dent, that all the rays, which are equally refrangible, fall
upon a circle answering to the sun’s di
c. Let, therefore,
A G (fig. 5.) represent the circle which all the most refran-
gible rays, transmitted from the whole disc of the sun, would
illuminate, and paint upon the opposite wall, if they were
alone. Let E I be the circle which all the least refrangible
rays would, in like manner, illuminate, and paint, if they
were alone, and let B H, C J, and D K, be the circles
which so many intermediate kinds of rays would successively
paint upon the wall, if they were singly propagated from the
fun, the reit being always intercepted, and conceive that
there are other intermediate circles without number, which
other innumerable intermediate kinds of rays would success-
ively paint upon the wall, if the sun should successively
emit every kind by itself. Now since the sun emits rays of
all these kinds at once, they must altogether illuminate and
paint innumerable equal circles, of all which, being ranged
according to their different degrees of refrangibility, the
oblong image P T before described is composed.

Now if the sun’s circular image, Y, which is made by an
unrefracted beam of light, was by any dilatation of the sin-
gle rays, or by any other irregularity in the refraction of the
first prism, converted into the oblong image P T, then
ought every circle in the image to be in like manner drawn
out into a similar oblong figure, contrary to the refult of
this experiment.

He considered further, that by the breadth of the hole
through which the light enters into the dark chamber, there
is a penumbra made in the circumference of the image Y,
which is also visible at the sides of the oblong images P T
and P I. He, therefore, placed at that hole a lens, or ob-
ject-glafs of a telescope, which might call the image of the
sun distinctly on Y, without any penumbra at all; and he
found that the penumbra of the reftilinear sides of the ob-
long images P T and P I was also thereby taken away, so
that they were as distinctly defined as the circumference of
the first image Y.

There are some other circumstances attending this experi-
ment, by which the conclusion drawn from it is made still
more plain and convincing.

Let the second prism, D H, (fig. 6.) be placed not im-
immediately after the first, but at some distance from it, so
that the light from the first prism may fall upon it in the
form of an oblong spectrum q r, parallel to this second
prism, and may be refracted sideways, to form the oblong
image, p t, upon the wall, and it will be found that this
image, p t, is inclined to the image P T, which the first
prism would have formed without the second; the blue
ends, P and p, being farther distant from one another than
the red ones, T and t; and, consequently, the rays which
go to the blue end, q, of the image q r, and which, there-
fore, suffer the greatest refraction in the first prism, are
again, in the second prism, more refracted than the reit.

At two holes made near another in his window-
flutter, he placed two prisms, one at each, which might
cait upon the opposite wall two oblong coloured images of
the sun; and at a little distance from the wall he placed a
long linder paper, with straight and parallel edges; and he
placed the prisms and paper, so that the red colour of one
image, at T, (fig. 7.) might fall directly upon one half of
the paper, and the violet colour, M, of the other image,
upon the other half of the same paper. Then with a black
cloth he covered the wall behind the paper, that no light
might be reflected from it to disturb the experiment; and
viewing the paper through a third prism, held parallel to it,
he saw that half of it which was illuminated by the violet
light to be divided from the other half, by a greater refra-
cction, especially when he retired to a considerable distance
from the paper.

He farther caused the two images, P T and M N (fig. 8.)
to coincide, in an inverted order of their colours, the red
end of each falling on the violet end of the other; and then
viewing them through a prism D H, held parallel to their
length, they no longer appeared coincident, as when they
were viewed with the naked eye, but in the form of two
different images, p t and m n, crossing another one
in the middle; which shews that the red of the one image, and
the violet of the other, which were coincident at P N and M T,
being parted from one another by a greater refraction of the
violet to p m, than that of the red to n and t, differ in de-
gree of refrangibility.

Having placed a prism, whose two angles at its base were
equal to one another, and half right ones, and the third a
right one, in a beam of the sun’s light, admitted into the
room as before, he turned it slowly about its axis, till all
the light which went through one of its angles, and was
refraffed by it, began to be reflected by its base, (at which
moment, till then, it went out of the glafs,) and then he observed
that those rays which had suffered the greatest refraction
were sooner reflected than the reit. He imagined, therefore,
that those rays of the reflected light, which were most re-
frangible, did first of all, by a total reflection, become more
copious in that light than the red; and that afterwards the
red, also, by a total reflection, became as copious as those.
To try this, he made the reflected light pass through another
prism, and, being reflected by it, to fall afterwards upon
sheet of white paper, at some distance behind it, and there
to paint the usual colours of the prism. Then causing the
first prism to be turned about its axis, he observed, that
when those rays which, in this prism, had suffered the
greatest
greatest refraction, and were of a blue and violet colour, began to be wholly reflected, the blue and violet light on the paper, which received the rays from the second prism, was sensibly increased, above that of the red and yellow, which was least refracted; and afterwards, when the rest of the light, which was green, yellow, and red, began to be wholly reflected in the first prism, the light of those colours on the paper received as great an increase as the violet and blue had done before. From this it is manifest, that the beam reflected by the base of the prism, being augmented first by the more refrangible rays, and afterwards by the less refrangible ones, is compounded of rays differently refrangible. This experiment is illustrated by fig. 9, in which $A B C$ represents the first prism, on the base of which the light falls, at $M$. When this prism is turned about its axis, according to the order of the letters $A B C$, the more refrangible rays, $M H$, emerge more and more obliquely; and at length, after their molli oblique emergence, are reflected towards $N$, and going on to $P$, increase the number of rays $N P$. By continuing the motion of the first prism, the less refrangible rays, $M G$, are reflected to $N$, and increase the number of rays $N A$.

Since it appears from Sir Isaac Newton’s experiments, that different rays of light have different degrees of refrangibility, it necessarily follows that the rules laid down by preceding philosophers, concerning the refractive power of water, glas, &c. must be limited to the middle kind of rays, as it may be supposed that Kepler, Snellius, and others would attend to them principally. Sir Isaac, however, proves that the fine the incidence of every kind of light, considered apart, is to its fine of refraction in a given ratio. This he deduces both by experiment, and also geometrically, from the supposition that bodies reflect the light by acting upon its rays in lines perpendicular to their surfaces.

Upon the whole it appears, that the blue rays are more refracted than the red ones, and that there is, likewise, unequal refraction in the intermediate rays; and upon the whole it appears, that the sun’s rays have not all the same refrangibility, and, consequently, are not of the same nature. It is also observed, that those rays which are most refrangible are also most reflexible. See the proof of this under Refrangibility. Newton’s Optics, p. 22, &c. ed. 3.

The difference between refrangibility and reflexibleness was first discovered by Sir Isaac Newton, in 1671-2, and communicated in a letter to the Royal Society, dated February 6, 1671-2, and published in the Philosophical Transactions, N° 86, p. 3075; and from that time vindicated by him from the objections of several authors; particularly F. Pardies, M. Mariotte, Fr. Linus, or Lin, and other gentlemen at the English college at Liege; and at length it was more fully laid down, illustrated, and confirmed, by a great variety of experiments, in his excellent treatise of Optics.

But farther, as not only those colours of light produced by refraction in a prism, but also those reflected from opaque bodies, have their different degrees of refrangibility and reflexibleness; and as a white light arises from a mixture of the several coloured rays, the same great author concluded all homogeneous light to have its proper colour, corresponding to its degree of refrangibility, and not capable of being changed by any reflections, or any refractions; that the sun’s light is composed of all the primary colours; and that all compound colours arise from a mixture of the primary ones, &c.

The different degrees of refrangibility he conjectures to arise from the different magnitude of the particles of which the different rays confit. Thus the most refrangible rays, i.e. the red ones, he supposes to consist of the largest particles; the least refrangible, i.e. the violet rays, of the smallest particles; and the intermediate rays, yellow, green, and blue, of particles of intermediate sizes.

Having given a general view of the Newtonian theory of colours, as they depend upon the refraction of light, under the article Colour, we shall here add some farther particulars on this subject. From a review of that article, and of what has been above delivered, we may infer that, as the rays of light differ in refrangibility, they also differ in their disposition to exhibit this or that particular colour; so that colours are not modifications of light, derived from refractions or reflections of natural bodies, but original and separate properties, which are different in different rays. Moreover, to the same degree of refrangibility always belongs the same colour, and to the same colour the same degree of refrangibility; nor are the same species of colour, and degree of refrangibility, that are proper to any particular kind of rays, subject to change by refraction and by reflection of natural bodies, nor by any other cause which for Sir Isaac Newton could be observed. Although a seeming transmutation of colours may be produced by a mixture of different kinds of rays, yet, in such mixtures, the component colours themselves do not appear; but, by their mutually allying each other, constitute a middle colour; and, therefore, if, by refraction, the different rays be separated, colours will emerge different from that of the composition. Thus blue and yellow powders, finely mixed, appear green to the naked eye; and yet the colours of the component particles are not thereby really changed, but only blended; for when they are viewed with a microscope, they still appear blue and yellow. It appears that there are also two sorts of colours: the one original and simple; the other compounded of these. The original and primary colours are red, orange, yellow, green, blue, indigo, and a violet purple, and an indefinite variety of intermediate gradations. The same colours in specie with those primary ones may be also produced by a composition; thus a mixture of yellow and blue makes green; of red and yellow, orange; and of orange and yellowish-green, yellow. In general, if any two colours are mixed, which, in the series of those that are produced by the prism, are not too far distant from one another, they, by their mutual alloy, compose that colour which appears in the midway between them; but those which are situated at too great distance have not this effect: e. g. orange and indigo do not produce the intermediate green, nor scarlet and green the intermediate yellow.

The most wondrous composition is that of whitening, which no one sort of rays alone can exhibit, but which is always compounded; so that all the aforesaid primary colours, mixed in a certain proportion, are necessary to form it. See Colour.

Having shewn, in the preceding part of this article, the extremes of the different degrees of refrangibility in the different kinds of light, we shall now proceed to give the result of Newton’s investigation, concerning the different degrees of refrangibility of all the different kinds of light, according to their several colours; particularizing this part of the subject with an explanation of the method which he made use of to define the boundaries of each colour, in the oblong image of the fun above described. In that image, though there was a manifest difference of colour, not only between the two extremes, but also in the intermediate parts, yet the exact place at which any one colour ended, and another began, was far from being sufficiently distinguishable.
guishable. The reason of this indistinctness is, that rays of every kind coming from all parts of the sun’s disk, an entire image of the sun is projected on the paper, consisting of a circle of each particular colour; and as the rays differ in kind by infinitesimal degrees, from the extreme red to the extreme violet, there must, in fact, be thousands of these circles in the same oblong image, the centres of which are infinitely near to one another; so that the light is intimately mixed, especially in the middle of the image, where it is the brightest.

If these circles, as he observes, whilst their centres keep their dilations and positions, could be made lenses in diameter, their interfering one with another, and consequently the mixture of heterogeneous rays, would be proportionately diminished. Thus, in PT (fig. 10.) the circles of which the solar image consists, expand into one another; but in the same figure, pt, being composed of two circles, but having their centres at the same distance as the former, do not extend into one another, the mixture being diminished in proportion to the diameters of the circles.

Now these circles would be diminished, if, without the room, at a great distance from the prism, towards the sun, some opaque body was placed, having a round hole in the middle of it, to intercept all the sun’s light, except so much as, coming from the middle of its disk, could pass through that hole to the prism; for so the separate circles would no longer answer to the whole disk of the sun, but only to that part of it which can be seen from the prism, through that hole. But that these circles may answer more distinctly to the hole, a lens is to be placed by the prism, to cast the image of the hole, that is, of each separate circle, distinctly upon the paper; and if this be done, it will not be necessary to place that hole very far off, not even beyond the window. Instead, therefore, of that hole, he made use of the hole in his window-shutter, in the following manner.

At about 10 or 12 feet from the window, he placed a lens, by which the image of the hole might be distinctly cast upon a sheet of white paper, at the distance of 6, 8, 10, or 12 feet from the lens. Then, immediately after the lens, he placed a prism, by which the reflected light might be thrown upwards, or sideways; and he moved the paper that received it, either towards the prism, or from it, till he found the exact distance at which the sides of the image appeared most distinct. By this means the circular images of the hole were terminated most distinctly, without any penumbra, and therefore extended into one another the least that they could; and consequently the mixture of the heterogeneous rays was the least of all. And by using a greater or lesser hole in the window-shutter, he made the circular images greater or less at pleasure, and thereby the mixture of rays in the oblong image was as much or as little as he chose. He sometimes made the breadth of the image 45 times, and sometimes 60 or 70 times less than its length. In this manner, he says, light is made sufficiently simple, and homogeneal, for trying any of his experiments about simple light; for that the heterogeneous rays in this light are so few, as hardly to be perceived, excepting, perhaps, in the indigo and violet, which, being dark colours, do easily suffer a sensible alloy by that little scattering light, which used to be refracted irregularly by the inequalities of the prism. The whole process of this experiment is so evident, by inspection of fig. 11, that it needs no particular illustration.

Instead of a circular hole, our author recommends a hole shaped like a long parallelogram, with its length parallel to the prism. For if this hole be an inch or two long, and but a tenth or twentieth part of an inch broad, or narrower, the light of the image will be as simple as before, or more simple, and the image will become much broader, and therefore much more fit for these experiments.

Or, instead of this hole, another may be formed of a triangle of equal sides, whose base may be about the 10th part of an inch, and its height an inch or more. For, by this means, if the basis of the prism be parallel to the perpendicular of the triangle, the image of it (fig. 12.) will now be formed of equicrural triangles, ag, bh, ei, dl, el, fm, &c. and innumerable other intermediate ones, answering to the triangular hole in shape and bigness, and lying one another in a continual series, between two parallel lines, af, gm.

These triangles are a little intermingled at their bases, but not at their vertices; and therefore the light on the brighter side, af, of the image, where the bases of the triangles are, is a little compounded, but on the darker side, gm, it is altogether uncompounded; and in all places between the sides, the composition is proportionable to the diliances of the places from that obfcurer side gm; and having an image of such a composition, we may try experiments either in its stronger and less simple light, near the side af; or in its weaker and more simple light, near the other side gm, as shall seem most convenient.

In making these experiments, he advises, that the chamber be made very dark, that the lens be very good, being made of glass free from bubbles and veins, the sides of the prism truly plane, and its polished, with an angle of about 65 or 70 degrees; and the edges of the prism and lens, as far as they make any irregular refraction, should be covered with black paper glued on them. He also observes, however, that all the useless light should be intercepted with black paper, or other black obstacles. It being difficult to get glasses prisms fit for these nice experiments, he sometimes used prismatic veils made with pieces of broken looking-glasses, and filled with rain-water; and to increase the refraction, he sometimes strongly impregnated the water with the gas deutus saturni. When he had, by this means, got the sides of the coloured image, as AT, GM, (fig. 13.) distinctly defined, he delineated on paper the outlines of it, FAPGM, T, and held the paper so that the image might fall on this figure, and coincide with it exactly; whilst an attendant, whose eyes could distinguish colours better than his own, did, by right lines drawn cross the image, mark the confines of each colour; and this operation being frequently repeated, both on the same and on different papers, he found that the observations agreed well enough with one another, and that the sides, MG and FA, were by these means divided like a musical chord; so that if GM were produced to X, making MX equal to GM, and if GX, IA, IB, BX, EX, GX, a, MX, were in proportion to one another, as the numbers 1, 2, 3, 4, 5, 6, 7, and 8, and so represented the chords of the key, and of a tone, a third minor, a fourth, a fifth, a sixth major, a seventh, and an eighth above that key. And the intervals MA, ag, ge, eb, bi, f, and /, were the spaces which the several colours, red, orange, yellow, green, blue, indigo, and violet, took up.

Now these intervals or spaces, subtending the differences of the refractions of the rays, going to the limit of these colours, that is to the points M, a, g, e, b, i, l, G, may, without any sensible error, be accounted proportionate to the differences of the lines of refraction of those rays, having one common line of incidence; and, therefore, since the common line of incidence of the most and least refrangible rays, out of glass into air, was found in proportion to their refractions as 50 to 77 and 78; if the difference between
tween 77 and 78 be divided, as the line GM is divided by
those intervals, there will be $77, 77^1, 77^2, 77^3, 77^4, 77^5, 77^6, 77^7, 78$, for the lines of refraction of those rays out of
glas into air, their common fine of incidence being 50. So
then the lines of the incidences of all the red-making rays
out of glass into air were to the lines of their refractions not
greater than 50 to 77, nor less than 50 to 77; but they varied
from one another according to all their intermediate
proportions, and of all the other colours.

Having demonstrated that the light of the sun consists of
certain proportion of differently coloured light, our author
proves, by another series of experiments, what has been al-
dready demonstrated by a single one mentioned above, that
when a beam of light has been divided into its component
parts, if they be again mixed, they will produce white; or
if any one of them be intercepted, the image will appear
muted, and in a different manner, according to the different
colours that are thereby prevented from mixing with the
red; and to complete the whole, he observes, that inter-
cepting all the colours that compose the white image except
one, and thereby making to exhibit the appearance of all
the other colours in order; yet, if he made this succession of
all the colours very quick, the appearance was always white,
though it was demonstrable that only one colour took place
at any one time; and he judiciously observes, that if each of these
colours in succession give the idea of whiteneß, much more
will they produce that effect, when they are so intimately
mixed as they are in a natural sun-beam.

Not content with composing whiteneß from the sepa-
ately coloured rays of the sun, he attempted, and succeeded
in his attempt, to do the same with natural coloured bodies,
oberving the same proportions of the respective colours
that he had found in the solar image. The coloured pow-
ders which he made use of at first produced only a kind of
grey; but this was in fact a dull white, or whiteneß mixed
with shade; for when he contrived to throw a very strong
light upon it, it became intensely white, so that a friend of
his, who happened to call upon him while he was busy
about these curious experiments, and who knew nothing of
what he had been doing, pronounced that the powders he
had been mixing, when thus illuminated, made a better
white than some very fine white paper, with which he was
comparing it.

As the preceding proportion of all the prismatic colours
makes a white, it is evident that when they are mixed in
different proportions, or when only a few of them are used,
they will make different colours; and our philosopher has
given us the following ingenious method of knowing, in a
mixture of primary colours, the quantity and quality of each
being given, the colour of the compound. With the centre
O, (fig. 14.) and the radius OD, describe a circle ADF,
and divide the circumference into seven parts, proportional
to the seven musical tones or intervals contained in an oc-
tave, that is in proportion to the numbers $\frac{1}{2}, \frac{1}{4}, \frac{1}{8}, \frac{7}{8}, \frac{1}{5}, \frac{7}{10}, \frac{7}{12}$. Let the first, DE, represent a red colour, the
second, EF, orange, and so of the red; and let all these
colours be supposèd to pass gradually into one another.
Let $p$ be the centre of gravity of the arc DE, and $r, s, t, u, v, w$ be the centres of gravity of the other arcs; and
about those centres let circles, proportional to the number of
rays of each colour in the given mixture, be described.
Then find a common centre of gravity of all those circles;
and if a line be drawn from the centre of the circle O,
through this point, as suppose at $z$, the point $Y$, in which
it terminates at the circumference, will shew the colour that
arises from the mixture; and the line OZ will be propor-
tioned to the fullness or intenseness of the colour, the centre
O representing perfect white. But if only two of the pri-
mary colours, which in this circle are opposite to one
another, be mixed in an equal proportion, the point Z will
fall upon the centre O, and yet the colour compounded of
those two will not be perfectly white; but some faint anony-
mous colour; so he could never, by mixing only two pri-
mary colours, produce a perfect white. Whether it might
be the result of three taken at equal distances in the circum-
ference he could not tell; but he did not much question,
but that four or five of them would be sufficient. These,
however, as he observes, are curiosities of little or no mo-
moment to the understanding of the phenomena of nature,
since, in all natural whites, there is a mixture of all kinds
of rays. Newton’s Optics. Prieëly’s Hist. of Light and
Colours.

For the method of correcting the effect of the differ-
ent refraction of the rays of light in glasses, see Aberra-
tion and Telescope; see also Dispersion of Light.

Radiant heat, as well as light, is not only refractionable,
but it is also subject to the laws of dispersion, arising from
its different refraction. The prism refractions radiant heat,
as so as to separate that which is less efficacious from that which is
greater. The whole quantity of radiant heat contained
in a sun-beam, if this different refraction did not exist,
must inevitably fall uniformly on a space equal to the area of
the prism, and if radiant heat were not refractionable at all, it
would fall upon an equal space, in the place where the
shadow of the prism, when covered, may be seen. But
neither of these events taking place, it is evident that the
radiant heat is subject to the laws of refraction, and also to
those of the different refraction of light. Whence Dr.
Herchel is led to surmise, that radiant heat consists of
particles of light of a certain range of moments, which
range may extend a little farther, on each side of refrangi-
bility, than that of light. (See Rays of Heat.) Dr. Her-
chel having found that two degrees of heat were obtained
from that part of the prismatic spectrum which contained
the violet rays, while the full red colour, on the opposite side,
gave no less than seven degrees, infers from these facts the
different refraction of the rays which occasion heat, as
clearly and certainly as it is concluded that the refraction
of light is ascertained by the dispersion and variety of
the colours. But he proceeds farther, and observes, that the
rays of heat are of a much more extensive refraction than
those of light. In order to make this appear, he delin-
ates a spectrum of light, by assuming a line of a certain
length; and, dividing it into seven parts, according to the
dimensions asigned to the seven colours by Sir Isaac Newton,
in the fourth figure of the second part of his Optics,
represents the illuminating power of which each colour
is possessed, by an ordinate drawn to that line. And here,
as the absolute length of the ordinates is arbitrary, provided
they be proportional to each other, he assumes the length
of that which is to express the maximum, equal to $\frac{7}{4}$ of
the whole line.

Thus, let GQ (fig. 15.) represent the line that contains the
arrangement of the colours, from the red to the violet.
Then, erecting on the confines of the yellow and green the line
L R = $\frac{4}{3}$ of GQ, it will represent the power of illumina-
tion of the rays in that place. For, by experiments al-
dready delivered, we have shewn that the maximum of illumina-
tion is in the brightest yellow or palest green rays. From
the same experiments we collect, that the illuminations of
yellow and green are equal to each other, and not much in-
ferior to the maximum; this gives us the ordinates K and M.
Then, by the rest of the same experiments, we obtain also
the
the ordinates $H$, $I$, $N$, $O$, $P$, with sufficient accuracy for the purpose here intended. All these being applied to the middle of the spaces which belong to the respective colours, we have the figure $G$, $R$, $Q$, $G$; representing what may be called the spectrum of illumination.

We are now, in the same manner, to find a figure to express the heating power of the refracted prismatic rays, or what may be called the spectrum of heat. In order to determine the length of the base, Dr. Herchel examined the extent of the invisible rays, and found, that at a distance of two inches beyond visible red, his thermometer, in a few minutes, acquired 1/4 degree of heat. The extent of the coloured spectrum at that time, or the line which answered to $G$ in his figure, measured 2,997 inches. If two inches had been the whole of the extent of the invisible part, it might be stated to be in proportion to the visible one as 2 to 3; but we are to make some allowance for a small space required beyond the last ordinate, that the curve of the heating power drawn through it may reach the base; and indeed, at 2.5 inches beyond visible red, Dr. Herchel could still find 1/4 degree of heat. It appears therefore sufficiently safe, to admit the base of the spectrum of heat $A$, to be so to that of the spectrum of light $G$, as 5:4 to 3; or, conforming to the Newtonian figure before mentioned, the base of which is 3.3 inches, as 575:33. Now, if we assume for the maximum of heat, an ordinate of an equal length with that which was fixed upon for the maximum of light, it will give us a method of comparing the two spectra together. Accordingly, Dr. Herchel has drawn the several ordinates $B$, $C$, $D$, $E$, $F$, $G$, $H$, $I$, $K$, $L$, $M$, $N$, $O$, $P$, of such lengths as, from experiments made on purpose, it appeared they should be, in order to express the heat indicated by the thermometer, when placed on the base, at the several positions pointed out by the letters.

A mere inspection of the two figures, which have been drawn as lying upon one another, will enable us now to see how very differently the prism disperses the heat-making rays, and those which occasion illumination, over the areas $A$, $S$, $Q$, $A$, of our two spectra! These rays neither agree in their mean refrangibility, nor in the situation of their maxima. At $R$, where we have most light, there is but little heat; and at $S$, where we have most heat, we find no light at all!

**REFRESHMENT, Quarters of.** See Quarters.

**REFRET, Fr.** The burden of a song. This word is only to be found in the second folio edition of Bailey's Dictionary, 1736. In no French dictionary is there authority for it. Cotgrave, Dict. du Vieux Langage; Trevoux, Dict. de l'Académie; and Glossaries, have been consulted in vain.

**REFRIGERANT, Refrigerative, in Medicine, or cooling, from frigus, cold, an appellation given to such remedies as were supposed to possess a power of cooling the internal parts. Hence all diuretics, such as petina, gruel, and other thin drinks, vegetable and mineral acids, neutral salts, and other substances, which are debase in stimulating qualities, and communicate a fomentation of coolness to the tongue and throat, have been considered as refrigerant. As they have no actual power of generating cold in the animal body, the term is somewhat incorrect; but as it expresses the opposite quality to that of stimulating, which is used also for a:nthimous with burning, it is still retained, and applied to drink, drink, and medicine of a non-stimulant quality. In this sense, the term is nearly synonymous with sedative.

Whatever, in fact, increases the circulation, increases the heat of the body, and vice versa; potentially, therefore, all sedative medicines may be said to be refrigerant. The use of refrigerants will thence be inferred to be proper in all those cases in which there is an over-excitation of the circulation, either locally or generally, as such local inflammations, febrile diseases, hemorrhages, and the like. In the case of external inflammations, indeed, actual refrigeration may be produced, by the application of cold substances, water or ice, or by the abstraction of heat by means of evaporation; both of which afford the means of directly diminishing the activity of the vessels of the part. Thus, in burns and scalds, the pain is instantly relieved, and the inflammation effectually reduced, by the immersion of the part in cold water, if sufficiently perfused in. But in respect to internal refrigerants, their operation is of a negative kind, and consists rather in the removal of uneasy sensations, and in the exclusion of stimulant substances, than in the actual suppression of increased action. See Sedative.

**REFRIGERATION, Refrigeratorium, in Chemistry, a copper vessel filled with cold water, folded round the capital of an alembic, to cool and condense the vapours raffled thither by the fire, and to convert them into a liquor, to be discharged thence by the beak. See ALEMBIC.

The lettering in the refrigerator is to be changed from time to time, as it begins to grow warm.

Sometimes they content themselves with wrapping a wet cloth about the head of the alembic, instead of a refrigerator; but the more usual method now is, to supply the place of the refrigerator by a worm, or spiral pipe, running through a tub of cold water.

Distillation chiefly consists in evaporation and refrigeration. See Distillation.

**REFUGE, Refugium, in our Old Customs, a sanctuary, or asylum; which see respectively.**

At Paris there is an hospital called the Refuge, in which dissolute women are shut up.

**REFUGE, Cities of, in Scripture History, fix cities selected from the 48 appropriated to the residence of the Levites, which were appointed for the protection of persons from the rigour of the law, who were defpicable or involuntary homicide. Some have supposed that all the cities of the Levites were safe; but it appears from Num. xxxvi. 6, that only six of them were appointed to this use. These may were intended not only for Jews, but for Gentiles, or for thrangers who dwelt among them. (Num. xxxvi. 15.) They were not designed as sanitis for willful murderers and all sorts of atrocious villains among the Jews, as they were among the Greeks and Romans, and as such places have since been in Roman Catholic countries, but merely for securing those who had been guilty of involuntary homicide (Deut. xix. 4—10) from the effects of private revenge, until they were cleared by a legal process. It is observable, that the Israelites are commanded to "prepare the way" that is, to make the road good, "that every flour may flee thither," without impediment, and with all expedition. (Deut. xix. 3.) By having good roads to them, at least 32 cubits, or about 48 feet in breadth, and bridges wherever
REG

wherever they were necessary, these cities were to be easy of access; and at crofs roads pofts were erected with inscriptions, directing the way to the "city of refuge." Upon this Hottinger remarks, that it was probably in allusion to this custom, that John the Baptist is described as "the voice of one crying in the wilderness, prepare ye the way of the Lord, make his paths straight." (Luke, iii. 4—6.) He was the Mediah's forerunner, and in that character was to remove the obstacles to men's flying to him as their asylum, and obtaining salvation, the salvation of God. Every year, on the 15th of Adar, (February,) the magistrates were to inspect the roads, and ascertain their good condition. These cities were to be supplied with water and provisions; but they were not to be the residence of any artificers who made weapons, by the use of which the relations of the deceased might gratify their revenge. It was necessary that those who took refuge in these places should understand some occupation, that might prevent their being chargeable, whilst they were waiting for their trial. In order to excite and maintain the greater horror even of involuntary bloodshed, the law punished it by a kind of banishment, for the accused person was to remain in this city, without departing from it, till the death of the high-priest, but after the high priest's death, he might safely go wherever he pleased.

REFUGEES, French Protestants, who, by the revocation of the edict of Nantes, in 1685, have been constrained to quit their country, and retire for refuge into Holland, Germany, England, &c. to save themselves from the necessity of abandoning their religion.

REFUGIO, El, in Geography, a harbour in one of the islands of Mayorga, where Mauere was supplied with water in 1784, and which, he says, affords shelter from the most furious winds. S. lat. 18° 30'. E. long. 177° 32'.

REFINGE, a town of Sweden, in the province of Halland; nine miles N.N.W. of Halmstad.

REFUSAL, in Law, is that where by law a right and power of having or doing something of advantage to him, and he declines it. An executor may refuse an executorship; but the refusal ought to be before the ordinary; if an executor be summoned to accept or refuse the executorship, and he doth not appear upon the summons and prove the will, the court may grant administration, &c. which shall be good in law till such executor hath proved the will; but no man can be compelled to undertake it upon the executorship, unless he hath intermeddled with the estate. (1 Leon. 154. Cro. Eliz. 553.) Where there are several executors, and they all refuse, none of them shall administer afterwards; but if there is a refusal by one, and the other proves the will, the refusing executor may administer when he will, during the life of his co-executor. (1 Rep. 28.) If there is but one executor, and he administers, he cannot refuse afterwards, and if once he refuse, he cannot administer afterwards.

There is a refusal of a clerk presented to a church, for want of literature, &c. and if a bishop once refuses a clerk for insufficiency, he cannot accept of him afterwards, if a new clerk is presented. (5 Rep. 59. Cro. Eliz. 27.) In action of trover and conversion, a demand of the goods, and refusal to deliver them must be proved, &c. 10 Rep. 56.

REFUTATION, Refutatio, in Rhetoric, that part of the answer made to an opponent, which disapproves what had been advanced by him.

REGA, in Geography, a river of Pomerania, which rises three miles N.W. of Dramburg, passes by Regenwalde, Plate, Grieffenberg, Treptow, &c., and then runs into the sea, 12 miles S.W. of Colberg.

REGA, a town of Egypt, on the left bank of the Nile; six miles N. of Atsfel.

REGAL, REGALIS, or Regalis, something belonging to a king. Regal is of the same import with royal; the former being formed of the Latin rex; the other of the French roi, king.

REGAL, Fr., a musical term, which the Encyclopédie defines, "fis, an ancient instrument composed of many ficks of sonorous wood of different lengths, forming a scale, played upon by an ivory ball fastened to the end of a fick." This is exactly the description of the flicaccio, said to be invented by the brother of Bremner, the late musician who wrote the book of instructions for playing upon it.

"Regal is, secondly, a spinet organized, or rather a small organ of two or three stops placed under a keyd instrument, very common in Spain and Italy. In France this kind of instrument is called a posifit." Craigne, an organbuilder in London about the middle of the last century, furnished organs of this kind to many harpichords and spinets in a virginal form. Smetzer, when he first came hither from Strasburg, was employed by Shudi to organize his harpichord.

But regal in all Roman Catholic countries is a portable organ used in processions, carried by one person and played by another. We have seen that use made of this kind of organ at Naples. The pipes are of reeds, for the lightness of carriage.

In the lift of Edward VI. and queen Elizabeth's musical establishments in the Sloane MSS. at the British Museum, among the instrument-makers, the regal-maker is allowed 20£ yearly. And in our own memory there was an office in the chapel royal under the title of "tuner of the regals;" but it was abolished, and united to some more useful officer in the chapel.

In the supplement to the folio Encyclopédie, we are told that the regal is a portable organ, which has no pipes, or at most such as are very short, the tones being produced by reeds. This we believe to be the truth. The instrument is sometimes fo small as to be set on a table.

REGAL Fijb. See ROYAL Fijb.

REGAL Sui. See Sui.
